1. Effectiveness of Empowerment Programme on Stress and Care Giving Burden among Care Givers of Chronically Ill Patients Admitted in MMIMS&R Hospital, Mullana Ambala, Haryana .......... 1  
   *Shalini Youssouf, Jyoti Sarin, Eenu, Bindu Joseph*

2. Study of Various Patterns of Azygos Venous System and its Clinical Significance ....................... 9  
   *Aarti Rohilla, Monika Rathee, Kamal Singh, Suresh Kanta Rathee*

3. Fetal Ilium as a Tool For Sex Determination: Discriminant Functional Analysis .......................... 14  
   *Aarti, Luv Sharma, Kamal Singh*

4. Review on Current Trends in Hypertension ....................................................................................... 22  
   *Aarti Thakur, Ruchi Kumari, Sakshi Tomar*

5. Effectiveness of Lockdown in Reducing the Spread of COVID-19 .................................................. 28  
   *Adyati Satya Puspita, Judya Sukmana, Lestari Dewi, Erina Yatmasari*

6. A Comparative Analysis of Misery Index and Its Impact on Health Indicators Across The Globe ...... 35  

7. The Relationship of Perceived Benefit, Perceived Barrier, and Knowledge with Vaccine Hesitancy among Anti- and Pro-Vaccine Community ................................................................. 41  
   *Aisyah Nur Izzati, Retno Indarwati, Makhfudli*

8. Knowledge and Attitude Regarding Medication Error among Nursing Students in a Selected College at Mangaluru ........................................................................................................................... 49  
   *Ajanya Shaju, Aleesha Babu, Dona Sebastian, Mary Joseph, Pavithra K*

   *Akanksha Monga, Thanveer K, Bhuvandeep Gupta, Aparna Aggarwal, Nisha Yadav, Meena Jain, Ankur Sharma*

10. Cytotoxic Effect of Silver Nanoparticles Prepared by Biosurfactant Produced from Pathogenic Bacteria ................................................................................................................................................ 63  
    *Aleaaabdulhusseinjamee*, *Nadhimhusanhayder*, *Amenah Rami Abdullah*, *Laithahmedyaaqoob*

11. A Review on Medication Synchronization Programs in Community Pharmacies to Improve Medication Adherence .................................................................................................................. 71  
    *Rakshith U.R Srikanth M.S*
12. Articaine: Opening up a New Vista For Pediatric Dentists ................................................................. 82
   Ananthu H, Ashwin P Rao, Suprabha B S

13. Maxillary Inter-canine Width at Three Stages of Dentition– A Cross-Sectional Study .................... 90
   Anita Thakur, Seema Thakur, Parul Singhal, Deepak Chauhan

14. Effectiveness of Structured Teaching Programme on Knowledge Regarding Post Exposure
    Prophylaxis Following Needle Stick Injury among B. Sc Nursing Students .......................................... 96
   Anjana A.P, Reshma Thomas, Renjitha

15. Fatal Poisoning Cases in a Teaching Hospital of West Bengal: a Descriptive Cross-Sectional
    Clinico-epidemiological Study ................................................................................................................. 101
   Ankur Bhattacharjee, Saptarshi Chatterjee, Partha Sarathi Hembram, Sobhan Kumar Das

16. A Study to Assess the Knowledge and Practice Regarding Prevention of Deep Vein Thrombosis
    among Bedridden Patients in a Selected Hospital, Mangalore ............................................................... 107
   Ann Sangeetha James, Fiona George, Grace Violet, Jomol Sebastian, Prashma Bharath

17. A Descriptive Study to Assess the Knowledge and Practice Regarding Prevention of Osteoporosis
    among Group D Female Workers of Selected Tertiary Care Hospitals in Mangaluru ............................ 113
   Anumol Shaju, Beeda K Jose, Geeta Fernandes, Jeevan, Josna Johny, Indumathi

18. Assessment and Comparison of Total Salivary Protein and Salivary Flow Rate among Type I,
    Type II Diabetics and Healthy Controls .................................................................................................... 117

19. Antifogging Measures for Protective Eyewear ...................................................................................... 124
   Bharti Sachdeva, Parul Saini

20. Women and Sexual and Reproductive Health Rights: Issues and Challenges due to Environmental
    Pollution and Covid-19 Pandemic .............................................................................................................. 127
   Bijaylaxmi Mohapatra, Itishri Sarangi

21. Relapse Prevention in Mental Illnesses: Concepts, Issues and Strategies with Perspectives of
    Psychiatric Nursing- Review Article ......................................................................................................... 134
   Mudakavi I, Rentala S., Irasangappa M

22. Histopathological Changes in Brain Tissues associated Withoral Administration of Tramadol in
    Male Rats .................................................................................................................................................. 147
   Abbas Ch. Mraisel, Sawsan, A. Ibrahim, Muntadher H. Dawood

23. Legal Civil Liability of the Forensic Medicine as a Judicial Expert from a Jurisprudential
    Perspective .................................................................................................................................................. 156
   Abdelawal Bassiouny, Saad Ramadan, Majd Manasra

24. Association between Gestational Diabetes and Proinflammatory Cytokine (IL-1β) ......................... 160
   Abdullah F. Yousif, Raid M. H. Al-Salih, Alaa H. Al-Naser

25. Prevalence of Pediatric Gastroenteritis Disease in Al-Diwaniyah Governorate-Iraq .................. 170
   Abdulridha T. Sarhan, Enas K. Alkhazraji, Takwa S. Al-Meamar
26. Patients’ Satisfaction about Quality of Health Care Services Provided in Maternity Wards at Al-Najaf City.................................................................................................................................................. 177
Abeer Miri Abdullah, Rehab Lafta Mohammad, Zainab Neamat Jumaah Altaei

27. An Epidemiological Study of Homicidal Cases Autopsied in the Mortuary of the Department of Forensic Medicine and Toxicology, North Bengal, Darjeeling.......................................................... 183
Achintya Biswas, Pappu Kumar, Sukanta Majumdar, Soumeek Chowdhuri, Somasish Ghosal, Prabir Kumar Deb

28. Increased Corticosterone Levels due to Chronic Stress Reduces IGF-II Expression in Rattus norvegicus . 188
Ade Septiari Rahman, Reny I’tishom, Ashon Sa’adi

29. Incense Smoke Exposure: An Appraisal of Organ Toxicity................................................................................. 193
Adebanji M. Akingbade, Samson A. Odukoya, Adeoye O. Oyewopo, Nalini Govender, Thajasvarie Naicker

30. wLearning in Indonesia based on a Commognitive Perspective .......................................................... 202
Adika Setyo Budi Lestari, Toto Nusantara, Susiswo, Tjang Daniel Chandra, Nonik Indrawatningsih

31. Age Estimation by the Morphometric Analysis of Sternal End of Fourth Rib....................................................... 210
Aditi Bhatnagar, Nirupma Gupta, Rachna Rohatgi

32. Isolation and Identification of Streptococcus pyogenes from Patients and Objects in Hospital Environment in Thi-Qarcity in Iraq.................................................................................................................. 216
AdyanNafee Abbas, Qasim Hassan Wida

33. Management of Pyogenic Granuloma (Clinicopathological Study) .............................................................. 222
Afrah A. Kh. Aldelaimi, Tahir N. Aldelaimi

34. The Role of Silver Nanoparticles Against Amoxicillin/Clavulanate-Induced Liver Damage in the Female Rats................................................................................................................................. 229
Afyaab Sabah Nasir, Basheer Sadoon Taher

35. A Multilevel Empowerment Approach to Prevent Relapse and Improve Quality of Life of People with Mental Disorders .................................................................................................................................................. 235
Agustin Widyowati, Bhisma Murti, Aris Sudiyanto, Suminah

Ahalya S P, Priyadharshini A, Dhivya D, Nila G

37. The Role of Forensic Medicine in the Criminal Justice Process in Jordan (Sexual Crimes) .................. 250
Ahmad Alshargawi

38. The Criminal Liability of the Forensic Doctor as a Judicial Expert According to Jordanian Law....... 254
Ahmad Mohammad El-refaie, Ahmad Hussein Alshargawi

39. Efficacy of Clinical Palpation to Detect Cervical Lymph Node Metastasis of Oropharyngeal Cancer 259
Ahmad Naeem Mahdi, Sabah Abdulaziz Issa, Saif Saadedeen Abdulrazzaq
IV

   Ahmad Sabbah, Rehanah Zain, Rohani Ismail, Siti Suraiya Noor, Mahaneem Mohamed, Norazliah Samsudin

41. The Correlation Study between Some Biochemical Parameters of 256 Covid-19 Cases Considering Diabetes .................................................................................................................. 277
   Ahmed Ab. Jabbar

42. Psychological Distress among Caregivers of Children with Down Syndrome at Al Najaf Province .... 288
   Ahmed Burhan Abdulameer, Arafat Hussein Al-Dujaili

43. Evaluation of the Antioxidant and Antibiofilm Activities of Rosmarinus Officinalis Essential Oil Extract 294
   Ahmed H. AL-Azawi, Kais Kassim Ghaima, Noor Saad Latteef, Alaa Aziz Abdulhassan

44. The Technical Value of Magnetic Resonance Imaging and Ultrasonography in Identifying Characterization of Ovarian Cysts ...................................................................................... 307
   Ali Hani Karim, Mahmood Radhi Jobayr, Lamyaa F.A. Al-Barram

45. Evaluation of Gingival Inflammation, Plasma IL-6, and TMJ Clicking after Masseters Muscle Botulinum Toxin Injection and Intra-Articular PRP Injection In Bruxism Patients.................. 315

46. Deleted ................................................................................................................................................... 322

47. Comparison between 3 Different Types of Mouthwash on the Healing Process of Periodontal Diseases .............................................................................................................................. 330
   Ammar Alwan Ali, Zainab Kasim Mohammad, Abeer Isam Abdulhameed

48. Deleted ................................................................................................................................................... 338

49. Histological Evaluation of Effect of Combined Local Application of Vitamin D3 and beta- Tricalcium Phosphate on Bone Formation in Rabbits ........................................................................... 346
   Noor Abdulkareem Razouki, Ban A. Ghani Jamil

50. Assessment of Serum Ferritin, Folate, Vitamin B12, C-reactive Protein, D-dimer and Homocysteine in Patients with Severe and Critical Covid-19 Infection ......................................................... 353
   Nawar Mazin AL-Alwan, Zainab A. Razak Al-Sharifi, Abbas Hashim Abdulsalam

51. The Effect of Acute Bronchitis on Blood Pressure ................................................................................ 359
   Haider Noori Dawood

52. Common complications of Behcet’s Disease in Baghdad Teaching Hospital ........................................... 366
   Barq Wameedh Azeez, Atta AH Al-Sarray, Ali H. Al-Hafidh

Dhara Vyas, Fiza Sherasiya, Ami Patel

1109

155. The Undernutrition Prevalence of Under-Two-Years Infant in Indonesia: Do breastfeeding Practices Ecologically Matter?

Fandaruzzahra Putri Perdani, Agung Dwi Laksono, Djazuly Chalidyanto, Fandaruzzahra Putri Perdani

1113

156. Development of Surface Coating based Hybrid Acrylic Copolymers for Coating Application, Preparation, Characterization and Processing

Farah Safi Khliwi, Mohamed Ali Mutar, Ramaah Abdulhassan Sabit; Entidhar Kadhim Sahib

1120

157. Evaluation of Primigravida Women’s Childbirth Self-efficacy at Al-Elwea Maternity Hospital in Baghdad City

Fatima Fadel Benyian, Rabea Mohsen Ali

1127

158. Neoplasia of the Nictitating Membrane in A Domestic Short-Haired Cat based on Cytology of Fine Needle Aspiration

Fatimah Alaydrus, Lita Rakhma Yustinasari, Juliano Mwenda Ntoruru

1134

159. Nursing Intervention Program for Enhancing Coping Patterns among Nursing Students

Fatma Adel Ahmed Ahmed, Sorayia Ramadan Abd El-fattah, Galila Shawky El-Ganzory, Hanaa Ezz El-din Prince

1137

160. Molecular Docking Human Plasma Kallikrein to Prevent Acute Respiratory Distress Syndrome(ARDS) in COVID-19 Patient

Feriawan Tan, Cindy ApriliaEkaPrasanty, Anna Surgean Veterini, YuaniSetiawati, Rizki Awaluddin, Fadilah Fadilah, Siti Khaerunnisa

1146
161. Effectiveness of Training Program Regarding Gullian Baree Syndrome Maneuver on Pediatric Nurses’ Knowledge and Practices
Amina Mohamed Thabet, Mahmud, Huda Shawky, Eman Hassan, Zahra Ahmed Sayed, Nora Abd-Elhamid Zaki, Naglaa Gamal Eldien Abdelhafez Hariedy

162. Molecular Detection of Helicobacter Pylori in Sheep at AL-Muthana Province of Iraq
Fiema Atiya Kareem, Nabeel M.H. Al-Maaly

163. Level of Knowledge and Perception Public of Forensic Odontology
Fuad Husain Akbar, Muliaty Yunus, Nadya Shefira Salsabillah

164. Serum Uric Acid Level in Oral Cancer Patients -Original Study

165. To Study the Effectiveness of Rotational Vestibular Stimulation on Improving Balance and Gravitational Insecurity in Children with Down Syndrome-A Research Protocol
Gauravi Desale, Ketaki Naik, Dipti Shinde, Rinkle Malani

166. Assess the Effectiveness of Planned Teaching Program on Knowledge Myths, Belief and Misconception Related to Complementary Feeding Practices
Geeta, Sunil Kumar Dular, Anu Grover, Akoijam Mamata Devi

167. Effect of an Educational Program for Patients Post Coronary Artery Bypass Surgery on the Compliance with Symptoms Management Strategies
Gehan Karawan Sayed Sallam, Kamelia Fouad Abdalla, Sara Fathi Mahmoud

168. Administrative Factors and Key Success Factors Affecting the Surveillance, Prevention and Control of Coronavirus Disease 2019 (COVID-19) among the Health Personnel at Sub-District Health Promoting Hospital
Gerattikun Kaenphrom, Prachak Bouphan, Krissana Aunthakot, Surachai Phimha

169. Total Quality Management (TQM) and Sports (Development, Concepts and Definitions)
Ghazwan Aziz Mohsen, Bashar Banwan Hasan, Haidar Mahmood Allawi

170. Deleted

171. Association between Metacognition and Obesity in Male Individuals of South Indian Population
Gokul.K, A.Sangeetha, Kumaresan M, Samuel Sundar Doss, Hemachandrika C

172. Profile of Rodenticide Poisoning at Vijayanagar Institute of Medical Sciences (VIMS), Ballari District, Karnataka, India: Retrospective Analysis of Cases from 2016 to 2020
Gururaj Biradar, Charan Kishor Shetty, Pavanchand Shetty H, V Yogiraj

173. Socialization Program for Prevention and Early Detection of Congenital Hearing Loss in the Families of Deaf Schoolchildren
Gwenny Ichsan Prabowo, Citrawati Dyah Kencono Wungu, Retno Handajani, Nyilo Purnami, Fis Citra Ariyanto
174. Deleted ................................................................................................................................................. 1244

175. Measurement of Some non-routine Markers in Patients with Chronic Kidney Disease............ 1252
   Haider Ali Laibi, Abdulkareem M. Jawad

176. Correlation between Total Ige and Cytokines (Interleukin-24 and Interleukin-4) in Patients with
   Allergic Urticaria .................................................................................................................................... 1257
   Hajır Salam Sabeeh Alghannami, Özcan Özkan, Fatih Bakır

177. Swimming Improves Memory Function and Decreases N-Methyl-D-Aspartate in Ageing Rats ...... 1264
   Hanik Badriyah Hidayati, Purwo Sri Rejeki, Lilik Herawati, Susi Wahyuning Asih, Suhartati
   Suhartati, Siti Khaerunnisa

178. Human Carbon Footprint as the Basis for Determining Healthy Indoor Volume Dimensions ........ 1270
   Harida Samudro, Sarwoko Mangkoedihardjo

179. Diarrhea Prevalence in East Java, Indonesia: Does Access to Sanitation and Health Behavior
   Ecologically Related? ............................................................................................................................ 1276
   Hario Megatsari, Agung Dwi Laksono, Anita Dewi Moelyaningrum

180. A Prospective Study to Determine the Timing of Complete Fusion of Spheno-Occipital
     Synchondrosis Using Computed Tomography ................................................................................... 1284
     Hariprasad T. Nambiar, Aysha Mehanaz, Nitika C. Panakkal, Suresh S, Visakh T

181. Autism Spectrum Disorder A Review ................................................................................................. 1290
     Harshith N, Kanakavalli K. Kundury

182. Deleted ................................................................................................................................................. 1293

183. Knowledge of Healthcare Providers toward New Corona Virus at Directorate of Military Medical
     Affairs Units ........................................................................................................................................... 1297
     Muhammed Hussein Ali, Wasnaa Jomaa Mohammed

184. Deleted ................................................................................................................................................. 1304

185. Gene Expression and Antioxidant Effects of Cinnamon (Cinnamomum Zeylanicum, Breyne) in
     Alloxan -Induced Diabetic Rats ........................................................................................................... 1312
     Hayder Ghazi Abdulshaheed, Haidar K.A. Alsaedi

186. The Role Sonographic Imaging Features in the Prediction of Necrotizing Enterocolitis Outcomes
     in Neonatal Patients .............................................................................................................................. 1321
     Hayder Neamah Hassan

187. Handwriting Change in Breast Cancer Patients .................................................................................. 1325
     Heba H Rohym, Ghada Mustafa Al-Galad, Noha Abdel Rahim Mohamad, Mohamed Ragab Teleb
188. Extraction and High Purification of Nicotine from Iraqi Tobacco Leaf For manufacturing, Pharmaceutical, and Medicinal Uses ................................................................. 1333
   Husam Alaa Hameed Al-Khinuliu, Essam Fadel Al-wan Al-Jumaili

189. Association of the TP53 Codon 72 Polymorphisms with PCOS Female Infertility in Karbala City .. 1340
   Inam Joudah Radhi, Abdullah Badr Manhy Alkhaleeli, Hameedah Hadi AbdulWahid

190. Immunological and Biological Manifestation of Rheumatoid Arthritis Patient in Iraq.................... 1344
   RusulH.Ahmad, AyaidK.Zgair

191. Isolation and Identification of Bacterial Burn Wound Infection in Iraqi Patient............................ 1351
   Jenan A. Ghafil, May. T. Flieh

192. Evaluation the Genotoxicity of PHB Nanoparticle by Micronucleus Assay................................. 1358
   Jenan A.Ghafil, May. T. Flieh

193. Molecular Screening of KI and WU Polyomaviruses among Patients with Chronic Kidney Disease and Urinary Tract Infections......................................................... 1366
   Manar Hussein AL-Aboudy, Musa Nima AL- Jiafry, Mahdi Hussein Al-Ammar

194. Effect of Noise on General Health Status of Electrical Generator Workers in Iraq ................... 1374
   Mohammed Fakhri Azeez, Fatima Wanas Khudair, Ali A. Al-Fahham

195. Effect Phenytoin Therapy to Fibroblasts and Angiogenesis of Enterocutaneous Fistula in Wistar Rat ................................................................. 1379
   Muhammad Budiman Irpan Bachtiar, Hermawan, Hardian, Ignatius Riwanto

196. Legal Policy in the Prevention of Narcotics in Indonesia............................................................ 1389
   Muhammad Yunus Idy, Marif, Handar Subhandi Bakhtiar

197. Recent Perspectives and Upcoming Directions in Molecular Diagnosis of Malaria: A Systematic Review .................................................................................................................. 1395
   Ola S. H. Almusaddar, Cyuzuzo Callixte

198. Synthesis and Characterization of New Oxo-Aztedine ,Imidazoldine and Thiazolidine Rings on Creatinine and Evaluation of their Biological Activity........................................................................ 1405
   RaadM.Muhiebes, Entesar O. AL-Tamimi

199. Evaluation of Diagnostic Accuracy of Ultrasonography and Low Dose Computed Tomography in Acute Appendicitis................................................................. 1412
   Saradiq Mudhafar Jebrur, MahmoudRadhi Jobayr, Haider Abdulameer Ghayad

200. The Inhibitory Effect of local T.bovei Volatile Oil Against ESBL- E.coli and Klebsiella pneumoniae Isolated From Patients with Urinary Tract Infections ................................................................. 1417
   Sawsan Qahtan Taha Al-Quhli, Safaa Abed Latef Al Maeni

201. Evaluation of Oral Manifestations of Patients with Parkinson’s Disease–An Observational Study ... 1424
202. Correlation between Superoxide Dismutase 1 and 2 Polymorphisms in Asthma Patients................. 1430
Walaa Najah Majid, Layla Mohsen Mehdi

203. The Biological Activity of Alcoholic Extracts of Cordia myxa Plant Against Klebsiella. Isolated from Infected Patients ................................................................. 1435
Bassam M. Shamkhy, Yass K. Abbas

204. Comparison of Akt Expression in the Cerebrum and Cerebellum of Newborn Mus musculus Exposed to Physical Stress and Psychological Stress During Pregnancy ........................................ 1440
Herlina Puji Angesti, Hermanto Tri Joewono, Widjiati

205. Clustering of Provinces in Indonesia based on Maternal Health Indicators ................................. 1446
Herti Maryani, Lusi Kristiana, Astridya Paramita, Pramita Andarwati, Nailul Izza

206. Steroidogenesis Mechanism, Disruption Factor, Gene Function, and Role in Male Fertility : A Mini Review .......................................................... 1456
I Gede Widhiantara ,, Anak Agung Ayu Putri Permatasari, I Wayan Rosiana , Putu Angga Wiradana, Bagus Komang Satriyasa

207. Nurses’ Knowledge about MCH Services at Primary Health Care Centers in Rural Areas of Babylon Governorate - Iraq ..................................................... 1469
Ibraheem Abdul-Hifid Hussein , Aysen Kamal Mohammed Noori

208. Case Report: A Rare Case of Glioblastoma in Patient with HIV-AIDS........................................ 1476
Ilham Munandar, M. Vitanata Arfijanto

Imelda EB Hutagaol ,, Muhamad Yusuf ,, Nicko Pisceski Kusika ,, Suyanto, Shinta Puja Tilusari

210. Varicella Pneumonia in an Elderly Patient .................................................................................. 1487
Isidro Lumanpauw, Usman Hadi

211. A Review on the Detection of Skull by Forensic Analysis.......................................................... 1492
J.Tracy Tina Angelina, Bathula Murali Krishna, A.R.Revathi, S.R.Preethi

212. Too Blue To Be True”: Indoxacarb Induced Methemoglobinemia- A Rare Case ...................... 1501
Jerry Jacob, Karthik Reddy C H , Jobin James, Nijila Janardhanan

213. Knowledge and Awareness towards Dental Management of Post-Cardio-Thoracic Surgery Patients among Dental Students........................................... 1508
Johara Maria Cruz, Keerthi Narayan. V, Vasumathi,D

214. Forensic Medical Assessment of Thanatogenesis in the Experience of Gunshot Injuries ............ 1515
Julia V. Zbrueva

215. A Study to Assess the Prevalence of Anemia and Knowledge Regarding Anemia among Adolescent Girls of Selected Schools of Gurugram, Haryana ...................... 1522
Jyoti, Varinder Kaur, Arindam Chatterjee
216. Effects of Medical Hand Washing on Hand Flora among Staff Nurses .................................................. 1530
   Kabita Dhami, Padmapriya S, Sasi Kumar S

217. Effect of Helichrysum Oil on Toothache .......................................................................................... 1543

218. Disorders of Kidney Function in Chronic Heart Failure .................................................................. 1547
   Kamilova Umida, Abdullaeva Charos, Atakhodjaeva Gulchehra, Beknazarova Saida,
   Masharipova Dilyafruz, Ikramova Feruza

219. A Review of Environmental Screening on Strategic Formulation in Health Care Sector .............. 1553
   KasihPuji Utami, Nur Wening

220. Basal Cell Adenoma – A Report of a Rarity in a Relatively Rare Site ................................................. 1558

221. Molecular Characteristics of Iraqi Lactobacillus plantarum Isolates and Evaluate its Natural
   Bacteriocin(plantaricins) Antimicrobial Activity against Pathogenic Bacteria ........................................ 1563
   Khadeeja S. Madhi, Mohammed H. Khudr, Rasha M. Othman

222. Outcomes of Fissurec to my and Advancement Flap in Management of Chronic Anal Fissure .......... 1574
   Khairallah Muzhir Gabash, Saleh Omairi, Sarab Muhammed Zeki Radhi

223. Evaluation of Leachate Quality at Municipal Solid Waste Landfill Site: Case Study in Sliwung,
   Situbondo Regency, East Java, Indonesia .................................................................................................. 1580
   Khoiron, Ari Probandari, Wiwik Setyaningsih, Heru Subaris Kasjono

224. A Study to Assess the Effectiveness of Planned Teaching Program on Knowledge Regarding
   Electro Convulsive Therapy among Patient’s Relatives Undergoing ECT in Selected Hospitals in
   Vadodara .................................................................................................................................................. 1588
   Kiran Patel, Seema Boresa, Mural Christian

225. Sensitivity and Specificity of Postmortem CT for Detection of Thoracic Injury .................................... 1593
   Komet Kosawiwat, RathachaiKaewlai, Pinporn Jenjitranant, Wisarn Worasuwannarak

226. Medical Coercive Measures Under the Albanian Legislation and their Application to Criminally
   Irresponsible Individuals ............................................................................................................................. 1604
   Kreshnik Myftari, Gëzim Myftari , Sevada Guço

227. The Role of IFN gamma and IL-10 in Breast Cancer ......................................................................... 1611
   LaleMaulin Prihatina, Willy Sandhika, Grace Ariani

228. Thyroid Storm in Post-Partum in Bangkalan Hospital: A Case Report .............................................. 1616
   Lambu Henderika Dacosta, Ferdy Royland. Marpaung
230. Role of Serum Levels of Thymidine Kinase 1 in Diagnosis and Differentiating of Prostatic Tumor. 1623
   Lara Balasim Al-Dahy, Basil O. Mohammed, Saad Dakhil F. Daraji, Mazin M. Farhan

231. Stigma and Mental Health During COVID-19 New Normal Transition in Indonesia ......................... 1629
   Leny Latifah, Yusi Dwi Nurcahyani, Diah Yunitawati, Marizka Khairunnisa, Cati Martiyana

   Lintang Puspita Prabarini, Kumboiyono Kumboiyono, Laily Yuliatun

233. Comparative Analysis of Acute Physiological Responses between Short and Middle Distance Swimming Athletes with Physical Loading Test ................................................................. 1645
   M. Ali Machfud, Muchammad Rif’at Fawaid As’ad, HariSetijono, Lilik Herawati

234. Utility of Percutaneous Endoscopic Gastrostomy for Nutritional Supportin Patients with Oropharyngeal Dysphagia ........................................................................................................... 1656
   Madhavan Iyengar, Niket Attarde, Arpan Shah, Pooja Shah, Poornima. V.

235. Effect of Health Literacy Intervention on Medication Adherence among Older Adults with Chronic Diseases ........................................................................................................................................ 1662
   Magda M. Mohsen, Bahiga Galal Abd El-Aal, Sally S. Hassan, Amal A. El-Abbassy

236. Self-management of Elderly Patients with Osteoarthritic Knee on Recovery Outcomes .................. 1670
   Magda M. Mohsen, Nabila E. Sabola, Nagwa I. El-khayat, Entsar A. Abd El-Salam

237. The Impact of Exclusive Breast Feeding on Infant Morbidity in The First Six Months of Infants Life ............................................................................................................................................... 1679
   Maha A. Muhsen, Jabbar T. Ahmed

238. Food Hygiene Knowledge and Practice among South Indian Women ................................................. 1686
   Mahadeva, Manasa P, Melby Elizabeth, Nancy Ruby, Priya Joy, Hezil Reema Barboza

239. How Can the Maternal Age and the Basal Level of Serum FSH Predict the ICSI Outcome? .......... 1694
   Maher Abbood Mukheef, Rihab Abbas Ali, Hind Hadi Majeed

240. A Cross Sectional Study of Deaths Due to Snakebite: Autopsied at a Tertiary Care Centre, Hubballi .................................................................................................................................................. 1701
   Mahesh M Devadas, Vijay N Tasgaonkar, Suresh Kumar Karthikean, Anand Patil

241. Comparative Study Thymol Oil and Some Gel Face Washing on Resistance Propionibacterium Acnes . 1706
   Mais E. Ahmed, Jenan A. Ghafil, Walaa Najim

   Makloph MG, Mohamed Masoud

243. Psychosomatic Effects of Sexual Harassment and Violence on Undergraduate University Female Students; A Cross Sectional Prevalence Study ................................................................................. 1722
   Makloph MG
244. Identification of Single Nucleotide Polymorphism on Bone Morphogenetic Protein 2 Gene in Non-Syndromic Cleft Lip/Palate Patient ................................................................................................................................. 1731
   Mala Kurniati, RM Coen Pramono D, Agung Sosiawan, David Sontani Perdanakusuma, Hari Basuki Notobroto, Andra Rizqiawan

245. Inhibitors in Hemophilia A with Posterior Dextra Femoral Region Hematoma ....................... 1738
   Malfira Iswary, Hartono Kahar

246. Topical Application of Povidone Iodine to Minimize Post Appendectomy Wound Infection .......... 1743
   Mamoon Othman Khalid Alabdulla, Asaad Mohammed Kadhim, Hussein Abduljabbar Shihab Al-Katrani

247. Factors Associated with the First Sexual Intercourse among Students: Population-Based Study ...... 1748
   Manasanun Limpavithayakul, Chuthamat Nopparat

248. Effect of Mannitol Hydration as Renoprotective on Cisplatin Induced Nephrotoxicity (CIN) in Head and Neck Cancer Patients ................................................................................................................................. 1757
   Mareta Rindang, Andarsari, Yunita Dyah, Kusumaningrum, Rosy Nurlita, Hapsari, Dwi Hari, Susilo, Dewi Wara, Shinta

249. The Function of the State in Providing Health Services: Indonesia Perspective ......................... 1766
   Marif, Muhammad Yunus Idy, Nurhaedah, Handar Subandi Bakhtiar

   Martino Handoyo, Hermina Novida

251. Assessment of Pesticide Biohazards in Neurodegenerative Diseases; Data Analysis Statistical Study ............................................................................................................................................................................. 1783
   Marwan M. Merkhan, Zeina A. Althanoon, Ahmed A Mohammed, Ibrahim M. Faisal

252. The Leptin Concentration Level in Progression of Hand Osteoarthritis Disease ......................... 1792
   Maryam Qais Ahmed, Ghaith Sael Mohammed

253. Formulation Herbal Mouthwash Combination Extract of Ginger and Lemongrass as Antibacterial Causes of Halitosis in Diabetes Mellitus Patients .............................................................. 1795
   Masriadi, Sukmawati, Hasta Handayani Idrus

254. The Concordance of Dysmorphic Erythrocyte and Cast Erythrocyte Examination using Flowcitometry, Low Condenser Light Microscope, and Phase Contrast Microscope in Children with Glomerular Hematuria ........................................................................................................... 1803
   Maya E. Roring, Jusak Nugraha, Risky V. Prasetyo, Ferdy R. Marpaung

255. Knowledge and Practice Regarding Prevention of Renal Calculi among Non Teaching Staffs of a Selected College of Health Sciences at Mangaluru ................................................................. 1810
   Maya Shaju, Amala Elsy Mathai, Dina Joseph, Albert Thampi, Jyothi

256. Financial Obstacles and Disadvantages of E-Learning From The Viewpoint of Dammam Teachers 1815
   Mayada Abu Alhomos, Tala H. Sasa, Nawal H. Bahtiti, Tasneem Aleyad, Omnaya Miri
257. Stature Prediction and Formulation of Regression Equation from Hand and Foot Anthropometry... 1823
Megha Rapotra, Jaswinder Kaur

258. Assessment of Knowledge Regarding First Aid among the Undergraduate Students: A Cross-
Sectional Study .................................................................................................................................... 1830
Melvin Jacob, Hezil Reema Barboza

259. Evaluation of Dental Implant Stability Regarding All-on-4 Concept Utilizing Two Different
Angles .................................................................................................................................................1836
Mohammad A. Hameed, Thair A. Hasan

260. The Effect of Oxidative Stress on Vitiligo Patients ................................................................. 1848
Mohammed Hasnawi Ali, Muthanna M. Awad

261. Effect of Exotoxin a isolated from Pseudomonas Aeruginosa against human Cancer Cell Lines......... 1853
Muthanna Hamid Hassan

262. A Comparison between Retro-Clavicular and Proximal Infraclavicular Approaches for Brachial
Plexus Block for Anesthesia of the Upper Limb ................................................................................. 1860
Mohammed Sami Hassan, Mohammad Asi Jabbar, Mortada Abd Al-Hussian Jubara

263. A Pathologist’s Perspective on Histopathology Examination of Autopsies and Various Incidental
Findings ................................................................................................................................................ 1867
Mohanvir Kaur, Lachhima Bhandari, Vijay Kumar Bodal, Sarbhjit Kaur

264. Incidental Neoplastic Tumours on Histopathology of Medico Legal Post Mortem Cases: A Ten
Year Study ............................................................................................................................................1876
Mohanvir Kaur, Kanwardeep Kaur Tiwana, Lachhima Bhandara, Shaina Goyal, Shiv Kumar,
Monika Kalyan

265. Stature Estimation and Formulation of Regression Equation from Ear Anthropometry in Haryanvi
Population ............................................................................................................................................ 1883
Monika Rathee, Jaswinder Kaur, Suresh Kanta Rathee

266. Facial Anthropometry: A Reliable Tool for Stature Estimation in Haryanvi Population.............. 1888
Monika Rathee, Jaswinder Kaur, Suresh Kanta Rathee

267. Stature Estimation and Formulation of Regression Equation from Ear Anthropometry in Haryanvi
Population ............................................................................................................................................ 1893
Monika Rathee, Jaswinder Kaur, Suresh Kanta Rathee

268. Therapy of Human Chorionic Gonadotropin (hCG) Hormone in Dairy Cattles that Have Repeat
Breeder on Pregnancy Rate in Tulungagung, East Java, Indonesia..................................................... 1898
Muhammad Aulia Rahman, Sri Pantja Madyawati, Oky Setyo Widodo, Pudji Srianto, Trilas
Sardjito, Rimayanti

269. The Impact of the COVID-19 Pandemic on Stopping and Completing the Period of Appeal
Against Judicial Rulings in Accordance with Jordanian law............................................................... 1903
Muhanned Farhan Al Taani
270. Unanticipated Ligature Strangulation: A Case Report
Mukul Sharma, Kimi Soumya Padhi, Manas Ranjan Sahu, Utkal Keshari Suna, Govinda Balmuchu

271. Self-Administration of Vecuronium by a Medical Student: An Autopsy Case Report
Mukul Sharma, Biplab Rath, Naveen A, Manas Ranjan Sahu

272. Copper Beaten Skull: An Incidental Finding in Autopsy
Mukul Sharma, Sasank Shekhar Maharik, Sarthak Aeron, Biplab Rath, Manoj Kumar Mohanty

273. Effects of Ascorbic Acid on Insulin Resistance in Hyper Insulinemic and Euglycemic Persons
Muntasder H. Dawood, Taha H. Al-Yasiri

274. Relation between Level of Some Immunological Markers and Liver Functions with Respiratory
Bacterial Infection in Sheep
Mustafa Ghazi Saeed, Bashar SadeqNooni, Entedhar Rifaat Sarhat

275. A Protocol of Low Dose Chest CT to Verify Suspected COVID-19 infection
Muthana Hussien Mohan, Mahmood Radhi Jobayr, Salam Mohmad Joori

276. Enhancement of Coping Patterns among Parents of Children with Attention Deficit Hyperactivity
Disorder
Nabila Atallah Attia Moawad, Ghada Mohamed Mourad, Fatma Ata

277. Knowledge, Attitude, Action, Ability to Pay (ATP), and Willingness to Pay (WTP) Young
Adults in Fulfilling the Need for Oral Hygiene Maintenance
Nadya Savira Giyansyah, Nadia Chairony, Indira Arella Harianto, Ulfie Rahmah Aliyah, Aryo
Dwipo Kusumo

278. Dental Health Care for Older Persons with Diabetes by Caregivers in Ubon Ratchathani
Namphet Tungyingyong, Ruengsin Thuennadee, Niruwan Turnbul

279. Endodontic Retreatment in Underfilled Root Canal of Maxillary First Molar with Chronic
Periapical Abscess: A Case Report
Nanik Zubaidah, Kun Ismiyatin, Cinitra Anindyia, Nindhira Puspita Sari, Singgih Harseno, Ahmad Asif Dzulfikar, Dian Dwi Pratiwi

280. Harlequin Ichthyosis the Most Severe Form of the Congenital Ichthyosis; A Case Report Study
Nasim Talebi-Azar, Mayam Rasouli, Babak Choobi Anzali, Rasoul Goli, Jaizech Karimi Johani, Navid Faraji, Amireh Hassanpour, Aynaz Bagherzadi

281. Assess the Effectiveness of Breast Crawl Technique on Selected Maternal and Neonatal Outcomes
among Mothers Admitted in Labour Ward at Selected Hospitals of Kheda-Anand District, Gujarat.
Neha Parmar, Patel Sonali, PrajapatiNilam, Patel Urja, Christian Richa, Patel Radhika, Parmar Mittal

282. The Effect of Capitation Value of Healthcare and Social Security Agency on Service Quality at
Primary Clinics
Neny Nurlaily, Titik Ernawati, FaraValeyria Irma Zain, Chomariyah
283. Patient Satisfaction with Hospital Services, Physicians and Nurses Care of Government Hospital in Sulaimani City ................................................................................................................................. 1993
   Niaz Mustafa KamalBekhal, Abdalwahid Amin, Bestun Ibrahim Hama Rahim

284. Multimodal Strategy to Improve Hand Hygiene Compliance to Practices among Staff Nurses .......2004
   Nilima Vasava, Praful Damor, Jayshree Vasava

285. Antimicrobial Peptide Cathelicidin and Vitamin D Receptor Gene Polymorphism in Oral Health....2011
   Nireeksha, Mithra N Hegde, Suchetha Kumari N

286. Primary Closure after Open Common Bile Duct Exploration in Comparison to T-tube Drainage.
   Our Experience in a New Medical College of Assam ................................................................. 2018
   Nirmal Kumar Agarwal, Jon Bordalai, Santanu Sarma

287. Detection of Mn – Dependent Chitinase for Wheat Root Rot Disease Control by Real time PCR.....2024
   Noor Maath Ahmed, Akeel Hussain Ali Al-Assie, Abdullah Abdulkareem Hassan

   Noor Syam Sidiq Himawan, Nur Wening

289. The Effectiveness of Dayak Song Art as a Media for Increasing Mother’s Knowledge about the
   Health and Development of Toddler ........................................................................................................... 2043
   Noordiati

290. Qari (Male Voice) Increases Higher Expression of Synapsin 1 than Qariah (Female Voice) in the
   Cerebrum Newborn Rattus Norvegicus ..................................................................................................... 2048
   Nur Laila Faizah, Hermanto Tri Joewono, Widjiati

291. Evaluation of Root Canal Morphology of Maxillary 2nd Premolars Using Cone Beam Computed
   Tomography in Chennai Population ......................................................................................................... 2053
   Nur Qistina Binti Ahmad Fauzi, Mahesh R

292. Application of Berry’s Index in the Analysis of Bite Mark ...................................................................... 2060
   Nur Qistina Binti Ahmad Fauzi, Gheena S

293. Mesiodistal Width of Mandibular Central Incisors between Different Genders in Chennai
   Population Using Cone Beam Computed Tomography .............................................................................. 2067
   Nur Qistina Binti Ahmad Fauzi, Mahesh R

294. Predispositions Factors Affecting Quality of Life in Children with T1DM During the Coronavirus
   Disease of 2019 Pandemic ............................................................................................................................. 2073
   Nur Rochmah, Muhammad Faizri, Yuni Hisbyiah Ike Wahyu Triastuti, Garindra Wicaksono,
   Anang Endaryanto, Soetjipto

295. The Effect of Collagen-Chitosan-Sodium Hyaluronates Intrastromal Implantation on Corneal
   Clarity and Transforming Growth Factor (TGF-B) (Experimental Study On New Zealand Rabbit) ..2080
   Nurul Fitri Shabrina, Reni Prasetyani, Prihatini Widiyanti

296. Review on Mobile Apps for Toxicovigilance .......................................................................................... 2090
   Nurul Syafika Nadiah Mohd Zabarudin, Sharifah Mashita Syed-Mohamad, Yulita Hanum P Iskandar
297. Stimulation of Male Voice during Pregnancy Results in Higher Expression of Brain Derived Neurotrophic Factor in Cerebellum of Newborn Rattus norvegicus .......................................................... 2101
   Nurvy Alief Aidillah, Hermanto Tri Joewono, Widjiati

298. Effect of Thunbergia Laurifolia Lindl. on Oxidative Stress and Blood Cholinesterase in farm Workers Exposed to Pesticides in the Mae Chai District of Phayao Province .......................................................... 2107
   Orapin Insuan, Padchanee Sangthong, Pennipat Nabheerong, Surachat Buddhisa, Peerawan Kengsangunsit, Suntorn Prompao, Benchaluk Thongchuai

299. Dental Panoramic Radiographs as Early Signs of Osteoporosis in Pre and Post Menopausal Women – An Observational Study .......................................................... 2114
   P.E. Chandra Mouli, Madhavan Prasad, T. Gopalakrishnan

300. Administrative Factors and Organization Climate Affecting the Performance of Health Personnel at the Emergency Department in Community Hospital .......................................................... 2121
   Padcharin Phomdonko, Prachak Bouphan, Nuttapol Yotha, Surachai Phimha

Effectiveness of Empowerment Programme on Stress and Care Giving Burden among Care Givers of Chronically Ill Patients Admitted in MMIMS&R Hospital, Mullana Ambala, Haryana

Shalini Youssouf¹, Jyoti Sarin², Eenu³, Bindu Joseph³

¹Nursing Tutor, ²Director Principal, ³Assistant Professor, Maharishi Markandeshwar University, M.M. College of Nursing, Mullana, Ambala, Haryana, India

Abstract

Background- One of the most compassionate and self-sacrificing things a person can do is care for a sick loved one. Caring for a family member with impaired mental and behavioral functioning presents the most stressful of care giving situations. Keeping family caregivers healthy and able to provide care is crucial to maintaining our nation’s long-term healthcare system.

Aims – To assess the effectiveness of Empowerment programme regarding stress and care giving burden among care givers of chronically ill patients in experimental and comparison group.

Material and Methods - A Quasi Experimental non Equivalent control group pretest post test design. 95 care givers of chronically ill patients (50 in experimental and 45 in comparison group) selected from hospital by using convenience sampling technique. Empowerment programme was administered in experimental group. Selected demographic characteristics, standardized perceived stress scale and standardized care giver burden scale were used to collect data.

Results- The study showed that the mean post test 1 and post test 2 stress score was 12.44 ± 2.10 & 12.26±2.05 and 14.11 ± 3.11 & 14.40± 3.12 in experimental and comparison group respectively. There was no significant correlation between stress and care giving burden. There was no association of care giving burden score of the care givers in experimental and comparison group with their selected patient demographic characteristics and there was no significant association of care giving burden scores with their selected care giver demographic characteristics in experimental group and in comparison group except gender.

Conclusion- Empowerment programme was effective in reducing stress and care giving burden among care givers of chronically ill patients

Keywords- Effectiveness, Empowerment programme, Stress, Care giving burden

Introduction

A chronic condition “is a physical or mental health condition that lasts more than one year and causes functional restrictions or requires ongoing monitoring or treatment”. Chronic diseases includes cancer, diabetes, hypertension, stroke, heart disease, respiratory diseases, arthritis, obesity, and oral diseases which can lead to hospitalization, long-term disability, reduced quality of life, and death and requires care giving. The experience of caring for a sick family member can represent a great burden on the caregiver, leading to deprivation and changes in family dynamics.

Around 68 millions Indians and 95 lakhs people of Haryana caregivers provide extensive help to impaired relatives with chronic illness. This is also because they are unprepared to provide care, have inadequate
knowledge about care giving.

Caregivers’ tasks include both direct assistance (e.g., helping with activities of daily living, medication and lifestyle management) and less visible tasks such as assessing symptoms and follow health care systems.1,2 The demands of care giving often get additional stressors in caregivers’ lives, commonly referred to as caregiver burden.3,4,5

It has been shown that long-term chronic illnesses create an even greater burden on the family in comparison to acute illnesses.6 Caregivers of patients with chronic physical illnesses often experience feelings of isolation and fatigue related to their increased responsibilities and challenges.7 Caregivers experience high levels of burden due to immense physical, psychological, and economic strain, facing not only stresses of care giving but also the impending death of a loved one.8,9 Caregiver burden has been explained as a multidimensional response to the negative appraisal and perceived stress resulting from caring sick individuals. Keeping caregivers healthy and able to provide care is crucial to maintain our nation’s long-term healthcare system.

If caregivers remain healthy, the quality of life for care recipients will substantially improve.9 It is important to reduce the burden of the care giver by training them how to do personal care (bathing, feeding, toilet, dressing etc.) properly in order to save their time and care giving burden. So that they can do all these activities effectively and by following all steps of the daily care procedures. Empowerment programme can be helpful in reducing care giving burden of the care givers of the chronically ill admitted patients.10

There are few studies in the literature, however, that has investigated the effect of PMR exercises and skill training programme on the care giving related stress and care giving burden for care givers. Thus, this study aimed to assessing the effect of empowerment programme and PMR technique on reducing stress and care giving burden among caregivers of chronically ill patients.11

### Materials & Method

A Quasi - Experimental design (non-equivalent control group pre-test- post-test design) was used to achieve the objectives of this study. Power analysis was used to select the sample size. The sample included 95 care givers were selected using the convenience sampling method. (50 in experimental group and 45 in comparison group) for this study.

Formal administrative approval was obtained from the Medical Superintendent and ethical committee of MM (Deemed to be University), Mullana, Ambala (Letter Number IEC- 1511) to conduct the final study. Ninety care givers were selected using the convenience sampling method. (50 in experimental group and 45 in comparison group) for this study. Research participants were enrolled in the study after written informed consent and they were assured about the confidentiality of their response. Permission for pilot study was taken from the Medical Superintendent of MMIMS&R Hospital, Ambala. Permission for final study was taken from the Medical superintendent of MMIMS&R Hospital Consent was prepared and filled for the study subjects regarding their willingness to participate in the research study. Purpose of the study was explained to the sample subjects before data collection.

### Data Collection

For data collection, the research team initially developed a demographic characteristics in two parts after an extensive review of the relevant literature to achieve good content validity. It consist of 10 items related to demographic characteristics of patient and care giver i.e. age, gender,religion, marital status, education, occupation, income, type of family, area of residence, family history, duration of illness, use of any relaxation technique. Two another standardized tools were used to collect data. Perceived stress scale was a standardized tool used by researcher to assess the stress. There were total 10 items in the tool each item is having maximum marks 4 and minimum mark 0. Care giver burden scale was a standardized tool and it included 22 statements refer to how much burden a care giver feels while
taking care of their patient. Per statement care giver can choose one out of four option categories, varying from lowest score as 1 and highest to 4. Application of intervention was proceeded by administration of Empowerment programme for 4 days to each care giver. The empowerment programme included Progressive muscle relaxation technique session for 4 days daily along with administration of video of orientation to various important places of hospital, demonstration of oral care and bed bath procedure to the care givers and group discussion regarding management of stress, financial burden, diet management and personal hygiene of caregiver.

Intervention was pre evaluated by the experts before proceeding for administration.

To insure content validity, the tool was submitted to 9 experts: 3 from mental health nursing department, 6 from medical surgical department. The experts were requested to review and judge the items of adequacy and relevancy. The scale content validity was calculated by averaging item content validity index. The acceptable range of validity is 0.7 – 1. The tools were found to be valid for the study.

To assess the suitable sample size, a power analysis was performed. It was done with the help of formula Cohen’s d i.e. \( \mu_1 - \mu_2 / \text{SD} \) where \( \mu_1 \) was mean score of non-randomized control group, \( \mu_2 \) was mean score of non-randomized experimental group and S.D. was pooled standard deviation of both groups. The estimated effect size was 0.63 at the power of 0.80, the recommended sample for each group was 44. 10% extra sample was taken from the calculated sample size. Thus a total of 105 caregivers were included in the study. Due to attrition during data collection time the final sample size was 95 care givers (50 in experimental group and 45 in comparison group). Pre test was conducted in both the groups. Empowerment programme was administered in experimental group and routine care was carried out. In comparison group post test 1 was taken on day 4 and post test 2 was taken on day 13-17. In experimental group, post test 1 was taken on day 4 immediately after completion of intervention and post test 2 was taken on day 13-17.

**Data Analysis**

To analyze data, descriptive tests, including frequency, percentage, mean, and standard deviation (SD) and analytical tests, including the Kolmogorov–Smirnov test was conducted to indicate that the data were sampled from a population with a normal distribution. The correlation between stress and care giving burden mean score was examined by the Pearson correlation coefficient, and ANOVA for repeated measuring using the SPSS software (version 20). There was a significant difference at the level of \( P < 0.05 \).

**Results**

The results showed that less than half (44%) of the patients were in age group of 36-51 years in experimental group and one third (33.3%) of them were in age group of 52-67 years in comparison group. More than half of them (54%) in experimental group were females and 53.3% in comparison group were males. All the patients (100%) had surgical diagnosis in experimental group and medical diagnosis in comparison group. One third of the patients (32%) in experimental group and comparison group (33.3%) were having 8-11 months duration of illness. Most of the patients (72%) in experimental group and (73.3%) in comparison group were married. More than half (56%) in experimental group and 55.6% in comparison group of the patients visit to hospital in a month. Also the result showed that half of the care givers (50%) in experimental group and less than half (42.2%) in comparison group of the care givers were spouse. More than one third of the care givers (36%) were in 18-33 years of age in experimental group and less than half of the care givers (44.4%) were in 34-49 years of age in comparison group. More than half group (58%) of the care givers in experimental and more than half (55.6%) of the care givers were in comparison group were females.

Less than half of the caregivers (42%) in experimental group were having 5th pass education and
in comparison group one third of the caregivers (33.3%) were non literate. Less than one third of the caregivers (30%) in experimental group were having private job and 26.7% in comparison group were farmers. Less than half of the caregivers (44%) in experimental group had 7000-8000 rupees income per month and 40% in comparison group had 9001-10,000 rupees income per month. More than half of the caregivers (58%) in experimental group and (53.3%) in comparison group belonged to nuclear family. All caregivers (100%) in both the groups were not using any type of relaxation technique.

Frequency and Percentage Distribution of Experimental and Comparison group in terms of Level of Stress among Caregivers of Chronically ill Patients before administration of Empowerment Programme

![Figure 1 Bar diagram showing Level of Stress among Caregivers of Chronically ill patients before administration of Empowerment Programme](image1)

Frequency and Percentage distribution showing Comparison of Experimental and Comparison group in terms of level of Care Giving Burden among Caregivers of Chronically ill Patients before administration of Empowerment Programme

![Figure 2 Bar diagram showing level of care giving burden among Caregivers of Chronically ill Patients before administration of Empowerment Programme.](image2)
Research findings showed that the comparison of mean stress among care givers before the administration of empowerment programme in experimental and comparison group by using independent ‘t’ test. The calculated ‘t’ value was found to be statistically significant ( ‘t (93) =1.98; p=0.00*) which showed the difference between stress score was significant in both the groups and the comparison of mean score of care giving burden score among care givers before the administration of empowerment programme in experimental and comparison group by using independent ‘t’ test. In the experimental group, the mean pre-test care giving burden score of care givers was found to be 54.94 ± 4.683 and 52.73 ±8.097 in comparison group before the administration of empowerment programme with the mean difference of 2.206 and standard error of mean difference was 1.34. The calculated ‘t’ value was found to be (t(93) =1.98; p=.150NS) statistically non significant which showed that the difference between care giving burden score was non significant in both the groups.

Research results revealed that post test 1 and post test 2 stress score ranged from 8-18 & 8-16 in experimental and 9-21 &10-21 in comparison group. The mean post test 1 and post test 2 stress score was 12.44 ± 2.10 & 12.26±2.05 and 14.11 ± 3.11 & 14.40±3.12 in experimental and comparison group respectively and post test 1 and post test 2 care giving burden score ranged from 35-53 & 33-53 in experimental and 34-66 & 34-66 in comparison group. The mean post test 1 and post test 2 stress score was 41.34 ± 3.52 & 40.84 ± 3.62 and 51.98 ± 5.28 & 51.56 ± 5.31 in experimental and comparison group respectively. [Table 1, Table 2]. Results of ANOVA with repeated measurement uncovered that in experimental and comparison group there was a significant difference in the mean stress score in pre test (25.96) (19.96), post test 1 (12.44) (14.11) and post test 2 (12.26) (14.40) and computed F value was 706.7 and 42.23, p= 0.00 which was statistically significant at 0.05 level of significance. Also, in experimental and comparison group there was a significant difference in the mean stress score in pre test (54.94) (52.73), post test 1 (41.34) (51.98) and post test 2 (40.84) (51.56) and computed F value was 28.94 and .885, p= 0.00 and p=.354NS in experimental and comparison group respectively, which was statistically significant at 0.05 level of significance in experimental group [Table 3, Table 4]. Pearson correlation coefficient showed that there is no significant relationship between stress and care giving burden. In addition, research results also demonstrated that there was no significant association of association of pre-test stress score of the care givers in experimental and comparison group with their selected patient demographic characteristics.

Discussion

In this study, more than half of the care givers (58%) were females and most were married (68%). This findings was consistent with the results of study conducted by Nimisha K. Parekha, Shamita Shahb et al which showed that most number of care givers were females (66.9%) and majority of them were married (87.7%). Another study conducted by Sharon L. Lewis, Denise Miner-Williams et al which showed that majority of the care givers (81.3%) were married.

In this study half of the care givers (50%) were spouse of patients. The finding was contradictory with the result of study conducted by Sharon L. Lewis, Denise Miner-Williams et al which showed that majority of the care givers (74.5%) relationship with the patient was spouse.

In the present study less than one third of the care givers (30%) were having private job. The finding was contradictory to the study conducted by Sharon L. Lewis, Denise Miner-Williams et al which showed that maximum (75.5%) of the care givers were unemployed.

In the present study none of the care givers were using any type of relaxation technique. This finding was contradictory with the result of study conducted by Nimisha K. Parekha, Shamita Shahb et al which showed that more than half (53%) of the care givers were not using any relaxation techniques.

In the present study, the mean stress scores of care givers in experimental group before and after the administration of empowerment programme was 25.96 and 12.44 in post test 1 respectively and the p value was statistically significant p=0.00*. The result was consistent with the study conducted by Palak Patel which showed that mean stress score before and after administration of the intervention was 64.67 and 36.67 respectively and the p value was statistically significant p=0.00*.

Recommendations

1. The study can be replicated on a large scale to investigate whether the significant findings can be sustained among a larger group.
2. A similar study can be conducted in different settings
3. The experimental study can be conducted to find out the effectiveness of Progressive Muscle Relaxation Therapy on stress among caregivers of mentally ill patients.
4. A comparative study can be conducted to find out the level of stress and care giving burden among care givers of patients admitted in the selected government and private hospitals.
5. A Qualitative study can be done to assess stress and care giving burden among care givers of chronically ill patients.

Conclusion

Empowerment programme was effective in reducing stress and care giving burden among care givers of chronically ill patients.

Acknowledgment: This paper is based on the findings of an approved research project with a registration number CTRI/2020/04/024895. Also, we would like to thank all the people who helped us to perform this study, especially care givers.

Study of Various Patterns of Azygos Venous System and its Clinical Significance

Aarti Rohilla¹, Monika Rathee², Kamal Singh¹, Suresh Kanta Rathee³
¹Professor, ²Demonstrator, ³Sr. Prof. & Head, Department of Anatomy, Pt. B. D. Sharma PGIMS, Rohtak

Abstract

Background: The azygos system includes those veins which are straight in course, paravertebral in position and not accompanied with the corresponding arteries. The azygos vein may arise as lumbar azygos vein from the back of inferior vena cava or by the union of right subcostal and right ascending lumbar veins. It enters the thorax, receives lower 8 right posterior intercostal veins, superior intercostal vein, hemiazygos and accessory hemiazygos veins and ends by joining the superior vena cava. The hemiazygos vein is formed on the left in a manner similar to that of azygos vein. The aim of the present study was to investigate the various patterns of the azygos venous system.

Methods: A total number of 30 cadavers were studied and were evaluated based on the study of Anson BJ and Mcvay CB.

Conclusion: Out of 30 specimens studied, 17 (56%) specimens showed normal pattern, 5 (16%) specimens showed caterpillar pattern and rest 8 (26%) specimens showed ladder pattern.

Azygos system of veins serve as an alternative drainage channel between superior vena cava and inferior vena cava in case of obstruction. The knowledge of various patterns could be useful for radiologists and surgeons to prevent intra-operative hazards.

Key Words: Azygos venous system, Caterpillar, Hemiazygos vein, Ladder.

Introduction

The azygos system includes those veins which are straight in course, paravertebral in position and not accompanied with the corresponding arteries. This system communicates with the vena caval system in front and with the vertebral venous plexus behind and can provide an alternative pathway for blood to the right atrium when either of the venae cavae is blocked. The terminal veins of this system are the azygos, the hemiazygos and the accessory hemiazygos veins.

The azygos vein is unpaired and mostly lies on the right side of the thoracic vertebral column draining itself into the superior vena cava. While the hemiazygos vein and the accessory hemiazygos vein present on the left side of the body, they are considered tributaries of azygos vein rather than its left side equivalent¹, hence the vein is so named.

Variations can be found by various researchers in origin and branches of different arteries like external carotid artery² and brachial artery³, unilateral or bilateral absence of nerves⁴ and also in venous system⁵. The azygos system of veins is also subjected to wide range of variations in relation to origin, course, pattern, tributaries and anastomoses⁶.
Anomalies of azygos veins are not very rare. Several deviations in pattern of this venous system are reported in the literature and these variations result predominately due to its complex embryological development. The development of this system is controversial but the azygos vein is considered to derive from the upper right supracardinal vein, the azygos arch from an upper segment of the right posterior cardinal vein and the hemiazygos and accessory hemiazygos veins from the left supracardinal vein and the terminal part of the left posterior cardinal vein.

The persistence of the embryological subcentral anastomosis between the right and left supracardinal veins form the transverse anastomosis between azygos and hemiazygos vein that gives the appearance of a ladder.

The various patterns of this system do exist and are physically normal. So, knowledge of these patterns is important during magnetic resonance imaging reports and mediastinal computed tomography and also important for cardiothoracic surgeons to prevent inadvertent haemorrhagic complications during mediastinal surgeries.

Results

In the present study, out of 30 specimens studied, 17 (56%) specimens showed normal pattern of azygos venous system, while the 5 (16%) specimens showed the (caterpillar pattern) single azygos vein towards midline and rest 8 (26%) specimens showed ladder pattern (as shown in Table 1). A ladder is a vertical or inclined set of rungs or steps.

Various patterns are as follows:

Type 1. Normal pattern of azygos venous system (Atypical).

Type 2. Caterpillar Pattern (Single Azygos Vein): Shifting of azygos vein towards midline along with absence of hemiazygos vein and accessory hemiazygos vein. The right and left posterior intercostal veins directly drain into the azygos vein and the pattern resembles to a caterpillar (Fig.1a, 1b, 1c).

Type 3. Ladder Pattern: There is transverse connection between the hemiazygos and accessory hemiazygos veins with the azygos vein across the vertebral column like a ladder (Fig.2a, 2b, 2c).

Discussion

According to Anson’s system of classification:

Type-I: This primitive and embryological form consists of two separate veins lying in parallel to each other in the posterior mediastinum, being anterior and lateral to the vertebral column with no connections between them. It is seen in 1% cases.

Type-II: 98% of all cases are in this form and it is known as the transition type. There are multiple retroaortic anastomoses between the azygos and hemiazygos venous systems.

Type-III: It consists of a single azygos vein lying at the midline, on the anterior surface of the vertebral column.

In the present study, 5 of our cases (caterpillar pattern) show shifting of azygos vein towards midline with the absence of hemiazygos vein and accessory hemiazygos vein comes under Anson’s type-III.

The other 8 cases (ladder pattern) show horizontal or retroaortic anastomosis between the hemiazygos and accessory hemiazygos veins with the azygos vein. This is according to type-II Anson’s classification. It is due to the persistence of venous channels between the azygos lines of two sides.

Bergmann et al have reported variations of azygos vein. The azygos vein receives the hemiazygos vein at T_8 or T_9 and accessory hemiazygos vein at T_6 or T_7 vertebra. When hemiazygos and the accessory hemiazygos veins are not completely formed, the posterior intercostal veins on the left side of thorax may drain into azygos vein independently and it lies in the midline.

Dharan N & Soames R reported a single vein which is formed by union of azygos and hemiazygos veins which is located in midline draining the right and left posterior intercostal veins into the superior vena cava and 26 cases of retroaortic communication in their study.

T. Kutoglu et al in his study observed 1 case of single azygos vein and 44 cases of multiple retroaortic anastomosis.

Shivanal U et al found shifting of azygos vein towards midline along with absence of accessory hemiazygos vein and similar type of transverse connections between azygos and hemiazygos venous system.

Satheesha Nayak et al observed the midline position of azygos vein which was possibly due to the old age and also reported 6 horizontal channels across the vertebral column connecting the azygos vein with the accessory hemiazygos and hemiazygos veins.

Saito A et al also reported the shifting of azygos vein towards the midline or left side due to aging.

Rao Y S & Banerjee A found the similar observation of three transverse retroaortic anastomosis between azygos and hemiazygos veins.

Kumar et al in his case report found a ladder pattern of azygos venous system.

Table 2. The following studies have classified the azygos venous system into three main types. Each of which have different sub-grouping.

Knowledge of these different variations is important in CT and MRI scans because some variations of azygos venous system can be confused with aneurysm, lymphadenopathy and tumours of posterior mediastinum.

Conclusion

Azygos system of veins serve as an alternative drainage channel between inferior vena cava and superior vena cava in case of obstruction. Anomalies of this system are often detected only during surgery which cause intra-operative hazards mainly haemorrhage. This knowledge of various patterns could be useful for surgeons to prevent such hazards.

Fetal Ilium as a Tool For Sex Determination: Discriminant Functional Analysis

Aarti¹, Luv Sharma², Kamal Singh¹

¹Professor, Department of Anatomy, ²Professor, Department of Forensic Medicine, Pt. B. D. Sharma PGIMS, Rohtak, Haryana, India

Abstract

Background: Sex determination has been the most intriguing puzzle for forensic pathologists and anthropologists for which efforts are being done since long. Sexual dimorphism is well established in the adult pelvis and it is known to provide the highest level of information about sexual dimorphism. This study was conducted to know whether this dimorphism exists in fetal bones?

Method: A total of 34 pairs of fetal pelvis bones (22 Males + 12 Females), age ranging from 4 months to full term were collected from unidentified dead fetuses brought in the Department of Forensic Medicine for the routine medicolegal autopsies, to study for sexual dimorphism in the Department of Anatomy, Pt. B. D. Sharma PGIMS, Rohtak. Samples were divided in 2 age groups and various metric parameters were recorded with the help of digital vernier caliper. Data obtained was subjected to descriptive & discriminant functional analysis.

Conclusion: Results of Descriptive and Discriminant Functional Analysis showed that sex determination can be done with 100% of accuracy by using different combinations of parameters of fetal ilium. This study illustrates that sexual dimorphism exists from early fetal life & after mid pregnancy; it can be clearly established by discriminant functional analysis.

This research was limited in its analysis due to less availability of specimens as this represents only the results in north Indian population. Future studies should be done to explore different populations to better understand the sexual dimorphism in fetal bones of different geographic contexts.

Key Words: Fetal Ilium; Sexual Dimorphism; Iliac Length.

Introduction

Sex determination is crucial for both archaeological inference and identification in forensic contexts. Forensic pathologists and anthropologists are trying to resolve the mystery of sex determination since long.

Although sexual dimorphism is well established with the adult pelvis and it is considered to supply the best level of data about sexual dimorphism.¹ However, studies on fetal specimens have reported contradictory results.²⁻⁴ Sexually distinctive features of fetal and neonatal pelvis have been reported.⁵ After that, there are many attempts to develop both metrical and morphological techniques for estimating sex in juvenile skeletons. The most consistent results so far have been obtained from morphological analysis of the ilium.⁶ Some researchers are of opinion that secondary sexual characteristics did not appear until puberty, so are the chances of estimating sex of foetal remains, while some have reported the
sexual differences in foetal ilium. The purpose of this research is to establish whether fetal specimens can be sexed accurately by discriminant analysis on ilium bone.

Material And Methods

The study was conducted in Department of Anatomy in collaboration with Department of Forensic Medicine, Pt. B. D. Sharma PGIMS Rohtak. A total of 34 pairs of fetal pelvis bones (22 Males + 12 Females), age ranging from 4 months to full term were collected unidentified dead fetuses brought in the Department of Forensic Medicine for the routine medicolegal autopsies during a period of three years. Only intact fetal pelvic bone sample from known and recognizable sex were collected. Fragmentary and unidentifiable fetal remains were not included in the study. Any gross malformation, congenital anomalies and fragmented bones were excluded from the study.

MEASUREMENTS FOR THE STUDY

Collected samples were divided in the following groups as shown in table 1.

<table>
<thead>
<tr>
<th>Specimen Sex/Side</th>
<th>Fetal Ilium Bone Specimen (Male)</th>
<th>Fetal Ilium Bone Specimen (Female)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>&lt;6 Months</td>
<td>&gt;6 Months</td>
</tr>
<tr>
<td></td>
<td>Left</td>
<td>Right</td>
</tr>
<tr>
<td></td>
<td>1a</td>
<td>2a</td>
</tr>
<tr>
<td></td>
<td>1b</td>
<td>2b</td>
</tr>
</tbody>
</table>

Each sample was measured separately and the following measurements were noted after careful examination. (Fig.1).

Fig.1: Showing Metric Parameters of Fetal Ilium: Iliac Length (A-B), Sciatic Notch Angle (D), Sciatic Notch Width (C-E), Sciatic Notch Depth (Perpendicular line at D), Anterior Sciatic Notch Length (E-D), Posterior Sciatic Notch Length (C-D)
Metric Parameters of Fetal Ilium

1. Iliac Length (mm): Maximum Length from anterior to posterior iliac spine (A to B).\(^1\)

2. Sciatic Notch Angle (\(0\)): Using the apex of the notch (D) as the angle point of origin, the maximum angle was formed by the anterior and posterior edges of the sciatic notch (Angle C-D-E).

3. Sciatic Notch Width (mm): Maximum Breadth from anterior and posterior sciatic notch edges (C to E).

4. Sciatic Notch Depth (mm): Maximum length of line drawn perpendicular from notch apex (D) to horizontal axis created by sciatic notch width (C to E).

5. Anterior Sciatic Notch Length (mm): Maximum Length from Anterior sciatic notch edge to Apex (E to D).

6. Posterior Sciatic Notch Length (mm): Maximum length from Posterior sciatic notch edge to Apex (C to D).

These were measured by the digital vernier caliper with the least count of 0.01 mm. All the measurements were taken by the same investigator in the same setting. Each reading was taken thrice at the interval of 1 month, and statistically analyzed to rule out intra-observer error. The results of the study were computed and analyzed with SPSS software 16. Normal Descriptive Statistics i.e., Mean, standard deviation & P-Value as well as Canonical discriminant function coefficients in Discriminant Function Analyses were performed. The discriminant function formula is as follows:

\[ F(X) = A_1X_1 + A_2X_2 + \ldots + A_NX_N + C \]

Where \(F(X)\) represents the discriminant function score, \(X_1\) to \(X_N\) are the measured variables, \(A_1\) to \(A_N\) are the unstandardized coefficients of each variable and \(C\) is the function’s constant.

Results

Descriptive statistics of both the sexes for Left & Right sides of Fetal Ilium Bone were analyzed and compared respectively (Table 2 & 3).

Parameters which showed the statistically significant difference on comparison among left sides of the same age group are: posterior sciatic notch length on comparison between Group 1a & Group 3a, iliac length & sciatic notch width on comparison between Group 2a & Group 4a (Table 2).

On applying DFA on the individual parameters in age group of less than six month (Group 1a & 3a) has produced a sex determination accuracy of 85.7% in males with posterior sciatic notch length; 100% in females with sciatic notch depth; and 80% accuracy with sciatic notch depth & posterior sciatic notch length in both on left side. Whereas, a sex determination accuracy of 71.4% in males with iliac length & sciatic notch depth; 66.7% in females with all the parameters except sciatic notch depth; and 70% accuracy with iliac length in both on right side in Group 1b & 3b (Table 4).

</table>

On applying DFA on the individual parameters in age group of more than six month (Group 2 & 4) has produced a sex determination accuracy of 100% in Males with Sciatic Notch Width; and 100% in males, females and both with Iliac Length on both right and left sides. A 100% of accuracy for sex determination has been observed with different combinations of parameters of fetal ilium (Table 5).

**Discussion**

Determination of sex had been the subject of interest since the eighteenth century. The difficulty in recognizing & applying morphological traits to the fetal bones has already been established & the methods prove unreliable when applied to different samples varying in the expression of morphological traits. Adult traits established for sexual dimorphism can’t be replicated & projected to fetal remains. In the adult pelvis, the primary focused area is the sciatic notch for sex determination. The same has been tried to project on fetal remains but with contrasting results.

Descriptive analysis of the present study showed that sciatic notch is wider in males than females in both the age groups (Group 1 & 2) and deeper in females in age group <6 months) and deeper in males in age groups >6 months. Thomson observed that the sciatic notch is wider and shallower in females than in males, the reason being the examined intact pelvis and measured the width...
of the sciatic notch as the length from the anterior greater sciatic notch to the margin of the sacrum that met the posterior inferior iliac spine posteriorly & it does not correspond to the standardized measurement currently applied. While Fazekas & Kosa (1978) stated that males show more significant notch depth and females display larger notch lengths.14

Schutkowski examined the Spitalfields London Juvenile Skeletal Collection, which contained individuals aged from birth to 11 years. The greater sciatic notch depth and angle, iliac crest curvature, and arch criterion were studied and it was concluded that the sciatic notch was mainly useful for the determination of sex. The visual assessment of sciatic notch angle determined angles more than 900 as females and ~ 900 as males. But the present study showed that sciatic notch angle was more than 1200 in all the age groups in both males and females.3 So, the sciatic notch has not been proved to be a good indicator of sex in fetal remains. Schutkowski used the fetal iliac bone outlines, especially the sciatic notch & proposed discriminant analysis, to determine the sex of fetus and infants based on the ilium, but did not consider age as criteria.4 Discriminant analysis is a versatile statistical method used to classify observations into two or more groups/categories or assign subjects to one group among several known groups. It has been used over descriptive analysis by researchers on various bone morphometric analyses to correctly classify the amongst the known groups.15-17 The discriminant analysis of fetal ilium by a 3D geometric morphometric approach with multi-slice computed tomography and results did not show any difference between male and female shapes in all age groups.18

The results of this study show that by discriminant analysis classification of sex can be done with 100% accuracy by taking fetal iliac length as criteria in late fetal age & early fetal age sex can be classified with 80% accuracy by taking Posterior Sciatic Notch as criteria and with 100% accuracy by the combination of parameters.

Embryological Basis

Ilium is the first bone to appear in both the cartilaginous template and the ossification centres. The sacroiliac joint both a synovial and synarthrosis joint is clearly formed by 10 weeks of intrauterine life.19 The three fetal pelvic bones are visible by ultrasound early in development; specifically, the iliac wings are evident by the end of the first trimester.20 Differences found in male and female pelvis reflect influences of hormones, particularly testosterone, on the development of the embryo as it progresses from an unsexed to sexed individual approximately the 8th week of intrauterine life.21, 22 At this time, testosterone is secreted at high levels and this continues until roughly the 20th week of intrauterine life. Male and female pelvic dimorphism has been clearly evident by 24th to 25th weeks of intrauterine life9, 23 with specific differences found in the angle and breadth of the sciatic notch, sub-pubic angle, and ischial length.8, 9, 14, 24

Conclusion

This study illustrates that sexual dimorphism exists from early fetal life & after mid-pregnancy; it can be clearly established by discriminant functional analysis. The findings in our study showed that discriminant functional analysis of fetal ilium bone determination of sex can be done with nearly 100% of accuracy and this can be used as a potential tool for forensic investigation for evaluation of sex in severely mutilated and decomposed bodies during post-mortem examination. Although a smaller number of samples and the only north-Indian population is a limitation to the study, future studies should explore different populations to better understand the sexual dimorphism in fetal bones of different geographic contexts.

Ethical Clearance: The samples were postmortem samples taken from unidentified bodies during routine medicolegal autopsies done by one of the authors himself. Thus, ethical clearance is not required.

Review on Current Trends in Hypertension

Aarti Thakur¹, Ruchi Kumari², Sakshi Tomar¹

¹Nursing Tutor, Department of Obstetrics and Gynaecology Nursing, ²Nursing Tutor, Department of Medical Surgical Nursing, Chitkara University College of Nursing, Chitkara University, Himachal Pradesh, India

Abstract

Hypertension is one of the serious medical condition that has risk factor for developing cardiovascular diseases. Around 33% of individuals having hypertension are undiagnosed and those who are diagnosed are not taking proper treatment. One of the significant reason for hypertension is premature death. In this review, we focused on modern directions of hypertension management with an attention on screening, diagnosis and drug selection. In urban areas of India hypertension incidence is estimated upto 20 to 40% and in rural area it is upto 12 to 17%. Hypertension shows no symptoms and during routine check-ups we can diagnose it. For management of hypertension the guidelines were developed by ministry of health. Various threats were identified regarding management of hypertension.

Keywords - Hypertension, Screening, Pre-hypertensive Stage, Malignant Hypertension

Introduction

World Health Organization has defined Hypertension as increase in systolic and diastolic B.P above 140/90mm Hg or both. When blood Pressure is more than 140/90 mm Hg we define it as Hypertension according to AHA.¹

In world everyone is facing common problem known as HTN. About 1 billion of individuals are suffering from HTN and it is expected that this figure may increase up to 2025. HTN is known as quiet executioner because it shows no symptoms. Sometimes during routine check-ups most of individuals are diagnosed as Hypertensive.² Systolic blood pressure is defined as contraction of pressure ventricles whereas when the ventricles are filling with the blood reflects is known as diastolic blood pressure. One of the most important determinant of cardiovascular, myocardial and coronary heart disease is systolic blood pressure.³

According to national committee on prevention, evaluation, detection and treatment of increased blood pressure classification of blood pressure is taken on 3 clinical visits.⁴

Pre-hypertensive stage is defined as High normal hypertension. Stage 1 is defined as when patients B.P is mild or borderline. Hypertension Stage 2 is defined as when patients diastolic B.P is 100 & systolic is >140. When patient’s diastolic B.P is more than 130 months & systolic B.P is more than 200 than it is termed as malignant HTN. This stage of hypertension can lead to renal failure as well as severe retinopathy. Some common Symptoms which may be seen in malignant HTN are visual disturbance and headache.5

On basis of etiology hypertension is of two types i.e. primary and secondary HTN. About 95% of cases are seen of primary hypertension whereas 5% of cases accounts for secondary HTN. The exact cause of primary hypertension is unknown but there are some specific causes of secondary HTN which are listed below in table.6

Pharmacological Management of HTN

The initial step for the treatment of HTN is assessment. Pharmacotherapy & non pharmacotherapy are also used for the treatment of hypertension. Guidelines which are recommended by joint national committee include 3 blood pressure measurements of both arms at alternate health check-up visits.7 Assessment should be done before starting the treatment of HTN. Assessment mainly includes client’s history, physical examination & causes through which basic investigation can be done for determining the first line agent for treatment of HTN. We must be aware of condition like DM, thyrotoxicosis& pregnancy. Assessment and diagnosis of hypertension should be done appropriately in clients.8 For clients having DM Blood Pressure should be done appropriately in clients. For clients having DM blood pressure should be managed till readings of 130/80 mm Hg and for other clients of BP should be managed at the readings of <140/85 mm Hg. Rapid Reduction of blood pressure can
be fatal because it may cause risk for developing stroke. Clients who are in HTN stage 1 are recommended for lifestyle changes, pharmacology & non pharmacologic therapy. Blood pressure should be reassessed for about 3 to 6 months prior to prescribing drugs. If there is no reduction in B.P after reassessment then it is suggested to start drug therapy.9

Non –Pharmacological approaches for Hypertension10:

- Bland Diet
- Exercise (Aerobic)
- Dieting Reduction
- Stress Buster
- Decrease alcohol
- Smoking Cessation
- Decrease exacerbate factors example- pain
- Controlling factors of arteriosclerosis

Drug selection Principle -

Pharmacological treatment should be given to clients with HTN or sustained pressure. If readings of HTN is more than 140/90 mm of Hg than decision for prescribing drugs depends upon risk of presence of diabetes, coronary events or end organ damage.11

Thiazides and blockers are agents for initiating treatment. Angiotensin receptor blockers are the agents which are less studied but are effective.12

If client condition is not getting improving from one drug it’s better to switch to another drug. The various factors such as Sex, age and race are considered as the most appropriate for first line treatment.13

ACE-I may retard progression of nephropathy in diabetes mellitus condition while beta blockers may retard progression of palpitations associated increased level of thyroid hormones.14

Thiazides and beta blockers are the first line agents for treating HTN having less side effects. Beta blockers drugs should be avoided in conditions such as DM because it may create hyperglycaemic reactions. Atenolol, metoprolol and bisoprolol are the drugs which must be used by considering appropriate dose in cardiovascular conditions.14

ACE-I agents are the first line agents or clients having left-ventricular dysfunction. Methyldopa or labetalol are the drugs which are used as first line agents during pregnancy because these drugs do not cause any harmful effect to foetus.15

In some of clients pulmonary edema is seen for that loop diuretics are prescribed because of their short duration .The effective antihypertensive drugs are ACE inhibitors. Drugs such as Diltiazen and Verampril cause adverse effects such as heart blockage, sinus tachycardia. The drugs that should be avoided are short acting CCBs because of large variations in tachycardia & B.P.16

Hypertensive crises

The blood pressure in accelerated hypertension is equal to or greater than systolic 18mmhg or diastolic 110mmhg. Some patients may be asymptomatic but some of them may report headache, breathing difficulty, visual failure, altered level of consciousness. The goal for management of hypertensive crisis is prompt which leads to sudden decrease in blood pressure. Hypertensive crisis does not have specific treatment, only furosemide plus hydralazine is advised every 15 minutes intravenously till the normal range of blood pressure is achieved.19

Major side-effects of antihypertensive drugs

The major side effects of thiazides are postural hypotension, hyperlipidaemia, impaired glucose tolerance, hypokalaemia, neonatal thrombocytopenia and hyperuricemia. Beta blockers have some adverse effects such as heart failure, cold peripheries, bradycardia, asthma, fatigue and bronchospasm.20

Low doses of ACE inhibitors are well tolerated and may cause side effects such as hyperkalaemia, renal failure, skin rashes and dry cough. Hydralazine causes systemic lupus erythematosus if given to slow acetylators but is reversible on omission of drug. Hydralazine
causes fever, vascular headache, hepatitis and peripheral neuropathy. CCBs causes adverse effects such as gum hyperplasia, headache, flushing, ankle edema and fatigue.20

Abstract

At the end of 2019, a mysterious outbreak appeared, forming an atypical pneumonia suspected of originating from an animal market in Wuhan China. The outbreak is a new type of coronavirus which is named as COVID-19 disease (2019 – nCoV, Novel Coronavirus). COVID 19 disease is a viral infection caused by SARS-CoV-2, namely the acute respiratory syndrome coronavirus 2 which emerged in Wuhan, China. Vaccines and antiviral drugs have not been found, meanwhile COVID-19 are prevented by using non-pharmacological interventions, one of the actions taken by several countries is to create policy protocols such as lockdowns.

The results of this study indicate that lockdown is effective in reducing the spread of COVID-19, it can be seen from the significant decrease in R0 and Rt, <1 in several countries after lockdown such as UK 0.99 (0.96–1.02), Italy 0.89 (0.87–0.91), French 0.76 (0.72–0.82) and Spain 0.74 (0.71–0.78) which means that someone who is infected cannot infect other people and the disease will die (disappear). The value of Rt also shows a consistent decline Rt to <1 (0.88) after 2 weeks of lockdown in Italy.

The conclusion from this literature show that lockdowns can reduce the spread of COVID-19 which is shown by the number of incidents before and after the lockdown which has decreased to zero cases in China. The decline in cases also occurred in Europe although at the beginning of the lockdown it was not significant but it was increasingly effective and continued to be significant after the lockdown was imposed.

Keywords: Effectiveness, COVID-19, Lockdown, Spread, R0, Rt

Introduction

At the end of 2019, a mysterious outbreak appeared in the form of atypical pneumonia suspected to have originated in an animal market in Wuhan China. The outbreak is a new type of coronavirus named Novel Coronavirus 2019 (2019-nCoV / COVID 19) by the World Health Organization (WHO)1.

Novel Coronavirus disease 19 (2019 - nCoV) is a viral infection caused by SARS-CoV-2, namely the acute respiratory syndrome coronavirus 2 which emerged in Wuhan, China2.

The rapid spread of the virus has led to implementation of preventive measures in the COVID-19 outbreak, such as reducing interactions between infected, uninfected and unidentified individuals. Recent research shows preventive measures begin with quarantine of infected and possibly infected individuals and prohibiting travel to restricted areas. Previous research has shown travel restrictions or interaction restrictions have had a positive effect on past SARS, Ebola, and Pes outbreaks. The lockdown in Wuhan is strictly limiting various activities and form of home quarantine. Social distancing, namely limiting community activities but not as strict as

Corresponding Author:

e-mail: judya.sukmana@hangtuah.ac.id
lockdown because residents are still allowed to leave the house for a maximum of 30 minutes³.

*Lockdown* is a limitation of physical contact between individuals and form of instructions not to leave the house in order to avoid the outside environment including with infected people without symptoms, in this condition only urgent matters or emergencies are allowed to do general activities. Lockdowns are increasingly being applied to countries affected by the COVID-19 outbreak such as Italy, China, UK, India, France and Spain but in contrast to the strict lockdown in China, the Italian government allows its people to continue to work, leave the house within hours and must maintain minimum distance of 1 meter per person. The State of Indonesia in the context of controlling the implementation of health quarantine based on Law Number 6 of 2018, one of the measures of health quarantine is large-scale social restrictions (PSBB) instead of lockdown ³–⁵.

**Methodology**

This study uses a literature study method with data from international journals (Scimago, Scopus) or national indexed (SINTA) which can be accessed completely. Articles were collected from the year 2015-2020.

**Lockdown**

A total of 214 countries have confirmed cases of COVID-19. With the increasing number of cases and deaths in this outbreak, many countries are taking strict restrictive measures such as school holidays, quarantine at home, working from home to imposing lockdowns (full restrictions on international and domestic travel) to slow the spread of the COVID-19 outbreak “Flatten the curve”. Lockdowns in each country is different depending on the effect it produces, apart from functioning to reduce the spread of the outbreak, lockdowns also have a good impact on the environment ⁶,⁷.

**Result**

The cases in Italy before the lockdown were 9,172 cases a day later to 10,149 cases. The number of cases in India before the lockdown was 492 which then continued to increase. The country of Paris before the lockdown numbered 2,281 cases while the UK country had 2,630 cases before the lockdown⁸. China on February 29, 2020 there were 79,394 confirmed cases and 2,838 deaths from COVID-19, 48,557 cases came from Wuhan ⁹. WHO data shows that as of May 12, 2020, more than 4 million confirmed cases, around 280,000 deaths and around 215 countries, regions or areas were confirmed infected. Europe and North America starting in May, were the continents worst affected by COVID-19, namely 1,755,790 and 1,743,717 cases as of 12 May 2020, Spain with 224,000 confirmed cases, followed by Russia 221,334 cases, England 219,187 cases, Italy 219,070 and Germany 169,575 which continues to grow rapidly⁸,¹⁰.

European countries report the number of cases up to 6.6 million cases (1.46% of the population), 1.2 million cases in Africa (0.10%) and 90,000 cases in China (0.01% of the population)¹¹.

Table 1 shows the estimation of R0 according to Lonergan and Chalmers that lockdown can reduce R0 below the number 1, even if only in some countries. In USA, the number of cases (n) 1,551,853 had R0 before 3.6 (3.4–3.8) and R0 after 0.97 (0.94–1.00), UK n 248,818 with R0 before 2.1 (1.8–2.3) and R0 after 0.99 (0.96–1.02), Italy with 227,364 cases and having R0 before 2.2 (2.0–2.4) and R0 after 0.89 (0.87–0.91), France with n 143,845 and R0 before 2.0 (1.8–2.1) and R0 after 0.76 (0.72–0.82), Spain with 233,286 cases with R0 before 2.2 (2.1–2.4) and R0 after 0.74 (0.71–0.78)\(^12\).

Table 2. R0 Before and After Lockdown in Wuhan, Hubei Province, China

Y. Li and friends’ research in China before Wuhan lockdown (before 23 January 2020) R0: 5.6015 in mainland China, after Wuhan lockdown and before the Hubei Province lockdown (23-26 January) R0: 6, 6037. Hubei Province in lockdown and without large-scale case screening, R0 in Hubei: 3.7732 and R0 outside Hubei Province: 0.9943, but after lockdown and large-scale case screening, R0 in Hubei becomes: 0.2020 and R0 outside Hubei province becomes: 0.0472 so that the average R0 in Hubei Province is 3.4094 until February 25, 2020\(^13\). Fang, Wang and Yang’s research shows that the lockdown in Wuhan shows a decrease in inflow into Wuhan by 76.64% and outflow from Wuhan by 56.35%, besides that with counterfactual simulations show that lockdown in the city of Wuhan has contributed to reducing the total infected cases outside of Wuhan, where if it is not carried out the lockdown shows the case rate was 64.81% higher in 347 cities in China outside Hubei Province and 52.64% higher in 16 cities outside of Wuhan that you are in Hubei Province \(^14\).
Figure 1. shows the curve of R0 after control measures in Wuhan on January 23, 2020. Lockdown shown by a blue vertical line, R0 begins to decline. The epidemic is slowly dying, seen from R0 starting at 2.71 on 23 January then dropping to below 1 on 8 February 2020 and dropping to 0.06 on 6 March 202015.

Another study showed complete lockdowns in Kensington and Chelsea without movement would reduce infections by 97%. Lockdown starts from March 9, 2020 in London. Based on several scenarios and baseline cases, it shows when the lockdown is eliminated on May 8, 2020 without any additional intervention R0: 2.56, while when weekly checks under lockdown conditions R0 shows 0.50 16.

COVID 19 resurfaced in the UK starting in late summer after most restrictions were lifted. In October, a large population-based study found 50,000-100,000 new infections each day. The British government on 12 October 2020 announced a social distancing program that is differentiated by each region which consists of 3 levels. The least restrictive grade 1 areas change to grade 2 or 3 as the incidence of infection increases. Tier 1 regions have a 10pm curfew and restrictions on the number of individuals when meeting. Region 2 is restrictions on individuals from neighbors and it is advisable not to travel if it is not important, while in region level 3 there are restrictions on closing places such as hotels and recreation areas such as pubs and restaurants. Incidence continues to increase in all regions of the UK despite these steps17.

The national lockdown will be carried out starting 5 November 2020 for 4 weeks. The 2nd lockdown is similar to the first one but schools and universities can be opened. Northern Ireland and Wales went into lockdown in mid-October. Lockdown in Northern Ireland allows retail can open and its citizens can gather with neighbors of up to 2 neighbors while in the country of Wales retail non-essential retail cannot open and residents are expected to always be at home and not make contact with neighbors.
Table 3. Types of Preventive Measures in the UK

</tr>
</tbody>
</table>

Research by Davies and colleagues showed that the Rt value decreased after various interventions such as: level 2 areas decreased by 2% (0 - 4), level 3 decreased by 10% (6 - 14), the type of lockdown in Northern Ireland, when schools were closed: 35% (30 - 41), schools opened: 22% (15 - 27), lockdown in Wales when schools closed: 44% (37 - 49), schools opened: 32% (25 - 39) and lockdowns in England decreased when the school was closed 36% (29 - 42), when the school was opened 22% (15 - 29).18

Evaluating the progressive result of transmission reduction through Rt which are divided into: 1) before lockdown, 2) the first week and 3) the second week after lockdown (18 and 25 March). Average R0 2.83 – 3.10 in 8 region in Italy. March 10, 2020 Rt 1.79 – 3.36, then 1 week after the lockdown (March 18) Rt fell consistently (Rt 1.28) and in the second week (March 25) Rt <1 (0.88) consecutively for 3 weeks in almost all regions.19

Lockdown show high effectiveness in reducing spread and mortality, but has a negative effect if it continues to be prolonged in the form of economic and social instability of the country.16 Journals about lockdown show when a country is late in lockdown the number of infected cases will be more and increase rapidly than countries that lockdown earlier. Countries that apply lockdowns with additional interventions or variables have better lockdown results besides that individual compliance with lockdowns shows a decrease in the spread of COVID-19 which is in accordance with the objectives of the lockdown itself.
Other studies showed no significant decrease in the number of daily cases after the lockdown instead an increase in the number of daily cases after 3 weeks during the lockdown. Cases are increasing rapidly possibly due to a lot of migration in various regions, besides that the failure of the lockdown in India during the lockdown period could be the result of several groups of individuals who did not follow the restrictions in India or because the number of tests carried out during a certain period has increased significantly which causes some studies have different results especially in some Indian country studies\textsuperscript{20}.

**Conclusion**

Lockdown is effective in reducing the spread of COVID-19 in several countries. Incidence of the spread of COVID-19 from several journals shows that after lockdown the case is lower than before the implementation of the lockdown, especially in China and European. Lockdown has the effectiveness in reducing the spread of COVID-19.

A Comparative Analysis of Misery Index and Its Impact on Health Indicators Across The Globe

Aishwarya¹, Rajmohan² Suganya.P³, Prabu.D⁴, Bharathwaj⁵, M.R.Prashanthy³
¹Undergraduate Student, ²Reader, ³Postgraduate Student, ⁴Professor and Head of the Department, ⁵Lecturer, SRM Dental College, Ramapuram

Abstract

Aim: This study aims to analyze the impact/relationship of the health indicators and the human development index over the globe’s misery index.

Materials and Method: In this paper, a comparative data analysis of the misery index, health indicators like mortality rate, disability rate, Quality of life index, and human development index, along with the ranking based on the human development index, were done by tabulating the data collected from the electronic sources.

Results: There was a strong correlation between the misery index, human development index, and health indicators.

Conclusion: This paper clearly shows that the misery index of a country was highly influenced by the health indicators, such as the mortality rate, disability rate, and Quality of life. Further, the human development index also had a comparative impact on the misery index of a country. Hence, this study depicted a descriptive statistical relationship among the misery index, the health indicators (mortality rate, disability rate, Quality of life) and the Human Development Index (HDI).

Keywords: Misery index, health indicators, mortality rate, Quality of life, Human Development Index (HDI).

Introduction

The misery index is an economic indicator, created by economist Arthur Okun. The index determines the performance of an average citizen economically in the macroeconomic states of a country. The misery index is calculated by adding up the inflation rate and unemployment rate of a nation.

The economic growth of a nation depends on the employment, price stability, and economic development of the citizen. These parameters are challenging to be calculated due to reasons like variables in the same units, etc. Hence, researchers have tried to use one figure that would help to represent the macroeconomic condition [1].

Okun’s Misery Index (economic discomfort index, 1970) was the first single variable index summarizing various macroeconomic indicators to deliver the economic state of the country [2]. Okun’s index is the most widely accepted and commonly used index attributable to its simplicity and competence to measure absolute values. This index is derived by adding up the unemployment rate and the inflation rates by catering equal weight to both the grades. An increase in the poor economic performance, unemployment, or rise in inflation rates will sequentially induce an increase in misery index. The misery index modified by Robert Baro (1999), Hanke (2009), but still Okun’s index is widely
used by the politicians to know whether the condition is getting worse or better [1,2].

Health is most important than anything in the world. The health of a population plays an influential role in the development of the country. Hence, specific indicators, such as the health indicators [3, 4], can measure the nation’s health status.

The main aim of health indicators is to keep the nation’s health score for the betterment [3]. There are ten leading health indicators to assess health status. Of those ten health indicators, the mortality rate, disability rate, and the Quality of life were the traditionally used indicators as death is a well-recorded event.

The mortality rate is a measure of the number of deaths in a particular population, per unit of time. The mortality rate expressed as the number of deaths per 1000 individuals per year. Quality of life is the general well-being of individuals in a society outlining the negative and positive features of life. Quality of life includes various contexts such as education, politics, religious belief, environment and many more country indicators.

Disability rate is a cumulative index of all types of disabilities, such as the visual disability, physical and mental disability seen per 1000 people of a country/community [3, 4]. The Human development index (HDI) is another similar index used commonly for the measurement of development. This index sums up the measure of life expectancy, education, and living standard, sequentially giving a clear quantifying idea for an individual [5].

This paper analyze the misery index all over the globe in the year 2019 and its relation with health indicators such as the mortality rate, disability rate, Quality of life and the human development index.

**Materials and Method**

In this paper, Misery index and its relationship with health indicators were evaluated. The Misery index for the year 2019 was retrieved from the electronic database [6]. Based on the misery index, the most ten miserable countries, the moderate ten countries, and the least ten miserable countries were only considered for ease and generalization of the analysis.

Simultaneously, the data regarding the health indicators among top ten, middle ten and least ten miserable countries for the year 2019 were also collected [7]. The health indicators such as disability rate, mortality rate and the Quality of life of an individual in a country were obtained from the electronic database [8].

Then the data regarding the Human Development Index (HDI) of these countries were also obtained from the online sources given by the United Nations development program for the year 2019 [9]. The collected data were analyzed and tabulated accordingly in the Microsoft excel using descriptive analysis.

Table 3 depicts the least miserable countries and its relation with health indicators. The mortality rate and the disability rate were considerably low while the quality of life index remains high.

**Discussion**

In this study, the misery index and its association with health indicators were evaluated. Table 1 shows about the most miserable countries and its relation with the mortality rate, disability rate, and Quality of life of the corresponding countries. Ukraine had the second highest mortality rate globally, with the highest disability rate sequentially being in the most miseries countries. On the contrary, Ukraine had an average quality of life index due to the best political and administrative structure [10].

Venezuela stands the top most miserable country in the world in the year 2019. This country had an average...
mortality and disability rate along with a good quality of life index on analysis. The main reason of this country to be among the top miseries countries was due to the fall in oil production, which made up to 95% of the country export, leading to fall of the inflation rate. Further, this country had high female empowerment along with specific educational transitions that aided the improvement of the country economic and social status. Additionally, table 1 shows that the countries with high misery index scores also had a high mortality and disability rate, whereas a comparatively low quality of life index.

In table 2, the countries had an average mortality rate, disability rate, and good Quality of life index without much variation. Further, these countries remain with the same misery index or mild variation for the past two years. This was attributed to the country’s political administration, workforce, and the environment. Except Bangladesh, Philippines, and El Salvador had a less quality of life index due to the insufficient remittances which affects the economic status of these countries. Further, table 2 shows India with an average misery index and an average mortality rate, disability rate, and good Quality of life value. The urbanization in India from traditional rural economies to a modern industrial country had been a problematic transformation as there were many barriers and obstacles leads the country to be miserable.

In table 3, all the countries had a high quality of life index, indicating that they can provide a sophisticated, comfortable, and safe environment for the people. Further, the other indicators like mortality rate and disability rate also appear to be below average, except Australia having a high disability rate due to indigenous Australians. Furthermore, studies conducted showed that countries like Australia, Switzerland, and Japan had a gradual increase in economic development as well as their expenditure and scheme implements to improve health sectors in the country.

On analyzing fig 2, 4 and 6, it can be noted that countries with high and average Misery index score have a low Human development index score and those countries with low misery index score had high Human development index score. Hence it can be concluded that the countries with lowest misery index have a good human development index.

On the overall analysis, the countries with high misery index scores had comparatively higher mortality and disability rate and simultaneously had a low quality of life and human development index. Similarly, the country with low misery index scores had a higher quality of life index and the human development index, along with a low mortality and disability rate.

Hence, the misery index is directly proportional to the mortality rate and disability rate of the country, i.e., higher the misery index, the higher will be the mortality and disability rate and vice versa. The misery index is inversely proportional to the Quality of life index and human development index, i.e., higher the misery index, lower the Quality of life and human development index, and vice versa.

Limitations:

This study only included available data till the year 2020. Only countries based on most, moderate and least miserable countries were considered, and the respective data about these countries was specifically collected for the year 2019. Further inclusion of all other countries will give more relevant results and a better understanding of this perspective.

Conclusion

The overall analysis of this study caters to a very strong point that the misery index of a country has a direct or indirect influence on the health indicators and the Human Development Index (HDI). Thus, a country with a high or low misery index scores will surely have a reflection on health indicators and HDI. Hence, the health indicators, the HDI, and the misery index of a country influence each other either directly or indirectly. This paper helps to identify the appropriate drawback of a particular nation which on rectification aids in the betterment of the same.

The Relationship of Perceived Benefit, Perceived Barrier, and Knowledge with Vaccine Hesitancy among Anti- and Pro-Vaccine Community

Aisyah Nur Izzati¹, Retno Indarwati², Makhfudli²
¹Student at Master of Nursing, Faculty of Nursing, ²Lecture, Department of Mental and Community, Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

Abstract

Introduction: The phenomenon of basic vaccine hesitancy in parents is the biggest challenge faced by health workers in the global era currently. This study aimed to analyze the relationship between perceived benefits, perceived barriers, and knowledge about vaccines towards vaccine hesitancy among anti and pro-vaccine communities on social media Facebook.

Methods: This study used a cross-sectional design. The sample was 150 members of the anti-vaccine community and 234 members of the pro-vaccine community on social media Facebook using a purposive sampling technique. Data were collected using questionnaire namely; HBM (health belief model) questionnaire which was translated and modified, and Vaccine Hesitancy Scale (VHS) questionnaire. The independent variables in this study were perceived benefits of vaccines, perceived barriers to vaccines, knowledge about vaccines. The dependent variable was vaccine hesitancy. Spearman rho analysis was used to measure the relationship between the dependent and independent variables.

Results: The results of the Spearman rho analysis showed that the perceived benefits of vaccines (p=0.363 of anti-vaccine, p=0.702 of pro-vaccine), the perceived barriers to vaccines (p=0.410 of anti-vaccine, p=0.341 of pro-vaccine), and knowledge about vaccines (p=0.413 of anti-vaccine, p=0.192 of pro-vaccine) was related to vaccine hesitancy in parents.

Discussion: This study results indicated that the perceived benefits of vaccines, perceived barriers to vaccines, and knowledge about vaccines are related to vaccine hesitancy in parents. The implications of the study are essential information for health workers to determine the right and wise strategy in responding to the increasing vaccine hesitancy in public so that basic vaccine coverage will increase.

Keywords: anti-vaccine, vaccine hesitancy, health belief model

Introduction

The number of countries reporting vaccine hesitancy in parents has continued to increase since 2017.¹ This controversial issue regarding vaccines is the biggest challenge for the implementation of vaccines in Indonesia.² It influences the stagnation of complete basic vaccine coverage. Basic Health Research of the Indonesian Ministry of Health showed that status of complete basic vaccination coverage in children aged 12-23 months had decreased from 59.2% in 2013 to 57.9% in 2018. Vaccination coverage must be maintained high and evenly distributed throughout the region to avoid the occurrence of extraordinary epidemic. Therefore, the government and health workers need to solve this...
problem immediately.³

World Health Organization stated that the anti-vaccine community was one of the ten most significant threats to global health in 2019 since this phenomenon could potentially increase the risk of an epidemic of a disease.⁴ The determinant of vaccine hesitancy among parents needs to be investigated further. A study conducted by Brunson stated that vaccine hesitancy and acceptance is a complex and multi-faceted issue so that the way health workers understand them also cannot be universally equalized.⁵

Pro-contra debate of vaccines in Indonesia has spread up again following the emergence of diverse arguments from society ranging from influencers, artists, and even health workers who are broadly spread through social media.⁶ Pro-vaccine community consider vaccines are essential to prevent infectious diseases for their children. On the contrary, anti-vaccine community consider vaccines contain dangerous substances that can harm their children. Community members on social media not only share textual context but also images to emphasize the message to other members.⁵ The debate between the anti- and pro-vaccine communities on the digital platform about vaccine controversy may decrease public trust in the government and healthcare providers in vaccination program.⁷

Vaccine hesitancy is one of the major challenges in achieving complete basic vaccine coverage. Some parents who accept the administration of vaccines are still worried.⁸ Schalkwyk⁹ in his study stated that social media is now used as a media to spread dangerous information about vaccines to strengthen the hesitancy of parents in giving vaccines to their children. Social media was chosen because of the increase people’s dependency online media to obtain accurate health information.¹⁰ The type of social media most used to spread anti-vaccine propaganda is the Facebook Group.¹¹

Indonesia is the fourth highest user of social media Facebook in the world with 130 million active users per month (Hootsuite and We Are Social, 2018).¹² Study results of the Ipsos-Center for International Governance Innovation (CIGI) showed that 65 percent of internet and social media users in Indonesia are susceptible to misinformation provided in cyberspace without prior confirmation. Thus, negative content including hoaxes about vaccines are easy to widespread in community. The current problems in the community obviously cause for concern for all health workers. Various studies on the pros and cons of vaccination have been broadly studied in several other countries, but still very limited in Indonesia. This study aimed to analyze basic vaccine hesitancy in the anti- and pro-vaccine communities on social media Facebook.

Material and Methods

This study used a cross-sectional design. The study was conducted in June-August 2020 by distributing questionnaires to respondents through Google form. The population in this study was mothers of the members of the anti-vaccine and pro-vaccine communities on social media Facebook. The number of the anti-vaccine community members on Facebook was 2,900 people, while the pro-vaccine community members on social media Facebook was 119,000 people. A total of 384 respondents (150 members of the anti-vaccine and 234 members of the pro-vaccine communities) were taken using purposive sampling technique. The inclusion criteria were mothers aged 18-40 years, are active real accounts, and are willing to be respondent. The independent variables in this study were perceived benefits of vaccines, perceived barriers to vaccines, and knowledge about vaccines. The dependent variable in this study was the basic vaccine hesitancy. The research instruments used in this study were adapted from the HBM questionnaire from Hwang et al. 2017, which was translated and modified. The vaccine hesitancy questionnaire was adapted from the Vaccine Hesitancy Scale (VHS) questionnaire by Saphiro G.K. et al. 2018

Quantitative data analysis in this study was performed using the Spearman Rho statistical test.

Results

Most of the anti- and pro-vaccine respondents
were 26-35 years old. Almost all of the religion of the respondents was Muslim, while only a few people were Christians and Catholics on the anti-vaccine group. The religions of pro-vaccine respondents were more diverse, ranging from Islam, Christianity, Catholicism, Hinduism, and Buddhism. The ethnicity of most of the respondents was Javanese, while the rest were Madurese, Batak, Chinese, Osing, and Balinese. Most respondents lived in urban areas, were university graduated, and almost half were high school graduated. More than 50% of the respondents were housewives, while the rest were self-employed, civil servants, and traders with most of them having income of more than 2,500,000 (Table 1).

Table 2 shows that all independent variables showed a significant relationship with basic vaccine hesitancy in the anti- and pro-vaccine communities.

Almost all pro-vaccine respondents had a high level of perceived benefits (95.7%). Meanwhile, for the anti-vaccine group, more than half of the respondents had a moderate level of perceived benefits (53.3%), 36% had a high level of perceived benefits, and 10.7% of respondents had a low level of perceived benefits. More than half of the anti-vaccine respondents had a moderate level of perceived barriers (66%), 24% were at a high level, and only 10% were at a low level. Meanwhile, in the pro-vaccine group, more than half of the respondents had a low level of perceived barriers (56.4%), while only 2 respondents had a high level of perceived barriers. More than half of the anti-vaccine respondents had good knowledge (59.3%), 28.7% was sufficient, and 12% had a lack of knowledge. Meanwhile, most of the pro-vaccine respondents had good knowledge about vaccines (85.9%) and only 4 respondents had a poor knowledge (1.7%). The results of statistical tests using Spearman Rho showed that perceived benefits, perceived barriers, and knowledge about vaccines had significant relationships with basic vaccine hesitancy.

**Discussion**

The results of this study indicated that the perceived benefits of vaccines are related to basic vaccine hesitancy in parents. Gowda\(^\text{13}\) stated that parents’ perceived benefits of vaccination are a specific factor that affects them in considering decisions about vaccination.

The results of a systematic review conducted by Forster\(^\text{14}\) found that there are different perspectives about the benefits of vaccination between people who refuse and accept vaccines. Anti-vaccines community doubt the benefit of vaccines and worry over their children safety. This study results were in line with the previous study, which showed that most of the anti-vaccine respondents in this study confirmed that they disapproved that vaccination was the same as maintaining the health of the surrounding community. They also disagreed with the arguments that all basic vaccines were given by the government is effective and beneficial when there are still incidents that may sacrifice a handful of children.

Karafillakis\(^\text{15}\) emphasized that as of today, scientists tended to discuss the importance of maintaining Vaccine-Preventable Disease (VPD) risks in a population, although most people are more interested in vaccines risks and side effects that might occur to their children. Analyzing the perceived benefits of vaccines felt by each parent seems tricky because it is easier for a person to overestimate risk by comparing its underestimated benefits. Parents are more interested in reading other people’s narratives or stories related to the negative effects of vaccines rather than considering the vaccines benefits at the population level.

The health workers must deliver information accurately regarding the risks and benefits of vaccines to the community.\(^\text{16}\) Health workers must be honest in explaining the possible side effects of vaccines because providing information focusing on the benefits of vaccination only is ineffective in influencing parents’ intention to vaccination program.\(^\text{17}\) Health workers should be encouraged to perform effective and open communication, such as by holding discussions while respecting the thoughts and perspectives of parents refusing vaccines.

This study also showed that perceived barriers to vaccination were related to basic vaccine hesitancy in parents. This result is in line with the previous research conducted by William\(^\text{18}\), which stated that parents who hesitate to vaccination had high perceived barriers to vaccines, one of which was a sense of concern about the safety of vaccines. The skepticism regarding to the vaccines safety is a complex issue that is being globalized today.\(^\text{19}\) The belief that giving vaccines into the children’s body will lead to various long-term dangerous side effects and even death is the essential reason for parents to refuse to vaccinate their children.\(^\text{20}\)

Anderson\(^\text{21}\) added that other barriers that can trigger vaccine hesitancy include confusing vaccine schedules, long queues, and inconvenience in the vaccine process. These various barriers indirectly contribute to the low rate of basic vaccine coverage and delays in the schedule for providing vaccination to children. The previous
study conducted in four countries by Olorunsaiye et al.\textsuperscript{22} showed that the waiting time period in health facilities becomes a barrier for parents to give vaccines. Some parents prefer to stay at home and carry out other essential work rather than have to queue for a long time at health services. This issue may often be underestimated but needs to be addressed immediately to shorten the waiting time for parents who intend to give vaccines in health services.

Another barrier experienced by almost all anti- and pro-vaccine participants was related to the depletion of vaccine stocks. Several participants complained that they had to go back home since the health services run out of vaccine stocks. Although health care worker had arranged the new scheduled, but the parents considered it was not effective. According to the statement of Panting\textsuperscript{23} that the lack of vaccine stocks and the poor organized schedule of vaccination in health services become one of the reasons for vaccine hesitancy in parents. Overcoming vaccine hesitancy needs a particular process of detection, diagnosis, and intervention since there is no simple strategy that can overcome all the barriers felt by parents in accepting vaccines.\textsuperscript{24} Health workers are required to collaborate with policymakers to minimize a number of barriers for parents to accept basic vaccines.\textsuperscript{19}

The results of this study indicated that knowledge about vaccines influences basic vaccine hesitancy. It is in accordance with the previous study conducted by Facciola\textsuperscript{25} which found that parents with low knowledge about vaccines tend to feel hesitant about vaccination. Consideration of parents’ decisions regarding vaccines is context-specific and does not rely on knowledge about vaccines and information obtained only but also on attitudes, values, experiences, and emotions.\textsuperscript{26} A study conducted by Ugezu\textsuperscript{27} stated that the knowledge and attitudes of health workers regarding vaccines influence the decision of parents to give vaccines. Therefore, health workers need to have the good knowledge and attitude about vaccination program since they are most trusted by the parents and community in the process of making decisions about vaccines (Dybsand, Hall and Carson, 2019).\textsuperscript{28}

Knowledge about vaccines is essential but not sufficient to change one’s perception of vaccine hesitancy.\textsuperscript{29} Providing information constantly and firmly to parents who are hesitant about vaccines can be contradictory because if someone is given continuous information that contradicts their values, they will react defensively and lead to resistance.\textsuperscript{30} Therefore, health workers need to identify the most appropriate communication strategies to reduce these unwanted impacts. According to Shapiro\textsuperscript{31} effective communication that is performed gradually is the main tool for health workers to disseminate the information about the vaccines needed, the timing of administration, and side effects to increase parents’ acceptance of vaccines.

**Conclusion**

The results of this study indicated that the perceived benefits of vaccines, perceived barriers to vaccines, and knowledge of vaccines are related to basic vaccine hesitancy in parents. The implications of the results of this study are essential information for health workers to determine the right and wise strategy to respond to the increasing vaccine hesitancy of the public so that basic vaccine coverage will increase. This study was conducted to analyze the background of vaccine hesitancy in mothers who are members of the anti and pro-vaccine communities on social media. Further research is needed to explore various other factors that cause vaccine hesitancy in parents in real life.

Knowledge and Attitude Regarding Medication Error among Nursing Students in a Selected College at Mangaluru

Ajanya Shaju1, Aleesha Babu1, Dona Sebastian1, Mary Joseph1, Pavithra K2
1IVth Year B.Sc Nursing Student, 2Lecturer, Department of Medical Surgical Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be Univesity), Mangaluru, Karnataka

Abstract

Background & Aim: Errors are an integral part of human life. In the human healthcare system, advancements are all time high. The system of treatment is becoming more hi-tech and more sophisticated which is vulnerable to the errors at the same time. Effective medication error reporting is a necessary tool to prevent and reduce its occurrence. This study aimed to assess the knowledge and attitude regarding medication error among nursing students.

Methods: A Descriptive approach was adopted for the study. By Stratified Random sampling 125 Nursing Students were selected. The data was collected using Demographic Performa, Structured knowledge questionnaire and Attitude scale. The data obtained were analyzed by descriptive and inferential statistics using SPSS version 16.0.

Results: Results showed that majority 67.2% of the Nursing students had average knowledge and 88% had positive attitude towards the reporting of medication error. There was no significant correlation between knowledge and attitude among nursing student regarding medication error.

Conclusion: The Study concluded that despite sufficient knowledge and favourable attitudes towards medication error reporting, there is still an under-reporting of medication errors when it comes to practice. It was clear that the nurses need specific information about what constitutes medication error.

Key words: Attitude, Knowledge, Medication error, Nursing Students

Introduction

Medicines cure, but they can also kill or cause severe adverse reactions if a wrong medicine or wrong dose is administered. Medication error represents the largest single cause of error in the hospital settings. Medication treatment is a basic primary treatment for any type of illness. It is a multi-disciplinary approach that requires coordinated efforts and involvement of healthcare professionals to carefully distribute medicines to the patients without causing any error.

Patient safety is a common goal for every healthcare provider. One of the major issues for safety is medication errors. It is important indicator of health care delivery system because potential injury to patients, Over 2 million serious ADRs requiring hospitalization, causing death occur each year.

Mostly everybody in the world takes medication at one time or another. In India, the medication errors and medication related problems are mainly due to irrational use of medications. The number of errors and distribution of errors might vary in different settings. It has been reported that experts believe at least one medication error occurs per hospital patient every day.

A study conducted on the medication error in a general hospital of Bangalore; Karnataka which showed that the overall incidence of medication error was 38.12%.
Medication error is caused by the health care professionals, who involve in the direct patient care such as Nurses, Doctors and the Pharmacists which lead to the harmful effects on the patients which can end up in death sometimes. However, it can be prevented largely if an extra caution and concern is taken by the Nurses.6

Nurses play a major role in preventing, identifying and reporting the medication error. Inspite of the medication error, some nurses fail to report the error because of their perceived barrier. In order to prevent the medication error completely, nurse’s perception should be changed by enhancing their knowledge regarding the safe practices of medication administration.7 Hence the awareness regarding the various causes, management and reporting the medication error plays a major role in reducing the medication error incidents and its consequences.

Materials and Methods

The Descriptive correlational research is being conducted in Yenepoya Nursing College, Karnataka, India after obtaining the ethical clearance (Protocol no 2019/029) from Institutional Ethics Committee, Yenepoya (Deemed to be University). Nursing students of 2nd yr, 3rd yr, 4th yr B.Sc. (N) course, 1st and 2nd yr P B B.Sc (N) course were included in the study. 125 Nursing students were selected by Stratified Random sampling. Informed consent was obtained and confidentiality of information were assured. Students of 1st yr B.Sc (N) not learnt about medication administration, Students of M.Sc Nursing course and Students who are not available during the period of data collection were excluded from the study. Data was collected using self prepared knowledge questionnaire and attitude scale, which was validated by 7 experts. The reliability coefficient of the tool was 0.795.

The data were analyzed by descriptive and inferential statistics using SPSS Version 16.0. Demographic variable, knowledge questionnaire, attitude scale were analyzed using the descriptive Statistics such as Frequency, Percentage, Mean and Standard Deviation, Karl Pearson co-relation co-efficient was used to correlate the knowledge and attitude score of nursing students and Chi-square test was used to find the association between the Knowledge and attitude score with selected demographic variable.

Results

Description of sample characteristics

Frequency and Percentage distribution was computed to describe the sample characteristics. The baseline sample characteristics of the participants showed that majority (93.6%) of the subjects was females and majority 46.4% belongs to the age group 18-20 years. With regard to education. Majority (72.8%) of the subjects were studying B.Sc Nursing. About 62.4% of the subjects had previous information about medication error through curriculum. About 84.8% of the subjects had medical professionals in the family of which 10.4% were doctors, 68.8% were nurses, 4.8% were pharmacists and 0.8% were dentist. Majority (76.2%) of the subjects have not witnessed medication error. 5 of the subjects have committed medication error. Majority 74.4% of the subjects have not attended any conference or workshops on medication error.

Knowledge on Medication error

Table no 2 depicts that The 5 most common barrier for reporting medication error was lengthy procedure to report medication error (18.16%), Too much time for reporting the error (17.83%), Think Medication administration errors not important to report (17.83%), Fear of reaction from peers groups or friends (17.41%) and Fear of decreasing evaluation score (15.83%).

**Correlation between knowledge and attitude score regarding Medication error**

Karl Pearson co- relation co-efficient was used to correlate the knowledge and attitude score of nursing students. There was a no significant correlation between knowledge and attitude score of nursing student regarding medication error (p=0.057).

Association between knowledge score with selected demographic variables

Chi square association with knowledge score indicated that Age ($\chi^2=4.967, p<0.05$), Year of study ($\chi^2=5.437, p <0.05$) and Attended any conference or workshop ($\chi^2= 11.129, p<0.05$) were statistically significant at 0.05 level.

The findings also revealed that gender, previous information, health professional in the family, witnessed medication error, committed medication error was statistically non significant at 0.05 level.

Association between Attitude score with selected demographic variables

Chi square association with Attitude score indicated that year of the study ($\chi^2 = 3.519, p < 0.05$), Previous information ($\chi^2=1.909, p <0.05$) were statistically significant at 0.05 level.

The findings also revealed that age, gender, health professional in the family, witnessed medication error, committed medication error, attended conferences was statistically non significant at 0.05 level.

**Discussion**

Medication error is a big threat to the patient’s safety. It is the commonest error occurring in the health care set up due to the negligence or malpractice. This study was intended to assess the knowledge and attitude of nursing students regarding medication error.

The demographics of this study reflected that majority (93.6%) of the participants were females. This observation was common in a study conducted by Remya. E (2016) which reveal that the maximum number of subjects was females (96%).

The present study showed that showed that 67.2% samples had average knowledge whereas 32.8% have poor knowledge regarding medication error. This finding is supported by a study conducted by A.Samundeeswari and G Muthamil Selvi (2018) which revealed that majority (34%) of them have average knowledge and 30% had poor knowledge regarding medication error.

According to the findings of the study most of the participants (88%) had positive attitude towards reporting of medication error. This finding was consistent with the study conducted by Alsulami SL et al (2019) which revealed that majority (90%) of them have positive attitude towards medication error reporting. Another study conducted by Remya. E (2016) majority (62%) of the nurses had favorable attitude.

This study finding revealed that there was no significant correlation between knowledge and attitude score of nursing students regarding medication error. This finding was consistent with the study conducted by Asem N (2019) which showed that there was no correlation between knowledge and attitude of the physicians.

The present study revealed that there was a significant association between knowledge score and selected demographic variable such as age ($\chi^2=4.967, p<0.05$). This finding was congruent with the study conducted by Carandang RR (2015) which showed that there was a significant association between knowledge score and selected demographic variable such as age ($\chi^2=7.370, p<0.05$).
As per the findings there was a significant association between attitude score and selected demographic variable such as education ($\chi^2=3.519$, $p<0.05$), this findings is supported by the study conducted by Ramya E (2016) which showed that there was no association between attitude score and selected demographic variable such as education status ($\chi^2=8.09$, $p<0.05$).

**Conclusion**

Medication error is one of the preventable problem which is leading to serious complications. By virtue of the direct patient-care activities, nurses are in an excellent position to detect and to report the medication errors. The quality of care delivered can be improved, if the errors is identified, reported and necessary actions are taken to minimize the errors. Through this study it is concluded that majority of the nursing students had average knowledge and favourable attitude towards reporting medication error. Nurses need to be updated and trained regarding the safe medication administration. This will increase the competence of the nurses and also to maintains the standards of the Quality health care.

**Acknowledgement:** We thank Yenepoya Nursing college, Yenepoya (Deemed to be University) for providing the opportunity to conduct the study and for their constant support for the completion of the work.

**Conflict of Intrest:** All the authors declare that they have no conflict of interest

Abstract

Introduction: Industrial workers are a well-defined group of a population. They have frequent shifts, low socio-economic status and neglected oral hygiene as they are at risk for health and dental problems. Industrial revolution has provided a lot of scope in employment worldwide for many which has improved the standard of living of many individuals. Health at workplace is considered essential now a days in various countries due to this rapid economic growth and industrial progress. In various industries like acid battery industry, chemical and textile industry, are exposed to hazardous substances and radiations. Studies have also reported a positive association between battery exposures to strong acids and periodontal pockets or gingival bleeding among exposed workers. Therefore, the purpose of the present study is to assess the oral health status of lead battery factory workers in Ghaziabad Uttar Pradesh.

Material and Method: The “World Health Organization (WHO) oral health assessment form -2013” was used to record the clinical findings. For the diagnosis of dental caries, WHO type III examination was carried out using mouth mirrors and explorers while using adequate illumination. The components of the form used were - General information, Dentition status (crown, root), periodontal status, loss of attachment, dental erosion, and oral mucosal lesions. Results: The mean DMFT scores were (5.72 3.17) females had more number of teeth with gingival bleeding compared to males. It was also found 72.3% of battery factory workers had pocket depth more than 6mm. 51.5% workers in the study had LOA of score 3 (as per WHO proforma) Mean number of teeth affected with erosion was more in males (4.76 4.02)

Conclusion: Oral health statuses of factory workers are highly affected due to lead acid used in industries.

Keywords – Oral health, Lead workers, dental erosion, oral lesions

Introduction

Human health is determined by many factors and environment is one among them which is very important.

The study of any disease means studying man and his environment so, key to man’s health depend mostly on his environment. Initially, disease was thought to be due to cosmological and magical effect of God. Hippocrates was the first person who related the environment and the disease¹.

The latest concept of the environment is not restricted to physical environment only, but it also means social, economic and occupational condition. Occupational environment is related to work place conditions which
Industrial workers are a well-defined group of a population. They have frequent shifts, low socioeconomic status and neglected oral hygiene as they are at risk for health and dental problems. Industrial revolution has provided a lot of scope in employment worldwide for many which has improved the standard of living of many individuals. Health at workplace is considered essential now a days in various countries due to this rapid economic growth and industrial progress. In various industries like acid battery industry, chemical and textile industry, are exposed to hazardous substances and radiations. This results in deterioration of the health of workers of these industries. Some studies have proven that there is an association between occupational exposure and increased incidence of diseases.

It has been already known that the teeth of industrial workers are affected who are exposed to inorganic acids at workplace. These acids have high corrosive effect on tooth structure which causes inflammatory reactions. Further, these inflammatory reactions cause a decrease in salivary Ph and compromised immunity, thus making the person more prone to various infections in oral cavity. Soft tissues also gets irritated due to chronic exposure to these acids which results in other oral diseases such as periodontal disease or oral mucosal lesions. Exposure to these acidic contaminants can occur in factories of sulfuric acid, lead acid, petrochemical, metals and semiconductors etc.

Sometimes, pathologic changes in oral cavity may be the first sign that indicates absorption or toxicity related to certain toxic agents. Due to the substantial increase in the use of chemical substances that have adverse effects on oral health, industrial dentistry has become a subject of major consideration and constituted a new branch in the field of dentistry. Many adverse oral health conditions were reported among workers exposed to lead and the most common reported adverse effects were the Dental erosion cases with decay, missed and filled teeth, gingivitis, pockets and other periodontal conditions including periodontal attachment loss (PAL). It is mainly in the battery industry, where vast quantities of lead acid are used as an essential part of the battery making process. Other than lead, nicotine and alcohol are also responsible for occurrence of severe forms of periodontal destruction, such as PAL.

Exposure to acid mists causes periodontal diseases. This occurs due to changes in intracellular and extracellular pH which affects cell growth and differentiation. The prevalence of dental erosions is higher in workers in battery and galvanizing occupations. Battery workers have the highest prevalence 60% of erosion. Acidic mist exposure can erode the enamel and dentin of teeth and makes teeth vulnerable to acidic de-calcification. Mainly the anterior teeth exposed to the atmosphere are affected and completely dissolved. Some studies have also reported a positive association between battery exposures to strong acids and periodontal pockets or gingival bleeding among exposed workers.

There is very little information on the effects of occupational hazards on oral health status of individuals in developing countries. Therefore, the purpose of the present study is to assess the oral health status of lead battery factory workers in Ghaziabad Uttar Pradesh.

**Material and Methods**

A cross-sectional study was conducted in district Ghaziabad lead battery factory workers from April 2019 to August 2019. Ethical clearance was obtained from institutional ethical committee (IEC). All information regarding battery factory workers was obtained from Ghaziabad Battery Udyog association. Permission to conduct the study was obtained from Ghaziabad Battery Udyog association. A group of 50 subjects were selected from a factory to conduct pilot study to check the feasibility. The examiner was calibrated and trained in department of public health dentistry before the main study. The entire sampling frame that is, all the battery factory workers in Ghaziabad city who had given consent, willing to participate and who will be present on the day of study will constitute the final sample of this study. There were 25 factories and 1 factory was included in pilot study the total population came among
them was 1111. Informed written consent was taken from the workers of the factory before their participation in the study in order to prevent any inconvenience and to ensure full cooperation. Out of 1111, 998 were present on the days of data collection from them 850 gave consent for participation in the study. Therefore, the response rate came out to be 85%.

The “World Health Organization (WHO) oral health assessment form 2013” was used to record the clinical findings. For the diagnosis of dental caries, WHO type III examination was carried out using mouth mirrors and explorers while using adequate illumination. Factory workers were allowed to sit on a chair or stool as per availability. A table to place the instruments was placed within easy reach of examiner. The recording assistant was allowed to sit close to the examiner. Periodontal assessments were done by community periodontal index (CPI)-probes. The diagnosis of oral lesions was carried out using WHO criteria.

The components of the form used were General information, Dentition status (crown, root), and periodontal status, loss of attachment, dental erosion and oral mucosal lesions. The data was analyzed using Statistical Package for Social Sciences (SPSS Inc., Chicago, IL, USA) version 23.0.

Results

This study was conducted on 850 battery factory workers of Ghaziabad to assess their oral health status. The mean age of the study population was (38.95 ± 13.22) with the youngest age being 18 and the oldest being 78. Among the 850 battery factory workers studied, 647 (76.1%) were males and 203 (23.9%) were females.

Mean number of teeth present in the study population was (28.79 ± 3.82) which was found to decrease as age increases Mean DMFT score for the study population was 5.72 ± 3.17 with highest mean DMFT found in the >64 years age group and the least mean DMFT score of 4.82 ± 2.22 seen among 35-44 year olds. Males and females had similar mean DMFT scores.

Root Caries

Mean number of teeth affected with root caries increased with age. Mean number of teeth with root caries was 0.38 ± 0.78 with male workers having comparatively higher mean root caries (0.47 ± 0.81) when compared to females (0.13 ± 0.62).

Gingival Bleeding

Female subjects were seen to be having more mean number of teeth with gingival bleeding (9.67 ± 6.16) compared to males (8.23 ± 4.68).

Periodontal Pocket

On examination for periodontal pockets, it was found that 615 (72.3%) of the battery workers had deep pockets (pocket depth 6 mm or more), 130 (15.2%) had shallow pockets (4 - 5 mm pocket depth) and 105 (12.3%) were free from any periodontal pockets.

Loss of Attachment

A loss of attachment score of 3 (Cemento-enamel junction is between 6 to mm and between the upper limit of black band and 8.55 ring of CPI probe) was seen in 435 (51.1%) of the subjects.

Dental Erosion

Mean number of eroded teeth was 4.48 ± 3.82 with the least number of teeth with erosion seen in <35 years old (2.81 ± 2.99) and the highest mean number of teeth with erosion was seen among 45-54 year old (7.4 ± 3.33). Teeth of male workers had higher mean number of affected teeth (4.76 ± 4.02) in comparison to female workers who had 3.59 ± 2.95 mean number of teeth with erosion.

Oral Mucosal Lesions

On examination for oral mucosal lesions, 195 (23%) of the battery workers did not have any kind of lesions. 128 (15%) of the workers had aphthous, herpetic or traumatic ulceration on lips, buccal mucosa and tongue. Lichen planus was seen in 14 (1.6%) of workers on their buccal mucosa. 17 (2%) workers were having candidiasis
on their tongue and 21 (2.47%) had ANUG (acute necrotizing gingivitis)

Discussion

It has been observed that oral injuries are common with direct contact in occupational exposure. In battery industries, sulfuric acid has been used in large quantity. This sulfuric acid contains >20% of sulfur dioxide dissolved in the acid, which has a sharp penetrating odor. Acid mist is frequently detected in the lead factory area as it continuously discharges from open containers and leakage from pipes. Exposure is detectable to human beings at a level of 0.5 to 0.7 mg/m$^3$, is irritating at 1.0 to 2.0 mg/m$^3$ and causes coughing at 5.0 to 6.0 mg/m$^3$.\(^2\)

In different study settings acid mist concentration varied from .08 to 5mg/m\(^2\).\(^{26,4,5}\) High concentration of acid fumes in the working environment is related to the higher prevalence of teeth erosion.\(^{27,28}\)

In our study it was found that dental caries experience is 95.8% with maximum caries in subjects of age below 35 years whereas the caries prevalence was 71.1% for age above 35 years in the study done by Rushabh J Dagli et al\(^{29}\) and the dental caries experience came out to be 62.5% in the study done by P. Basavraj et al\(^{30}\)

Results of this study showed the prevalence of periodontal disease in battery factory workers to be 88.9%. Bleeding was observed for all age groups. Similar results were observed by Wang et al (2002)\(^{31}\) and Baelum et al (2003)\(^{32}\). Periodontitis was less frequently seen in other studies (Garcia and Cutress, 1986)\(^{33}\)(Oliver et al, 1989)\(^{34}\) (El-Quaderi and QueteishTaani, 2004)\(^{35}\).
The results of this study are in accordance with the findings of the WHO Global Oral Data Bank, as most of the patients show some type of bleeding when different sextants are evaluated (over 90%).

In the present study, 69.8% showed some degree of dental erosion, this may be attributed to the working environment. The reason for this could be the Lead and sulfuric acid being used as one of the ingredients in the production work of factory. Whereas, Zabińska O et al (1982)36, Lie T et al (1988)37 found most of the workers with dental erosion (90%) 23.7% of the workers with more than 10 years of working experience showed 3rd degree of Dental erosion compared to 0% from 1-10 years and the difference is statistically significant. This is in agreement with the study done by Amin WM et al (2001)38. They studied dental erosion on workers of battery industries of Jordan and found significant increase in the erosion among the study. In our study we found highest mean number of eroded teeth was 7.40 among 45 – 54 years of age group.

Limitations

1. Grouping the participants into study and comparison group was not done based on the working site of the study participants.

2. Work experience was not counted as more no. of subjects were below 35 years of age.

3. The exposure level of the participants to the acid fumes was not measured quantitatively.

Conclusion

Industrial sector plays a key role in national development. The factory employees who form the lifeline of any factory area, working in a confined factory environment in par with machines are at high health risks. However, many a times they are not given due importance. Hence, continuous professional research and development is essential to improve overall health and development of such population, so as to have a healthy productive labor population for development of any nation.

As a revitalization of existing oral health service which is mainly of treatment aspect, it should be oriented more towards preventive health care. So we conclude that in such population continuous research and interventions are needed to improve the overall health status of these specific occupational subjects.

Recommendations

In the light of the present alarming findings associated with excessive exposure to sulphuric acid fumes in the workplace, occupational health authorities are invited to implement effective safety measures, including:

- Efficient surveillance and routine monitoring of acid fumes in workplace air
- Installation of efficient ventilation and exhaust systems of the work sites
- Automation of manufacturing processes
- To reduce the threshold limits below the level that is safe for teeth might be the measure of choice to decrease the risk of dental erosion
- Government must take suitable measures and a strict law for the rights of workers regarding health should be formulated along with regular inspections and follow up.

Abstract

This study was aimed to biosynthesis of silver nanoparticles by using biosurfactant (lipopeptides) produced from local isolate L. plantarum isolated from clinical samples of Iraqi healthy women which previous identify grown in natural media (BCDFTM), then studied it cytotoxic effect against MCF-7 cell line. The cytotoxic effect of biosurfactant against MCF-7 cell line using 400 μg/ml reached 61.49 % of growth inhibition which is acceptable from cytotoxicity viewpoint. Silver nanoparticles application in vitro as cytotoxic activity against MCF-7 cell line using 400 μg/ml reached 55.67 % in growth inhibition, while when nanoparticles combined with lipopeptides obtained increase the growth inhibition MCF-7 cell and reached 68.44% at the same concentration of AgNPs.

Keywords: Biosurfactant, lipopeptide, nanoparticles, XRD, AFM, TEM

Introduction

Microbes occupy a strong population in the living world. They possess extra and intracellular vital products such as antibiotics, enzymes, toxins, biopolymers and pigments. More than 10,000 active broad-spectrum metabolites with medicinal properties have been isolated from these microbes (1). However, most of the microbial worlds remain unexplored owing to its vastness. Recent studies confirmed that only <0.1% of microbial world has been investigated till date (2). When listing microbial bioactive compounds, biosurfactants (BSs) are such metabolites with many interesting properties due to their multiple diversities in both structures and functions also with their pronounced usage in industries. BSs are basically amphiphilic surface active agents in bacteria, fungi, and classes of actinomycetes. They belong to classes of glycolipid, glycolipoproteins, glycopeptides, or lipoproteins, lipopeptides or derivatives of fatty acids (3), and less likely glycoglycerolipids too (4).

Biosurfactant are now mediating new developments in the field of Nanotechnology. It observed that biosurfactant produced by microorganisms could play a very important role in aggregation and stabilization process (5). Biosurfactant use has therefore now emerged as a green alternative for enhancing both nanoparticles synthesis (reducing agent) and stabilization (stabilizing agent). One of the modes of action is through adsorbing onto nanoparticles, surface stabilizing the nanoparticles and prevent of formation subsequent aggregation (6). Silver nanoparticles contain a wide spectrum of inhibition of bacteria and other microorganisms. Numerous possible mechanism of action for anticancer activity of silver NPs can be proposed.
Cytotoxic activity of the silver NPs might be due to its physiochemical interaction with the intracellular DNA and proteins. Reports have shown that the cytotoxicity might also be due to initiation of apoptosis activated by the caspase-3 enzyme (7). (8) reported that oxidative stress is one of the crucial mechanisms of cytotoxicity induced by silver NPs. The shape and size are important properties that influence the toxicity of silver NPs by elevating reactive oxygen species (9). Because of the physicochemical differences, some silver NPs are broken-down in the lysosomes and then the release of silver ions result in oxidative stress. In addition, oxidative stress can also lead to genotoxic stress and even up regulation of p53 gene (10), which is an important lead for the application of nanomaterial as anticancer Nano-medicine, as up regulation of p53 gene initiates apoptosis (11).

The aim of the present work is to synthesis nanoparticles prepared by biosurfactant produced by L. plantarum isolated from vagina and testing its cytotoxic effect against cell line.

Methods

Synthesis of silver nanoparticles:

Silver nitrate (AgNO3, 99%) (Aldrich/Germany) was used in the preparation of the silver nanoparticles from biosurfactant produced by selected isolate that grown on natural medium (BCDFTM). Silver nanoparticles were synthesized according to a method described by Martinez-Gutierrez et al. (12).

Characterization of AgNPs

Characterization was performed using a variety of analytical techniques including : The X-ray diffraction (XRD) was used to determine phase identification, crystals structure, composition and physical properties of the synthesized materials silver nanoparticles (AgNPs) (13). The AFM was also used to determine surface topography of the silver nanoparticles by SPM-AA300 of angstrom advanced Inc. USA, using AFM contact mode (14). Transmission Electron Microscopy (TEM) analysis was performed to investigate the size, shape, and morphology of bare and lipopeptidebiosurfactant stabilized Ag NPs (15).

The biological activity of biosurfactant

In vitro method was performed to investigate the possible cytotoxic effect of extracted biosurfactant isolated from selected isolate and biosynthesized nanoparticles on two cell lines on of them is human breast cancer cell line (MCF-7) and another is a normal cell line such as human normal liver cell line (WRL 68).

Maintenance of cell cultures: MCF-7 and WRL 68 cells were maintained in RPMI-1640 supplemented with 10% fetal bovine serum, 100 unit’s/mL penicillin, and 100 µg/mL streptomycin. Cells were passaged using Trypsin-EDTA reseeded at 80% confluence twice a week, and incubated at 37 °C (16).

Cytotoxicity Assays: To determine the cytotoxic effect of (biosurfactant produced from natural media (BCDFTM), and the effect of the mixture of both biosurfactant and nanoparticles), the MTT cell viability assay was done using 96-well plates. Cell lines (MCF-7 and WRL 68) were seeded at 1 × 10⁴ cells / well. After 24 hrs. or a confluent monolayer was achieved, cells were treated with tested compounds at different concentration (12.5, 25, 50, 100, 200, and 400µg/ml). Cell viability was measured after 24 h of treatment by removing the medium, adding 28 µL of 2 mg/mL solution of MTT and incubating the cells for 2.5 h at 37 °C. After removing the MTT solution, the crystals remaining in the wells were solubilized by the addition of 130 µL of DMSO followed by 37 °C incubation for 15 min with shaking (16-17).

Statistical Analysis: The obtained data were statically analyzed using an unpaired t-test with Graph Pad Prism 6. The values were presented as the mean ± SEM of triplicate measurements (18).

Results

Noble metal nanoparticles (plasmonic) are distinguished from other nanoparticles such as semiconductor quantum dots, polymeric, and magnetic
nanoparticles by their unique surface Plasmon resonance (SPR). The synthesis of AgNPs was monitored by a color change and UV–Vis spectroscopy. The formation of AgNPs was confirmed by changes in the solution color from colorless to yellow brown. Samples are examined by using the UV–V is spectroscopy and the application of the Nano product as an anticancer agent.

The XRD patterns figure (1) show the distinctive diffraction peaks of AgNPs at $\theta = 27.80^\circ$, $32.02^\circ$, $35.09^\circ$, $46.18^\circ$ and $57.38^\circ$. These peaks were well matched with standard diffraction data of AgNPs (JCPDS file no. 040783) and attributed to the (110), (333), (111), (200) and (220).

![Figure 1](image)

**Figure (1) The results of X-ray Diffraction (XRD) for AgNPs.**

Surface analysis (AFM) requires good attention because of factors that effect on results such as pollutions. The size of silver nanoparticles was estimated by using AFM-SPM shown in table (1). The result shows that the average size of AgNPs was 52 nm figure (3).

TEM is a valuable tool to analyze the size and morphology of nanoparticles. TEM images of AgNPs as figure (2) showed distributed spherical shaped particles with numerous sizes ranging from 20 to 300 nm.
The biological activity of biosurfactant against cell line.

Results in table (2) show that growth inhibition of REF cell line decreased gradually when biosurfactant concentration increased. biosurfactant has significant differences of cytotoxic effect on MCF-7 cell line (P≤0.05), 32.67, 54.47 and 61.49 % growth inhibition was showed at concentrations 100, 200, and 400 µg/ml respectively in biosurfactant produced from natural media (BCDFTM).

**Discussion**

Biosurfactants usually act as a stabilizing agent of the non-toxic, non-hazardous synthesis of nanoparticles. Biosurfactant use has now emerged as an eco-friendly alternative for enhancing both nanoparticles synthesis and stabilization. Because of the biodegradable nature of biosurfactants, they are more environmentally friendly than chemical surfactants (19).

Biosurfactant produced by microorganisms plays a very important role in aggregation and stabilization process. One of the modes of action is through adsorbing onto metallic nanoparticles, surface stabilizing the nanoparticles and preventing subsequent aggregation. The mechanism of surfactant absorption depends on the type of surfactant and the thickness of the adsorbed layer. So far no comparative study has been published concerning the influence of the biosurfactants nature and composition on the properties and ability to control the production of nanoparticles, Lipopeptidesbiosurfactant has also been reported in nanoparticles synthesis (20).

Clarified that silver with a lattice parameter (21) of a = 4.0862 Å were in good agreement with reference of the face-centered cubic (fcc) crystal lattice of metallic silver, the size of the AgNPs calculated by the Debye-Scherrer equation (D = 0.94λ/d cosθ), and concluded the size of the AgNPs was 38 nm.

Atomic force microscope (AFM) was used to know the surface morphology and to determine topography, the (AFM) gives a two and three-dimensional image of the surface of nanoparticles at an atomic level (21). The average particle diameter was calculated in nanoscale size. The AgNPs prepared by using biosurfactant were studied using (AFM).

In previous studies, TEM images revealed a size of 30–60 nm spherical-shaped polymeric nanoparticles produced from Cs-Hk fungal cultures, *Streptomyces sp.* MBRC-91 and *Bacillus subtilis* MSBN17 (22). AgNPs with a size around 30–50 nm have been reported for bactericidal activity against various pathogens (23). Polymeric nanoparticles ranging from 20 to 300 nm have the maximum potential for *in-vivo* applications (24).

Mentioned that the new therapeutic strategies may be designed by (25), considering that, the use of biosurfactant can alter lipid content to fluidize rigid cancerous tissues and to modulate interfacial properties. While (25) found that the ability of biosurfactant to disrupt cell membranes, leading to a sequence of events that include lysis, increased membrane permeability, and metabolite leakage, have also been suggested as a probable mechanism of antitumor activity. (26) showed that surfactin induces ROS formation, leading to mitochondrial permeability and membrane potential collapse that ultimately results in an increase of calcium ion concentration in the cytoplasm afterwards, cytochrome C released from mitochondria to the cytoplasm activates caspase-9 eventually inducing apoptosis. The apoptotic effect induced was associated with a significant decrease in the unsaturated degree of the cellular fatty acids in Bcap-37 cells due to a reduction in the amount of fatty acids, thereby enhancing membrane fluidization (27).

**Conclusion**

Biosynthesis of AgNPs using produced BS is efficient to convert AgNO₃ to spherical shaped particles with numerous size ranging 20 – 100 nm. The result of sytotoxic effect showed that the potent effect was seen obviously in MCF-7 cell line than WRL68 when used BS and / or AgNPs.

A Review on Medication Synchronization Programs in Community Pharmacies to Improve Medication Adherence

Rakshith U.R 1 Srikanth M.S 1
1 Lecturer, Dept of Pharmacy Practice JSS College of Pharmacy, SS. Nagar, JSS Academy of Higher Education and Research, Mysuru, Karnataka

Abstract

Adherence to the prescribed medications plays an important role in treatment of chronic diseases. Hypertension, Ischemic heart diseases, Diabetes mellitus, Dyslipidaemia’s are major health challenges of 21st Century and are more expensive. A total 79% of Projected deaths are caused due to chronic diseases in developing countries. Non adherence to prescribed medications is one of major health threat worldwide. Patients who are on chronic diseases are often visits multiple health care practitioners, numerous pharmacies, and who take multiple drugs results in medication non-adherence. The new primary care models suggest that there is no promotion of close physician-patient-pharmacist relationships. Training for the treatment of chronic diseases is seldom satisfactory and there is inadequate consistency and communication between health care providers. Among health care profession community pharmacist are the ideal position to assist the management of patients with chronic disease. The Synchronization services are offered by several community pharmacies to improve medication adherence. These programs work by overcoming the barriers of medication non adherence by refilling their prescription in their single visits. Although there are Numerous medication synchronization programs are available in community pharmacies effectiveness of medication synchronization programs are confined to its type synchronization programs implemented.

Key words: Medication synchronization, Adherence, Medication, Community Pharmacies

Introduction

Health care practitioners describes the definition of medication adherence in their own way. The exact definition of medication adherence is lacking. It is defined as the extent to which patient takes the medication as prescribed by the health care practitioner.1 Non-adherence to prescribed medications occurs in 50% of patients in chronic diseases which leads to increase in emergency visits, hospitalization stay, medical cost. As per world Health organisation chronic diseases kills 38 million people globally every year. Over 20% of Indian populations suffers from chronic diseases which are estimated to cost $6.2 trillion during the period of 2012-2030 42. 70-90% of the population burden of diabetes, hypertension and obesity are having higher social economic status 44. Patient with chronic diseases often prescribed with multiple drugs to treat their conditions, prevent complications, and to improve overall health related quality of life. Elderly populations are at higher risk for chronic disease where they find difficulty in taking the medications and following the medications as prescribed by the doctors.2 chronic diseases patients may feel burden because of increase in visits to the pharmacy to pick up their medications...3 Nonadherence is attributed to multiple factors including like social, economic,
therapy-related, patient-related, condition-related, and health system factors, & Polypharmacy. Community Pharmacist are in better position to improve medication adherence by providing better patient care Medication synchronization program has shown better impact on medication adherence. Medication synchronization programs are implemented and have grown very rapidly. Medication synchronization program works by refilling of prescription as prescribed by medical practitioners in their single visits, which results in convenience for the patients to take their medications. Studies have shown that the rate of medication adherence was increased to 2-6 times when it compared with patients who are managing their disease by own.

Review of Research and Development in the Subject

International status:

In most of the developed part of the world, pharmacist is in better position to improve medication adherence in chronic diseases. Pharmacist can provide drug therapy training, access to all patient’s medication refill data. Medication synchronization programs is one of the popular strategies to improve medication adherence. A study conducted by Jalpa A Doshi et al. mentioned that refilling of prescribed medication using medication synchronization program using health insurance program through mail order community pharmacy results in increase medication adherence to antihypertensive, lipid lowering and antidiabetic agents. A study conducted by Matthew J et al. suggests that pharmacist was positive about medication synchronization programs, although some negative views were present Chayla Stanton Robinson et al. emphasis more about patient specific barriers and pharmacist interventions to improve medication adherence. This study showed that 37.9% were adherent at 90day of follow-up and 69% were adherent at 180days of follow-up Hence More research is needed to carried out to understand the barriers and facilitators to how medication synchronization programs are implemented to achieve better outcomes.

National Status

In India community pharmacy practice is predominantly confined to trade. Majority of registered pharmacists are with diploma in pharmacy qualification and their knowledge regarding professional services is very limited. Pharmacy Council of India and respective state pharmacy councils are providing educational motivation to change their trader attitude. In our health care system, more than 80% of the prescriptions are filled by the community pharmacist. The high number of prescriptions especially to chronic diseases leads to medication non adherence. Hence community pharmacist can sensitize and enroll the patients in medication synchronization programs offers in community pharmacy to prevent medication non-adherence Community Pharmacy based programs are used to enhance medication adherence by incorporating medication synchronization programs. Currently limited available evidences suggestive of medication synchronization might improve patient’s health outcomes in chronic diseases hence more research need to be carried out

Medication synchronization services:

Medication synchronization program defines as synchronized, same day, filling and refilling of all chronic disease medications. Medication synchronization services works by aligning of prescriptions, refilling the quantity of medications which are prescribed for the chronic diseases. These programs are getting benefited for the patients who are on chronic diseases so that they will refill their medications on same day. The chosen date becomes the patient pick-up date. A week before that a patient’s medications are due, a pharmacy team member calls the patient to determine if changes are made in patient’ treatments such as new or changed medications or hospitalizations. Subsequently, based on the discussion, the pharmacy team member fills all of the medications as appropriate. In order to achieve synchronization, some prescriptions will have to be filled for smaller quantities for the first 1-3 months. In day today practice Pharmacist are assisting the patients
in adhering to their prescribed Medications. Several community pharmacies are providing synchronization services to improve medication adherence programs such as Appointment based model, script your future, simply my Meds, Refilling using Auto-refilling, refilling using batching, Refilling using grouping, CVS script sync, patient counselling, pill reminders etc. These services can help patients by remembering to take their medications in a timely manner and to refill chronic medications regularly through patient counselling. Pharmacist are in better position in identifying barriers to nonadherence by providing product information leaflets and educating the patients on their diseases and drugs. Community pharmacists plays an important role on patients in their personalized ways to change a patient’s behaviour and to improved overall health quality of life of patients. These programs run by collecting patients’ past prescribed data from insurance claims to determine their adherence rate which help them achieving higher adherence through patient counselling, providing additional materials which could help by overcoming their specific barriers to nonadherence. The automatic refill programs identify only irregular filing of prescriptions and it will not address the patient specific barrier for medication non adherence Hence there is a need for community-based medication synchronization programs to enhance the medication adherence. Synchronization services allows the pharmacist to check all of medications at one time allowing for more thorough and effective therapeutic check. Refills and/or therapeutic recommendations are sent to the physician and any issues are resolved before the patient picks up the medications. The result is a proactive workflow which reduces the patient’s need to call the pharmacy or wait for extended periods of time while team members resolve last minute issues Medication synchronization can improve both patient satisfaction and pharmacy operations. By helping to improve patient adherence and pharmacy efficiency, the pharmacy team is able to provide a higher level of care. The proactive approach allows patients to feel individually cared for, increasing their confidence in the pharmacy and in optimizing their health.

Advantages:

1) Medication synchronization are the way to promote operation effectiveness 2) It ensures medication appropriateness to improve patient safety and care 3) It improves rapport between pharmacy, patient, physician relationship 4) It allows systematic management, organized and prepared patient appointments to facilitate services like medication reviews, immunizations, medication therapy management, patient counselling etc 5) Patient satisfaction is one of most crucial part of medication synchronization program. 6) It reduces the number of prescription paper works through medication adherence in chronic diseases.

Medication synchronization services offering in community pharmacies.

1) Appointment based model: ABM is one of the patient most important patient care centric model, implemented in the community pharmacies to enhance medication adherence and to build efficiency in pharmacy operations. Appointment based model mainly address on patient and provided based barriers Appointment based model works by pharmacy team members from community pharmacies are actively contacting patients prior to their refill dates. Along with their process of refilling prescriptions pharmacy teams’ members were also actively involved in educating patients on drug-drug, drug-food interactions, adverse drug reactions, direction for use of medication etc. Appointment based model works by scheduling an appointment to the patients so that patient can visit pharmacy at a scheduled time to refill their prescriptions. Before scheduling an appointment, pharmacy team member should contact the patients to identify any changes are made in their prescriptions or in their treatment regimens. These programs develop the rapport between patients and physicians through patient and physicians co-ordinating relationships to improve medication adherence. Appointment based model and their work process are described below.

1) Patient brings new or old refill prescription to the community pharmacy 2) Pharmacy team member explains about Appointment based model and its process,
enrolments & procedures. 3) Patient decided to enrol in appointment-based model where he will enquire more about synchronized appointment with pharmacy team members so that patient can pick up their prescription on a single visit. 4) The Pharmacy team member will review patient profile to prepare their medicaments, where he plans for synchronization services such that patient can pick up all of their chronic medications in a single visit. 5) Pharmacy staff will formulate short refilling of prescriptions (short period of time) or long refilling of prescriptions as advised by their physician (for long period of time) which depends up regimens the doctor was prescribed or based on cost of chronic medication...

6) Every month Pharmacy team member will contact the patients one week prior to the appointment date to check the prescription should be refilled or it required any changes in their prescriptions. 7) Pharmacy staffs reviews for the potential changes in patient medication regimen, prepares for prescription and creates package for the patients so that they can pick up their medications as per scheduled time. 8) Every month community pharmacist reviews the prescription order comprehensively to evaluate any changes in prescription or same prescription can be refilled once again so patient can pick up their medication without any disturbances. 9) On the selected day patients visits the pharmacy to collect all of the prescriptions that are prepared.

3) **Simplify My Meds:** It’s a program which provides tools and training programs to implement the medication synchronization programs for NCPA (Nation community Pharmacist Associations) members. These programs help the pharmacist to consolidate and co-ordinate a patient prescription so that they can re-fill their prescription on a particular time and date in a month, which leads to improving patient medication adherence and change in pharmacy operations. These programs work by improving medication adherence through convenience for synchronizing all of the patient’s chronic medications are refilled in a single day of each month. through this service offered by the several community pharmacies’ patients will get benefited to improve adherence and also it provides an opportunity for the patients to interact with the community pharmacist to clear all their queries.

4) **Refilling using Auto- Refilling:** Pharmacy which have the facilities of Auto- refilling software features and ability to keep electronic record of patient due dates for medications are considered for this type of synchronization programs. Following are the methods that should be considered: 1) Print the auto-refill list at the beginning of each day 2) Review the refill list to ensure all of the patient’s medications are included. If a medication is omitted, complete the syncing process as described above to ensure resynchronization. 3) Call the patient in the afternoon or evening to inform them that their medications have come up in our system and they are ready to be picked up from the pharmacy. 4) If patient informs the team member of any changes, this is taken into account and any resynchronization is completed as required.

5) Review the number of refills left for each medication. If this is the last refill, send a refill request to the physician. If refill request is denied inform patients right away to ensure they book an appointment. 6) Process and refill all the medications.
5) **Refilling – Using Batching:** This type of Synchronization Programs usually offers in Pharmacy whose software does not have the auto refill features, or if the pharmacy prefers not to use this feature, medication can be refilled using batch. Following are the methods that should be considered using batching. 1) Complete the synchronization for each patient.

2) Determine which day of the month patients’ medications will become due and place them into the batch for that respective date. 3) Run the batch each morning and review the batch list to ensure all of the patient’s medications are included. If a medication is omitted, complete the syncing process as described above to ensure resynchronization. 4) Complete steps 3-6 times as per auto refill method.

6) **Refilling using Grouping:** This type of Synchronization Programs usually offers in Pharmacy whose software does not allow or prefer not to use the auto refilling or batching methods. Following are the methods that should be considered using Grouping.

1) Complete the synchronization process for each patient. 2) Determine if patients will be receiving a 28- or 84-day supply of their medications. 3) Based on the patient’s refill date, determine which week of the month medications are to be refilled. a. For those receiving 28 days, on a calendar, mark the first four weeks of your program as Groups A-D. b. For those receiving 84 days of medication, on a separate calendar, label the first 12 weeks of your program as Groups 1-12. 4) Develop a list of patients in each group based on their refill quantity and date. This will be the master list that staff members can refer to each week when determining who is due for medication refills. Additionally, place a note in each file as to which group each patient falls into for easy reference. 5) Create a binder with sections for each group to organize the required patient information. 6) Using the calendar as a guide, call patients the week their medications are due to be filled to determine if any changes have been made. 7) Review the patient’s medication file and complete any synchronization as required. 8) Process and refill all of the medications. 9) Review the number of refills left for each medication. If this is the last refill, send a refill request to the physician. If refill requests are denied, inform patients right away to ensure they book an appointment.

Discussion

Current Scenario:

This comprehensive review identified 10 research studies relevant to medication synchronization programs offering in community pharmacies to improve medication adherence in chronic diseases among elderly population²²⁻³⁰. Limited available evidences suggestive of medication synchronization programs might improve patient’s health outcomes in chronic diseases. Hence more research needs to carried out to understand better outcomes among elderly populations. More over most
of the studies are conducted in different locations of United States of America, we could not able to identify sufficient evidences other than United States of America. Medication synchronization programs in Community Pharmacies are yet to be implemented and established among Indian population. Majority of registered pharmacists are with diploma in pharmacy qualification and their knowledge regarding professional services are very limited. Practicing pharmacist lacks proper techniques to improve medication adherence hence Pharmacy Council of India and respective state pharmacy councils are providing educational interventions like continuing professional development programs, seminars, webinars, preparing books and manuals to update their knowledge, skills, techniques to increase medication adherence.

Effectiveness of Medication synchronization program:

Medication synchronization program constitutes multiple methods that address patient needs and manage the continuity of care in patients receiving pharmacotherapy for chronic diseases. Literature emphasises that these programs are effective in managing clinical and economic outcomes for patients at various stages. Jalpa A Doshi et al. emphasis on pharmacy mail order programme effectively showed larger proportion of days covered and adherence rate in synchronized group. However, this programme was unable to demonstrate the information on common roots of medication non-adherence (e.g., forgetting of dose, or ambivalence) among the patients through this system. David Holdford et al. addressed that the synchronized patient appointment-based model showed a greater proportion of days covered than the patient not enrolled, but this study has some limitations associated with adherence and persistence measures. Emily Ghassemi et al. demonstrates that script of your future program had a positive impact on patient enrolled in the synchronization program as compared to non-enrolled patients. Synchronized patients have significantly improved ART adherence than non-infected outpatients, but this study does not evaluate patient satisfaction among synchronized groups. Alexis A. Krumme et al. conducted telephonic interviews states that antihypertensive, hyper lipidemic, and oral hypoglycaemic therapy was found to be effective in increasing the medication adherence among synchronized patients as compared with usual care, but this study states that under report of current number of programs and enrolled patients. Anthony Pattin et al. show that participants in appointment-based study model have significant blood pressure reduction, but this study involves lack of randomization at the point of entry into the study. Compared to other programs, the appointment-based model was found to be better medication synchronization program as per the literature finding.

Applicability of Medication Synchronization program in Indian Health Care System:

Although literature contains studies and pilot programs that demonstrated medication synchronization programs can increase in adherence measured by proportion of days covered, decreased overall health care cost, decreased in hospitalization stay, and emergency visits future research is required. However, MSP are not implemented in our system it our belief that strict government regulatory frame works will hinder the progress. Since India is a developing country implementing these programs are quite challenging.

Barriers for Medication synchronization program.

Community Pharmacies have included a medication synchronization program in their workflow to improve the quality of pharmacy care and medication adherence. MSP showed decrease in-patient emergency visits, hospitalization stay & address the barriers of medication non-adherence. These programs are well established in most of the developed countries were as among Indian population pharmacy services are lacking. Common perception about community pharmacists are primary limited to trade, but the majority of registered pharmacists are qualified in pharmacy and have limited knowledge of professional system. Practising pharmacist does not have proper techniques to improve medication
adherence. However, in most of the developed countries pharmacist will play vital role in providing patient educations to minimize medication non-adherence. Majority of patients are having lack of knowledge about their disease, drug usage and their treatment. Developing and implementing medication synchronization program can be quite challenging.

**Conclusion**

Medication synchronization programs are the newer pharmacy services implemented to restore the refilling process. It is one of tools to improve medication adherence and decrease over all health care cost. These programs work by aligning of prescriptions, refilling the quantity of medications prescribed for chronic disease on single visits. Although there are numerous medication synchronization programs are available in community pharmacies to improve medication adherence each MPS has its own pro’s and con’s. Effectives of medication synchronization programs are confined to the type synchronization programs are implemented. Appointment-based model was found to be better MSP as compared to other programs in community pharmacies as per the literature evidence. Since these programs are well established in most of the developed countries among Indian population pharmacy-based services are lacking. Newer pharmacy services are yet to be implemented among Indian health care system Developing and implementing MPS in health care system is quite challenging. This comprehensive review focus on applicability, effectiveness, barrier’s, of medication synchronization programs in India.

Articaine: Opening up a New Vista For Pediatric Dentists

Ananthu H1, Ashwin P Rao2, Suprabha B S3

1 Post Graduate Student, 2 Associate Professor, 3 Professor and Head, Department of Pediatric And Preventive Dentistry, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education (Mahe), Manipal, Department of Pediatric And Preventive Dentistry, Manipal College of Dental Sciences

Abstract

Lidocaine has remained the gold standard local anaesthetic agent to perform dental procedures both in the adult as well as in the pediatric patients. However, the invent of articaine has offered the clinicians with a newer and more potent local anaesthetic agent, which causes minimal side effects. Articaine is 1.5 times more potent and 0.6 times less toxic than lidocaine. Also, adequate anaesthesia achieved through infiltration route of administration of the drug, almost eliminates the need for the painful and difficult inferior alveolar nerve block in children, thereby minimising the side effects. Thus, achieving adequate anaesthesia through the administration of a small volume of the drug has opened up a new vista for pediatric dentists in managing pain in children, although manufacturers do not recommend the usage of articaine in children less than 4 years of age due to paucity of evidence. So, this review article tries to throw light on the use of articaine in pediatric patients, citing evidence from literature and also tries to portray the recent advances in the research on articaine use in pediatric patients less than 4 years of age.

Key words: articaine, local anesthsia, pain, children

Introduction

Pain management plays a crucial role in the success of any dental treatment in a pediatric patient (1). Minimising the fear and anxiety, a proper management protocol employed, can help develop a positive attitude towards dental treatment in the patient. Though considered a painful and challenging procedure, the administration of local anaesthesia continues to be one of the most commonly used methods for managing pain in the pediatric age group (2). Maximum efficacy through minimum number of injections with negligible adverse events effected, should be the objective of the local anaesthetic agent used (3).

The discovery of the first amide local anaesthetic agent Lidocaine (Proprietary name: Xylocaine), also known as Lignocaine, in the 1940s, marked a revolution in the arena of pain management in dentistry as it offered better potency and triggered less allergic reactions when compared to the then commonly used local anaesthetic Novocain (Procaine) (4). Since its inception, Lidocaine has remained the “gold standard” local anaesthetic agent to perform dental procedures, all around the globe. However, the search for more effective local anaesthetic agents led to the discovery of newer local anaesthetic agents in the subsequent years. Articaine was one among the newer local anaesthetic drugs developed (5). It was originally developed and
synthesised as ‘Carticaine HCl’ by H. Rusching et al in 1969 (6). It was introduced into clinical practice first in 1976 in Germany and Switzerland followed by the other European countries and Canada (7)(8). In the United States, the US Food and Drug Administration approved the use of articaine in April 2000 (9). Gradually, articaine started to gain attention and clinicians began employing articaine in adult dentistry. However, the use of the drug in the pediatric age group has raised concern over times, though literature shows that the efficacy and safety of articaine is comparable to the other commercially available local anaesthetic including lignocaine (10,11) or even superior (12,13). A survey among pediatric dentists in India concluded that the majority of the respondents still preferred lidocaine with epinephrine as local anaesthetic for use in children (14).

**UNIQUENESS OF ARTICACINE**

Articaine or Articaine HCl (“4-methyl-3-[2-(propylamino)-propionamido]-2-thiophene-carboxylic acid, methyl ester hydrochloride”) is an amide type local anaesthetic. The molecular weight of articaine HCl is 320.84 and it contains a thiophene group instead of a benzene ring, a peculiar characteristic that differentiates it from the other local anaesthetic agents. The greater lipid solubility and potency offered by the thiophene ring helps in the entry of a greater amount of the administered anaesthetic solution into the neurons. It is also able to diffuse more easily through soft tissue surfaces and has a high degree of plasma protein binding of 95%, when compared with the other local anaesthetics. Though classified as an amide, owing to its linkage of intermediate chain, articaine also contains an ester side chain, which triggers the plasma esterases and the hepatic microsomal enzymes to bring about the biotransormation of articaine in plasma and liver respectively. The greater half-life of 20 minutes and the primary metabolite obtained is articainic acid which is pharmacologically inactive. This accounts to the decreased systemic toxicity effected by articaine, thereby rendering itself as a safer alternative (15). Articainic acid (64.2 ± 14.4%), articainic acid glucuronide (13.4 ± 5.0%) and the parent drug (1.45 ± 0.77%) are excreted via urine after the metabolism of articaine (16).

4% solution with 1:100,000 or 1: 200,000 adrenals are the commonly manufactured forms of articaine and they are dispensed in 2.2ml and 1.7ml glass dental cartridges. The two articaine formulations have been used in both adults as well as in children.

**SAFETY OF ARTICACINE IN CHILDREN**

Articaine is well tolerated and safe to use in children above 4 years of age. The potency of articaine is 1.5 times that of lidocaine, which enables the administration of a smaller volume of the drug. The reduced volume may help decrease the discomfort felt by the child during anaesthesia administration, especially in cases where an inadequate co-operation of the child is experienced. It is also 0.6 times less toxic as compared to lidocaine (17). There is also a lesser need for supplemental injections in articaine. Articaine can be given via buccal infiltration to children requiring pulp therapy and extractions and can thereby be used to replace inferior alveolar nerve block (IANB). The high risk of inferior alveolar and lingual nerve damage can be avoided by replacing IANB. The extent of soft tissue analgesia experienced by the patient can be reduced and therefore the incidence of complications like lip biting can be minimized (18,19). When buccal and palatal infiltration with other local anaesthetic agents was replaced by a single buccal infiltration using articaine, it yielded favourable results during the extraction of primary molars in the maxillary arch. Also, articaine delivered via intraligamentary injection can be used to replace IANB to extract primary molars (20).

According to Lemay et al, the onset of anaesthesia by articaine was 168±131 sec (nerve block) and 85±60 sec (infiltration) in children; for adults it was 170±131 sec (nerve block) and 119±84 sec (infiltration) (21). For maxillary infiltration, the duration of action on soft tissues ranges from 2.6 to 4.5 hours whereas for nerve block, it ranges from 4.3 to 5.3 hours (6,8). The volume of distribution of articaine is inversely proportional to the patient’s age. For children between ages 4–12 years, the dosage of articaine ranges from 5-7 mg/kg body weight,
however a lower limit of ≤5mg/kg was advocated in children aged 4-12 years by authors who performed studies using articaine in conjunction with sedative agents (22). In any case, it should always be remembered that the concentration of articaine can be considered double as that of lidocaine, and thus will require half the safe number of cartridges.

**COMPARISON WITH OTHER LOCAL ANESTHETIC AGENTS IN PEDIATRIC DENTISTRY**

Multiple investigators have reported their findings and conclusions on the use of articaine as a local anaesthetic agent in pediatric population.

Malamed in 2000 (6) compared the pain control property of “4% Articaine HCl (with 1: 100,000 epinephrine)” with “2% Lidocaine HCl (with 1: 100,000 epinephrine)” in children under the age of 13 years, by employing the Visual Analogue Scale (VAS). He found Articaine to be comparable to Lidocaine and gave a green signal to its use in the branch of pediatric dentistry citing its safety and efficacy.

Ram and Amir in 2006 (11) compared Articaine and Lidocaine during operative procedures in children aged 5-13 years. They stated that “Articaine 4% with 1:200 000 epinephrine is as effective as lidocaine 2% with 1:100 000 epinephrine”. However, articaine produced a longer lasting anaesthetic effect on the soft tissues as compared to lidocaine.

Yilmaz et al in 2011 (23) compared Articaine 4% with (1:100000 epinephrine) and Prilocaine 3% (with felypressin) in 162 children belonging to the 6 to 8 age group, undergoing primary molar pulpotomy. Similar intensity of pain was reported during administration of both the anaesthetic solutions. However, coronal pulp amputation, prilocaine gave a pain score which was 1.5 times higher than that of articaine. The adverse events reported were also comparable.

In a review by Leith et al in 2012 (17), it was also reported that 4% articaine showed better pain control than 2% lidocaine for both simple and complex dental procedures.

In 2012, Odabaş (24) compared 4% articaine with 3% mepivacaine, to study the pain reaction and duration of soft tissue numbness during the administration of local anaesthesia in children. A “randomized, double-blind, split-mouth” design was adopted for the study which included a sample size of 50 children (25 girls and 25 boys) belonging to the 7- to 13-year-old age group, who required comparable operative treatment needs in symmetric primary teeth. The objective evaluation of the children was carried out by the modified behaviour rating scale and the subjective evaluation by using the Wong-Baker FACES pain rating scale which helped assess the post injection and post treatment experience. The duration of numbness felt was recorded by the parents by asking the children. Articaine (140.69±49.76 minutes) presented with a prolonged time period of soft tissue anaesthesia than mepivacaine (117.52±42.99 minutes). Neither did the efficacy of the anesthesia nor did the heart rate, blood pressure, or oxygen saturation show any significant differences during all evaluation spans for both anaesthetic solutions. The two anaesthetic solutions also showed similar post treatment experience. It was concluded that same efficacy and identical child behaviour was observed with 4% articaine and 3% mepivacaine, though articaine reported longer soft tissue numbness.

In 2012, Arrow (25) compared “4% Articaine (with 1: 100,000 epinephrine)” administered via buccal infiltration to “2% Lignocaine (with 1: 80,000 epinephrine)” administered via buccal infiltration (BI) or inferior alveolar nerve block (IANB) during standard restorative procedures in the posterior teeth of the mandibular arch among school children. The study assessed pain response via the Faces Pain Scale – Revised (IASP) and found no statistical difference in pain response between both the solutions. The study declared that both Articaine and Lignocaine, were declared equally effective in pain management in children for routine restorative procedures.

In 2014, Thakare (26) evaluated and compared 4% Articaine and 0.5% Bupivacaine through his randomized
controlled crossover clinical trial, in patients aged 10-18 years who had their premolars indicated for orthodontic extractions. The study showed that 4% Articaine presented with a quicker onset of action and lesser Visual Analog Scale scores as compared to Bupivacaine. However, Bupivacaine presented with a longer time period of analgesia and time to the first uptake of medication for rescue analgesia. Articaine was declared more potent and effective considering its quicker onset of action and low pain scale scores.

In 2015, Arali and Mytri P (27) studied the anaesthetic efficacy of “4% articaine (with 1: 100,000 epinephrine)” delivered via buccal infiltration and “2% lignocaine (with 1: 100,000 epinephrine)” delivered via inferior alveolar nerve block (IANB) by employing a “randomized, double-blind, cross over” study design in children aged 5-8 years, presenting with the clinical condition of irreversible pulpitis. The study also assessed the necessity for the administration of supplemental injections. The trial reported that the anaesthetic onset was quicker with 4% articaine than 2% lignocaine. A shorter span of anaesthesia was observed with articaine infiltration and with a lesser requirement for the administration of supplemental injections. The study concluded that 4% articaine can be given via buccal infiltration to children undergoing management for irreversible pulpitis. The study also highlighted the potential of articaine delivered via buccal infiltration to replace IANB to avoid complications such as lip biting.

A study by Zurfluh et al in 2015 (28) assessed whether an articaine solution could reduce the period of soft tissue anaesthesia and thereby reduce the risk of self-inflicted soft tissue lesions, while still providing an adequate anaesthesia. The study reported that owing to its high efficacy, tolerance, and reduced soft tissue anaesthesia, 4% articaine (with 1: 400,000 epinephrine) was considered safe for treatment in paediatric population.

In 2015, a study was performed by Mittal (29) in 112 children, to compare the anaesthetic efficacy of articaine with lidocaine during the extraction of primary molars in the maxillary arch and assess whether a buccal infiltration injection could achieve sufficient palatal anaesthesia as well. The study reported that buccal infiltration with articaine can be considered a potential substitute for lidocaine in achieving local anesthesia in children, though it did not succeed in achieving sufficient palatal anaesthesia.

In 2016, Chopra et al (30) compared the efficacy of buccal infiltration with articaine against inferior alveolar nerve block with lignocaine for primary molars in children aged 4-8 years, indicated for pulpectomy or pulpotomy. The efficacy of both the anaesthetic agents were assessed using the Pain Scores, the Facial Image score, Sound Eye Motor (SEM) scores and Heft-Parker Visual Analogue Score (HP-VAS). Buccal infiltration with articaine showed significant lower pain scores as compared to IANB (p<0.001). SEM scores at the time of pulp extirpation were also higher for IANB than infiltration (p<0.001).

Kolli et al in 2017 (31) stated that Articaine buccal infiltration can be used as an alternate to conventional local anaesthetic delivered via buccal and palatal infiltration, for extracting primary molars in the maxillary arch.

In 2018, Sharan et al (32) assessed the effectiveness of “2% lidocaine (with 1:80,000 epinephrine)” and “4% articaine (with 1:100,000 epinephrine)” to extract primary mandibular molars in children aged 6-10 years, by employing the intraligamentary injection technique. The study utilised the Sound eye motor scale to assess pain perception. The study showed 80% success rate in Articaine group and 30% success rate in lidocaine group. The study concluded that the intraligamentary injection technique using articaine might serve as an alternative to IANB during extraction of primary molars in the mandibular arch.

Rathi conducted a study in 2019 (33) among 100 children to compare the anaesthetic efficacy of articaine with that of lignocaine. It was concluded that a single buccal infiltration of 4% articaine with 1:100,000 epinephrine is more effective when compared to 2% lidocaine with 1:80,000 epinephrine for extracting
primary molars in children aged 7 to 12 years.

Massignan in 2020 (34) stated that though articaine reported a higher pain incidence during the injection, no difference in efficacy was observed when the anaesthetic administration of articaine was compared to lidocaine in the extraction of primary molars. In the study, the efficacy and the adverse events of “4% articaine with epinephrine 1:100 000” was compared with that of “2% lidocaine with epinephrine 1:100 000” during the extraction of primary molars, by employing anaesthesia via buccal infiltration in forty-three children belonging to the 6-10 age group. 21 children received local buccal infiltration with 4% articaine whereas 22 children received lidocaine 2%. The pain experienced during injection of the anaesthetic solution and during extraction of the tooth was the major outcome assessed. The anaesthetic efficacy of both the solutions was observed to be identical though a higher pain incidence was reported by children belonging to the articaine group. Similar adverse effects were observed in both the groups which included post-operative pain, edema and nausea.

It can be summarised that there is evidence to conclude that 4% articaine is comparable to or more efficacious than the other local anaesthetic agents used in children. However, the parents should be cautioned about self-inflicted soft tissue injuries that may arise due to the prolonged numbness, commonly reported with articaine administration. However, the evidence suggests that articaine is safe in children, as the administration of the drug triggers few adverse events, which are commonly noticed with lidocaine as well.

**EVIDENCE FOR USE IN CHILDREN BELOW 4 YEARS OF AGE**

Some studies have specifically reported the use of articaine in paediatric dental patients less than 4 years of age with positive results, however the manufacturers still do not recommend it for children younger than 4 years.

Wright et al in 1989 (22) conducted a retrospective research which analysed the usage of articaine hydrochloride as an anaesthetic agent in children aged less than 4 years of age. Records of articaine administration on 211 patients, with additional administrations of the agent on 29 patients was retrieved from two pediatric dentistry offices by a record audit. Some cases even reported administration of higher doses of the drug than recommended for older children. The clinicians have not noted the occurrence of any systemic adverse reactions. The report provided initial evidence for the use of articaine in children under 4 years of age.

Jakobs et al in 1995 (35) studied the pharmacokinetics of articaine on 27 children, 3 to 12 years of age, who underwent dental procedures under intubation anesthesia. They determined the serum concentrations after local anesthesia with 2% and 4% articaine solutions in this age group of children. They concluded that articaine shows age-related differences in the pharmacokinetics and hence there is no need to fix a lower mg/kg dose limit while administration in children.

A study was conducted in young children below four years of age by Elheeny in 2020 (36) to assess the efficacy and safety of 4 % articaine as a local anesthetic agent by comparing it with 2 % lidocaine hydrochloride. The study had an equivalent randomized control trial design, with two parallel arms including 184 young children (92 per group) aged from 36 to 47 months, in whom, pulpotomy of mandibular primary molars was indicated after administering anesthesia by buccal infiltration injection. The results of the study indicated that during pulpotomy, children who received articaine showed less pain as compared to their counterparts in the lidocaine group and no statistically significant differences were observed between both the drugs, considering the post-operative complications. It was concluded that the findings supported the efficient and safe use of articaine hydrochloride 4% with epinephrine 1:100 000 as a local anaesthetic agent during dental procedures in children aged between 3 and 4 years.

The evidence supports the use of articaine in children less than 4 years of age. However, limited research demands clinical trials on a larger sample size.
to be performed before employing articaine as a local anaesthetic agent in children less than 4 years of age.

**Conclusion**

Articaine is a safe and effective local anesthetic drug which can be employed in pediatric patients to help achieve dental analgesia during invasive procedures. The evidence that articaine administered via infiltration technique can replace Inferior Alveolar Nerve Block makes it even more interesting. The ability of articaine to penetrate into deeper spaces by diffusing through bone and soft tissue should be understood by the clinicians as it helps to achieve excellent depth of anesthesia, while avoiding block and palatal anesthesia for dental treatment in children. However, advanced research and clinical trials is a necessity, as articaine is not recommended by manufacturers in children below 4 years of age.

Maxillary Inter-canine Width at Three Stages of Dentition– A Cross-Sectional Study

Anita Thakur1, Seema Thakur2, Parul Singhal3, Deepak Chauhan3

1Post Graduate Student, 2Professor & Head, 3Assistant Professor, Department of Pediatric and Preventive Dentistry, H.P Government Dental College and Hospital Shimla, Himachal Pradesh

Abstract

Objective: To determine the palatal intercanine width from deciduous dentition to permanent dentition in 5years to 16 years old children.

Materials and Methods: the study sample comprised of 168 children who fulfilled the inclusion and exclusion criteria were examined. Study models were constructed and maxillary intercanine width was measured using Vernier digital caliper.

Results: Statistically significant difference was found in upper intercanine width (UICW) between males and females in primary dentition (p<0.034). Statistically non-significant difference was found in upper intercanine width (UICW) in mixed and permanent dentition. Data were analysed using SPSS 22 (SPSS Inc., Chicago, IL, USA). One-way ANOVA followed by Tukey’s post hoc test and t- test were applied to verify the existence of significant differences between the groups.

Conclusion: The present study found that there is significant increase in intercanine width in upper dental arch from primary dentition to permanent dentition.

Keywords: Intercanine width, arch, maxillary, dimensions

Introduction

The human craniofacial complex and associated dental arches undergo visible alterations as they grow and adapt1 from childhood to early permanent dentition. Morphological variations in the dental arch measurements in primary dentition, mixed dentition and permanent dentition are of great concern to a dentist as they encounter clinical problems associated with developing dentition like tooth anomalies, caries and malocclusion.

Individual occlusal variables are not functionally or anatomically independent. Their interdependence means that sets of occlusal features could have different pattern of inheritance or response to environmental influences than individual attributes2. These morphogenetic characteristics expressed differently in different ethnic people. The size and shape of dental arches presents with different variability within and among different population groups ranging from short and wide to long and narrow.

Thus; Understanding the peculiar features of the developing dentition and changes in dental arches that will take place from primary dentition to permanent dentition for a particular population is important for the Paediatric dentists who are involved in the guidance of eruption, preventive procedures and planning early orthodontic interventions before the peak of growth.

Although various studies have been done on the malocclusion status of the children of Himachal Pradesh, but there are no reported studies showing changes in upper intercanine width (UICW) from primary to permanent dentition. This investigation evaluated the changes in intercanine width cross-sectionally from primary dentition to permanent dentition in 5 years to 16
years old children of Shimla, a district in northern hilly state of India.

**Material and Methods**

This cross-sectional study was conducted in the Department of Pediatric and Preventive Dentistry, Himachal Pradesh Government Dental College and Hospital, Shimla (Himachal Pradesh) between 1st April 2019 to 30th June 2019. The study has been approved by the institutional ethical committee. A total of 823 school going children between the age of 5 years to 16 years were examined and the dentition stage was clinically determined for each subject by a trained examiner. Informed consent was taken from each subject and head of the corresponding school after explaining the purpose, methodology involved, the related risks and benefits. A sample of 150 (each dentition stage consisted of 50 children) was estimated based on the study done by Younes et al\(^3\). Stratified random sampling was done and students were selected from 10 kindergarten, 10 elementary and 10 middle schools which were evenly distributed in the four regions of the district\(^4\) and the patients attending the outpatient department of Pediatric and Preventive Dentistry, as per the defined inclusion and exclusion criteria. Demographic information was taken regarding age and gender. Subjects with their parents and grandparents belonging to Shimla were selected to participate in the study, with an average age of 5.3 year in primary dentition, 9.64 year in mixed dentition and 14.28 years in permanent dentition (Table 1). They were diagnosed as having canines bilaterally in normal occlusion (Normal occlusion was considered as dental and skeletal class I occlusion with a satisfactory clinical occlusion\(^5,6\)) with no history of orthodontic treatment\(^6\).

**Measurement Reliability:** Measurements were obtained for each parameter with a Vernier caliper accurate to 0.01 mm for canine area. Intercanine width was measured as the distance between the crown tips of the canines (transverse width in between deciduous canines in primary and mixed dentition and transverse width in permanent canines in permanent dentition)\(^6\).

**Statistical Analysis:** Data were analysed using SPSS 22 (SPSS Inc., Chicago, IL, USA). One-way ANOVA followed by Tukey’s post hoc test and t-test were applied to verify the existence of significant differences in “Primary Dentition (Group I), Mixed Dentition (Group II), and Permanent Dentition (Group III),” variables among dentition stages respectively. The level of significance was set at \(p < 0.05\).

For the purpose of this study, it was concluded that this level of accuracy was appropriate.

**Results**

A total of 823 subjects were examined in different schools for the study in the age group of 5-16 years.
Among these examined subjects, 168 impressions were poured. The casts which were fractured and had bubbles on the canine tips were excluded. Finally; the study included a total of 150 casts which were divided into three groups equally i.e. Group I, Group II and Group III. The mean age at different stages of dentition were calculated. Measurements of the arch dimension like inter-canine width, was measured on the cast using Vernier caliper.

Table 2 shows the mean (±SD) of Intercanine width using digital caliper in Group I, Group II and Group III which are 28.33±1.01, 33.96±1.29 & 35.07±1.24 respectively. The Group I have statistically significant difference between males and females i.e. p=0.034. In Group II and Group III male and female mean (±SD) do not differ significantly having p=0.088 and p=0.189 respectively. Statistically significant difference is found between Group I & Group II, Group I & Group III and Group II & Group III which are p<0.001, p<0.001 and p<0.001 respectively.

Discussion

India is a developing country and oral health, particularly the treatment of malocclusion is still not the priority of the people. Hence it is necessary to know about the normal dento-skeletal measurements for future diagnosis and treatment planning. Thus, the present study was conducted to evaluate the findings of palatal intercanine width from deciduous dentition to permanent dentition in 5 years to 16 years old children of district Shimla, Himachal Pradesh. In the present study, increase of 5.6 mm from age 5.2 to 9.8 years in overall palatal intercanine width from primary dentition to mixed dentition was found, which was statistically significant (p<0.0001). There was significant difference between males and females in primary dentition. Ahn et al \(^9\) reported that the intercanine width increased from ages 6 to 8 years in maxilla, both in girls and boys.

Most of the studies in literature reported lesser increase in palatal intercanine width from primary to mixed dentition when compared to our study. Rapid increase in palatal intercanine width was reported by the studies done by Barrow & White\(^{11}\) (increase of 4mm), Moorrees et al\(^{14}\) (increase of 3mm) and Sillman\(^{19}\). Very little increase in palatal intercanine width from primary to mixed dentition was found by Hasanali & Odhiambo\(^{13}\) (an increase of 0.21mm from 6-8 to 12 years of age for Kikuyu, Maasai and Kalenjin sample), Ahn et al\(^{9}\) (1.08mm from 6 years to 9 years), and Eslami Amirabadi\(^4\) et al (an increase of 0.47mm from 5 years to 9 years of age). Virgenia B Knott\(^{15}\) and Thialander B\(^6\) reported an increase in palatal intercanine width from primary to mixed dentition due to eruption of permanent incisors in mixed dentition stage which leads to an increase of the anterior segment of maxilla. The studies done by Ruth Elaine Ross -Powell\(^{8}\) & Edward F Harris\(^2\) reported an increase in palatal intercanine width of 4.3mm between ages of 5 and 10 years which he concluded that it could be due to the expansion at maxillary-premaxillary sutures. There was an increase of 1.02 mm in palatal intercanine width from mixed dentition to permanent dentition from the age of 10 years to 14 years in the present study, which was found to be statistically significant (p<0.0001). Similar results were reported in several studies [(0.92mm (Arslan et al\(^{18}\)), 2mm (Sillman\(^{19}\) and Virgenia B Knott\(^{15}\)), Eslami Amirabadi et al\(^4\) (4.60mm for Saudis) and Yang D et al\(^{10}\) (0.95mm from 10 years to 12 years)]. These findings were in contrast with the finding of the studies done by Sinclair & Little\(^{16}\) which showed decrease of 0.31mm, additionally Moorrees et al\(^{14}\) and Tsujino & Machida et al\(^{17}\) also showed a decrease from the mixed to the permanent stage. Samir E Bishara\(^{12}\) stated that the arch width dimensions were established in the mixed dentition by 8 years of age with some, but minimal, increase until the early permanent dentition (13 years) and progressive but minimal decrease in early and mid-adulthood. Burdi and Moyers\(^{20}\) pointed that the direction of the vertical alveolar growth differs significantly in the maxillary and mandibular arches. The maxillary alveolar processes diverge as the teeth erupt, whereas the growth of the mandibular alveolar process is more parallel. Such changes have significant clinical implications because they may allow for a greater differential increase in the maxillary arch width during treatment. The Study done by Thialander B\(^6\) stated that with the eruption of permanent canines, a further minor increase was observed in the maxillary arch. Ahn SJ\(^9\) stated that the permanent canines establish their final position and get stabilized by surrounding functional structures. Because of this stability, teeth are generally considered to move within bony confines and surrounding bone would change according to these functionally stabilized teeth which should be analyzed in future studies\(^9\). Furthermore; Ciusa V et al\(^{21}\) stated that “in children with a complete deciduous dentition, the lack of age-related modifications in maxillary intercanine width implies careful consideration of treatment timing of patients with crossbites and when a functional cause has been ruled out, the diagnosis of a crossbite at the deciduous canines should be a priority, because a relatively reduced maxillary intercanine distance will probably not correct spontaneously with growth”.

The present study indicated that there is increase of 6.62mm in intercanine width from primary to permanent
dentition. However, it is important to construct more precise findings for the width in anterior maxillary arch in canine region for children of Shimla origin of Himachal Pradesh. These progressive changes from deciduous to permanent dentition could not be indicated due to our cross-sectional research. Hence; further longitudinal studies are required to be done for the follow up of the dental arch development in children throughout the whole growth period to ascertain changes that may occur during the transitional periods from primary dentition to permanent dentition22.

**Conclusion**

Intercanine width varies among different populations. To summarize, the present study found that there is significant increase in intercanine width in upper dental arch from primary dentition to permanent dentition. Statistically significant difference was found in upper intercanine width (UICW) between males and females in primary dentition. Statistically non-significant difference was found in upper intercanine width (UICW) in mixed and permanent dentition.

Effectiveness of Structured Teaching Programme on Knowledge Regarding Post Exposure Prophylaxis Following Needle Stick Injury among B. Sc Nursing Students

Anjana A.P1, Reshma Thomas2, Renjitha2
1Assistant Professor, Department of Medical Surgical Nursing, 2 IV Year B. Sc Nursing Students, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi, Kerala, India

Abstract

Background and Objective: A needle stick injury is a percutaneous piercing wound typically set by a needle point, but possibly also by other sharp instruments or objects. Needle stick injuries are more common among health workers during night shifts, and for less experienced people, fatigue, high work load, high pressure, or high perception of risk can all increase the chances of needle stick injury. The present study was conducted with an Objective, to evaluate the effectiveness of structured teaching programme on knowledge regarding post exposure prophylaxis following needle stick injury among B. Sc Nursing students. Methods and Materials: Approach was quantitative approach. The study design was Quasi experimental one group pre test post test design. 157 samples were included in the study by using convenience sampling technique. The knowledge of nursing students regarding post exposure prophylaxis following needle stick injury were assessed before and after the implementation of education programme. The data was collected by using semistructured knowledge questionnaire. Post test was done seven days after the intervention. Results: Application of paired t test revealed a statistically significant increase in knowledge score regarding post exposure prophylaxis following needle stick injury after the implementation of the education programme (t= 9.40, p<0.001). There was a significant increase in the knowledge of each components of post exposure prophylaxis also. Conclusion: Based on the study findings it was concluded that the education programme was effective in improving the knowledge level of nursing students regarding post exposure prophylaxis following needle stick injury.

Key words: Knowledge, Needle stick injury, post exposure prophylaxis

Introduction

A needle stick injury is a percutaneous piercing wound typically set by a needle point, but possibly also by other sharp instruments or objects. Needle stick injuries are more common among health workers during night shifts, and for less experienced people, fatigue, high work load, high pressure, or high perception of risk can all increase the chances of needle stick injury1. Generally needle stick injuries cause only minor visible trauma or bleeding, however, even in the absence of bleeding the risk of viral infection remains. The world health organization estimated annual global needle stick injuries at 2 million per year, and another investigation estimated 3.5 million injuries yearly. The European biosafety network estimated 1 million needle stick injuries occurs annually in Europe 2. In India, authentic data on NSI are scarce. More than 90% infections occur in developing countries.3 CDC estimates that each year 3,85,000 needle stick injuries are sustained by hospital based health care personnel. According to WHO study, the annual estimated proportions of HCWs exposed to
blood borne pathogens globally were 2.6% of HCV, 5.9% for HBV & 0.5 % for HIV. 4

Anjana A. P., Gisha Joseph, Revathy A.Valsan conducted a descriptive study to assess the knowledge regarding Post Exposure Prophylaxis following needle stick injury among 134 B. Sc. Nursing Students at Kochi using convenience sampling technique. The data were collected using semi structured knowledge questionnaire. The results revealed that out of 134 respondents 125 (93%) had an average knowledge regarding post exposure prophylaxis following needle stick injury. Regarding students’ knowledge on different variables on PEP following needle stick injury, they had good knowledge on prevention, average knowledge on meaning and risk factor of needle stick injuries and the lowest mean score in the area of management and complications of PEP 5.

Mittal Garima, Taneja Anmol. R K, Garwal R K, Gupta Pratima and Gupta Priyanka conducted a cross-sectional observational study to assess the knowledge, awareness and prevalence of needle stick injury among undergraduates, postgraduates and nursing students (100 in each category) of the SRHU, Uttarakhand, India. Data was collected on a pretested structured questionnaire distributed among the students which consisted of questions to assess the knowledge and awareness towards needle stick injuries. Out of 300 students, needle prick injury was reported in 6 undergraduates, 7 postgraduates and 20 nursing students in past twelve months. Out of 300 students, 22% (66) knew the definition of needle stick injury and 58.6% (176) knew the immediate measure to be taken i.e. to wash the wound with soap and water. Out of the 33 students who contracted NSI, 38.5% cannot remember the cause of needle stick injury, while 34.9% mentions the cause of NSI due to the carelessness/accident and 21.7% reports the NSI due to poor disposal of needle. Only 56.6% reported the incident, whereas only 21.7 filled an incident report at integrated counselling and testing centre.6

Based on the findings of the above studies it is concluded that the nursing students have an average knowledge regarding post exposure prophylaxis following needle stick injury. Therefore, there is a need for regular training and education to update the awareness and knowledge about post exposure prophylaxis which serves as an effective strategy to prevent the spread of blood borne disease. Hence the topic was selected for study.

Methods and Materials

This study was conducted in Amrita College of Nursing, Kochi, Kerala during the month of January 2019. Quantitative approach was used for the study. The design adopted for the study was quasi experimental one group pretest posttest design. By using convenience sampling technique samples were selected. 157 Second- and Third-Year B Sc Nursing students, who were present on the day of data collection was selected for the study.

Data collection began with pretest by using semi structured questionnaire which includes sociodemographic data and knowledge questionnaire. After that teaching was given with lecture cum discussion method. After seven days posttest was obtained.

Data were analyzed by using descriptive and inferential statistics. Continuous data were expressed in terms of mean and standard deviation (SD). Comparison of mean pre test and post test knowledge scores using paired t test.

Results

Regarding the sociodemographic data most of the sample 128 (81.5%) were belongs to the age group of 18-20 years. 153 (97.5%) were females. 152 (97%) were heard about needle stick injury and majority of them 141 (90%) were vaccinated against blood borne infection. 27(17%) had experienced needlestick injury and the frequency of needle stick injury were 1-2 times. Only 24 (89%) were reported on needle stick injury and 3 (11%) were not reported. Reason for not reporting the incident was lack of knowledge 23 (86%). Among the sample 10 (37%) had needlestick injury while disposing the
waste and 10 (37%) had needle stick injury while giving injections. 124 (79%) had previous knowledge on post exposure prophylaxis and they got training regarding the same. 145 (92%) sample agreed postexposure prophylaxis is effective in preventing blood borne infections.

Regarding the level of knowledge, in pretest 133 students had average knowledge and 3 had poor knowledge. Only 21 students had good knowledge regarding postexposure prophylaxis. After the intervention 73 students gained good knowledge and 84 had average knowledge.

### Discussion

The study shows an overall average knowledge among nursing students before participation in education programme. The present study was supported by another study conducted by Sudhir Sing. A pre-experimental study was conducted to assess the effectiveness of structured teaching programme regarding knowledge of needle stick injury and its prevention among nursing students in selected Nursing institutes Faridabad, Haryana. 60 sample were selected for the study. The study finding revealed that, in pre-test, out of 60 sample, most of them 42 (70%) had inadequate, 18(30%) had
moderate level of knowledge. In post-test, out of 60 sample most of them 40 (66.66%) had adequate and 20 (33.33%) had moderate level of knowledge and none of them had Inadequate level of knowledge. In pre-test overall mean score was 5.41 with the SD of 3.29 and in post-test, the overall mean score was increased to 14.10 with SD of 3.71. The mean difference of pre and post-test was 8.69. The calculated ‘t’ value was 35.58, which is significant at p <0.05. This indicates that structured teaching programme was effective. 

Aswin Kumar, G. K. Ratnaprabha conducted a cross-sectional study to assess the Awareness about HIV and post exposure prophylaxis among students of a nursing college from central Karnataka. Out of 108 students 72 (66.67%) students heard about post exposure prophylaxis. Majority were unaware about time of initiation (94.6%) and duration of PEP (86.1%). The study concluded that knowledge about HIV/AIDS and PEP are inadequate among nursing students.

Conclusion

Continuous education about postexposure prophylaxis among nursing students helps to improve their knowledge, which serves as an effective strategy to prevent blood borne diseases.

Fatal Poisoning Cases in a Teaching Hospital of West Bengal: a Descriptive Cross-Sectional Clinico-epidemiological Study

Ankur Bhattacharjee¹, Saptarshi Chatterjee², Partha Sarathi Hembram², Sobhan Kumar Das³
¹Assistant Professor, Department of Forensic Medicine and Toxicology, N.R.S. Medical College, Kolkata, West Bengal, ²Associate Professor, Department of Forensic Medicine and Toxicology, Bankura Sammilani Medical College, Bankura, West Bengal, ³Professor, Department of Forensic Medicine and Toxicology, R.G. Kar Medical College, Kolkata, West Bengal

Abstract

**Background:** Poisoning is a global health issue and one of the leading causes of morbidity and mortality in India. Pattern of poisoning depends on factors, such as availability of poisons, socioeconomic status of the population, religious and cultural influences, thus creating varied epidemiological trends across time and regions. The present study is planned to address the epidemiological profiles of fatal poisoning cases, with reference to the gastric findings during autopsy.

**Methods:** This is a descriptive, observational, cross-sectional study analysing 184 fatal poisoning cases, who attended to R.G. Kar Medical College Police Mortuary during the period of 2014-2015.

**Conclusion:** People of age group 20-29 years were mostly affected, with a male preponderance and an incidence of 8.03%. People from the rural regions constituted more than 80% of the study sample, with suicide as the commonest manner of death. Organophosphorus compounds and acids were the mainly detected, with mucosal congestion and submucosal hemorrhage of stomach as the most reported findings. The authors feel that a prospective study is an option, which could accurately identify the cases and deaths, which could formulate stringent measures so as to decrease the morbidity and mortality due to poisoning.

**Keywords:** Demography, Gastric findings, Intentional poisoning

Introduction

Poisoning is a global health issue and one of the leading causes of mortality and morbidity in India.¹ According to World Health Organization (WHO), approximately 0.03 million people die annually due to various types of poisoning.² In India, it has been estimated that about 5 to 6 persons per lakh of population die due to poisoning every year.³

Corresponding author:
Dr. Mainak Tarafder
Assistant Professor, Department of Forensic Medicine and Toxicology, BankuraSammilani Medical College, Bankura, West Bengal

Wide availability, easy access and extensive use in medical, industrial, household and agricultural applications increase the risk, exposure and incidence of poisoning.⁴ Pattern of poisoning in a region depends on a variety of factors, such as availability of poisons, socioeconomic status of the population, religious and cultural influences,⁵ thus creating varied epidemiological trends across time and regions. Similarly, the mortality and morbidity in any case of acute poisoning depends upon a number of factors, such as the nature of poison, dose consumed, availability of medical facilities, treatment by qualified persons and the time interval between intake of poison and provision of medical help.

Though literature on poisoning in India is widely available, there is a significant lack of data from the
eastern parts of the country. Moreover, most of the studies, so conducted, aimed at the clinical presentation and management protocols of the poisoning cases, based on in-hospital records, or are retrospective studies. The present study is hence planned to address the epidemiological profiles of fatal poisoning cases in West Bengal, with reference to the gastric findings during autopsy. In due course, it may estimate the nature and severity of poisoning, with demographic profiles of the victims, thus providing the stakeholders some recommendations in order to take appropriate preventive measures.

Aims and Objectives

1. To study the prevalence of deaths due to poisoning from 2014 to 2015
2. To study the socio-demographic profiles of the victims of fatal poisoning
3. To analyse the type of poisons
4. To study the gastric findings in fatal poisoning cases

Materials and methods

a. Place of study: R.G. Kar Medical College Police Mortuary, Kolkata, West Bengal, India.

b. Period of study: 1st April, 2014 to 31st March, 2015

c. Study population: All the victims of fatal poisoning, attended to R.G. Kar Medical College Police Mortuary for autopsy examination between 2014 to 2015.

- Inclusion criteria: All the victims of fatal poisoning between 2014 to 2015, who attended for autopsy examination at R.G. Kar Medical College Police Mortuary.

- Exclusion criteria:
  i. Victims of fatal animal, snake and insect bites
  ii. Cases with incomplete or inadequate history
  iii. Grossly decomposed bodies
  d. Study design: Descriptive observational cross-sectional study
  e. Statistical analysis: Details regarding the cases were obtained from the inquest report, interviewing the eyewitnesses and the family members of the deceased. All the data were manually checked and edited for completeness in a pre-determined format and were then coded for computer entry. Collected data was recorded in Microsoft Excel worksheet and SPSS IBM 19.

Results

1. Prevalence of Fatal Poisoning cases

The number of victims due to poisoning was 184 (8.03%) among 2290 cases sent for autopsy.

2. Distribution according to age and gender

Majority of the victims of fatal poisoning belong to the age group of 20-29 years, with a male predominance in almost all the age groups (except victims below 10 years and between 40-49 years).[Table 1].

3. Distribution according to religion and residence

In our study, 141 out of total 184 victims (76.63%), were Hindus and the rest 43 victims (23.37%) belonged to the Muslim community. 148 of the victims (80.4%) were from the rural regions and the rest 36 of the victims (19.6%) belonged to urban areas.

4. Distribution according to the type of poison

Majority of the fatal poisoning cases were due to Organophosphorus poisoning (22.8%), followed by 21.1% victims of acid ingestion [Figure 1].

5. Distribution according to manners of poisoning (as per Police inquests)

Deaths due to suicide (91.3%) were maximum, followed by accidental (7%) and homicidal poisonings (1.7%).
6. Distribution according to smell of gastric contents

Gastric contents mostly exhibited pungent odours (47.4%), followed by 23.9% of the victims with no untoward smell [Table 2].

7. Distribution according to appearance of gastric mucosa

Congested mucosa (46.2%) was mostly found, followed by submucosal hemorrhage (30.5%) and 15.8% of victims with charred mucosa and perforation [Figure 2].

#### Discussion

The present study examines the prevalence, socio-demographic profiles and nature of fatal poisoning among cases who was brought to the Institutional Police Mortuary for autopsy examination. The higher prevalence among males by 1.5 times that of females is also noted in other parts around India. In a study from Karnataka, the males dominated the study with male:female ratio of 3:1. In continuation to the data from Southern parts of the country, the majority of the fatal poisoning cases in our study belonged to the age group of 2nd to 3rd decade. The possible reasons for increased poisoning in this age group may be because of problems in family, studies, marriage, life settlement and employment which may themselves act as stressors to suicidal ideation and attempts. Owing to the geographical location, though religion was not considered for analysis, but the people...
from the rural areas contributes to a significantly higher percentage (80.4%) of the study sample. Similarly, a study from North India shares that 60% of their victims were from rural background, with lesser resources available to them than their urban counterparts. This compounded by the usually large family size, high illiteracy, ignorance and superstitions, complete dependence on the fate of their crop- both in the field and in the market may be responsible for the trend observed in our study.

Various national and international studies have projected the rise of prevalence of suicidal poisoning cases. During the study period, 184 fatal poisoning cases were collected, with more than 90% of the deaths attributable to suicides. This endorses the view that the demands put forth by the materialistic modern society is the main factor for deaths due to poisoning. Studies across the country have revealed a rapidly increasing trend of Organophosphorus poisoning. Similarly, Organophosphorus compound was the single most culprit agent in about 23% of cases in our study, followed by acids in 21%. India is a country, where agriculture is the prime profession for majority of people in rural areas and pest control is one of the most common problems faced by the farmers in agriculture. In order to eradicate the weeds and pests, farmers procure and keep pesticides at their houses. Because of easy availability of the pesticides, people tend to use them for intentional poisoning.

Though odour of the gastric contents being a subjective data was not considered for analysis, stomach was affected in all the poisoning cases. This may be due to the fact that stomach being a reservoir, the contact period of poison with stomach is more. In the present study, congestion was noted in more than 45% of cases which is in accordance to other studies, conducted elsewhere around the country. However, there are numerous factors that contribute to the stomach mucosal finding in poisoning cases. These are the dosage, biological factors, route of administration, treatment interventions and the post-mortem interval. With all these factors affecting, it is difficult to predict the gross mucosal findings attributable to specific poisons. Generally, the findings are seen in combination, and are not consistent with a type of poison. However, if the poison suspected is mentioned in the requisition to the Forensic Science Laboratory, it shall help in early analysis and also avoids blind testing and wastage of chemicals.

**Conclusion**

The present study is an observational, descriptive, cross-sectional study. Other than reporting an annual prevalence of 8.03% of fatal poisoning cases, it also reflects that the individuals between 2nd to 3rd decade as the most vulnerable, with a male preponderance in almost all the age groups. People from the rural regions were mostly the victims of fatal poisoning, with suicidal poisoning being shared as the most common manner of death. Organophosphorus compounds and acids were the mainly involved in almost 50% of the cases, with mucosal congestion and submucosal hemorrhage of stomach as the most reported findings. However, the authors feel that a prospective study is the need of the hour, which could accurately identify the cases and deaths, which could formulate stringent measures so as to decrease the morbidity and mortality due to poisoning.

A Study to Assess the Knowledge and Practice Regarding Prevention of Deep Vein Thrombosis among Bedridden Patients in a Selected Hospital, Mangalore

Ann Sangeetha James¹, Fiona George¹, GraceViolet¹, Jomol Sebastian¹, Prashma Bharath²

¹IV B.Sc. Nursing Students, ²Lecturer, Department of Medical Surgical Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be University) Mangaluru, Karnataka, India

Abstract

Introduction: The vascular system is a vast network of vessels through which blood circulates in the body. Blood leaving the ventricles is distributed through arteries and arterioles in progressively smaller branches to the capillaries. Deep vein thrombosis is a medical condition that occurs when a blood clot forms in a deep vein. A world wide survey conducted by CDC shows that 900,000 people could be affected by DVT (1 to 2 per 1,000) each year in the United States. Among people who have had a DVT, one-half will have long-term complications. DVT is a serious condition that can be life-threatening. However, it’s largely preventable and treatable. Aim: To assess the knowledge and practice regarding prevention of deep vein thrombosis among bedridden patients. Materials and Methods: A cross-sectional study was carried out among the bedridden patients of Yenepoya Medical College Hospital, Mangalore. The content validity of the tool was established in consultation with 7 experts. The reliability of the tools were found to be $r(6) = 0.8$ and 0.7 which was statistically significant. The tools were found to be reliable. Non probability convenience sampling was used to select the subjects for the study. Pilot study was conducted to find out the feasibility of the study. Data collected from the 95 subjects were analyzed by descriptive and inferential statistics using SPSS (Version 23). Results: The findings of the study demonstrated that among 95 bedridden patients, that maximum percentage (61%) were belonged to the age group of 47 years and above. Majority (72%) were males. (41%) of were completed primary education. Majority (62%) of the respondents were physically active workers. 58% of subjects had inadequate knowledge and 42% of subjects had moderate knowledge and none of the subjects had adequate knowledge on prevention of deep vein thrombosis and 22% of subjects had low practice, whereas majority 66% of respondents had moderate practice level and 12% of subjects had high practice level. Mean knowledge score was 11.14 and mean practice score was 9.85. There existed a positive relationship between knowledge and practice (correlation coefficient =0.662*) at 0.05 level of significance. The study also indicated that chi-square value of demographic variables have no significant association with knowledge scores and practice scores of bedridden patients.

Keywords: Knowledge, Practice, Deep Vein thrombosis.

Introduction

Venous thrombosis, including deep vein thrombosis and pulmonary embolism, occurs at an annual incidence of about 1 per 1000 adults. Rates increase sharply after around age 45 years, and are slightly higher in men than women in older age ¹. Death from DVT-associated massive pulmonary embolism (PE) causes as many as 300,000 deaths annually in the United States ². VTE is a major healthcare problem worldwide. In 2007, over 500,000 deaths in the EU were associated with an estimated 1.1 million venous thromboembolic events approximately one-third of these events manifested as
PE. In the US, DVT and PE together affect an estimated 350,000–600,000 people each year, leading to an estimated 100,000 –300,000 deaths ³.

According to a study done on 60,000 patients in more than 32 countries, almost one out of every two hospitalized patients in medical and surgical wards worldwide and in India was at risk of developing DVT. The study revealed that although the risk of DVT was very high, only 17 per cent of these patients in India received any prophylaxis ⁴. DVT is a serious condition that can be life-threatening. However, it’s largely preventable and treatable ⁵. DVT is preventable and treatable if discovered early ⁶.

In the 21st century, venous thromboembolism still accounts for 10% of deaths in hospital patients. Venous ulcers develop in at least 300 per 100,000 population and the proportion due to DVT is approximately 25%. ⁴, ⁵ It has been estimated that the management of venous ulcers in the UK costs £100-300 million every year, nursing time accounting for most of this cost ⁷.

Global public awareness is substantially lower for pulmonary embolism (54%) and deep-vein thrombosis (44%) than heart attack (88%) and stroke (85%). Over time, the incidence and MRs of these conditions have improved in developed countries, but are increasing in developing countries. Public health efforts to measure disease burden and increase awareness of symptoms and risk factors need to improve in developing countries ⁸.

**Material and Methods**

A descriptive cross-sectional study was conducted from 19 September 2019 to 29 September 2019 at Yenepoya Medical College Hospital, Mangalore after getting ethical permission (Ref.no: YEC-1/061/2019). By using the Non-probability convenience sampling technique, 95 bedridden patients of Yenepoya Medical College Hospital were selected. The patients were informed and explained the objective of the study. The written informed consent duly signed individually by them was obtained. The inclusion criteria were: Patients Confined to bed for duration of 14 days and more and patients in medical ward, surgical ward, orthopedic ward and intensive care units. Patients who were unconscious and who were seriously ill and sedated were excluded from the study. Demographic variables were collected in terms of Age, gender, education, marital status, monthly income, place of residence, occupation, and duration of hospitalization.

A structured knowledge questionnaire has 32 multiple choice questions and these were classified in different areas, such as i) Information regarding deep vein thrombosis, ii) General information about deep vein thrombosis iii) Causes and symptoms for deep vein thrombosis iv) Complications of deep vein thrombosis v) Prevention of deep vein thrombosis. A self reported checklist consisting of 20 items were prepared to assess the practice. The both tools were prepared based on the extensive review of the literature. Each correct answer carries one mark and the total score was 32 and 20 respectively. The prepared tool was validated by the seven experts, out of this 6 were from the nursing department, one was from the General medicine department and another from the General surgery department. The Reliability analysis was computed by Guttman split-half coefficient and Kuder-Richardson Formula 20(KR-20). The reliability obtained was 0.8 and 0.7 respectively, hence the tools were found reliable, valid and feasible.

**Statistical Analysis**

The collected data were coded, tabulated and analyzed by using descriptive and inferential statistics. Association of knowledge and practice with demographic variables was done by Chi-square test and Karl Pearson’s correlation co-efficient was calculated to find the correlation between knowledge and practice scores.

**Results**

**Distribution of subjects according to their demographic characteristics.**

The study shows that majority (61%) of the subjects belonged to the age group of 47 and years above.
Majority (72%) were males. (41%) of subjects were completed primary education. Majority (62%) of the respondents were physically active workers, (77%) were married, majority (39%) had income between 1001-3000, 65% of subjects belonged to rural area, (72%) were admitted between 14 days -30 days, Majority (76%) of the respondents got information from verbal report.

Table 3. Depicts that mean knowledge score is 11.14 and mean practice score is 9.85. There exists a positive relationship between knowledge and practice (correlation coefficient $r = 0.662^*$) at 0.05 level of significance.

Association between level of knowledge and selected demographic variables

The study reveals that the calculated chi-square value with regard to the age ($\chi^2= 29.931$ $p>0.05$), gender ($\chi^2=13.698$), educational status ($\chi^2=57.691$), occupation ($\chi^2=30.631$), marital status($\chi^2=18.992$), monthly income ($\chi^2=42.108$), place of residence($\chi^2=13.524$) duration of hospitalization ($\chi^2 =32.965$) and source of information ($\chi^2=26.448$) $p> 0.05$ were less than table values at 0.05 level of significance.

Association between practice scores and selected demographic variables

The study reveals that the calculated chi-square value with regard the age ($\chi^2=49.131$) ,gender ($\chi^2=18.762$), educational status ($\chi^2=78.707$) ,occupation($\chi^2=35.080$), marital status($\chi^2=23.821$), monthly income ($\chi^2=60.272$), place of residence($\chi^2=25.313$), duration of hospitalization ($\chi^2=43.726$) and source of information($\chi^2=36.613$) $p>0.05$ were less than table values at 0.05 level of significance.

Discussion

Alberto Okuhara et al., (2014)- A study was conducted in Brazil to determine the incidence of deep vein thrombosis and prophylaxis quality in hospitalized patients undergoing vascular and orthopedic surgical procedures. The total sample comprised 335 patients. Regarding the distribution of sex, 98 (33.3%) were women and 198 (66.6%) men. The mean age was 57.7 years.9

A study conducted to assess knowledge of venous thromboembolism among hospitalized patients. Among the study samples (83%) were aware that they were receiving injections to prevent blood clots and (81.2%) reported hearing of DVT, of the participants who had heard of DVT knew immobility was a risk factor but had limited knowledge of symptoms and prevention modalities.10

A study was conducted to assess the knowledge and practice of immobilized orthopedic patients and their caregivers regarding prevention of complication of immobility. The sample consisted of 40 patients and their caregivers and study results showed that the highest mean percentage practice score of patients was in the area of constipation (61.75%) and least mean percentage of practice score of patients was in the area of pressure sore (35.5%).11

The current study findings were supported by a study conducted to assess correlation between the knowledge scores and practice scores on prevention of deep vein thrombosis among bedridden patients. The study showed that correlation between the post test level of knowledge with skill regarding prevention of DVT in the experimental group was calculated by using Karl Pearson’s correlation coefficient and it was found that the ‘r’ value of $r =0.15$,was not statistically significant .10

Almodaimegh H et al., (2017) - A cross sectional study was conducted in Saudi Arabia to assess the awareness of venous thromboembolism and thromboprophylaxis among hospitalized patients. The percentage of respondents reporting awareness of DVT or PE was significantly higher among those with a personal or family history of VTE: 68% versus 32%, $p = 0.001$, and 57% versus 35%, $p = 0.046$, respectively. Awareness of DVT was not associated with any of the other factors such as age, gender and level of education.12

Jemini K - A study was conducted to assess the knowledge and practice of immobilized orthopedic patients and their caregivers regarding prevention of complication of immobility. The sample consisted of 40 patients and their caregivers and study results showed that association between practice score in relation to age ($r= 0.13$), gender ( $p=0.45$), level of education ($r=.00$), marital status ($p=0.72$) was not significant.11
Conclusion

The findings of the study showed that majority of the bedridden patients have poor knowledge and low practice regarding prevention of deep vein thrombosis. This study will help the bedridden patients to understand about the seriousness of this condition thereby they have to learn and practice about how to tackle the particular condition in safer way. The present Study was conducted on a Small group within a specific areas and only confined to bedridden patients of selected hospital. A similar study can be replicated on a large sample and in different settings.

of complications related to immobilization in St. John’s medical college hospital with a view to develop a pamphlet (Doctoral dissertation). http://52.172.27.147:8080/jspui/handle/123456789/2768

A Descriptive Study to Assess the Knowledge and Practice Regarding Prevention of Osteoporosis among Group D Female Workers of Selected Tertiary Care Hospitals in Mangaluru

Anumol Shaju¹, Beeda K Jose¹, Geeta Fernandes¹, Jeevan¹, Josna Johny¹, Indumathi²
¹Yenepoya Nursing College, 4th BS.c(N) Student, Deralakatte, Mangaluru, Karnataka, India, ²Lecturer, Yenepoya Nursing College, Yenepoya (Deemed to be University), Department of Community Health Nursing, Deralakatte, Mangaluru, Karnataka, India

Abstract

Background: Osteoporosis knowledge is one of several factors that are associated with osteoporosis preventive behaviour. Moreover, the educational level of individual has the potential to change the perception of health and illness to a much better level. The objective of the study was to assess the level of knowledge regarding prevention of osteoporosis among Group D female workers, to determine the level of practice regarding prevention of osteoporosis among Group D female workers, to find correlation between knowledge and practice on prevention of osteoporosis among group D female workers, to find association of knowledge and practice with selected demographic variables. Methodology: A descriptive study design was adopted for this study. The samples were drawn through Purposive sampling technique and the sample comprised of 87 female group D workers. The tool used for this study was demographic proforma, OKAT questionnaire, and self reported practice checklist. Conclusion: The mean percentage of knowledge score was 37.05% and the mean percentage of practice score was 37.18%.

Key words: osteoporosis, OKAT, Group D female workers

Introduction

Osteoporosis knowledge is one of several factors that are associated with osteoporosis preventive behaviour. Moreover, the educational level of individual has the potential to change the perception of health and illness to a much better level. Thus, highly educated people usually seek knowledge and have an opportunity to learn about health preventive behaviour more than those with lower education¹. Bone density peaks when a person is in their late 20s, and it starts to weaken at around 35 years of age, as a person grows older, bone breaks down faster than it rebuilds. It occurs more in women after menopause because of the sudden decrease in estrogens².

Worldwide, osteoporosis cause more than 8.9 million fractures annually, resulting in an osteoporotic fracture every 3 seconds. It is estimated to affect some 200 million women globally – approximately one – tenth of the aged 60, one fifth aged 70, two fifth aged 80, two third aged 90, also one in every three women over the age 50 years will experience osteoporotic fracture, as in one in every 5 men of the same age group.³ It is projected that more than about 50 % of all the osteoporotic hip fractures will occur in Asia by the year 2050.⁴

Osteoporosis develops in older adult when the normal process of bone formation and resorption become impaired. Treatment program should therefore

A focus on strategies that reduce falls, optimum treatment and prevention of osteoporosis require modification of risk factor particularly smoking, physical activity, and diet in addition to pharmacology interventions.

**Material and Methods**

A descriptive correlational research design was adopted for this study. The respondents in the study were Group D female workers in selected Tertiary care hospitals in Mangaluru. The 87 respondents were selected using purposive sampling technique.

**Sampling Criteria**

**Inclusion criteria:**
- Women’s between 30-60 years of age
- Able to communicate in Kannada or English.
- Person available at the time of data collection

**Exclusion criteria:**
- Women’s above 60 and below 30 years of age
- Women’s taking calcium supplementation
- Women’s those who are suffering from mental illness

Sample is selected through purposive sampling method. The tool used for the study consists of demographic variables like Age, educational status, marital status, type of family, habits, regular exercise, previous family history, history of earlier menopause, previous source of information, Modified OKAT and self reported practice checklist was developed by the investigator and used to collect the data. The reliability of knowledge questionnaire was calculated by split half method, and practice scale by cronbach’s alpha. The reliability co-efficient was \( r=0.91 \) for OKAT which indicated that the tool is reliable. The data collection period extended from 14th September to 22nd September 2020. The investigator explained the purpose of the study and requested the participants’ full cooperation and assured the confidentiality of the data. Written consent was taken from subjects. Participants cooperated well during the time of data collection process. Formal written permission was obtained from the authorities to conduct the study. Data collected from the sample were analyzed using descriptive and inferential statistics using SPSS version 23.

**Results**

**Section I: Sample Characteristics**

The findings of the study demonstrated that among 87 group D female workers who are working in Yenepoya Medical college Hospital surveyed, the highest percentage of the subject (49.43%) belonged to an age group of 40-50 years. Maximum number of subject had Higher secondary education (85.06%), majority of the subjects (90.80%) were married, maximum number of the subjects (87.36%) were belongs to nuclear family. Most of the subjects (82.76%) had caffeine intake. Almost (78.16%) of the subjects had no exercise. Majority of the subjects (88.51%) had no previous family history. The maximum number of subjects (87.36%) had no history of earlier menopause. Majority of the subjects (88.51%) were not received any information.

**Section II: Distribution of subjects according to their knowledge score**

Maximum score 11  n=87

The data presented in Table 2 shows that, majority of the subjects (72.4%) had average practice, 20.7% of the subjects had poor practice, and 6.9% of the subjects had good practice.

Correlation between knowledge and practice

Finding of the study revealed that there is a positive correlation between knowledge and practice. As the knowledge increase practice also increase. The result shows that r =0.277.

Association between knowledge score and selected demographic variables

The findings of the study revealed that there was a significant association between knowledge score and the following demographic variables such as Type of family, Previous Information but rest of all there is no significant association between knowledge score and demographical variables.

Association between practice score and selected demographic variables

The findings of the study revealed that there is a significant association between practice score and demographic variables such as type of family, earlier menopause, previous information whereas rest of all there is no significant association between the practice score and demographic variables.

Discussion

Distribution of subjects according to their knowledge score

Majority of the subjects (70.1%) having good knowledge on prevention of osteoporosis, 1.2% of the subjects having excellent knowledge and 28.7% of the subjects having poor knowledge. The mean percentage of overall level of knowledge was 37.05%.

The following study supports the findings of current study

A cross sectional study was conducted to assess Knowledge on Osteoporosis prevention among Bahraini women. Sample consisted 400 Bahraini women using convenience sampling technique in a community setting. The data were collected using Osteoporosis Knowledge Assessment Tool (OKT). The study revealed that Most of the women (73%) had moderately adequate knowledge on osteoporosis.5

Association between practice score and selected demographic variables

The findings of the study revealed that the majority (72.4%) of the subjects had average practice, 20.7% of the subjects had poor practice and 6.9% of the subjects had good practice. The mean percentage of overall level of practice was 37.18%.

The following study supports the findings of current study:

A descriptive study was conducted to assess knowledge, beliefs and practices regarding osteoporosis among female medical school entrants in Sri Lanka. A self administered questionnaire was used to assess knowledge, beliefs and practices on osteoporosis, including a food frequency chart to assess the calcium intake. Majority of the participants (51.6%, n=96) had an average score (40–60) on the knowledge test, while 40.8% (n=76) had a poor score (<40). However, in depth knowledge on risk factors, and protective factors was
lacking. Perceived susceptibility for osteoporosis was low with only 13.9%. Only 7(3.8%) participants were currently engaged in specific behaviours to improve bone health whilst 20(10.8%) had thought of routinely engaging in such behaviour.

**Conclusion**

The following conclusions were drawn on the basis of the findings of the study:

- v majority of the subjects had good knowledge (70.1%), 28.7% of the subjects had poor knowledge.

- v Most of the subjects (72.4%), had average practice 20.7% of the subjects had poor practice, and 6.9% of the subjects had good practice.

**Limitations:**

- v The study is limited to group D female workers in Yenepoya Medical College Hospital, Mangaluru.

- v Study is limited to Knowledge Questionnaire and Practice Checklist

**Disclosure of potential conflicts of interest:** The authors declare that they have no conflict of interest

**Ethics approval:** Approval was granted by the Yenepoya Ethics Committee-2, Yenepoya (deemed to be university) of Mangaluru.

**Consent to participate:** Written informed consent was obtained from the study participants.

**Source of Funding:** Self-funding

Dental College & Hospital, Coimbatore

Abstract

Introduction: Diabetes mellitus characterized by either absolute insulin deficiency (Type I) or target tissue resistance (Type II) is associated with oral complications like xerostomia, gingivitis, periodontitis, odontogenic abcesses and soft tissue lesions of the oral mucosa. Saliva is a unique biological fluid and is also a characteristic biomarkers for different diseases. Several classes of drugs are found to be associated with dry mouth or salivary gland dysfunction or hypofunction, which in turn influences concentration of salivary proteins. This leads to changes of oral health status among individuals using these drugs.

Aim of the Study: To evaluate and compare the total salivary protein and salivary flow rate among Type I Diabetics, Type II Diabetics and healthy controls.

Materials and Methods: A total of 60 individuals have participated in the study which include 20 with Type I diabetes, 20 with Type II diabetes and 20 healthy controls. The study was prospective in nature. Patients were asked not to eat or drink 2 hours before the time of saliva collection. The samples were collected in the same time of the day to avoid circadian variations. Unstimulated saliva was collected using spit technique. Patient was instructed to spit the saliva in graduated containers for a period of two minutes. The flow rates were determined visually from graduated salivary containers as ml/min. After measuring the saliva volume the saliva sample was stored in deep freeze until protein estimation. The total salivary protein in each salivary sample was determined using BioRad Protein Assay Dye Concentrate method using BSA standard.

Results: On comparing the total salivary protein among Type I, Type II Diabetics and healthy controls, a significant difference in total salivary protein was found among Type I Diabetics and healthy controls and also among Type I and Type II Diabetics and there was an insignificant difference in Type II Diabetics and controls. There was an insignificant difference in total salivary flow rate among Type I and Type II Diabetics and healthy controls. Conclusion: A significant difference in total salivary protein level among the diabetic and non diabetics emphasized that protein utilization by other biochemical metabolic pathways has an overall systemic response to glucose intolerance. With regards to salivary flow rate, the inconsistent results obtained may be due to the duration of diabetes, age range of patients and metabolic control of patients, class of drugs taken by the patient.

Keywords: Diabetes mellitus, Salivary flow rate, Protein, Glucose

Introduction

Diabetes mellitus is a syndrome characterized by abnormalities in carbohydrate, protein and fat metabolism that result either from a profound or absolute deficiency...
of insulin (Type I), or from target tissue resistance to its cellular metabolic effects (Type II). It is found to have a multitude of oral manifestations in the oral cavity.

Saliva is a unique biological fluid, which when compared to other diagnostic media, such as tissue samples, serum, CSF, saliva sample is easily collectable, cost effective, non invasive diagnostic tool for research and is often preferred as an alternative diagnostic approach.

Alterations in salivary parameters cause disorders of the hard and soft tissues of the mouth leading to gingival lesions, increased prevalence of caries and finally bad oral health. Dry mouth is a complaint among diabetic patients and may be associated with several classes of drugs, which in turn influence concentration of salivary proteins. This leads to changes of oral health status among individuals using these drugs.

Since saliva is a non diagnostic tool the present study aims to detect and compare the difference in salivary flow rate and total salivary protein among Type I and Type II diabetics and healthy controls, which may be useful in describing and further understanding of oral findings in this condition.

**Methodology**

The present study is a prospective study which includes a total sample of 60 patients which includes 20 in the Type I diabetic group, 20 in the Type II diabetic group and 20 in the healthy control groups. Patients with symptoms of diabetes including polyphagia, polydipsia and polyuria, with a non fasting glucose level of greater than 200 mg/dl and HbA1c level greater than 6.5% were included in the study. The control group consisted of gender matched non diabetic subjects without symptoms of diabetes. Patients with other systemic illness, smoking/alcohol habits, those treated on radiotherapy and pregnancy were excluded from the study.

Patients were asked not to eat or drink 2 hours before the time of saliva collection. The samples were collected in the same time of the day to avoid circadian variations. Unstimulated saliva was collected using spit technique. Patients were instructed to spit the saliva in graduated containers for a period of two minutes. The flow rates were determined visually from graduated salivary containers as ml/min. After measuring the saliva volume the saliva sample was stored in deep freeze until protein estimation. The total salivary protein in each sample was determined using BioRad Protein Assay Dye Concentrate method using BSA standard. Bio-Rad Protein Assay Dye Reagent Concentrate is a colorimetric assay for protein concentration similar to the Lowry assay, but with the following improvements: Within 15 minutes, the reaction reaches its maximum colour change and the change in colour is not more than 5% in one hour. A standard curve is prepared each time the assay is performed.

BioRad assay is prepared by diluting the assay dye in the ratio of 1:5, where 2 ml of Bio Rad dye is mixed with 10 ml of distilled water and the mix is stirred well. The volume of the bovine serum albumin sample used as standard is 5µl and the sample is also 5 µl. 100 µl of diluted dye is then treated with 5µl of the standard and 5µl of the sample and then ultraviolet spectrometer with a wavelength of 595nm is then used to determine the total protein in each sample of saliva.

**Statistical Analysis**

Turkey HSD test was used to correlate the difference in salivary proteins and salivary flow rate among diabetic and healthy controls. The mean difference is taken as significant at the .05 level. The SPSS 13 software analysis is used.

**Results**

A comparison of total salivary protein among Type I, Type II Diabetics and healthy controls were performed in male and female subjects. The total salivary flow rate was also compared among Type I, Type II Diabetics and healthy controls with the following results:

On comparing the total salivary protein among the Type I, Type II diabetics and healthy controls in male subjects, it was found that the mean difference between the total salivary protein in controls and type
I diabetics was -1.96046 with a P value of 0.015 which was statistically significant. The mean difference between the total salivary protein in controls and type II diabetics was -1.3536 with a P value of 0.977 which was statistically insignificant. The mean difference between the total salivary protein in type I and type II diabetics was 1.82510 with a P value of 0.025 which was statistically significant.

The results of our study are in accordance to the study conducted by Laisi T.J et al (2012) and Syed Shabaz et al (2017).

In the study conducted by Laisi T.J et al (2012) in a sample of total of 40 subjects of 20 type II diabetics...
and 20 healthy controls, it was found that the P value was greater than 0.005 which was statistically insignificant. In the study conducted by Syed shahbaz et al (2017)\(^8\), in a sample of total of 100 patients of 50 type 1 diabetics and 50 healthy controls, it was found that the P value was <0.01 which was statistically significant.

The results of our study are in contradiction to the results of the study done by Prathibha et al (2013)\(^9\), Indira M et al (2015)\(^10\), Juan Aitken, Saveendra et al (2015)\(^11\).

In the study conducted by Prathibha et al (2013)\(^9\), in a total sample of 60 subjects, 30 in the diabetic group and 30 as healthy controls, it was found that the P value was 0.000 which was statistically highly significant. In the study conducted by Indira et al (2015)\(^10\), in a total sample of 40 subjects, 20 in the type 2 diabetic group and 20 in the healthy controls, it was found that the P value was <0.001 which was statistically significant. In the study carried out by Juan Aitken Saveendra et al (2015)\(^11\), in a total sample of 74 patients, it was found that the P value was 0.000 which was statistically highly significant.

The contradiction could be explained by the fact that there is a variation in the salivary fluid secretion among the diabetic patients and varying oral health conditions like periodontitis influence the leakage of proteins from the gingival crevicular fluid.

On comparing the salivary flow rate of controls with type I and type II diabetics, it was found that the mean difference in salivary flow rate between controls and type I diabetics was 0.2245 with a P value of 0.089 which was statistically insignificant. The mean difference in salivary flow rate between controls and type II diabetics was 0.0790 with a P value of 0.731 which was statistically insignificant.

The results of our study are in accordance with the results of the study done by Arati S Panchbai (2010)\(^6\) and Juan Aiket Saveendra (2015)\(^11\).

In the study done by Arati S Panchbai (2010)\(^6\), in a total of 120 subjects, 40 in the uncontrolled diabetic, 40 in the controlled diabetic group and 40 in the healthy controls group, it was found that the P value was 0.56 which was not statistically significant. In a study done by Juan Aiket Saveendra et al (2015)\(^11\), in a sample of 72 patients with type 2 diabetes, it was found that the P value was 0.518 which was not statistically significant.

The results of our study are in contradiction to the results of the study done by Laisi T J et al (2012)\(^7\) and Prathibha et al (2013)\(^9\).

In the study performed by Laisi et al (2012)\(^7\) to compare the salivary flow rate among diabetic and non-diabetic subjects in a total of 40 subjects, the P value was 0.004 which was statistically significant. In a study performed by Prathibha et al (2013)\(^9\) to compare the salivary flow rate among the diabetic and non-diabetic subjects in a total of 60 subjects, the P value was 0.002 which was statistically significant.

The reason for such contradiction may be due to the fact that oral dryness occurring in diabetic patients could be multifactorial, either due to fatty infiltration of cells into the salivary glands, or physical alteration of mucosal cells subsequent to dehydration due to polyuria or microvascular disease, local inflammation and irritation in the oral cavity, infections, metabolic disturbances, and neuropathy affecting the salivary glands, and may be due to drug therapy for diabetes or concomitant drugs.

Conclusion

A significant difference in total salivary protein level among the diabetic and non diabetics emphasized that protein utilization by other biochemical metabolic pathways has an overall systemic response to glucose intolerance. Insulin is known to have the potential to alter protein metabolism. Further many studies have confirmed that increase in whole salivary proteins was not associated with dental caries, except for the 17kDa protein which might be a risk marker for dental caries. Nevertheless, the overall results obtained from various studies regarding salivary proteins in diabetics remains controversial.

Various studies conducted to assess the salivary flow rate among diabetic patient have found to give inconsistent results, which may be attributed to the duration of diabetes, age range of patients and metabolic control of patients, class of drugs taken by the patient.

The present study has certain limitations like a small sample size, and hence the results are entirely conclusive, the study has provided a platform for further research.

Ethical Approval:

All authors at this moment declare that all the experiments have been approved by the appropriate ethics committee ( Institutional Review Board, Ragas Dental College and Hospital, Chennai) and have therefore been performed by ethical standards.

Antifogging Measures for Protective Eyewear

Bharti Sachdeva¹, Parul Saini¹

¹Assistant Professor, Faculty of Nursing, SGT University, Gurugram

Abstract

Fogging of protective eyewear is commonly encountered by healthcare workers and there exists a number of ways to combat this. This article presents a comparison various anti-fogging measures of protective eyewear in terms of their mechanism of action, advantages and disadvantages.

Keywords: Fogging, Misting, Condensation, Anti-fogging, Protective eyewear

Introduction

Coronavirus disease (COVID-19) is an infectious disease caused by SARS-CoV-2 Virus. It can cause respiratory infections ranging from the common cold to more severe diseases such as Middle East Respiratory Syndrome (MERS) and Severe Acute Respiratory Syndrome (SARS). COVID-19 outbreak has severely abolished the world’s health, economics and social progress. In India, over 10.8 million confirmed COVID-19 cases and more than 1, 55,000 deaths have been reported as of 11th February, 2021 [1]. COVID-19 predominantly spreads by contact, droplet or airborne transmission necessitating the use personal protective equipment (PPE) to prevent cross infection. Before we understand the use of Protective eyewear and the challenges associated with it, let’s first explore the mode of SARS-CoV-2 viral transmission.

Mode of viral transmission

Droplet transmission generally occurs via larger respiratory particles which tend to settle down and travel not more than one meter. Once the virus settles on a surface, it remains there for a no. of hours or possibly days and becomes the source of potential infection to the ones who come in contact with these. Although the SARS-CoV-2 is not considered to be airborne but the risk is associated with production of smaller respiratory particles during certain procedures such as endo-tracheal intubation and cardiac compressions. These smaller particles remain suspended in air for longer and can travel distances more than two meters. Thus the use of PPEs needs to be at par with the level of contact, droplet and airborne transmission [1].

Therefore, the challenge arises where both mask and eyewear are required and that is fogged up eyewear [2]. It happens on escaping of warm exhaled air through ridge of the mask and accumulating on the eyewear. This commonly occurring but rather risky phenomenon interested the authors to compiling the data on various antifogging measures. We started with interviewing our nursing officers at SGT Hospital, Gurugram and observed that the fogging of goggles was a great occupational health hazard. As the healthcare workers tend to remove the protective eyewear once it is mistified, putting at risk the safety of their own as well as their patients. In order to support healthcare workers overcome this problem, we decided to retrieve the existing data on antifogging measures. We performed an extensive search on PubMed using keywords ‘anti-fogging of eyewear’, ‘fogging of protective eyewear’, ‘fogging and eyewear’, ‘misting of eyewear’, ‘condensation of eyewear’, ‘anti-fogging measures’. The search displayed 12 results that were relevant to the purpose of study.
We concised the findings of our study as under:

1. Tightly sealing the mask against nasal ridge by crossing over the ear loops or mask ties, by pressing nasal rim hard, by putting on adhesive tape over the junction of mask and nasal ridge [2]. A tight seal blocks the exhaled air escaping from superior margin of the mask and thus prevents it from accumulating on the eyewear. It is the most convenient and practical option but tight seal may cause face marks and may be uneasy to wear for long. Adhesive tape may cause skin irritation, if hypoallergenic one is not used.

2. Applying soap-water solution [3,4,5,7-9]. Soap is a good surfactant, known to reduce surface tension. The reduced surface evenly spreads out water vapors and prevents fogging. It is cost-effective and suitable for low resource areas but may distort the vision, if not wiped adequately.

3. Alcohol based sanitizer [3, 4, 7]; Alcohol is believed to decrease scattering of light. It is readily available in good resource settings. The down side is that alcohol may be irritating to eyes causing burning sensation, may cause complications in some cases such as conjunctivitis, keratitis and rarely corneal scarring.

4. Anti-fogging sprays or gels [3, 4, 7]: It works on the same principle as that of soap by decreasing surface tension and spreading of water molecules to prevent scattering of light. These are commercially available surfactants exclusively meant for anti-fogging of eyeglasses, goggles or wind shields. Their use is limited in healthcare settings due to cost constraint.

5. Filtered eye mask [4]; Since it is airtight, it prevents fogging and also gives a good protection against COVID-19 infection.

6. Iodophor [3,7]; These are iodine based substances which are readily available but they take longer (approx. 10 minutes) to dry and leave yellow stain on eyewear.

7. Application of hydrogel patches on the upper surface of mask [9]; These are better than other measures for achieving a tight fit without compromising the comfort.

**Conclusion**

As the COVID-19 cases continue to rise across the world, wearing mask and protective eyewear is going to stay in practice for uncertain times. This article provides a range of antifogging measures to choose from; in terms of cost, availability, feasibility and comfort.

Women and Sexual and Reproductive Health Rights: Issues and Challenges due to Environmental Pollution and Covid-19 Pandemic

Bijaylaxmi Mohapatra¹, Itishri Sarangi²
¹Research Scholar, ²Associate Professor, Department of Humanities, Kalinga Institute of Industrial Technology, Deemed to be University, Bhubaneswar, Odisha

Abstract

The situation emerging out of COVID-19 pandemic is not only just a health issue that has affected people but it has entrenched structural and gender inequalities and inequities in addition to the economic shock. Women as care giver, at home and communities are at the more challenging end in terms of getting attention and care across the societies, be at the rural, tribal or urban areas. degree of vulnerability has increased due to COVID-19 in every sphere be it in domestic space, labour market or access to health care. Worse situation is the provision of sexual- and reproductive-health services where women face innumerable challenges to address them. (Linde & Gonzalez,2020). Further, rising environmental pollution has further worsened the health situation, particularly in case of sexual and reproductive health for women and girls. This paper explores how women’s health is affected by Air pollution during COVID-19 situations. The paper discusses how women’s health in general and particularly, sexual reproductive health is affected by COVID-19 and environmental pollution, particularly, Air pollution.

Keywords: COVID-19, Environment, Pollution, Women, Sexual and Reproductive Health

Introduction

The situation emerging out of COVID-19 pandemic is not only just a health issue that has affected people but “it has also profoundly impacted economy worldwide, socio-cultural compatibility, political situations, academic atmosphere, and moreover people’s living standards particularly in developing and underdeveloped countries” [1]. The COVID-19 was declared as global pandemic by the World Health Organization on March 11, 2020. The first confirmed case of COVID-19 in India was on January 30, 2020. Since then, there has been a consistent increase in the number of cases within the country. “As on 1st April, 2021, the highest number of active cases of COVID-19 were found in Maharashtra, followed by Kerala, Karnataka, Andhra Pradesh, Tamilnadu and Delhi” [2].

Before the COVID-19 situation, the world has experienced severe health crisis such as the Spanish Flu of 1918, outbreak of HIV/AIDS, MERS (Middle East Respiratory Syndrome), SARS (Severe Acute Respiratory Syndrome) and Ebola. “India has also witnessed and dealt with diseases such as the small pox, polio and plague. All of these individually have also affected the economy and loss to humanity in some way” [3,4]. However, the Covid-19 which was found for the first time in China in December 2019 and rapidly spread to almost all countries of the world and turned out to the worst biggest health crisis in the history. It has also caused a great damage to world economy. “It has had devastative effects on various section of society such as the poor, socially marginalised groups, people those who are working in the informal sectors and those employed in contact-intensive sectors.” [5] Further, rising environmental pollution has further worsened the health situation.

For girls and women, degree of vulnerability has increased as a result of COVID-19 pandemic in every
sphere be it in domestic sphere, labour market or access to health care. Worse situation is the provision of sexual- and reproductive-health services where women face innumerable challenges to address them on, particularly in case of sexual and reproductive health for women and girls. This paper explores how women’s health is affected by Air pollution during COVID-19 situations. The paper discusses impact of air pollution on reproductive health and health of women in general in different locations both in rural and urban areas.

Objectives

The study aims:

- To understand the Social, Economic and health Impact of COVID-19 and Environmental Pollution at national and international level
- To explore the issues of issues of Sexual and Reproductive health Rights of women being affected by COVID-19 Pandemic and Environmental pollution
- To suggest mechanism, need to be provided to women to address issues of sexual and reproductive health.

Research Questions:

1. What was the Social, Economic and health Impact of COVID-19 and Environmental Pollution at national and international level.

2. How are sexual and reproductive health Rights of women affected by COVID-19 Pandemic and Environmental pollution?

3. What kind of solution be provided to address the sexual and reproductive health issues of women.

Methodology

This study is based on non-empirical method. For the purpose of the research, secondary data such as books, articles, newspapers and various reports of national and international agencies such as ILO, UNFPA, UN Women and UN were referred and analyzed Social, Economic and health Impact of COVID-19 and Environmental Pollution

“COVID-19’ is also likely to set back human capital development”.[6]. The spells of unemployment which is currently in a longer mode will depress workers from the left-out labour force, that could noticeably erode skills and lead to more job losses. “In earlier crises of economy, susceptible groups confronted with complex rates of school dropout and compacted skills development, which amplified income differences.”[7] As per the estimation of International Labour organization (ILO), full or partial lockdown measures has affected almost 2.7 billion workers, constituting around 81% of the world’s total workforce.

In India, where the economy was already deteriorated before the pandemic by stress in non-bank financial corporations, has pushed as many as 75 million people into the ranks of the poor (those who earn $2 or less a day) as per the estimation by the Pew Research Centre. Similarly, the numbers of India’s middle class (Those who earns income of $10.01–$20 per day) are projected to have shrunk by 32 million to about 66 million. The level of poverty may increase as there are other risks involved such as financial distress due to an abrupt shrinking of financing conditions or corporate bankruptcies, extreme weather and climate change, and further a possibility of worsening of policy- and security-related uncertainty.

The impacts are not just economic. The loss of earnings and livelihoods has higher chances of hampering women’s access to sexual and reproductive health as they are not able to spend the money on their health aspects. There were also rising cases of Violence against women as widespread stay-at home orders compel women to stay for a long time at one place with their abusers and often with disastrous consequences. Further, the burden of unpaid care and domestic work also exacerbated the situation for women and girls during Covid outbreak. Women and girls those who are in the vicious circle of institutionalized poverty, domestic violence and other forms of discrimination.
are particularly at high risk. “Their probability of being affected by COVID-19 transmission and fatalities are higher and are most exposed to more adverse situation such as loss of job and livelihood.” [8]

Women as care giver, at home and communities are at the more challenging end in terms of getting attention and care across the societies, be at the rural, tribal or urban areas. Further, School closures during COVID situation have put additional stress and demand on women and girls. As formal and informal provision of childcare were on decline, the demand for unpaid childcare and education was falling more heavily on women. This has further constrained their ability to work, particularly during the situation when it is difficult to carry out jobs remotely.

The lack of childcare support during covid-19 has not only costs economic loss but it also caused poor physical and mental health for women. A recent study done on young people in three Indian states of Uttar Pradesh, Rajasthan and Bihar by Population Foundation of India points out that “51% female adolescents experienced an increase in workload as a result of the nationwide lockdown due to COVID-19, against 23% male adolescents. In Uttar Pradesh, 96% females experienced an increase in workload was experienced by 96 percent female and out of them 67% are below 18 years of age”.[9]

Environmental pollution particularly air pollution has been a major contributor to ill-health. As per The State of Global Air (SoGA) 2020 report, long-term exposure to outdoor and household air pollution has caused to over 16.7 lakh annual deaths across age groups in India. With Covid-19 situation, the health challenges become very acute. Although there is not enough study to substantiate the link between long-term exposure to air pollution and COVID-19 outcomes, a recent study done to find out “the link between air pollution and COVID-19 outcomes done in the united states reveals that someone who lives for decades in a county with high levels of fine particulate pollution(PM$_{2.5}$) is 8%* more likely to die from COVID-19 than someone who lives in a region that has just one unit (one microgram per cubic meter) less of such pollution.”[10] Another study done also reveals that “around 15% deaths worldwide happened due to exposure to air pollution for a long period of time. While in Europe, the proportion of COVID death happening due to exposure to air pollution for along period of time was about 19%, proportion of death in North America was 17%, and it was about 27% in East Asia.” [11]

Most fine particulate matter that cause air pollution comes from sources such as fuel combustion, like automobiles, refineries and power plants and also from some indoor sources like tobacco smoke. Breathing in such microscopic pollutants inflames and damages the lining of the lungs over time, weakening the body’s ability to fend off respiratory infections. While exposure to such fine particulate matter have caused heightened risk for lung cancer, heart attacks, strokes and even premature death for people, it has really put life at more risk during COVID-19 periods.

### Environmental Pollution and issues of Women’s Sexual and Reproductive health Rights during COVID-19

The COVID-19 pandemic has potentially disastrous direct and indirect impacts on the health of women and girls around the world. As COVID-19 demands health care and caution at every level, it is less likely that women will have adequate access to sexual and reproductive health services and rights. This will lead to sharp rises in maternal and neonatal mortality. “During such times, some sexual and reproductive health services, such as contraception and safe abortion care, are also often considered as non-essential or even illegitimate. These services are deprioritized considering that as it is not urgent.”[12] In this regard, “The WHO has strictly noted such restrictions on access to services are a violation of human rights.” [13] This has provided rights-based interim operational guidance on how States should maintain essential services in the context of the pandemic, including sexual and reproductive health services.
One important lesson from the “West Africa Ebola outbreak of 2014-2016 is that the major threat to women’s lives was not the Ebola virus itself, rather the closure of routine health services and people’s fear that going to health centers/hospitals where their chance of being infected could be higher. Death of thousands more women happened as safe delivery, neonatal, and family planning services became inaccessible due to the Ebola outbreak. Now, the same dynamics are being faced by women on a much larger scale and more affected are aspiring mothers."[14,15,16]

“A study by United Nations Population Fund (UNFPA) held in April 2020 suggests that as result of COVID-19 Pandemic, 47 million women in 114 low- and middle-income countries would not be able to access the facilities of modern contraceptives and 7 million unintended pregnancies would have occur if the lockdown or related disruptions continues for the period of six months. The study further points out that for every three months the lockdown continues, up to an additional two million women would be unable to access modern contraceptives.”[17]

Another study conducted by UNFPA and Avenir Health done in 115 low- and middle-income countries in January 2021 estimated that as many as “1.4 million unintended pregnancies may have occurred lasting an average of 3.6 months as a result of COVID-19. At the higher end of projections, it could be as high as 2.7 million and on the other hand, it could be as low as 500,000 at the lower end of projections. “[18]A detailed study done by The Foundation for Reproductive Health Services India, in May, 2020 suggests that in likely cases, the disruption caused from lockdowns could leave up to 25.63 million couples in Indian will be unable to access contraceptives. In addition, “COVID-19 is also going to result in 2.38 million unintended pregnancies and 1.45 million abortions.”[19]

With environmental pollution, particularly air pollution, the risk is higher for women, particularly pregnant women. “Air pollution has largely impacted the lives of women too particularly when it comes to pregnancy and infant mortality. Bad air quality impacts the intrauterine growth retardation (IUGR) in the first month of gestation which leads to many challenges, including premature birth or major health complication or deaths in new born babies. Mothers’ exposure to airborne pollutants during pregnancy has much adverse effects as babies may either be born prematurely or with a lower weight. If a woman during pregnancy is exposed to air pollution, there is a chance of both women and new born to be affected to respiratory disorders like Chronic Obstructive Pulmonary Disease (COPD), asthma, chronic bronchitis, cancer”.[20]

The pregnant women being in the environment affected by toxic air are at the disadvantage as there are higher chances of some amount of damage occurring to the baby being nurtured in their uterus. When the new born baby comes out after delivery and breathes for the first time, if the air quality level PM 2.5 which is close to 500-600 [AQI] – equal to about 30 cigarettes of smoke in terms of damage – the new born baby becomes a smoker from the first breath. It is going to have sever health impact on the new born baby. When tiny particles enter the foetal side of the placenta, it impacts the development of the unborn baby. This increases the high risk of infant mortality. With COVID-19 pandemic, the situation has become much worrisome for the women.

As per The State of Global Air 2020 published by Health Effects Institute (HEI) in the year 2020, 21 percent of all neonatal deaths in India has happened due to air pollution. 116,000 infants die in India in the first month alone, due to the impact of air pollution on newborns. The report further states that half of these infant deaths were caused by outdoor air pollution. “…Various south Asian nations like India, Bangladesh, Pakistan and Nepal were among the top 10 countries contributing highest PM 2.5 levels in 2019 and thus, affected the life of infants. Among these countries, the level of air pollutants in India was dangerously higher in 2019. The annual average concentration of outdoor air pollutant was measured at 83.2 micrograms per cubic meter in India which was eight times higher than the World Health Organization’s air quality guideline of 10 µg/m.
This is being recorded highest in the world, which puts higher risk for women and children.”[21]

During November, 2019, World Health Organization reported that out of the world’s 15 most polluted cities, 14 cities are in India. “During winter season every year, smoke generated through farmers’ fires along with industrial and vehicle emissions turn towns and cities located in northern India into smog-blanketed hellholes, which heavily pollutes the air. As air get devastatingly polluted, this becomes challenging both for pregnant mothers and new born kids. New born infants breathe the noxious air twice as fast as adults as they have the smaller lungs and this causes respiratory problems and even impairing brain development.”[22] With COVID-19, the pregnant women are in doubly disadvantaged position struggling with both health challenges from environmental pollution and COVID-19 pandemic.

The COVID-19 has also put disastrous impact on the couples experiencing infertility and undergoing fertility treatment to have their babies. However, due to COVID-19, fertility treatment of these couples either postponed or cancelled. “While Women experiencing infertility are already affected with a disproportionate share of the psychological burden and consistently reporting anxiety, lower self-esteem, more depression and lower life satisfaction.”[23,24] The situations arising out of COVID-19 has disastrously affected the women’s health. These fertility treatment postponement or suspension has considerable effect on mental health and quality of life of women.

In India, COVID-19 has posed challenging situation for 3 million infertile couples in India seeking fertility treatment. “As per the data analysis done in 1100 IVF centers across India from April to June, almost 90% drop was observed in number of clientele undergoing IVF cycles.”[25] It is not only due to the decision of government or health centers arising out of COVID-19 but also due to the lack of public transport and communication, travel restriction and also due to the concern that COVID-19 may affect pregnancy. Although there are rare studies in India depicting the impact of COVID-19 done on fertility treatment and overall quality of life of women, a study conducted on “92 women from United States and Canada, the aged between 20–45 years whose fertility treatments had been cancelled revealed that majority of them (52%) endorsed clinical levels of depressive symptoms.”[26] This also causes various social and emotional problems terms of adjustment between couples and in the family.

### Conclusion and Future Recommendations

It is important that Sexual and Reproductive Health services and rights be considered as a significant public health issue during pandemic and it should be a priority call for the nations to address this issue with care and attention. Women particularly aspiring mothers and their new born babies may be more likely to require specialist care and attention. This is particularly true for women who are located in urban areas where the cases of air pollution are widespread and therefore, more precautions are to be taken for them. It is also important to note that there are high chances of the increased stress and anxiety may be experienced by pregnant women and their partners, and families. Therefore, it is important that healthcare providers have to play a crucial role in to deal with pregnant women with proper attention and care and compassionate manner.

Provision of uninterrupted abortion and contraceptive counselling, devices and care services are vital to protect and safeguard the reproductive rights of women. Efforts must be made to continue the services through various measures such as telemedicine including those on telemedicine medication abortion, and extending digital access, ensuring continued coverage of birth control methods and detailed counseling and resolving drug supply chain disruptions etc.

More importantly, there is need to strengthen operational strategies and actions to protect Sexual and Reproductive Health and rights of women, young people, and marginalised populations during the epidemic. There should be concerted effort not only from the scientists and physicians, but also policy-
makers, community-based organizations, and national and international agencies, need to work tandem with each other to deal with such a human rights issues as this are integral to well-being of women and also the larger benefit of society and nation.

Relapse Prevention in Mental Illnesses: Concepts, Issues and Strategies with Perspectives of Psychiatric Nursing- Review Article

Mudakavi I1, Rentala S.2, Irasangappa M3
1Ph.D Nursing Scholar, INC, New Delhi. Nursing Tutor, College of Nursing, All India Institute of Medical Sciences, Basni Phase II, Jodhpur, Rajasthan. India, 2 Professor & Head of the Department, Department of Psychiatric Nursing, Dharawad Institute of Mental Health & Neurosciences (DIMHANS), Dharawad, Karnataka. India, 3Nursing Tutor, College of Nursing, All India Institute of Medical Sciences, Basni Phase II, Jodhpur, Rajasthan.

Abstract
The aim of this review article was to explore and understand the concepts, issues and preventive strategies of mental health relapse with psychiatric nursing perspectives and also to present a comprehensive concept of relapse and its prevention in a narrative form based on the evidences from the various sources of literature. The review materials were included from the books, journals, news papers, online data base and grey literature of last three decades to 2018. The significant articles were searched by using key words: “Relapse”, “Mental illness”, “Prevention of Relapse”, “Relapse AND Mental illness”, “Relapse Prevention AND Mental illness” in PubMed, CINHAL, PsychINFO SCOPUS and Google Scholar data bases. Based on the relevant and significant facts found with respect to the aim of the review, concepts were evolved and evidence based narration was made under each concepts to understand prevention of mental health relapse with regards to identification of issues and formulating strategies to overcome such issues with psychiatric nursing perspectives. The study concluded that, relapse is a major obstacle for recovery of mental illness, but can be preventable by addressing underlying issues with preventive approaches across various health care settings.

Keywords: Relapse, Mental illness, Prevention of Relapse, Relapse and Mental illness, Relapse Prevention and Mental illness.

Introduction
“What remains in diseases after the crisis is apt to produce relapses.” -Hippocrates

World Health Organization (WHO) reported mental illness constitutes the highest burden of disease in the world with relapse being one of the most pertinent barriers to recovery and rehabilitation.1 In spite of the availability of various treatment modalities and advancement of the evidences, relapse rate among the mentally-ill is relatively high, reports among those with schizophrenia has put relapse rate between 50% and 92%.2

Relapse is a recurrence of symptoms of mental illness similar to those that have previously been experienced. Relapse is generally agreed to have occurred when the person experiencing the symptoms is not able to cope using their usual supports and requires a greater intensity of intervention.3 Relapse prevention is an important element of the recovery process. It focuses
on maximizing wellness for people with mental illness by reducing the likelihood and impact of relapse.4

Relapse prevention is based on communication and understanding between the person experiencing mental illness, their family and caregivers, primary health care, the specialist mental health system, and community support services about access to support or treatment if there are early signs of relapse.3

Relapse prevention immensely improves the quality of life of individuals with mental illness and enables them to more fully participate in work, leisure and relationships. Effective relapse prevention enables people to gain mastery over their symptoms, which increases their sense of control over their lives (Mueser et al 2002).4

Methods

The aim of this review article was to explore and understand the concepts, issues and preventive strategies of mental health relapse with psychiatric nursing perspectives and also to present a comprehensive concept of relapse and its prevention in a narrative form based on the evidences from the various sources of literature. The review materials were included from the books, journals, news papers, online data base and grey literature of last three decades to 2018. The significant articles were searched with following key words: “Relapse”, “Mental illness”, “Prevention of Relapse”, “Relapse AND Mental illness”, “Relapse Prevention AND Mental illness”. Based on the relevant and significant facts found with respect to the aim of the review, concepts were evolved and evidence based narration was made under each component to understand prevention of mental health relapse with regards to identification of issues and formulating strategies to overcome such issues with psychiatric nursing perspectives.

Findings

Findings of the review on evolved concepts are discussed under following headings:

I. Relevance / Need for Understanding Prevention of Relapse of Mental Illnesses

Global and National scenarios related to prevalence of relapse of mental illness presents apprehensive data, which made every stake holders to think about it.

a) Prevalence of Relapse among Mentally Ill Patients: Global and Indian

A study conducted in Ethiopia to assess the prevalence of relapse of schizophrenia in 2011. They stated that relapse rates vary from 50% to 90% globally. In different studies, the prevalence of relapse of schizophrenia ranged from 44% to 50% and 48% in developed and developing countries.

Severe mental disorders (SMDs), including schizophrenia, bipolar disorder, schizoaffective disorder and depressive psychosis, have a relatively low prevalence (1%-2%), and they are associated with increased risk of relapse and hospitalizations in USA.7

Relapse is most common and carries a serious burden in patients with schizophrenia. Patient with schizophrenia has been estimated to be 3.5% risk of relapse per month, and about ~40% of patients experience a relapse within a year following hospital admission.8, 9

A study conducted in institute of psychiatry, London, indicated that up to 90% of patients with bipolar disorder have at least one relapse in their lifetime, with an average of 0.6 relapses per year. After recovery from a mood episode, nearly 50% subsequently have a relapse within two years of remission.7

A study conducted by Chabungbam G in Chandigarh on 40 schizophrenic patients to examine socio-demographic and clinical factors associated with relapse in schizophrenia. The findings suggested that a severe illness, psychological stress and inappropriate treatment (side-effects of medicines) may be causally related to relapse in schizophrenia10

A similar study was conducted to assess the relapse rates among first episode psychosis patients identified in Nottingham. The reassessment of 168 cases of first
episode psychosis after 3 years later, they found high rates of relapses (21/32, 65.6%), when patients with diagnostic changes were excluded, only 4 of 11 patients (36.3%) with acute transient psychotic disorder had more than one episode.\(^{11}\) A follow-up study of acute transient psychotic disorder (ATPD) over 3–7 years found that 58% of patients relapsed.\(^{12}\)

**b) Gap in Health Care Burden of Mental Disorders and Resources**

WHO report (2003) on Investing in Mental Health has detailed explanation of global scenario regarding gap between the healthcare burden of mental disorders and the resources. In developed countries with well-organized health care systems, between 44% and 70% of patients with depression, schizophrenia, alcohol-use disorders and child and adolescent mental illnesses do not receive treatment in any given year. In developing countries, where the treatment gap is likely to be closer to 90% for these disorders, most individuals with severe mental disorders are left to cope as best they can. Worldwide more than 40% of all countries have no mental health policy and over 30% have no mental health programme.\(^{13}\)

Further reported, over 90% of countries have no mental health policy that includes children and adolescents. Out-of-pocket expenditure was the primary method of financing mental health care in many (16.4%) countries. Even in countries where insurance cover is provided, health plans frequently do not cover mental and behavioral disorders at the same level as other illnesses; this creates significant economic difficulties for patients and their families.\(^{13}\)

**c) Common Conditions of Relapse in Mental Illnesses**

There is a high rate of relapse within 5 years of recovery from a first episode of schizophrenia and schizoaffective disorder (Robinson D et al.).\(^{14}\) People with severe depression were more likely to relapse or commit suicide than people with milder depression (Goldney R D).\(^{15}\) High prevalence of relapse among patients with psychotic disorder. Nearly one-fourth of participants who were diagnosed as having schizophrenia (n=70), schizophreniform and schizoaffective disorders (n=13) had psychotic relapse (Mahlet F, Matiwos S, Garumma T F).\(^{16}\)

**d) Triggering factors of relapse in major mental illnesses**

Patient and caregivers of mentally ill perceived non adherence to antipsychotic medication as a leading risk factor of relapse; other risks included poor family support, stressful life events and substance use (Adellah ES, Anne HO, Khadija IY).\(^{17}\) Similarly, it is reported non adherence to antipsychotic medication, substance related factors, low social support and co-morbid psychiatric illness were major factors for relapse.

**e) Economic burden of mental illness due to relapse**

The economic burden during the first post discharge year is relatively higher due to loss of efficacy; whereas the burden from noncompliance is higher in the second year. (Weiden PJ, Olfson M.\(^{18}\) The costs of treatment were found to be high but with wide variations in the range. Costs for bipolar disorder were somewhat higher than those for schizophrenia at least for the period of study (Sharma P, Das S.K, Deshpande S.N).\(^{19}\)

**f) Evidences on relapse prevention in mental illnesses**

The Relapse Prevention Programme was efficient in detecting prodromal symptoms of relapse early in an episode. Crisis intervention including increased antipsychotic medication use during the prodromal phase reduced relapse and rehospitalization rates (Marvin I. Herz et al.).\(^{20}\)

Specialist Psychosis programs are effective in preventing relapse. Cognitive-based individual and family interventions may need to specifically target relapse to obtain relapse prevention benefits that extend beyond those provided by specialist FEP programs. First and second generation antipsychotics have potential
to reduce the relapse rates (Maria A J, Alexandra GP, Sarah EH, Patrick DM, John FG.).21

II. Existing Practices / Situation/ Knowledge on Relapse Prevention in Mental Illnesses

a) Factors Associated With Relapse in Mental Illnesses

Early identification and prevention of relapse in patients with mental illness has significant therapeutic and socioeconomic implications. Relapse is common in the cases of patients who had documented evidence of either re-emergence or aggravation of psychotic symptoms. Globally, the factors commonly associated with relapse include deprived treatment adherence, substance abuse, co-morbid psychiatric illness, a co-morbid medical and/or surgical condition, stressful events in life, and the treatment setting.

A meta-analysis conducted on factors associated with relapse of schizophrenia in University of Johannesburg22. As mentioned in the results, the figure 01 depict following factors are most commonly associated with the mental illness:

![Figure 01: Factors Associated with Relapse of Mental illnesses](image)

b) Awareness of Early Warning Signs of Relapse

Fundamental aspects of relapse prevention are recognition and awareness of early warning signs and of the risk and protective factors for mental health. This awareness should focus on individual, family and service levels. Early warning signs vary among individuals, and a personal set of early warning signs is referred to as a ‘relapse signature’.

As mentioned by Van Miejel et al., in 2002 there are two types of monitoring that are relevant to recognition of early warning signs: direct monitoring, where the existence or nonexistence of symptoms is ascertained; and indirect monitoring, where situations are assessed to determine the presence or absence of risk and protective factors. Therefore, it is essential to include both types of monitoring for a thorough and holistic relapse prevention approach.23 Box 02 illustrate early warning signs of relapse (Birchwood, Spencer & McGovern 2000)

Box 02: Early Warning Signs of Relapse (Birchwood, Spencer & McGovern 2000)

**c) Importance of Relapse Prevention in Mental Illnesses**

Relapse prevention is desirable for several realistic reasons, namely

- It reduces the negative impact of mental illness on individuals and their families and caregivers, as well as their communities.

- Prolonged and recurring periods experiencing the symptoms of mental disorder severely affect a person’s life and also erode their confidence in work and wellbeing.

- Evidence shows that each relapse increases both residual symptoms and social disabilities.

- Relapse greatly increases the burden on families and caregivers, contributing to their distress and reducing their quality of life.

- Preventing relapse reduces the cost of mental illness to the community.

**III. Existing Problems/Shortcomings Regarding Relapse Prevention**

With reference to many evidences from the literature, relapse prevention of mental illnesses is literally challenging task for the health care providers. The most important problems experienced by the health care providers, patients and caregivers are as follows:
a) **Revolving Door Syndrome**

The tendency of clients to get better for a while, and then end up relapsing is known as revolving door syndrome refers to. It most often applies to those with severe mental illness, such as schizophrenia, but a person with a mental health disorder could potentially be at risk.25

A cross-sectional study was conducted on revolving-door patients in public psychiatric hospital in Israel which aim to study social, demographic, clinical, and forensic profiles of frequently re-hospitalized (revolving-door) psychiatric patients. They suggest that, revolving-door patients had significantly shorter mean interval between hospitalizations, showed less violence, and were usually discharged against to medical advice from health care providers. 26

b) **Major Issues of Relapse Prevention in Mental Illnesses**

A critical review of selected literature regarding relapse among schizophrenics identifies following major problems of relapse:

1. Relapse rates are extremely high among mentally ill after treatment discontinuation, even after a single episode of psychosis.

2. Risk of relapse does not decrease even after longer treatment period prior to discontinuation.

3. Many patients relapse very soon after treatment discontinuation.

4. The transition from remission to relapse may be abrupt, with few early warning signs.

5. Once relapse occurs, symptom severity rapidly returns to previous psychotic episode.

6. The majority of patients after relapse respond rapidly to re-introduction of antipsychotic treatment, the response time is unpredictable and whereas frank treatment failure may emerge in a subset of patients.27

c) **Growing Health Care Costs: Consequence of Relapse**

A significant toll on patients, caregivers, and society in terms of direct and indirect costs of schizophrenia.28

Total per year excess cost of schizophrenia in the US was estimated at $62.7 billion in 2002. In this economic burden, 52% was due to indirect costs ($32.4 billion, including unemployment, reduced workplace productivity, premature mortality from suicide, and family care giving), 36% was due to direct healthcare costs ($22.7 billion, including outpatient, inpatient, long-term care, and medications), and the remaining 12% was due to direct non-healthcare costs ($7.6 billion).29

Healthcare Cost and Utilization Project show that in comparison with patients of other mental health and substance abuse disorders, patients with schizophrenia admitted for treatment have the second-longest average length of stay (11.1 days), highest average total price per stay ($7500), and highest aggregate cost of hospitalization ($2.7 billion).30

A primary driver of medical costs in schizophrenia patient is relapse and associated care (including hospitalizations). A study shown that patients who experienced a relapse of psychotic symptoms within the previous six months incurred four times higher costs than schizophrenia patients without a recent relapse (p<0.01).31 Similarly, in another published, prospective, observational study (1997–2003); the 12-month direct mental healthcare costs for patients with a prior relapse (within the previous six months) were three times higher than costs for patients without a relapse ($33,187 vs $11,771; p<0.01).32 These results underscore the economic importance of relapse prevention.

d) **Knowledge and Skill Gap Regarding Relapse Prevention**

Tricia Nagel and associates conducted a retrospective study to review the quality of care provided in the Top End in-patient setting, and the involvement of Aboriginal Mental Health Workers (AMHWs) in the care of Indigenous people who are hospitalized for mental
illness. This review was a part of relapse prevention project in Australia. The findings suggest that, low rates of AMHW engagement in care. They were involved in the care of only 55% of Indigenous patients in 2004. There is a need to explore strategies for reorientation of services to deliver consistent quality care and promote relapse prevention, self-management and empowerment of all clients and families.33

Mental health professionals are not skilled in working with families. Some recent programs now train mental health workers to provide families with the skills needed to be active, positive caregivers rather than passive victims to the difficult situations created by a relative’s illness. The nature of this care giving role is often not understood by professional mental health workers. Families’ still experiencing blame from others for causing these illnesses, although it is diminishing as evidence suggest for a neurobiological explanation of mental illness.34

IV Strategies to Improve the Situation / Minimize or Solve Problems of Relapse Prevention in Mental Illnesses

a) Major Approaches to Relapse Prevention and Evidence of their Effectiveness

In the medical and academic literatures, relapse prevention interventions have been categorized in following types of approaches5:

1. **Awareness of early warning signs**: The primary intervention approach of relapse prevention are programs that focus on teaching people how to recognize their early warning signs and the environmental triggers of their symptoms. Such programs generally involve training in identification of early warning signs and stress management.

2. **Compliance with medication**: Medication non-compliance is a major risk factor for relapse. This is the case for psychotic illnesses as well as depression. There is clear evidence that maintenance medication and taking medication as prescribed significantly reduces the risk of relapse.

3. **Coping skills training and cognitive behavioral approaches**: Coping skills programs aim to help people manage stress or deal with persistent symptoms. Review of randomized controlled trials for four coping skills programs were shown to be effective in terms of reducing symptom severity.
4. Broad-based psycho-education programs (BBPP): It is a commonly held belief that greater knowledge empowers people to make better decisions regarding many behavioral choices, including those affecting their health. BBPPs provide information people about their mental illness, generally focusing on symptoms, stress-vulnerability, and treatment options.

5. Self-help programs: Consumer self-help groups developed partly out of dissatisfaction with the mental health care system and the need for consumers to combat the stigma of mental illness (Emerick 1990). These groups have extended to include a wide range of programs and to also encompass family and caregiver support groups.

6. Risk and protective factors: A more holistic approach to prevention focuses on identifying the multiple risk and protective factors for mental health. Risk factors are those that always responsible to a individual’s susceptibility to relapse, whereas protective factors alleviate relapse by enhancing wellbeing; “risk factors increase the possibility that a disorder will develop and can aggravate the burden of existing condition, while protective factors provide people resilience in the face of difficulty and moderate the impact of stress and transient symptoms on social and emotional wellbeing, thereby decreasing the probability of disorders.

b) Basic Elements of Relapse Prevention

Essentially, prevention of relapse requires awareness, planning, and the provision of timely and appropriate intervention responses. Laurie identifies prevention of relapse as the 4As of crisis prevention: 1) awareness, 2) anticipation, 3) alternatives and 4) access. To implement such an approach, actions need to be undertaken by all those concerned in the continuing care and recovery of people with mental illness: by people who have experienced mental illness, their families and caregivers, clinical service providers and planners, non-clinical service providers and planners, policy makers, and communities.35

Assertive Community Treatment Model

 Assertive Community Treatment (ACT) is planned and implemented by an interdisciplinary team that ensures service availability for whole day, all the days of week and is prepared to carry out all possible treatment functions as and when needed. A person may referred to the ACT team service when it has been determined that his/her needs are so pervasive and/or not expected that it is unlikely that they can be met efficiently by other combinations of accessible community services, or in situation where other levels of outpatient care have not been successful to maintain stability in the community.36

Assertive community treatment offers significant advantages over standard case management models in reducing homelessness and symptom severity in homeless persons with severe mental illness.37

V Nursing Implications in Relapse Prevention in Mental Illnesses

a) Role of Nurse in Relapse Prevention in all Possible Settings

Traditionally, the public health concept of disease prevention has conceptualized prevention as primary, secondary or tertiary depending on whether the strategy prevents the disease itself, the severity of the illness or the associated disability.38

Preventive strategies are always reducing risk factors; hence to get maximum effect, these strategies need to be implemented at specific periods before the onset of the disorder. On the other hand, it is still possible to decrease severity, course, duration, and associated disability of disease once it has developed, by taking preventive measures throughout the course of the disorder.

The following three categories of primary prevention have been identified:

- Universal prevention: In universal prevention, will focusing on the general public or a whole population group.
**Selective prevention:** Selective prevention targeting individuals or subgroups of the population whose risk of developing a mental illness is considerably higher than that of the rest of the population.

**Indicated prevention:** Persons at high-risk for mental disorders will be targeting for indicated prevention.

**Secondary prevention** refers to preventive measures undertaken to decrease the prevalence of all specific treatment-related strategies.

**Tertiary prevention** would embrace interventions that reduce disability and all forms/types of rehabilitation as well as prevention of relapses of the mental illness.

**b) Psychiatric Nurse-Led Preventive Strategies/Recommendations for Mental Health Relapse**

Psychiatric nurses become involved in prevention of relapse programs in many different ways. They can act as a referral source for the program, trainer or leader of the programs, or an after care sources for patients when the program is completed. In addition mental health nurses can help the patient and family by promoting optimism, sticking to goals and aspirations, and focusing on individual strength.

- Psychiatric nurses serve in various pivotal functions across the continuum of care. These functions can involve both direct care and coordination of the care delivered by others.

- The intensification of research in nursing practice is of great importance because a considerable portion of the therapeutic efforts is and can be executed with the context of nursing care. Reasons for these results indicated that effectiveness research should be continued on psychotic relapse.

- Nurse-led psycho-education program showed an increased level of knowledge about the disease and health resources as well as a positive displacement in terms of some Outcome Indicators such as Participation, Attention and greater Satisfaction with health services. These programs may result in greater health gains.

- Psychiatric nurses facilitate the incorporation of shared decision making into clinical practice to improve medication follow-through. Globally, the most trusted health care professionals are nurses. They continuously assess treatment effectiveness and medication side effects.

- Statistically significant improvement in attitude toward medication and quality of life of patients with schizophrenia after implementation of a psychiatric nursing intervention. In improvement of medication adherence and quality of life of schizophrenic patients, the psychiatric nursing intervention was effective.

**Available Resources in Indian Context for Relapse Prevention**

**Human resources**

- “Tapasya” Mental Health Rehabilitation And De-Addiction Centre, Indore
- Shraddha Rehabilitation Foundation, Mumbai
- Chaitanya Centre for Psycho-social Rehabilitation, Cochin, Kerala
- Tulasi Best Psychiatrist Rehabilitaiton and Rehab centre, Delhi
- PapayaCare Assisted Livivng and Long Term Care, Ahmedabad
- SuVitas-Rehabilitation Center, Hyderabad

**Physical infrastructure**

National Institute of Mental Health and Neurosciences, Bengaluru

Central Institute of Psychiatry, Delhi
Institute of Human Behavior and Allied Sciences
- Schizophrenia Research foundation, Chennai
- Institute of psychiatry and Human Behavior, Goa

**National Programs Related to Relapse Prevention**
- National Mental Health Program, 1982
- District Mental Health Program, 1996
- National Program for Health Care of the Elderly, 2010
- National Mental Health Policy, 2014
- National Health Mission, 2017
- Mental Health Care Act, 2017

**Conclusion**
Relapse prevention must become a routine component of continuing care for all people who have been seriously affected by mental illness. It needs to be incorporated alongside rehabilitation as one of the tools within a recovery oriented mental health care system. Relapse prevention should commence at the earliest possible opportunity, even during treatment of the first episode, and then be adapted according to each person’s changing needs across the lifespan, across the course of their ongoing experience of mental health and mental illness, and across changing life circumstances.

**Ethical Clearance**
Since it is a review article and has been written as narrative concept article. Further, not needed informed consent as human subjects were not involved in this scientific work. Review is based upon available primary and secondary literatures, therefore does not require ethical permission. Journal guidelines have been followed in writing references. However, based on the conclusion of the present review a study has been undertaken which aims to prevent relapse and readmissions among patients with severe mental illness and ethical permission was taken to conduct the present study from Institutional Ethical Committee of AIIMS, Jodhpur.

Histopathological Changes in Brain Tissues associated With Oral Administration of Tramadol in Male Rats

Abbas Ch. Mraisel1, Sawsan, A. Ibrahim2, Muntadher H. Dawood3

1Prof. Assistant, Clinical Libratory Science Department /Pharmacy College / Misan University, Iraq. 2Lecturer Assistant, Basic Science Department /Nursing College / Misan University, Iraq. 3Lecturer, Pharmacy College, Misan University

Abstract

Background: Repeated and long treatment with tramadol might lead to accumulation of toxic metabolites in the body and increase the risk for pharmacokinetic interaction and decrease the clearance of tramadol, therefore this study was performed to investigate the toxic impact of the tramadol on the tissues of the brain in the male rats.

Method: The experiment was carried out at Environmental Toxicology Laboratory, Department of Environmental Studies, Institute of Graduate Studies and Research, Alexandria University, Alexandria, Egypt. Thirty-two Albano Waster male rats weighing (200-250 g) were obtained from the animal house of the Faculty of Medicine, Alexandria University, and grouping into four groups (8 rats for each group in each cage). The Control group was fed a basal diet and given tap water daily for ten days. In group two the rats were fed basal diet and given Tramadol HCL orally in dose 45mg/ kg .B.W dissolved in (5ml) normal saline (0.9%) by gastric tube, daily for Ten days. In group three the rats were fed with basal diet and given Tramadol HCL orally in dose 45mg/ kg .B.W dissolved in (5ml) normal saline (0.9%) by gastric tube, daily for Twenty days. The group for the rats was fed with basal diet and given Tramadol HCL orally in dose 45mg/ kg .B.W dissolved in (5ml) normal saline (0.9%) by gastric tube, daily for Thirty days. At the end of the experimental period Kidney tissues of each rat were immediately removed and after weighted put into 10% neutral buffer formalin as a fixative solution and stained with Hematoxylin –Eosin stain.

The Results: The results observed a significant decrease in the weight of the brain in the groups of the rats that were given the Tramadol HCL in dose 45mg/ kg .B.W with increasing the time of administration as compared with the control group. Histopathological changes were observed in rats brain tissues section the rats that given Tramadol HCL orally in dose 45mg/ kg .B.W dissolved in (5ml) normal saline for ten days revealed a mild degree of tissue injury in the cerebral cortex, with few vacuolar degeneration and dilatation of blood vessels, and the tissue sections of group two after ten days revealed a mild degree of tissue injury in the cerebral cortex, with few vacuolar degeneration and dilatation of blood vessels, while the three groups observed increase in the vacuolar degeneration, with neural atrophy and degeneration of neurons with reduction the neural process and pyknosis of the nuclei dilatation of blood vessels after twenty days of tramadol administration. The tissue Sections obtained from group four after thirty days revealed an increase in the vacuolar degeneration, with more atrophy of the neural cells and complete reduction of the neural process and pyknosis of the nucleus in the injured neural cells and gliosis.

The conclusion of this study there are harmful toxic effects when administrated tramadol for long period on the brain tissues, therefore an abuse of tramadol should be avoided except with medical prescription owing to its toxic effects.

Key words: Tramadol HCL, Histopathological changes, Brain tissues
Introduction

Clinically the tramadol has been used for relieving mild and moderate pain in human and veterinary medicine and used as anesthesia especially in veterinary medicine. Tramadol is marketed as the hydrochloride salt and is available in a variety of pharmaceutical formulations for oral (tablets, capsules), sublingual (drops), intranasal, rectal (suppositories), intravenous, subcutaneous, and intramuscular administration. It is also available in combination with acetaminophen (paracetamol), as immediate- and extended-release formulations, and for once-a-day dosing described variously as ‘controlled’, ‘sustained’, or ‘delayed’ release.

The tramadol is rapidly absorbed orally and 30% of tramadol excreted through the kidney with half-life elimination (5-6) hours, while the remaining dose is metabolized in the liver. Tramadol in the liver is converted to O-desmethyl-tramadol by cytochrome P 450 which is an active substance and is two to four times more potent than tramadol. Persistent tramadol administration might lead to the accumulation of toxic metabolites in the body, increase the risk for its toxic kinetics effects, and/or lower the clearance of tramadol, thus increasing its potential for toxicity. The most common mechanisms of death after tramadol overdose are cardiorespiratory depression, resistant shock, asystole, and liver failure. Fatal toxicity of tramadol has been reported after coadministration of other medications including propranolol, ethanol, barbiturates, and benzodiazepines.

Repeated administration of tramadol might lead to toxic metabolites in the body and cause many adverse effects such as headache, constipation, nausea, dizziness, and central nerve disturbances. Neurotoxicity of tramadol has been reported in patients administrated tramadol both at the recommended dosage and the high dosage ranges in animal and human studies. The neurotoxicity of tramadol commonly manifests as generalized tonic-clonic seizures. Chronic use of tramadol in increasing doses causes neuronal degeneration in the rat brain, which probably contributes to cerebral dysfunction.

Many types of research were performed to detect the biochemical and histopathological changes due to long-term abuse the tramadol on the liver, kidney, and brain, also some studies dealt with abnormal histological changes in the testis.

The study was performed by Atici et al. (2005) founds biochemical and histological changes in the rat’s liver with significantly higher serum Alanine aminotransferase (ALT), Aspartateaminotransferase (AST), Lactate dehydrogenase (LDH), and creatinine, also severe congestion and focal necrosis in the hepatocytes.

Youssif et al. (2016) found hemorrhage and cytolysis in the hepatocytes of the liver with complete cell membrane degeneration with changes in testicular tissues and atrophy in the somniferous tubules accompanied with interstitial calcification after administration of different doses of tramadol in experimental rats for 60 days. Hafez et al. (2015) observed that the toxic effect of tramadol on the parenchymatous organs such as liver, kidney, and thyroid glands in rats after intramuscular injection in different doses (12.5mg, 25mg, 50mg, and 300mg /Kg B.W) respectively for two weeks.

Many researchers have evaluated the effects of chronic use of tramadol on many organs, for example, liver, kidney, testes, heart, and thyroid gland. and scanty data dealt with the effects use of tramadol on the brain, therefore the objective of this study was designed to evaluate the toxic impact of the tramadol on the tissues of the brain in the male rats.

Material and Methods

Tramadol (tramadol HCL) 200mg/Kg B.W Tablet (Indian origin), were purchased from the outer pharmaceutical, Missan, Iraq. Experimental animals: Thirty-two Albano Waster male rats weighing (200-250 g) were obtained from the animal house of the Faculty of Medicine, Alexandria University. Animals were handled following the principles of laboratory animal care as contained in the NIH Guide for laboratory animal welfare and the experimental protocol was approved by the Local Ethics Committee and Animals Research. The
rats were housed in stainless steel bottomed wire cages after grouping into four groups (8 rats for each group) and maintained at a temperature of 22 ± 2°C, relative humidity of 40-60%, with a 12 h/12 h light/dark cycle and allowed free access to food and water, the test substances were administrated to the animals according to the following experimental protocol:

- Group I: Control rats were fed basal diet and given tap water as drinking water daily for Ten days.

- Group II: Rats were fed basal diet and given Tramadol HCL orally in dose 45mg/kg .B.W dissolved in (5ml) normal saline (0.9%) by gastric tube, daily for Ten days.

- Group III: Rats were fed with basal diet and given Tramadol HCL orally in dose 45mg/kg .B.W dissolved in (5ml) normal saline (0.9%) by gastric tube, daily for Twenty days.

- Group IV: Rats were fed with basal diet and given Tramadol HCL orally in dose 45mg/kg .B.W dissolved in (5ml) normal saline (0.9%) by gastric tube, daily for Thirty days.

At the end of the experimental period, the rats were overnight fasted (control and experimental animals) and sacrificed after 24 hours of the last dose of different administration under light ether anesthesia. Brain tissues of each rat were immediately removed taking care to handle specimens gently to minimize trauma, weighted, and put into 10% neutral buffer formalin as a fixative solution. Fixation time was limited to 24 hours and the fixed tissues were stored in 70% ethyl alcohol until they were processed. The fixed tissues were dehydrated through a graded series of ethanol and embedded in paraffin, sectioned according to the Luna (1968) method for histopathological examination, and stained with Hematoxylin –Eosin stain.16

**Statistical Analysis**

Statistical analyses were made with one-way analysis of variance (ANOVA) to compared the experimental groups(SPSS for windows version 17). P < 0.05 was considered statistical significance.

Table (1) showed the weight of the Brain obtained from the rats in the experimental groups, the results observed a significant decrease in the weight of the Brain in the groups of the rats that given the Tramadol HCL in dose 45mg/kg B.W with increasing the time of administration incompared with the control group.

Histopathological changes in the brain:

**Group I** (Control group): Microscopic examination of brain tissue sections observed normal cerebral cortex with a normal distribution of neurons and fibers (N) in the neuropit, also the glial cells (GC) and oligodendroial cells (ODC) were found in normal structure (Fig 1).

**Section of group (II)** which represent the rats that given Tramadol HCL orally in dose 45mg/kg B.W dissolved in (5ml) normal saline for ten days revealed a mild degree of tissue injury in the cerebral cortex, with few vacuolar degeneration and dilatation of blood vessels (Fig 2).

Figure (1): High power micrograph of rat brain section in control group stained with Haematoxylin & Eosin (H&E, X400), N: neural cells, GC: glial cells, OD: oligodendroial cells.
Section of group (III): Observed the rats that given Tramadol HCL orally in dose 45mg/kg .B.W dissolved in (5ml) normal saline for Twenty days characterized by an increase in the vacuolar degeneration, with neural atrophy and degeneration of neurons with reduction the neural process and pyknosis of the nucleidilatation of blood vessels(Fig 3).

Figure (2): High power micrograph of rat brain section of group (II ) stained with Haematoxylin & Eosin (H&E, X400), V: Vacuolar degeneration, BV: Blood Vessels.

Figure (3): High power micrograph of rat brain section of group (III ) stained with Haematoxylin & Eosin (H&E, X400), V: Vacuolar degeneration, BV: Blood Vessels, NCA: Neural Cell Atrophy, NP: Neural Process.
Section of group (IV): Which represent the rats that given Tramadol HCL orally in dose 45mg/kg B.W dissolved in (5ml) normal saline for Thirty days revealed an increase in the vacuolar degeneration, with more atrophy of the neural cells and complete reduction the neural process and pyknosis of the nucleus in the injured neural cells and gliosis (Fig 4).

Figure (4): High power micrograph of rat brain section of group (IV) stained with Haematoxylin & Eosin (H&E, X400), V: Vacuolar degeneration, BV: Blood Vessels, NA: Neural Atrophy, NP: Neural Process.

Discussion

Oxidative stress, an imbalance between oxidant and antioxidant mechanisms in animal bodies, this imbalance may result in either form excessive exposure to pro-oxidants or from compromised anti-oxidant mechanisms. Which may result from deficiency of essential elements or incapacitation of disease, while the former might emanate from exposure to exogenous toxins or the pathologic stress of disease\textsuperscript{17,18}.

Tramadol hydrochloride used as analgesic drugs, therefore in the 70s used for treating moderate and severe pain but in recent years the tramadol abuse among youngers and teens in different countries especially between males, therefore the present study performed to investigate histopathological changes in the brain tissues accompanied with the toxic effect of tramadol in male rats.

The result revealed a significant decrease in the weight of the brain in a group of rats that administrated tramadol at different times as compared with the control group, this result agrees with Balhara \textit{et al} (2018) that founds the administration of tramadol caused a reduction in the cells volume and nuclear condensation in the brain of rats which probably contributes to cerebral dysfunction\textsuperscript{19}.
In present study observed varied adverse effects in morphological and histological structures of the brain tissues with increasing the time of given dose of tramadol. Essam et al (2015) found histological changes in the brain tissues of rats after continuous administration of tramadol for a long period.

Mohamed et al (2013) found changes in the pyramidal cells which lost the shape and increase the hemorrhage in the brain and disrupted ependyma and the choroid plexus become hypertrophoid.

Chronic administration of tramadol with increasing the doses of the drug may cause degeneration in the red neurons and apoptosis in the brain which contributes to cerebral dysfunction (Atici et al, 2005).

Some researchers have reported the adverse effect of tramadol on other organs in the body, where Azari et al (2014) referred the long term administration of tramadol can cause to the testicular tissues and deposition of acidophilic PSA-positive materials in male rats. Yousef and Sheweita et al (2018) reported that administration of morphine and tramadol can cause degeneration in the hepatocytes and dilatation in the central vein with dilation in the sinusoid.

The study was performed by AbouEluaga et al (2020) to investigate the effect of tramadol on the histological structures of the testes in Albano rats which observed abnormal changes in the seminiferous tubules with long-term administration of tramadol.

Salma et al (2003) referred that tramadol may increase the accumulation of free radicals and ROS which can cause an increase in nitric oxide level in the brain and lead to hypofunction of Leydig cells with consequent reduction of the testosterone secretion.

Caju et al (2012) reported that exposed the mature rats to high doses of tramadol and morphine for a long time can cause testicular changes due to disorders in the endocrine and paracrine functions with reduction of Sertoli and Leydig cells leading to disorders in LH, estradiol, somatotropin, somatostatin, and gonadotrophin-releasing hormone.

Hussein et al (2017) recorded an increase in the area and creatinin levels in rats after received tramadol (22.5 mg/Kg B.W/day for nine weeks) due to evidence of renal damage and impaired renal function.

In conclusion, the results of this study observed a harmful toxic effect on the histological structures and function of the brain in male rats when administrated the tramadol for long period, therefore abuse of tramadol should be avoided except with medical prescription owing to its toxic effects.

Legal Civil Liability of the Forensic Medicine as a Judicial Expert from a Jurisprudential Perspective

Abdelawal Bassiouny1, Saad Ramadan2, Majd Manasra3

1Faculty of Law/ The American University in the Emirates in the United Arab Emirates, 2Faculty of Law/ Umm Al Quwain University/ United Arab Emirates, 3Faculty of Law/ Applied Science Private University/ Jordan

Abstract

This study dealt with the long-term liability of the forensic medicine expert as a judicial expert. This study clarifies the concept of civil liability for the judicial expert, the forensic medicine, for the implementation of it is expertise, through introducing the judicial expert to the forensic medicine, and what is the nature and types of this liability, then the study also addressed elements of the civil liability of the forensic medicine.

The study concluded that the civil liability of the expert is a tort liability, provided that the elements of this civil liability arising from the breach and the occurrence of damage, and the existence of causation where the strength of this liability is the damage resulting from the expert’s evacuation of the obligations incumbent upon expert.

Keywords: Forensic Medicine, Legal Expert, Civil Liability, Contractual Liability, Tort Liability, Causation, Damages, Breach.

Introduction

This research deals with the issue of civil liability of the judicial expert, forensic medicine. It is known that many courts of different types and degrees seek help in many cases, whether criminal, civil, commercial or religious, the opinion of people of experience and know-how about certain issues that are difficult or prevented for the judge to decide on them spontaneously.

Forensic medicine knows the doctor who devotes all his time to the job and is not allowed to practice his profession abroad in order to go to study the technical cases and issues that are presented to him and to have ample time to see and follow up on new scientific research in the various branches of forensic medicine.

The judicial expert forensic medicine is considered an assistant to the judiciary to clarify and remove the ambiguity of some of the difficulties encountered by the judge during the exercise of his profession in adjudicating the disputes presented to him.

From this standpoint, the courts are seeking the help of forensic medicine to determine the cause of death for the victim, estimate the period of suspension for it, or indicate whether the injury that the victim received poses a threat to his life or not, or determine the mental and psychological state of the offender to ensure his eligibility for trial and punishment And many other things.

The civil liability of the expert means the positive and negative actions that commit during the practice that accommodates the issue stipulated in the legislation and laws, as civil liability is a person’s breach of a spot on him and imposed on him to implement it either as a law or an obligation. It resulted in damage and this damage
is matched by compensation and liability here means a personal obligation to compensate for the damage that he caused to the expert, either as a result of a breach of a legal rule or a breach of the obligation he owes.

**Discussion**

Forensic medicine is the specialist in treating and studying cases that are considered by lawmen from a medical point of view and in which an opinion has been expressed. He also knows that every person undertakes a technical examination or gives a professional opinion specialized in a judicial incident and thus includes a doctor, a weapons expert, a specialist in examining fingerprints, and a forensic photographer. And the investigation expert is every doctor who undertakes an examination of a judicial incident and issues an oral or written opinion, and he is not required to be a specialist, for example, a general practitioner who examines simple daily judicial medical facts and gives preliminary judicial medical reports. The internal diseases specialist who undertakes the examination and treatment of a poisoned, the dermatologist examines and treats an injured or infected venereal disease and links it to a time related to a sexual accident, and the surgeon who treats a person with a gunshot wound, acute instrument, or a traumatic wound caused by a traffic accident, and the radiologist gives him a radiological report on a fracture Updated with a specific mechanism.

Forensic medicine in the capacity as a judicial expert when the judge resorts to the election in the event that a technical or medical scientific issue outside the jurisdiction of the judge is presented. A civil liability asks the forensic medicine in the capacity as an expert for every mistake he commits. Contractual liability and tort liability resulting from what the expert does to others in terms of the harm that commits against them.

Regarding the civil liability of forensic medicine in the capacity of a judicial expert, many disputes have arisen between the jurists regarding the legal nature of the civil liability of forensic medicine. Is it a contractual liability or a tort liability?

And considering that forensic medicine, in the capacity of a judicial expert, does not enjoy any of his immunity, he is subject to civil liability provisions based on the legal rule. Any damages to others obliges the perpetrator to pay compensation.

The civil liability of the forensic medicine is proven as soon as its elements are available, but there is a variation in cases in which the responsibility of the forensic medicine is contractual and in which it is negligent in the work of the expert, so the work of the expert is subject to an oversight during the performance of the tasks assigned to him, and the lack of commitment to caution and prudence in his work exposes forensic medicine civil liability as a judicial expert.

Most of the legislation, judicial jurisprudence and jurisprudential opinions are unanimously agreed that forensic medicine is responsible for the capacity as a judicial expert. It is responsible for the damages that may occur during the exercise of the profession.

A debate arose in jurisprudence about the nature of the judicial expert’s civil liability. There is an aspect of jurisprudence that considers the civil liability of the judicial expert to be a moral responsibility. That this point of view from a personal or subjective can only trigger his moral responsibility. In order to enable the expert to carry out his responsibility to the fullest and free from the influence of potential legal liability. Another aspect of jurisprudence in France is considered by the forensic medicine expert being subject to the responsibility of the judge if he issues his report with a final judgment.

A dispute also arose over the nature of the forensic medicine expert civil liability, as he is a judicial expert about whether it was a contractual or tort liability.

The Tort Liability of Forensic Medicine as a Judicial Expert:

The liability of forensic medicine is considered one of the most important manifestations of civil liability at all. Social coexistence requires individuals to respect the controls on which this coexistence is based, such
as respecting the rights of others and not violating their property or rights and any breach of this system unless the owner bears the consequences of this breach.

The legal civil liability of forensic medicine is proven as soon as the expert commits a professional mistake that harms the litigants, this responsibility is subject to the general rules of limitation.

For the establishment of the tort liability of forensic medicine, the three founding elements of the tort, breach, Damages and Causation, must present.

Breach: An error on the part of a forensic medicine expert considers every deficiency or breach thereof. The jurisprudential definitions that were given to the breaches have varied so that the idea of breach is not controlled in terms of limits, and one of the most famous definitions of breach is the definition of the jurist Baniol and the jurist Mancini, but the jurist SulaimanMorcos defined it based on the moral element, and the scholar Al-Sanhouri sees it as a deviation in the due behavior and he had the ability to distinguish so that he realizes that has deviated.

The forms of the contemporary breach of the task and the responsibility of the forensic medicine expert in the delay in carrying out the mission and omission in its implementation or refusal to do it without justification, and the acceptance of the task despite his knowledge of his inability to accomplish it and his deviation from the ethical principles that must be met such as objectivity and integrity. As for the forms of the breach during the execution of the task, they may be legal or technical.

As for the legal breach that arises as a result of the neglect of the legal principles and the obligations that the expert under the law regulating the experience, such as the failure of the forensic medicine expert to undertake the task himself, exceeding the limits of the task, or the delay in filing the report and receiving any fees from the litigants directly under any form. And the technical errors of the judicial expert, which makes during the exercise of the work and deviates from the established technical and scientific principles in relation to the specialization. As for the forms of breach after the implementation of the task, such as failure to respect the principle of confrontation, attend sessions and discussion, lack of respect for confidentiality.

The majority of jurisprudence is unanimous that the civil liability of the forensic medicine expert is fulfilled for all errors that make regardless of their seriousness. As long as the mistake committed by the forensic medicine expert is not committed by another expert with the same circumstances.

Damage: damage is the second element in tort liability, so there is no negligence if no damage occurs to others, and the damage is of two types, material and moral. Material if the forensic medicine expert deviates from the behavior of the common man taking into account the circumstances of time and place and leads to injury to the injured in money or a diminution of rights, and it will be a moral act of awareness and will, and it will strike the affected person, not with money, but in emotion and feeling.

In the field of compensation for the damage caused by the forensic medicine expert, the effort and expenses spent by the litigant, and the opportunities that were lost from him, represented in the loss of his right in whole or in part, according to events and circumstances, and the delay in deciding the case by changing its course in a way that harms him. It is stipulated that the damage be done personally, and that the damage be actuality and affect an acquired right.

Causation: It is not sufficient for the tort liability of the forensic medicine expert to be a breach on the one hand and the damage on the other hand. The tort liability for the breaching act must not be realized until it is proven that that act is the direct cause of the damage. In the area of expertise, causation is established between the breach of forensic medicine expert and the damage caused to the plaintiff litigant in the liability lawsuit.

Although causation is an essential element in the realization of tort liability. However, in the report of the forensic medicine expert, the judge does not base judgment on it, to some extent the judge has the right to
recognise it or not recognise it\textsuperscript{10}.

The Contractual Liability of Forensic Medicine as a Judicial Expert

The forensic medicine expert, usually appointed by the court regarding the understanding of facts of a technical or scientific nature concerning a dispute before it awaiting an urgent solution.

An opinion in French jurisprudence went to regard the responsibility of forensic medicine expert as a liability of a contractual nature, supporting their position that the appointed expert is a joint agent of the litigants. Accordingly, the responsibility of forensic medicine expert is a liability of a contractual nature. The DEMOGUE\textsuperscript{5} jurist went to support this trend, considering that the forensic medicine expert had contracted with the litigants as soon as accepted the mission. However, these trends have been criticized because the forensic medicine expert works under the supervision, direction and control of the judge and court, and he is not an attorney for the parties to the case\textsuperscript{11}.

Conflict of Interest: Nil

Ethical Clearance: Ethical Clearance was not necessary this study

Conclusion

Forensic medicine expert is every person who undertakes a technical examination or expresses a professional opinion on judicial cases, after reviewing the civil liability of the forensic medicine expert, whether it is a contractual liability or tort liability, it was found that the forensic medicine expert has the legal civil liability responsible based on tort liability. Forensic medicine expert has legal liability in the capacity as an expert for every breach commits by forensic medicine expert, as he finds himself a litigant defendant if the elements of tort liability, including a breach, damage, and causation for every damage caused by forensic medicine expert for the judicial experience.

Association between Gestational Diabetes and Proinflammatory Cytokine (IL-1β)

Abdullah F. Yousif 1, Raid M. H. Al-Salih 2, Alaa H. Al-Naser 3
1 Assistant Lecturer, Department of Chemistry, Directorate of Education Thi Qar, Ministry of Education, Iraq,
2 Professor, Department of Chemistry, College of Science, University of Thi-Qar, Iraq, 3 Professor, Doctor Obstetricians and Gynecologists, College of Medicine, University of Thi-Qar, Iraq

Abstract

Gestational diabetes mellitus (GDM) defined according to the (World Health Organization) as glucose intolerance of varying degrees of severity with start or first recognition during pregnancy. This definition applies whether or not insulin is needed and whether or not it disappears after pregnancy. It is not apply to pregnant women with a pre-pregnancy diagnosis of T1DM or T2DM. This study included (150) pregnant women in first trimester (9-13 weeks) of pregnancy, during follow up in [late second trimester and early third trimester (24-28 weeks) of pregnancy], 75 of them diagnosed of GDM, and 75 of them without GDM (Control group). The FBG, Insulin, HOMA-IR, OGTT, HbA 1c and IL-1β levels were increase in women with GDM than control group (P≤0.05). Conclusions: In late second trimester and early third trimester of pregnancy, IL-1β levels were increase in women with GDM compared with healthy pregnant, therefore, IL-1β as an early biomarker may help to predict the development of GDM later in pregnancy.

Keywords: Interleukin-1 Beta (IL-1β), Hemoglobin A 1c Ratio, Insulin, HOMA-IR.

Introduction

The most recent definition of GDM is by the (American Diabetes Association), as GDM has been defined as diabetes diagnosed in the second or third trimester of pregnancy (24-28 weeks) that was unclear of diabetes before pregnancy.1 GDM is a pregnancy complication describe by the impaired glucose tolerance, and it develops when the pancreatic b-cell reserve is not enough to recompense for the arise IR during pregnancy. As a result, there is an increase in hepatic gluconeogenesis, severe insulin resistance and thus hyperglycemia.2

The dominant protein in red blood cells is hemoglobin it’s also oxygen carrying tincture and that gives blood its red color. Approximately 97% of hemoglobin is (hemoglobin A). 92 percent of (hemoglobin A) is made up of one chemical component, while approximately 8 percent is made up of minor components that are chemically slightly various. The minor components have (hemoglobin A 1c, A 1b, A 1a 1 and A 1a 2). Glucose is bound with hemoglobin A 1c (HbA 1c). Sometimes HbA 1c is also referred to as “glycosylated hemoglobin or glycohemoglobin”. In addendum to random FBG levels, HbA 1c levels are routinely measured in monitoring diabetes patients.3

HbA 1c concentration are depend on the levels of glucose in the blood. That is, any arise in the of glucose level in the blood leads to an increase in the HbA 1c concentration. HbA 1c concentration are not influenced by daily fluctuations in the blood glucose levels. HbA 1c is a beneficial index of how well blood glucose level has been controlled in the recent past (more than two to three months) Also it may be used to monitor the effects of diet, exercise, and drug therapy on blood glucose in people with diabetes.3

Interleukin-1 Beta (IL-1β) is a strong pro-inflammatory cytokine that is decisive for host-define responses to injury and infection. It is also the best characterized and most studied of the 11 IL-1 family members. Also known as leukocyticpyrogen, lymphocyte activating factor, leukocytic endogenous moderator, mononuclear cell factor and other names, is a cytokine protein that in humans is encoded by the IL-1β gene.

This cytokine is secreted and producting by a diverse of cell types although the vast majority of studies have focused on its production within cells of the innate immune system, such as macrophages and monocytes. It’s a precursor is cleaved by cytosolic caspase1(Interleukin 1 Beta convertase) to form mature IL-1β.

Cytokine IL-1β is a major mediator of the inflammatory response, and is includes in a assortment of cellular activities, involved apoptosis, cell proliferation, and differentiation. Necessary for host - response and resistance to pathogens, as well as exacerbation of damage through acute tissue injury and chronic disease. So it is not surprising that there has been a great deal of interest in how this protein is produced and exported from cells. However, the IL-1β release mechanism has proven elusive. It does not secrete through the traditional ER-Golgi pathway. The literature full of diverging observations arising from the many experimental systems contributed to a complex mixture of diverse propositions.

Materials and Methods

The present study included (150) pregnant women in the first trimester (9-13 weeks) of pregnancy, during follow up in [late second trimester and early third trimester (24-28 weeks)], 75 of them diagnosed of GDM, and 75 of them without GDM (Control group). It was determined sample size according to the equation Stephen Thompson. Serum blood glucose estimated by assay kit (Randox, England). Serum insulin and IL-1β were measured using ELISA Kits (Demeditec Diagnostics GmbH, Germany). HbA1c in whole blood measured by NycoCard™ HbA1c analyzer. Biochemical parameters measured in the [first trimester (9-13 weeks)] and [second and third trimester (24-28 weeks)].

Calculate Homeostatic Model Assessment-Insulin Resistance (HOMA-IR) :

Serum of (glucose and insulin) estimated from fasting morning blood samples were utilised to calculate IR by the homeostatic model assessment-insulin resistance (HOMA-IR), which is approximated using the equation below.

\[
\text{HOMA-IR} = \frac{\text{Glucose (mmol/L)} \times \text{Insulin (µIU/mL)}}{22.5}
\]

Protocol of OGTT

1- The subjects should have a normal mixed diet for the prior three days previous to the test.
2- The subjects is fasted overnight and blood is drawn for glucose measurement before 75 grams is administered orally in 200 mL of water.
3- Blood glucose is measured every sixty minutes for two hours.

Collection of Blood Sample

After an overnight fasting for about 8 hr, (5 mL) of venous blood was collected from pregnant women with and without GDM, then divided into the following:

A) 2 mL of blood sample was transferred to tubes containing EDTA (Ethylene diamine tetra acetic acid) and used for HbA1c estimation.

B) 3 mL were transferred to plain tube and allowed to clot at room temperature to get serum by putting it in empty disposable tubes and centrifuged to separate it at 3000 rotor per minute (rpm) for 10 min, the serum samples were separated and stored at (-20°C) for later measurement biochemical parameters, unless used immediately.

Statistical Analysis

Statistical analysis was done using statistical package.
for the social sciences version 23, results were expressed the (mean ± standard deviation). T test was applied to compare parameters in studied groups. P-values (P≤0.05 ) were considered.

**Result and Discussion**

The characteristics of the studied groups are presented in Table (1). The results show no marked difference in the age of gestational, age of maternal and BMI in GDM group in comparison with the Controls group (p≤0.05).

Table (1): General characteristics data of the patients and controls groups

**Fasting Blood Glucose Concentration**

Table (2) shows a marked a rise in the levels of serum FBG in GDM-2 group in compare with the Cont-2 group (p≤0.05). The results obtained in this study show a marked a rise in the levels of serum FBG in the GDM-2 group in compare with the GDM-1 group (p≤0.05).

FBG is a strong predictor for diagnosing GDM, but it has been stated that using FBG as a diagnostic basis for GDM in early pregnancy is inappropriate because FBG is lower with rising gestational age. Riskin-Mashiah _et al._ it has been found that FBG useful to be a risk assessment screening tool but not as a diagnostic test in early pregnancy: Although FBG rises in the first trimester and remains within normal limits, it increases the risk of GDM later in pregnancy.

**Serum Insulin Concentration**

The results in Table (2) illustrating a marked a rise in the levels of serum insulin in GDM-2 group in compare with the Cont-2 group (p≤0.05). The results obtained in this study show a marked a rise in the levels of serum insulin in the GDM-2 group in compare with the GDM-1 group (p≤0.05).

Insulin needs are raised during pregnancy due to the presence of insulin antagonists, such as the lactogen secreted by the human placenta, and these hormones stimulate lipolysis and reduce glucose utilization. Various inherited disorders of the β-cells, insulin function, exocrine pancreas diseases, and endocrinopathies may result in varying degrees of glucose intolerance. As a result, glucose intolerance increases in GDM when β-cells are unable to compensate for the increased insulin resistance that occurs during pregnancy. In T2DM the cells of body be resistant to the action of insulin as the receptors that bind to the hormone become less receptive.
to insulin levels. This results in a rise in insulin levels (hyperinsulinemia) and insulin secretion disruptions, as well as a decreased insulin response. Hyperinsulinemia occurs when beta cells release elevated levels of insulin in response to persistently high levels of glucose in the blood. Insulin resistance is a hallmark of gestational diabetes mellitus. Insulin’s effect is thought to be hampered by gestational hormones and other factors because it binds to the insulin receptor. This interfering could happen at the level of the cell signaling pathway following the insulin receptor.17

Accurate measures of insulin sensitivity applied in the last trimester show slightly larger insulin resistance in females with gestational diabetes mellitus than in healthy pregnant females. The further resistance occurs for insulin’s effects to stimulate glucose elimination and to suppress glucose creation and decrease fatty acid concentrations.47 As a results the level of insulin in pregnant women with gestational diabetes mellitus are higher than insulin level in pregnant women without gestational diabetes mellitus due to the a raise levels of insulin resistance in women with gestational diabetes mellitus.17

Hemostatic Model Assessment-Insulin Resistance (HOMA-IR)

Table (2) illustrating a significant increase in the HOMA-IR in GDM-2 group in compare with the Cont-2 group (p≤0.05). The results obtained in this study show a significant increase in the HOMA-IR in the GDM-2 group in compare with the GDM-1 group (p≤0.05).

HOMA-IR method requires measuring single fasting serum glucose and the conformable fasting serum insulin level, that have been used to estimate insulin resistance.18,19

Insulin excretion in female with GDM can arise extremely over weeks or months in linked with the acquired insulin resistance of pregnancy. However, the arise occurs along an insulin sensitivity–excretion curve that is approximately 50% lower than that of normal pregnancy.20

Most GDM patients are linked with insulin resistance as noticed previously.21 GDM occurs in female who are unable to compensate for the natural metabolic changes of pregnancy.22 In order to enclose sufficient energy supply to the fetus, there is a rise in the levels of several hormones that oppose the effects of insulin, thus creating a state of insulin resistance. These hormones include human placental lactogen, placental growth hormone, estrogen, progesterone, cortisol, human chorionic gonadotrophin and prolactin.23 Norma glycaemia in pregnancy can only be preserve with a near doubling of basal insulin levels, as well as enhanced nutrient catalyze insulin excretion In humans, it appears that enhanced function of existing beta cells accounts for the majority of the a rise in insulin secretion, rather than hyperplasia. The arise insulin resistance reverts with delivery of the placenta.24

Oral Glucose Tolerance Test (OGTT)

The results in Table (3) show a marked increase in the OGTT in GDM-2 group in compare with the Cont-2 group (p≤0.05).

Oral glucose tolerance test used to diagnosis of GDM during pregnancy. The thresholds and method for diagnostic screening tests in GDM have changed according to the results of some recent studies. The Hyperglycemia and inverse Pregnancy Outcome study showed continuous correlation between carrying out a 75-g OGTT at (24-32 weeks’ gestation) and perinatal outcomes. The International Association of Diabetes and Pregnancy Study Groups (IADPSG) does not recommend a 75-g OGTT at 24 weeks of pregnancy due to a lack of evidence on the connection between 75-g OGTTs and perinatal outcomes. At <24 weeks of pregnancy, fasting blood glucose (FBG) is used to diagnose GDM. GDM is diagnosed using a 75-g OGTT at 24-28 weeks of pregnancy.

**Hemoglobin A₁c Ratio:**

Table (4) shows a marked increase in the ratio of HbA₁c in GDM-2 group in comparison with the Cont-2 group \( (p \leq 0.05) \). The present study shows no marked difference in the ratio of HbA₁c between GDM-1 group and Cont-1 group \( (p \leq 0.05) \). The results obtained in this study show a marked increase in the ratio of HbA₁c in the GDM-2 group in comparison with the GDM-1 group \( (p \leq 0.05) \). Also the results show no marked difference in the ratio of HbA₁c between Cont-2 group and Cont-1 group \( (p \leq 0.05) \).

Some authors do not find statistically marked differences throughout the whole period of pregnancy\textsuperscript{25}, other authors find decreases \textsuperscript{26,27}, and still others find increases in the third trimester\textsuperscript{28,29}.

In this study both groups of female pregnant showed a little a rise in HbA₁c in the 2\textsuperscript{nd} trimester comparison to the first one, though only the GDM group reached statistical marked, most probably due to an a rise in the medium postprandial glycemia.

Female with GDM are at a rise risk of perinatal morbidity, impaired glucose tolerance, and type 2 diabetes in the years after pregnancy. Many researcher have tried to apply HbA₁c to the diagnosis and monitoring of GDM patients. Rajput \textit{et al.} studied HbA₁c in Asian Indian female pregnant and reported higher mean HbA₁c levels in GDM patients than in normal female pregnant\textsuperscript{30}.

High levels of glucose can arise the glycation of common proteins such as hemoglobin, forming HbA₁c. However, it is important to note that HbA₁c is neither considered dysfunctional nor harmful. The levels of the HbA₁c predicts diabetes complications because it reflects more harmful glycation sequelae of diabetes, such as retinopathy and nephropathy, which are understood to be due to harmful advanced glycation end products\textsuperscript{31}.

**Serum IL-1β Concentration:**

Table (5) illustrating a marked a rise in the levels of serum IL-1β in GDM-2 group in comparison with the Cont-2 group \( (p \leq 0.05) \). The present study shows no marked difference in the levels of serum IL-1β between GDM-1 group and Cont-1 group \( (p \leq 0.05) \). The results obtained in this study show a marked a rise in the levels of serum IL-1β in the GDM-2 group in comparison with the GDM-1 group \( (p \leq 0.05) \). Also the results show no marked difference in the levels of serum IL-1β between Cont-2 group and Cont-1 group \( (p \leq 0.05) \).

The investigation of IL-1β in pregnant women with risk factors for the development of GDM was prompted by a clinical interest in inflammatory markers in pregnancy. The results indicate a rise of serum IL-1β Levels in GDM compared to normal pregnancy. Similar
The placenta is an endocrine organ that produces hormones and cytokines and is involved in the processes of pregnancy and labor induction. In normal pregnancy, cytokines like adiponectin and IL-1β are produced in the placenta, according to previous research.

In this study, female pregnant with GDM had higher insulin resistance in the second trimester (a time when insulin resistance develops) than female pregnant without GDM with the same age and BMI.

Furthermore, female pregnant with GDM had higher IL-1β levels and lower serum adiponectin in the second trimester than female without GDM. As a result, it appears that GDM is linked with a rise production of pro-inflammatory cytokines including IL-1β and lower production of adiponectin, an insulin sensitivity-related adipocytokine. These results are consistent with modern research that has related GDM pregnancies to low adiponectin levels in the second trimester and a rise levels of TNF-α, IL-6 and high sensitivity (hs) CRP, all indicators of a pro-inflammatory status. The present specific metabolic can moderated the functional nature and inflammatory phenotype of immune cell. May be immune cell undergo bath a proinflammatory and metabolic, which in their function. May be inflammatory mediators, such as, IL-1β levels is induced by saturated fatty acid and disrupt insulin signaling.

In the current research, it was discovered that IL-1β levels in GDM pregnancies follow a pattern close to that of other pro-inflammatory cytokines. pregnancy with GDM is a state of insulin resistance linked with a rise IL-1β values. Both of these changes may be linked to placental involvement in pregnancies with GDM.

### Conclusion

In late second trimester and early third trimester of pregnancy, IL-1β concentrations were increase in female with GDM in compare with healthy pregnant, therefore, IL-1β as an early biomarker can assist in the prediction the development of GDM later in pregnancy. The presence of GDM in pregnant patients lead to disturbances in FBG, Insulin, HOMA-IR and HbA₁c.

Prevalence of Pediatric Gastroenteritis Disease in Al-Diwaniyah Governorate-Iraq

Abdulridha T. Sarhan 1, Enas K. Alkhazraji 1, Takwa S. Al-Meamar 1
1 Research Scholar, Dentistry Department, Hilla University College, Babylon, Iraq

Abstract

This study was conducted to evaluate the gastroenteritis disease among hospitalized children in Women and Children Hospital, Al-Diwaniyah Governorate-Iraq, between August 2020 and January 2021. Data about age, gender, feeding, clinical symptoms and the causal agents were collected. A total of 723 children were screened, 616 patients (85.2%) of the infants and children under five years old with gastroenteritis disease, including 332 patient males (53.9%) and 284 patient females (46.1%). The lowest infection was recorded among 60 infant patients (9.7%), while the highest infections were recorded among 392 patients (63.6%) of one year old as compared to 164 patients (26.6%) among children above one to five years old. Also, results revealed two types of diarrhea, acute and chronic diarrhea. There was no significant difference between patients gender. The acute diarrhea was revealed the highest percentage of all cases (78.4%) and the remaining cases were chronic diarrhea (21.6%). Concerning the relation between the types of feeding and diarrhea, higher percentage (52.2%) was recorded with the bottle feeding, while the lowest percentage (20.1%) was with breast feeding. The clinical symptoms among infected children had gastroenteritis were diarrhea, stomach pains, vomiting, fever, urinary tract infection and malnutrition. Also, results showed that diarrhea infections usually happen in the seasons with high-moderate temperatures. This study concluded that most significant factors that caused the incidence of gastroenteritis in children were type of water, feeding or complementary feeding practices and mothers’ lack of care to reduce the risk of diarrhea among children under five years old.

Keywords: gastroenteritis, pediatric diarrhea, acute diarrhea, chronic diarrhea.

Introduction

The gastrointestinal tract is a vulnerable organ for infections as there is constant contact with the outside, mainly via the oral route(1). Gastroenteritis is a very common problem for children, major cause of morbidity and remains a major cause of hospitalization(2). It can lead to dehydration, which alters the children natural balance of water to electrolytes(3). Diarrhea can be dangerous if not treated properly because it drains water and salts from the children, if these fluids are not put back quickly, children may become dehydrated and may need to be hospitalized(4). Sometimes children with diarrhea have other symptoms, such as fever, loss of appetite, nausea, vomiting, stomach pains, and blood and/or mucus in the bowel movement(5). Globally, diarrhea is one of the leading causes of death among children under five year old(6). Acute diarrhea lasts less than one week, while chronic diarrhea lasts for 14 days or more and these include patients who were presented at first with acute diarrhea. The most common cause of acute diarrhea is a viral, bacterial, fungal or parasitical...
infection\(^7\). The evaluation of diarrhea in children requires a careful review of medical history, a physical examination and occasion diagnostic testing\(^8\). Other causes include the side effects of antibiotics and infections not related to the gastrointestinal system, such as ear infection that can cause diarrhea\(^9\). Most children with bacterial infection do not require antibiotics and will improve with time and supportive measures, antibiotics can cause side effects and lead to development of antibiotic resistance\(^ {10,11}\). Signs and symptoms of mild dehydration include a slightly dry mouth, increased thirst, and slightly decreased urine output\(^ {12,13}\). This study was done to evaluate gastroenteritis disease among hospitalized children and determine the proportion of acute and chronic diarrhea in infants and children less than five years old and the associated risk factors.

Materials and Methods

This study was carried out in Women and Children Hospital, Al-Diwaniyah Governorate-Iraq, between September 2020 and January 2021. A total of 723 children were screened, 616 patients which presented gastroenteritis aged between 2 months to 5 years old were examined. The information of admitted children to the hospital during this period was obtained from the statistical department of the hospital. A questionnaire form were used for all patients with gastroenteritis, the following data were recorded: name, age, gender, date of infection, address, duration of diarrhea, type of feeding, previous hospitalization for diarrhea and clinical symptoms appeared on the patients. Laboratory data where ever available were included in the study, like: assessment of hemoglobin level, stool examination for parasite, leukocytes, red blood cells, pH and urine samples for microbial culture. The evaluation of gastroenteritis in children requires a careful review of them medical history, a physical examination, physical examination and occasion diagnostic testing. The clinician will perform a thorough examination because there are some infections unrelated to the bowels (such as an ear infection) that can cause diarrhea. Bloody diarrhea that contains mucus is somewhat more common with bacterial infection which persistent high fever. Diarrhea from microbial infections may last longer than two weeks. For infants with chronic diarrhea, the total days of hospital stay were calculated from time of admission (either less than or more than 5 days). Data about different therapeutic interventions for patients with chronic diarrhea were obtained. The data were collected and analyzed by the statistical method, analysis of variance (ANOVA).

Results and Discussion

During the period of this study, a total of 723 patients admitted to the hospital, 616 patients of the infants and children under five years old were with diarrheal diseases represent (85.2\%) of total hospitalization of children to the hospital, including 332 (53.9\%) patients males and 284(46.1\%) patients females. It was found that the incidence of infection in male is higher than in female, this is consistent with De Camp et al.\(^ {14}\), who indicated that the occurrence of infection is higher in males than females. Overall, lower infection 9.7 \% was in infants represent 60 patients and the higher infection 63.6 \% represents 392 patients was in children less than one year oldof all those less than five years old children admitted to the hospital with diarrhea compared to 164 patients which represent (26.7 \%) in those above one to five years old (Table 1). The acute diarrhea cases were revealed the highest percentage of all cases(78.4 \%) and (21.6 \%) is for chronic cases. These results were confirmed by Pérez-Gaxiola et al.\(^ {15}\).

LSD at $P = 0.05$ between types of diarrhea = 2.14 and gender = 2.81

The data in (Table 2) revealed the results of the two types of diarrhea, acute and chronic diarrhea according to gender, there was a significant difference between the males and females, and also between acute and chronic diarrhea. The percentages of children with acute diarrhea were (79.5% vs. 77.0%) and chronic diarrhea were (20.5% vs. 23.0%) respectively, Block et al.\(^{(16)}\).

Results in Table 4 show the clinical symptoms among infants and children less than one year old with acute and chronic diarrhea, 107(23.7%) patients had stomach pains, 83(18.4%) patients had vomiting. Other significant symptoms include fever 75(16.6%) patients, urinary tract infections 86(19.0%) patients and ear infection 39(8.6%) patients, in addition to malnutrition 62(13.7%) patients. When sick children have diarrhea or vomiting, they can lose large amounts of salts and water from their bodies and can become dehydrated very quickly\(^{(18)}\). Dehydration can be very dangerous, especially for babies and toddlers. Children can even die if they are not treated\(^{(19,20)}\).

Also, results in Table 5 are showed that diarrhea infections usually happen in the periods with high temperatures (August and September), this means that outbreak of diarrhea infections usually happen in the warm season which not consistent with the results of William et al.\cite{21} who reported that diarrhea usually happen in cold season. The clinical support for infected children with acute gastroenteritis is very important for recovering from infection.

LSD at $P = 0.05$ between months $= 1.78$ and between ages of children $= 4.22$

**Conclusions**

As conclusions from this study, it observed that diarrhea was a common infection in infants from two months to one year old and there were two types of diarrhea (acute and chronic). The higher appearance of diarrhea was happened at the season with high and moderate temperature (August and September). Concerning the geographic characteristics, the rural area showed higher percentage of infections than urban area. Also, the most predominant infections occurred with children received bottle feeding. There were other clinical symptoms among children with chronic diarrhea, urinary tract infection and ear infection. Our findings highlight the high prevalence of *C. albicans*, *E. coli* and *E. histolatica* infections as the major cause of pediatric gastroenteritis in hospitalized children.

Patients’ Satisfaction about Quality of Health Care Services Provided in Maternity Wards at Al-Najaf City

Abeer Miri Abdullah¹, Rehab Lafta Mohammad¹, Zainab Neamat Jumaah Altaei¹
¹Research Scholar, University of Kufa, Faculty of Nursing, Iraq

Abstract

The study aimed to assess patients’ Satisfaction about Quality of Health Care Services Provided in maternity wards at Al-Zahraa teaching hospital at Al-Najaf city. A descriptive study was carried out through the present study in order to achieve the early stated objectives. The study was began from November, 2nd, 2019 to April, 22, 2019. The finding of this study reveals that that the patients are unsatisfied about quality of health care services provided at wards for most domain of health care services quality, while there is few patients satisfied about some health care services provided for them. The study concluded that most patients are unsatisfied about quality of health care services that provided at maternity wards. Recommendations The study recommends Assessing quality of health care services in the wards continuously, so that we can apply the quality improvement and/or quality assurance in wards, The domains and items related to the quality of health care services must be educate to health worker (physician, nurse … etc.) to teach them how they can apply it in the wards.

Keywords: Satisfaction, Quality, Health care services, Maternity Wards

Introduction

Patient satisfaction is deemed to be one of the important factors which determine the success of health care facility. The real challenge is not getting ready with mere requirements, but also delivers services ensuring good quality. Thus, there is a need to assess the health care systems regarding patient satisfaction as often as possible. The purpose of health care services is to improve the health status of the population. The scope of health services varies widely from country to country and influenced by general and ever changing national, state and local health problems, needs and attitudes as well as the available resources to provide these services. There is now broad agreement that health services should be comprehensive, accessible, acceptable, provide scope for community participation and available at a cost the community and country can afford(1). Patient satisfaction is deemed to be one of the important factors which determine the success of health care facility. It is easier to evaluate the patient’s satisfaction towards the services provided than to evaluate the quality of medical services that they receive(2). Therefore, a research on patient satisfaction can be an important tool to improve the quality of services. Health care consumers today, are more sophisticated than in the past and now demand increasingly more accurate and valid evidence of health plan quality. Health care organizations are operating in an extremely competitive environment, and patient satisfaction has become a key to gaining and maintaining market share. The health care system depends on availability, affordability, efficiency, feasibility and other factor (3)

Consumer satisfaction regarding medical care organization like our tertiary care hospital is important in the provision of services to patients. This study was therefore undertaken with the aim to find out the level
of patient satisfaction related to different parameters of quality of health care (4). Improving maternal health is one of the eight major developmental aims of the third millennium of World Health Organization (WHO) 2000 summit. Two important criteria for achieving this goal are reducing the maternal mortality ratio by three quarters compared to the year 1990, and improving women’s access to reproductive health services by 2015 (5). Today, maternal mortality is not only a health indicator but also one of the indicators used in developing communities, and shows the extent of care of the societies regarding maternal health (6). WHO has set its main activity goal as reducing the maternal and children mortality, and one of the key strategies for achieving this goal is providing parental care and care during and after delivery (7).

The main purpose of providing health care services is to improve public health through the provision of desirable and necessary health and treatment services. Improvement of quality of care requires evaluation of the quality of services and the level of clients’ satisfaction with the services provided (8) and (9). Patient satisfaction is a concept that is of a particular importance in today’s health care (10). Patient satisfaction depends on the health care that the patient receives, and this issue is very important. Satisfied clients compared with unsatisfied clients show different responses to the care services received. Satisfied clients adapt to the recommendations and follow them, and often invite other people to use these services. Therefore, satisfied clients not only continue using the healthcare services, but also promote their use (6).

Worldwide an estimated 515 000 women die of complications of pregnancy and childbirth every year, a rate of over 1400 maternal deaths each day (11). At least 7 million women who survive childbirth suffer serious health problems, and a further 50 million women suffer adverse health consequences after childbirth. The overwhelming majority of these deaths and complications occur in developing countries. Maternal mortality is the main factor that substantially lowers the life expectancy of women and it is a basic human right that pregnancy be made safe for all women (12), (13). Improving the quality at maternity care services is an effective strategy to reduce maternal mortality (14). The World Health Organization (WHO) emphasizes the importance of evaluating the structure, process and outcome of health services to improve the quality of care (15).

Methods

A descriptive study was carried out through the present study in order to achieve the early stated objectives. The study was began from November, 2nd , 2019 to April, 22, 2019. The study was conducted in Al-Najaf City / in maternity wards at Al-Zahraa teaching hospital. The study was carried out with 100 patients after excluding those who declined to participate. Data were collected by face-to-face interviews.

Discussion

Concerning their age, the majority of study sample are at age group of (20-25) years. This result match with the result of (12) in their study “Quality of maternity care and satisfaction of patients attended teaching and non-teaching hospital” They conclude (most women at age (≥20 years). Regarding the marital status, the present study shows that the majority of sample in the study groups are married (16). They pointed in their study that the highest percent of study sample were married.

In addition, the study results indicate that the majority of the research sample are living in urban area (17), they revealed in their study that the majority of the study subjects are urban residents.

Concerning the socio-economic status, the highest percentage of study sample is Satisfied to some extent. High percent of the study sample does not read and write (18). In agreement with this result, they found that the majority of study subject were Illiterate. Regarding to the occupation status, the present study sample shows the high percentage (74.0%) were housewives. This result is supported by a study done by (4) as his result indicated that the higher percentage of study sample were housewives.

Regarding patients satisfaction concerning tangible domain of quality of health care services table (2), that based on the subjects’ responses, the results indicate that in the following items (In ward all amenities are provided such as continuous electricity, water, sanitation, ventilation and unpleasant odors) and (ward provides all required medication in the pharmacy) the responses of the study subjects are acceptable, while in the remaining responses for the services quality in the ward are insufficient to the patients’ requirements. This means that they are unacceptable for most of the subjects. The researcher suggest this result comes because the hospitals are provide an appropriate material and equipment that is enough for patients need. While not provided materials are not affect on patients satisfaction because this materials don’t directly related to the patients need. In addition, the subjects’ responses regarding reliability domain of the QHCS table (2), the study show that services of the ward are not adequate to the patient’s requirements at all items.

Also regarding responsiveness domain of the quality of health care services table (2), the study indicates that services are insufficient to meet the patients’ requirements at all items. Furthermore, the subjects’ responses regarding empathy and assurance domains of the quality of health care services respectively, the subjects responses are insufficient to their requirements at all items. This result disagree with the result of the study done by (19) who showed in his study that health care services that provided in public hospitals within acceptable and satisfying level. The researcher believe the reasoned is that most of nurses who work in maternity ward not graduated from institutes and with
poor knowledge and experience to caring patients. The study shows that patients are unsatisfied with the quality of health care services provided at the wards table (2), tangibility, reliability, responsiveness, empathy and assurance dimensions of the health care services quality, this results disagree with the results of the study done by (19) they mentioned that the majority of the patients are satisfied with health care services, but this result in agreement with study done by (20). they stated in their study that the quality of health services provided in health centers according to the dimensions of quality of health services (tangibility, reliability, power of responsiveness, empathy, trust and safety) are unsatisfied.

**Conclusion**

According to the present study findings, the researcher can mention the following conclusions: Most patients are unsatisfied with the services provided in the wards regarding all domain of healthcare services. There is satisfied from few of patients about the health care services provided in the wards regarding tangible domain of healthcare services related to (medication, continuous electricity, water, sanitation, ventilation). As general the study indicates that most of patients are unsatisfied toward all quality of health care services domains.

Abstract

Homicide is regarded as a notorious crime against the society that causes intentional killing, aggravated assaults resulting in death. This brings a massive burden on national economies, law enforcement and lost productivity. The present study highlighted the epidemiological profile of homicidal deaths which accounted (3.9%) of all unnatural deaths autopsied. Overall trend shows high male predominance with low economic background where illiteracy, poverty and other social circumstances play a considerable role. Homicidal records have their importance in interpretation of socio-economic implications and overall administrative attributes on executing law and order in respect to time, place and conditions.

Keywords: Forensic medicine, homicidal cases, epidemiology.

Introduction

Homicides are heinous crime against the society and there has been a global increase in homicide that causes over 5000,000 deaths per year worldwide [1]. It includes premeditated murder, intentional killing, and aggravated assaults causing death. It may be a result of arguments between acquaintances, domestic violence, robberies, drug addiction and terrorism [2]. Homicides are regarded as one of the oldest crimes in human civilization. It is a common end point of many different behavioral pathways [3]. Grossly, death that occurs from violence also encompasses a wide range of physical, sexual, reproductive and mental health problems that imposes massive burden on national economics, law enforcement and lost productivity. In addition, homicide results in significant personal, social and economic loss [4].

As homicides comprise a major portion of medico-legal autopsies, they get special importance for general criminal profile of the society [5]. Medico-legal autopsies provide statistical significance related to legal incidents in the society along with the cause and manner of death [6]. In the present day world, violence is recognized as a global public health problem. It accounts for 9% of global mortality and 12% of all disability adjusted life years (DAILY) [7].

As per Global Burden of Armed Violence Report (2011), the average annual global violent death rate between 2004 and 2009 were 79 per million. Globally...
around 520,000 people die each year as a result of interpersonal violence which equates to 1400 deaths every single day [8]. Although official data from the National Crime Records Bureau (NCRB) shows that murder rate in India has been steadily declining over the past two decades [9], still it needed to be assessed from time to time.

There is a pressing need for socio-demographic studies on homicidal cases with rising trends of organized crimes being executed in a professional manner. Although quite a good number of work have already been done in different parts of India and in other countries, not much work have been reported from North Bengal regions. The present study shows the different aspects of homicides in relation to victims with special emphasis on its epidemiologic profile.

**Materials and Method**

In the present study all homicidal cases brought for medico-legal autopsies in the mortuary of North Bengal medical college and hospital (NBMCH) attached to the Department of Forensic Medicine and Toxicology, West Bengal, during the period of 1st May, 2018 to 30th April, 2019 were evaluated. This cross-sectional study included a total 94 cases of homicidal deaths. Autopsies on all cases of alleged homicidal deaths were included in the study, whereas, all cases of natural, suicidal deaths and either decomposed or unidentified bodies where autopsy findings were not suggested to homicidal mode of death even with the history of homicide were excluded from the study.

Parameters used in the study were police/ magistrate inquest report, history obtained from family members and autopsy findings. A descriptive study was designed to explore the epidemiologic profile of homicidal cases. Data was analyzed using SPSS software.

**Results**

In the present investigation of total 2423 unnatural deaths autopsied during the study period 94 cases (n=94) were homicidal (3.9%).

As per distribution of age (as shown in Table 1), it was found that 39.6% of victims were in the age group of 31-40 years. 23.4% victims were aged between 51-60 years. 18% victims were aged between 41 to 50 years. 7.4% victims were young adults aged between 21-30 years of age group. Only 3.1% victims were aged above 70 years.

As per distribution of sex (as shown in Table 2), it was observed that most of the victims (76.6%) were male and few (23.4%) were female. As per month and year wise distribution of victims (n= 94), the incidences of homicide were maximum (20.2 %) in the month of December 2018, followed January 2019 (17.1 %), March 2019 (10.6%), May 2018 and April 2019 (8.5%), October 2018 (6.4%), August 2018 (5.4%), November 2018 (5.3%), September 2018 (4.2%), June 2018 (3.2%) and July 2018 (2.1%).

Regarding seasonal variation, homicidal incidences were maximum in winter (51%) in the months of Nov-Feb, followed by summer (30.9%) and Monsoon (18.1%) as shown in Table 3. As per religion wise distribution, incidences of homicides were maximum in Hindus (69.14%) followed in Muslim (27.65%) followed Buddhist (2.12%) and Christian (1.06%). As per demographic distribution, rural cases comprises 66% and 34% belonged to urban area.

Educational status distribution, the maximum number observed (51.1%) of victims were illiterate followed by primary (34%), secondary (9.6%) and graduate (2.1%). Socio-economic status of the homicidal victims showed majority (70.2%) from low, followed by 25.5% middle class and 4.3% of high class. Of the distribution in marital status married victims were the major (80.9%), followed by unmarried (14.9%) and low among widower (4.2%). Among distribution of occupational status majority of victims were workers (34%), followed by businessman (22.3%), farmers (16%), housewife (12.8%), private employee (7.4%), retired persons (4.3%) and government employee only (3.2%).
As per distribution on time of incidence, most of the incident of homicide happened during late evening (33%) between 7pm to 10pm, followed by evening (23.4%), morning (12.8%), early morning (8.5%), midday (7.4%), afternoon and night (6.4%) and late night (2.1%). Distribution on place of occurrence showed majority of the incidence occurred in the public place (62%) and (32%) occurred at home. Majority of the victims (74.5%) did not get any medical care where only (25.5%) victims received it. As per methods of homicidal injury is concerned blunt weapon was used in maximum cases (45.7%), followed by heavy sharp weapon (23.4%), light sharp weapon and stab injury (9.6%), manual force (6.2%), firearm (3.2%) and strangulation (2.1%). Among the cause of death, instantaneous death (47.9%) was the most common followed by shock and hemorrhage (25.5%), coma (17%) and asphyxia (9.6%). By the distribution of the homicidal victims according to the region of injury, brain was the commonest organ to get injured (36.3%), followed by lungs (10.6%), stomach (7.5%), heart and intestines (6.4%), liver (4.2%), pancreas and kidneys (2.1%) and multiple organ involvement was observed in 22.3%.

Discussions

In the present investigation of total 2423 bodies brought for medico-legal autopsies in mortuary of NBMCH during the period of 1st May, 2018 to 30th April, 2019, 94 cases were sorted for homicidal which accounted (3.9%).

Prior study from Bangalore [10] showed that this age group was accounted for 61.50% cases of homicidal death. The factors responsible for highest incidents in the 18-40 years age groups (64.3%) were due to marital disputes, property disputes, infidelity, dowry death in females, gang rivalry, unemployment and heated arguments. Our study showed highest incidence (39.6%) in age group of 31 to 40 years.

Sex wise distribution showed 3.27 times more in male compared to female. The cause for male predominance may be because of their number, unemployment, jealousy, revenge, lack of patience, intake of alcohol and bad accomplices etc. the lower incidence in females is mainly attributed to custom, social values and preference of females to stay indoors.

In consistent to the study done by Sisti et al. (2012) [11] in Italy, with maximum homicidal death in a bimodal pattern, summer (July and August) and winter (December and January) seasons, our study showed maximum (20.2%) in the month of December with 51% in winter season (Nov-Feb).

The majority of victims (51.1%) were from illiterate backgrounds. This could be related to poverty, unemployment, prevalence of multicast system of the society and inability to solve the dispute by fruitful peaceful discussions.

Conclusion

However, trends of homicidal deaths differ from country to country, region to region and from time to time based on overall economic turbulences and social circumstances. Still deaths related to homicides are commonly found in low economic class with male predominance where illiteracy, poverty and mistrust definitely play a considerable role.

Therefore, along with the socio-economic improvement, the crime investigating agencies including medico-legal aspects and judiciary system has to be strengthened so that the law can be enforced stringently. Understanding the burden of issue on the socio-economical, cultural and multidirectional implications, continuous research in this field is necessary to validate data from different time, place and conditions.

Increased Corticosterone Levels due to Chronic Stress Reduces IGF-II Expression in *Rattus norvegicus*

Ade Septiari Rahman¹, Reny I’tishom², Ashon Sa’adi³

¹Master Degree of Reproductive Health Science Faculty of Medicine Universitas Airlangga, Surabaya, Indonesia, ²Lecturer in Department of Medical Biology Faculty of Medicine Universitas Airlangga, Surabaya, Indonesia, ³Lecturer and Consultant in Department of Obstetrics and Gynecology Faculty of Medicine Universitas Airlangga/ Dr. Soetomo General Hospital, Surabaya, Indonesia

Abstract

The optimal folliculogenesis process describes a good condition of the female reproductive system. One of the main growth factors in the folliculogenesis is IGF-II which is important for proliferation and differentiation of granulosa cells and also steroidogenesis. Chronic stress can cause ovulation failure and folliculogenesis disorders. Increased corticosterone levels due to chronic stress will cause disruption in the GnRH pulse, causing a decrease in the gonadotropin and lead to folliculogenesis disorders, and decrease IGF-II production. This study aims to prove the effect of increased corticosterone levels due to chronic stress on IGF-II expression in the ovaries of Rattus norvegicus. The research sample consisted of 34 Rattus norvegicus which were divided into 2 groups. The treatment group was given Chronic Unpredictable Mild Stress (CUMS) method for 20 days. Corticosterone levels were detected by the ELISA method as a marker of chronic stress and IGF-II expression was evaluated by immunohistochemical methods. The results of statistical tests showed that there were significant differences in corticosterone levels (p = 0.000) and IGF-II expression (p = 0.042) in the two groups (p <0.05). So the conclusion is increased corticosterone levels due to chronic stress can reduce IGF-II expression in the ovaries of Rattus norvegicus.

**Keywords:** Corticosterone, Chronic Stress, CUMS, IGF-II, Folliculogenesis

Introduction

Infertility problems are experienced in women as much as 35% of all cases(1). According to WHO, the most common causes of infertility in women are ovarian failure, which is 33% was caused by folliculogenesis disorders(2). Stress that that occurs continuously or chronic stress can cause ovulation failure and folliculogenesis disorders, and can subsequently lead to infertility.

Stress has been shown to inhibit oocyte maturation and produce many immature oocytes(3), and reduce the number of dominant follicles(4). Stress also causing a decrease in the number of fertilized oocytes, pregnancy rates, live births and birth weight in women undergoing in vitro fertilization (FIV)(5). Chronic stress has also been shown to reduce the thickness of the antral follicular granulosa cells, and as a result, folliculogenesis is disrupted(6).

Chronic stress can cause the distress condition, which causes the hypothalamus to produce Corticotrophin Releasing Hormone (CRH)(7), and then the anterior pituitary will produce Adenocorticotrophine Hormone (ACTH) which stimulates the adrenal glands to produce glucocorticoid hormones, namely cortisol(7,8). Glucocorticoid synthesis in response to chronic stress
will further impair reproductive function\textsuperscript{(7,9)}.

There are various kinds of growth factors that help the folliculogenesis process. One of them is the main and most abundant growth factor in the human ovarian system during folliculogenesis, namely Insulin-like Growth Factor-II (IGF-II). IGF-II plays a role in cell growth, proliferation, differentiation and acts as a regulator of the remodeling of the extracellular matrix of granulosa cells\textsuperscript{(10)}. In addition, IGF-II also increases the production of estradiol and progesterone by granulosa cells\textsuperscript{(11)}.

Increased levels of cortisol (corticosterone in rattus) due to chronic stress can indirectly interfere with GnRH pulses, causing a decrease in the amount of gonadotropin hormones. Because gonadotropins stimulate IGF production, the IGF-II formed will be reduced\textsuperscript{(7,9)}. Activation of IGF-II from the IGF-I and AKT receptors required FSH to stimulate CYP19A1 expression and granulosa cell proliferation. So with reduced IGF-II production, it will cause cell proliferation and steroidogenesis disrupted, followed by folliculogenesis disorder\textsuperscript{(11,12)}.

This study aims to prove that an increase in the hormone corticosterone due to chronic stress can result in a decrease in IGF-II expression in \textit{Rattus norvegicus}.

**Material and Method**

The design of this research is True Experimental with Post Test Only Control Group design. The study was conducted from April to June 2019 at the Animal Laboratory, Department of Biology, Faculty of Science and Technology, Airlangga University. The sample unit in this study was female rats (\textit{Rattus norvegicus}) 5-6 months old who had given birth, weighing 300-350 g and in good health. All sample units were adapted for 7 days and injected PGF2\alpha at a dose of 25 µg/gBW intraperitoneally to synchronize lust. This aims to get the diestrus phase at the time of surgery. Female rats were divided into 2 groups consisting of 17 individuals per group. The treatment was carried out using the Chronic Unpredictable Chronic Stress (CUMS) method, which is a model of giving minor intensity stressors that resemble stressors of daily life for several weeks\textsuperscript{(13)}. In this study, stress exposure was given for 20 days with 8 forms of treatment.

Ovarian tissue samples are taken surgically, and blood samples are taken intracardially. Corticosterone levels taken from the blood were detected by the ELISA method. IGF-II expression was detected by immunohistochemistry. The data obtained were then converted with the Remelle Scale Index. Statistical tests were performed using SPSS 25 software. The data obtained were first tested for normality by the Kolmogoroff-Smirnov and Shaporo-Wilk tests. Followed by a parametric statistical test, the Independent T-Test. If the data is not normally distributed, the Mann Whitney statistical test is used.

**Results and Discussion**

The sample unit in this study was 34 \textit{Rattus norvegicus} which were divided into two groups. The control (K1) and treatment (K2) groups each consisted of 17 \textit{Rattus norvegicus}. In the K1 group, there were two samples whose corticosterone level were undetectable, so they were excluded. In the K2 group, there was one sample unit that dropped out due to death. The death of \textit{Rattus norvegicus} occurred on the 16th day of the stressor treatment. Thus, the final number of sample units for each group is 15 in K1 and 16 in K2. This number is qualify the minimum sample size in this study (15).

**Table 1. Mean and SD of corticosterone levels in the blood serum of \textit{Rattus norvegicus}**

<td>23.29 ± 8.42</td>
</tr>
<tr>
<td>K2</td>
<td>16</td>
<td>72.84 ± 64.03</td>
</tr>
</tbody>
</table>

The mean of corticosterone levels in the K2 group (72.84 ± 64.03) were higher than the K1 group (23.29 ± 8.42).
The results of the Mann Whitney test showed p=0.000 (p < 0.05), it means that there was a significant difference in corticosterone levels between the K1 and K2 groups.

The examination of IGF-II expression using immunohistochemical methods. Observation of IGF-II expression was carried out using a microscope connected to a computer with 64-bit Nikon NIS-Elements F-4.60.00 software. IGF-II expression can be seen in Figure 1.

![Figure 1](image)

</tbody>
</table>

Based on the table, the mean of IGF-II expression in the K2 group was lower (2.44 ± 1.15) than the K1 group 3.73 ± 1.79.

**Table 4.** Mann Whitney analysis results of IGF-II expression in the ovary of Rattus norvegicus

<table>
<thead>
<tr>
<th>P Value</th>
<th>Different tes analysis</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.042*</td>
<td>Mann Whitney test</td>
</tr>
</tbody>
</table>
The results of the Mann Whitney test showed the value of $p = 0.042$ ($p < \alpha$), it can be concluded that there was a significant difference in IGF-II expression of K1 and K2 groups.

The results showed that after 20 days treatment of stress, corticosterone levels in the treatment (K2) group increased significantly compared to the control (K1) group. And after giving CUMS method for 20 days, the IGF-II expression in the treatment group was lower than the control group (significantly different). This proves that chronic stress, which is characterized by an increase in corticosterone levels, can result in a decrease in IGF-II expression. Increased cortisol levels due to chronic stress will disrupt the GnRH pulsation, causing a decrease in gonadotropins. Because gonadotropins stimulate IGF production, the IGF-II formed will be reduced\(^7\)\(^9\). The increased cortisol hormone will lower the FSH hormone levels. FSH is also a strong enhancer of IGF-II expression, so that by decreasing FSH due to increased cortisol, IGF-II will also decrease, and consequently cell proliferation can be disrupted, and steroidogenesis as well\(^{11}\).

IGF-II interacts with IGF-1R, which causes activation of the PI3-kinase/Akt signaling pathway which impacts protein translation as well as cell proliferation and differentiation. IGF-II also interacts with IGF-2R which results in increasing steroidogenesis in human and mouse granulosa and theca cells. IGF-II increases the production of estradiol and progesterone by granulosa cells\(^{14}\). Studies on human ovarian follicle cultures proved that the addition of IGF-II to culture media stimulated primary follicle production and reduced the number of atretic follicles compared to the control group. This means that if IGF-II decreases, folliculogenesis can’t be optimal because IGF-II serve as a protector and stimulator for follicular development\(^{15}\).

**Conclusion**

The increase in corticosterone levels as a result of chronic stress can reduce IGF-II expression in *Rattus norvegicus*.

Incense Smoke Exposure: An Appraisal of Organ Toxicity

Adebanji M. Akingbade¹, Samson A. Odukoya², Adeoye O. Oyewopo³, Nalini Govender⁴, Thajasvarie Naicker⁵

¹Lecturer, Department of Anatomy, Faculty of Basic Medical Sciences, College of Medicine Ekiti State University Ado-Ekiti, Nigeria PMB, 5363, ²Senior Lecturer, Department of Anatomy and Cell Biology, Faculty of Basic Medical Sciences, College of Medicine and Health Sciences, Obafemi Awolowo University, Ile-Ife, Nigeria PMB 13, ³Associate Professor, Department of Anatomy, Faculty of Basic Medical Sciences, College of Medicine and Health Sciences, University of Ilorin, Ilorin, Nigeria PMB 1515, ⁴Senior Lecturer, Department of Basic Medical Sciences, Durban University of Technology, P O Box 1334, Durban, South Africa, ⁵Professor, Optics and Imaging Centre, University of KwaZulu Natal, Doris Duke Medical Research Institute

Abstract

Background: This narrative type review aimed to address organ toxicity emanating from incense usage.

Methods: An online search using the following MeSH terms “Incense smoke,” “adverse effects,” “organotoxicity,” “oxidative stress” and “inflammation” was done to identify studies directly applicable to adverse effects of incense smoke exposure.

Findings: Exposure to incense smoke demonstrated various toxicity changes in the kidney, testes, lungs, liver and heart. Renal effects included a decrease in oxidative stress markers GSH and CAT, increase in MDA, serum creatinine uric acid and blood urea nitrogen (BUN). Testicular toxicity revealed significant disturbances in spermatogenetic patterns, testicular atrophy, germinal aplasia, hypospermia and damage to the basal seminiferous epithelia tissue. In the cardiac muscle, ultrastructural changes, increased oxidative stress, inflammation, and altered cardiac hypertrophic gene expression was noted. Thenegative impact of incense smoke emanating from free radical (ROS), lipid peroxidation and GSH destabilizes vascular homeostasis and initiates a hyperinflammatory response, warranting the need to understand the conceptual basis of the mode of action linked to incense exposure.

Conclusion: We highlight that incense generates ROS which initiates lipid peroxidation through ATP energy depletion and reduction in the natural antioxidants. This subsequently triggers oxidative stress, inflammation and endothelial dysfunction resulting in organotoxicity.

Keywords: Heart, incense, liver, lungs, organotoxicity, skin, testes

Introduction

Incense (from Latin incendere “to burn”) is composed of aromatic biotic materials and essential oils, which when burned release fragrant smoke (¹). The term “incense” refers to the substance itself rather than the odour produced (²). The use of incense dates back to Egyptian antiquity, Babylonians, Indus civilization and the early dynasties of China (Xia, Shang, Zhou and Song).

The presentation of incense is variable in that they may occur as sticks, joss sticks, cones, coils, powders, rope and rocks/charcoal (³). Incense usage differs with regard to culture, custom and the reason for usage.
with many using it for the simple appreciation of its aroma and as a deodorizer/fragrance within their homes\textsuperscript{(5, 6)}. It is used in religious ceremonies for ritual purification, to appease the Gods with its sweet smell and to deter demons\textsuperscript{(1)}, in aromatherapy\textsuperscript{(6)}, an insect repellant and at funeral ceremonies to mask the smell of decay\textsuperscript{(7, 8)}. In most South East Asian and Middle East countries, domestic incense burning is routine during daily religious rituals\textsuperscript{(9)}.

When incense is burnt, it emits smoke that contains CO, CO\textsubscript{2}, NO\textsubscript{2} and SO\textsubscript{2}, aldehydes, metallic elements, polycyclic aromatic hydrocarbons (PAHs) including benzo(a)pyrene (BaP), naphthalene, fluoranthene and volatile organic compounds (VOCs) such as benzene, toluene and xylene\textsuperscript{(10-12)}. Inhalation of these pollutants in a closed environment are detrimental to human health. In fact, particulate matter from incense burning is 45 mg/g compared a cigarette, which is 10 mg/g\textsuperscript{(13)}. Moreover, incense is associated with a weak mutagenic activity\textsuperscript{(14)}.

Nonetheless, despite its widespread availability and access, the mechanism of its adverse effect and toxicity remains a public health challenge\textsuperscript{(14)}. Several studies demonstrate that continuous exposure to incense smoke predisposes the development of asthma, dermatitis, respiratory complications and hypertension\textsuperscript{(15-17)}. Moreover, exposure to carcinogens emitted from incense burning increases the risk of cancer development\textsuperscript{(18-20)}. Furthermore, the pathological and pharmacological effect of incense smoke on organs have been reported in the lung, testis, skin, liver and kidney\textsuperscript{(19, 21-23)}.

The adverse effect of incense exposure on different organs is based on short-term and long-term exposure. In fact, long-term exposure to incense smoke increases inflammation of blood vessels thereby influencing blood flow\textsuperscript{(22)}. In light of the negative consequences associated with incense smoke exposure, this narrative type review aimed to address organ toxicity emanating from incense usage.

Pathogenesis of organotoxicity emanating from incense exposure

Although the underlying causal mechanisms of incense exposure remains unclear, changes to oxidative stress, reactive oxygen species (ROS), inflammation, endothelial dysfunction and lipid peroxidation pathways may synergistically and concurrently contribute to pathology.

i. Oxidative stress

Reactive oxygen species are chemically reactive molecules containing oxygen \textit{e.g.,} oxygen ions and peroxides. ROS is a natural by-product of the metabolism of oxygen and has an important role in cell signaling and homeostasis\textsuperscript{(24)}. The production of ROS such as peroxides and free radicals lead oxidative stress that causes considerable damage to proteins, lipids and DNA of a cell.

Oxidative stress contributes to NO depletion, emanating from excess superoxide anions generation\textsuperscript{(25)}. Also, the superoxide anions react with NO to produce peroxynitrate. This subsequently oxidizes tetrahydrobiopterin (BH4)\textsuperscript{(26)} which inactivates eNOS thereby exacerbating superoxide anions production\textsuperscript{(27)}. Oxidative stress also upregulates endothelin-1 expression and causes endothelial dysfunction\textsuperscript{(28)}.

Oxidative stress activates the specific adaptive stress response via enhanced protein expression of endogenous anti-oxidant enzymes\textsuperscript{(29)}. This stress response protects cells against the reactive oxygen species mediated toxicity whilst maintaining a tissue redox balance\textsuperscript{(29)}. The gene transcription of most anti-oxidant enzymes is regulated via transcription factors, nuclear factor-E2-related factor (Nrf2) and anti-oxidant response elements (ARE) in the genes encoding enzymatic anti-oxidants\textsuperscript{(30)}. Under physiological conditions, Nrf2 is linked to an actin-bound Kelch-like ECH-associated protein 1 (Keap1) that is located within the cytoplasm\textsuperscript{(31)}. However, under the influence of oxidative stress, Nrf2 dissociates from Keap1 and translocates to the nucleus, where it induces the transcription of ARE-regulated genes\textsuperscript{(30)}. Anti-oxidant enzymes such as superoxide dismutase, catalase and glutathione defend the host against the damaging effects
of the free radicals species \(^{(30, 32)}\). Several studies have also associated incense exposure to pathophysiological disturbances with increased generation of ROS and/or a depletion of anti-oxidants within the kidney, testes, liver, heart, skin and lungs \(^{(33-37)}\).

ii. Inflammation

Inflammation is a natural defense mechanism associated with microbial and viral infection, exposure to allergens, radiation and toxic chemicals, autoimmune, chronic diseases, obesity, alcohol consumption, tobacco use, and a high-calorie diet \(^{(38)}\). Notably, chronic diseases such as cancer, insulin resistance, diabetes mellitus, cardiovascular diseases, atherosclerosis, and aging are associated with an up-regulation of ROS, oxidative stress together with protein oxidation \(^{(39, 40)}\).

Inflammation is a major indicator of endothelial dysfunction as endothelial stress is associated with an increased endothelial secretion of chemokines and cytokines \(^{(41)}\). Persistent inflammation may further exacerbate the oxidative stress induced pathology \(^{(42)}\). Oxidative stress is also implicated in vasconstriction of vascular smooth muscle via upregulation of endothelin-1 expression within endothelial cells, with consequent abnormal vascular function \(^{(28)}\). Thus, oxidative stress is the key force that drives endothelial dysfunction by destabilizing vascular homeostasis via the down-regulation of NO together with an up-regulation of endothelin-1. A strong correlation between incense smoke and oxidative stress was demonstrated by Hussain et al \(^{(2019)}\). A significant reversal of oxidative stress was observed within 30 days of cessation of incense smoke exposure, with consequential up-regulation of endothelial function and inflammation, thus confirming that incense smoke may be responsible for the induction of the pathology \(^{(37)}\).

Furthermore, the induction of Cytochromes P450 (CYPs) by BaP or other constituents either alone or in combination in rats exposed to incense smoke, maybe responsible for the mechanistic event for the increase in oxidative stress and inflammation of kidney dysfunction and tissue degeneration \(^{(19)}\). Additionally, myocardial degeneration together with increased oxidative stress and inflammation may contribute to the increased risk of cardiovascular and endothelial dysfunction, as well as irregularity in heart rate amongst incense-smoke exposed subjects \(^{(43)}\). Similarly, rhodinol-based incense generates reactive oxygen species via ROS production that exceeds the body's own natural anti-oxidant defense thereby resulting in oxidative stress and consequent cellular damage \(^{(23, 44)}\). This may explain the decrease in enzymatic and non-enzymatic anti-oxidants such as CAT, SOD, GSH and GPx. Similarly, Ahmed et al., (2013) also reported a decrease in both enzymatic and non-enzymatic anti-oxidants after exposure to incense smoke \(^{(34)}\). Moreover, treatment of human alveolar epithelial cells, A549 with particle matter emanating from incense smoke correlates with increased oxidative stress \(^{(45)}\). Incense smoke combustion is also reported to contribute to reactive oxygen species generation and to increase oxidative stress and induce DNA damage \(^{(11)}\).

iii. Lipid peroxidation

Lipid oxidation is a naturally generated process in the body, occurring mainly as an effect of several reactive oxygen species (hydroxyl radical, hydrogen peroxide, etc.) or by the action of several phagocytes \(^{(46)}\). Since lipid peroxidation is a self-propagating chain-reaction, the initial oxidation of only a few lipid molecules may lead to significant tissue damage \(^{(47)}\). Lipid peroxidation has been implicated in diseases such as pre-eclampsia and in hepatoxicity, kidney damage, skin damage and testiculotoxicity \(^{(34, 48)}\). The mammalian spermatozoon is particularly vulnerable to lipid peroxidation because of the molecular anatomy of its plasma membrane \(^{(23)}\). Unlike somatic cells, mammalian sperm cells have a highly specific lipidic composition with a high content of polyunsaturated fatty acids (PUFA), plasmologens and sphingomyelins \(^{(23)}\). Their unusual plasmalemma content is responsible for its flexibility and the functional ability of sperm cells. The high PUFA content is the main substrate for peroxidation and may provoke severe sperm dysfunction \(^{(49, 50)}\). It is possible that the testicular oxidative status of rats exposed to varying weights of incense (2g and 3g) increases the
action of malondialdehyde (MDA), a product of lipid peroxidation and damages their structure (23, 34). An earlier study demonstrated that the incense smoke exposure significantly decreased the liver alkaline phosphatase (ALP), alanine aminotransferase (ALT) and aspartate aminotransferase (AST) glutathione (GSH) and the activities of SOD, CAT and GPx by significantly up-regulating lipid peroxidation (51).

In light of the above mechanistic actions of incense smoke, physiologic function of various organs may be compromised. These include:

a) Kidney

A significant increase in serum creatinine, uric acid, blood urea nitrogen (BUN), tissue MDA, tumor necrosis factor-alpha (TNF-α) and interleukin-4 (IL-4) level have been reported in rats exposed to incense smoke (19). They also reported a significant decline in tissue glutathione (GSH) and catalase activity together with associated ultrastructural kidney pathology. Furthermore, a significant increase in tissue gene expression of both CYP1A1 and CYP1A2 were noted in incense exposed rats (19). In Singapore, the long-term daily exposure of the Chinese population to domestic incense burning has been associated with an increased development of end stage renal disease (52).

b) Testes

Rats exposed daily to *Boswelliapapyrifera* and *Boswelliacartetii* - based incense show significant disturbances in sperm kinetics compared to unexposed rats (34). More specifically, incense smoke causes a secretory dysfunction of Leydig cells with a deficiency in sperm maturation and spermatogenesis (53). Similarly, over a ten-week period incense burning activates a secretory deficiency in Leydig and Sertoli cells with resultant impairment of epidymal sperm maturation and consequential diminished capacity of spermatozoa to penetrate oocytes (54). Furthermore, a deregulation of the oxidative pathway is believed to cause a derangement in testicular histology and sperm viability in Wistar rats exposed to rhodinol-based incense (23). Additionally, a histomorphometric and spermatogenic evaluation of musk-based incense induced testiculotoxicity in adult albino rats with concomitant decrease in sperm viability, testicular atrophy, germinal aplasia, hypospermatozoa formation and damage to the basal seminiferous epithelial tissue (23).

c) Lung

The continuous exposure to incense smoke initially causes physiological and cellular changes that directly affect the efficiency of respiratory organs especially the lung (55). Exposure to incense smoke correlates with moderate inflammation and lymphocyte infiltration in lungs of albino rats (56), while other studies have recorded pathology such as lung carcinoma (57). Alarifi et al., (2004b) reported ultra-structural changes of the alveolar pneumocytes of animals exposed to *tobakhour*-based incense (21). These changes affect the cell organelles and surfactant material of type II cells. Similarly, Alokail et al., (2004) showed that *bakhour* burning adversely affects respiratory health. Moreover, light microscopy evaluation of lung tissue revealed focal emphysema, rupture of alveolar walls, hemorrhage, congestion, edema and peri-bronchial lymphoid cells (36). In addition, chronic exposure elicits focal necrosis and degradation of epithelial bronchioles together with fibrosis of peribronchial tubes, thickening of alveolar walls and aggregation of lymphoid cells (58).

d) Liver

Using an animal model exposed to Arabian incense smoke a significant decrease in anti-oxidant enzyme activity with concomitant significant elevation in lipid peroxidation; MDA was noted, signifying its hepatotoxic effects (35). The impact of long-term exposure to incense induces the expression of CYP1A1, CYP1A2, and CYP1B1 mRNAs within the lung and liver (36). Incense smoke exposure also increases MDA, TNF-α and IL-4 levels with a concurrent reduction of glutathione thereby reducing catalase activity within the liver (36).
e) Heart

Particulate matter generated during incense burning is responsible for variability in heart rate and impaired endothelial function (43). Importantly, regular exposure to incense is correlated with increased cardiovascular dysfunction (18). Moreover, ultrastructural changes, increased oxidative stress, inflammation, and altered cardiac hypertrophic gene expression was noted in cardiac muscle exposed to incense smoke (56).

f) Skin

Incense smoke exposure is also associated with dermatological problems since it may elevate IgE levels, and cause allergic contact dermatitis (4, 15). An early study observed itchy depigmented macules on the dorsum manus, left shoulder and the abdomen (59). The same research group also reported cases of contact dermatitis due to long-term exposure to musk ambrette vaporized from incense burning (33).

g) Brain

Indoor incense burning is associated with vascular disease to predispose poor cognitive performance related to decreased brain connectivity (60). An earlier report indicates that incense smoke contains various N-nitroso compounds, which are powerful nervous system carcinogens (61).

1. Figure 1. Conceptual pathway of how incense exposure mediates organ toxicity. Incense generates free radicals (ROS) which initiates lipid peroxidation through ATP energy depletion and reduction in natural body antioxidant such as GSH that triggers oxidative stress, inflammation and endothelial dysfunction resulting in organotoxicity. Moreover, lipid peroxidation is a process generated naturally in small amounts in the body mainly by the effect of several phagocytes. Since lipid peroxidation is a self-propagating chain reaction, the initial oxidation of only a few lipid molecules can lead to significant tissue damage. In addition, oxidative stress can trigger the infiltration of inflammatory mediator which in turn can leads to inflammation of affected tissues. Also, oxidative stress appears to be a key force driving endothelial dysfunction via destabilizing vascular homeostatic by down-regulating NO levels as well as up-regulating endothelin-1 in vascular tissue (developed from Mukhtar et al., 2013; Alokai et al., 2014; Akingbade et al., 2015, Hussain et al., 2016).

![Figure 1. Conceptual pathway of how incense exposure mediates organ toxicity](image)
Conclusions and Recommendation

Incense burning remains an environmental agent of important public health concern, hence it is necessary to understand the conceptual basis of its mode of action. The deleterious capacity of incense smoke induces physiological and cellular oxidative stress that emanates from ROS. Consequently, a decline in lipid peroxidation and GSH destabilizes vascular homeostasis thereby initiating inflammatory elevation of mediators such as MDA, TNF-α and IL-4 levels. Finally, there is an urgent need to create public awareness of the potential side effects of these common household and religious products. Awareness will lead to a reduction in exposure time and increase ventilation of homes and temples to ameliorate the pathological side effects of incense smoke.

Covid-19: The Effects of Distance Learning in Indonesia based on a Commognitive Perspective

Adika Setyo Budi Lestari¹, Toto Nusantara², Susiswo³, Tjang Daniel Chandra⁴, Nonik Indrawatiningsih⁵

¹Doctoral Student, Mathematics Education, Universitas Negeri Malang, East Java, Indonesia, ²Professor, Corresponding Author, Mathematics Education, Universitas Negeri Malang, East Java, Indonesia, ³Associate Professor, Mathematics Education, Universitas Negeri Malang, East Java, Indonesia, ⁴Assistant Professor, Mathematics, Universitas Negeri Malang, East Java, Indonesia, ⁵Lecturer, Department of Mathematics Education, Universitas PGRI Wiranegara Pasuruan, East Java, Indonesia

Abstract

Distance learning is a learning system that does not take place in one room and there is no face-to-face interaction between the teacher and the learner. This study aims to determine the impact of implementing distance learning in Indonesia from a commognitive point of view. This research is a descriptive type of research with a total of 543 participants who come from high school students in Pasuruan district, Indonesia. Data collection using a questionnaire. After the questionnaire is collected, it is analyzed using the Miles and Huberman method through reduction, display data, and conclusion, then it will be studied based on the commognitive theory. The results show that based on commognitive studies, students are more likely to still need a visual mediator as a visible object to be used as a communication medium, its realization depends on the material context. Students need to communicate to ask questions related to material that has not been understood. So it can be said that visual mediator is important during distance learning.

Keywords – Distance Learning, Visual Mediator, Commognitive.

Introduction

The learning process is a two-way interaction process that involves face-to-face communication between teachers and students in a class. However, with the Covid-19 pandemic since March 2020, the face-to-face learning process in schools has to be temporarily halted. This is due to preventing massive transmission of Covid-19. The Ministry of Education and Culture provides instructions for schools to organize distance learning (online) and advises students to study from their homes. This condition forces educators to innovate and try digital platforms that are widely available to support the learning process as a solution to implementing learning from home policies (¹). Like it or not, ready or not, all elements in the world of education must be able to carry out distance learning.

Distance learning is a learning system that does not take place in one room and there is no face-to-face interaction between teacher and learner(²). Various kinds of platforms can be used in distance learning, both in the form of learning management systems and in the form of video conferencing. Learning management systems that are widely used include, google classrooms and E-learning portals owned by schools or colleges(¹). Meanwhile, video conferencing applications that are widely used during distance learning include the zoom meeting application, Google Meet and Visco Webex. Apart from these applications, Whatsapp Group is also

Corresponding author:
Toto Nusantara
Professor, Mathematics Education, Universitas Negeri Malang, East Java, Indonesia
andikalestari123@gmail.com
an alternative in implementing distance learning\(^{(3)(4)}\).

To succeed distance learning requires cooperation from various parties, not only from the educators but also from the students and families. Distance learning is a new challenge for educators because so far learning has been done directly.

Even though educators use digital platforms, communication is the main factor needed during the learning process using online. In solving a problem, communication and cognition skills are needed. Communication skills and cognition are combined with the term commognitive \(^{(5)}\). Commognitive is a method of analyzing how students solve a problem \(^{(6)}\). Solving problems is one of the abilities that must be possessed by students.

Distance learning is one way to continue education during a pandemic\(^{(7)}\). Distance learning is still designed in such a way as to be able to train students in solving problems. Distance learning is a new thing that must be applied in Indonesia during the pandemic period, so it still needs improvement. It can be said that distance learning is a transition period from conventional learning to digital learning \(^{(8)(9)}\). To be able to determine the impact of distance learning can be done by analyzing it in terms of communication and cognitive. Commognitive is a communicative cognitive process related to what is being thought, as a combination of communication and cognitive which consists of four components, including word use, routine, visual mediator, and narrative\(^{(5)(10)}\). Routine is the tendency of choosing terms or choosing representations in the process of pouring out ideas to solve the problems or problems faced so that they can support the narrative. Visual Mediators are visible objects that are used as communication media, the manifestation depends on the material context. Word use is the use of words that can reflect or represent the situation at hand. A narrative is a series of sentences that describe objects, relationships, and processes, such as definitions, theorems, and proofs.

Distance learning is closely related to the four commognitive components. The main question in this research is how is the impact of implementing distance learning based on a commognitive point of view?

**Research Methodology**

This research is qualitative research with a descriptive design conducted to determine the impact of the application of distance learning in Indonesia according to a commognitive view.

**Participant**

The population in this study were all junior high school students in Pasuruan Regency. The sample of this study was 543 students who came from junior high schools in Pasuruan district and had an average age of 13-15 years. The sample collection technique used is random sample sampling, which means that each member of the population has the same opportunity and opportunity to become a research sample.

**Procedure**

The procedure in this study is as follows: 543 junior high school students were given a questionnaire. The questionnaire was used to obtain preliminary data on the assessment of the application of distance learning carried out in Indonesia during the Covid 19 Pandemic, then after knowing the initial data, it will be studied about the impact of distance learning from a commognitive point of view. The questionnaire consisted of two parts, the first part related to the impact when implementing distance learning which consisted of 1 question with 5 answer choices. The second part deals with the impact after implementing distance learning which consists of 1 question with 3 answer choices.

The questionnaire instrument given to students is as follows:

1. What do you find burdensome in online learning? (choose only one answer that you think is the most burdensome).

   a. Duration online
   
   b. Pulse costs
2. After you have participated in online/online distance learning for almost 2 weeks, how do you feel?
   a. Troubled or restless
   b. Happy
   c. Ordinary
   d. Too many tasks
   e. Others

Data collection technique
The data collection technique was done by filling out a questionnaire online. The data obtained from the questionnaire were then analyzed using the Miles and Huberman concept through reduction, display data, and a conclusion.

Result and Discussion
Based on initial data obtained from a questionnaire distributed to 543 junior high school students, data is obtained in Table 1 and Table 2 below.

<table>
<thead>
<tr>
<th>Table 1. Student Response when Application of Distance Learning</th>

</table>

Table 1 above shows that when implementing distance learning (online), students still find it difficult to learn the subject matter provided by the teacher through online learning with a percentage of 37%. The second place is students objecting because students get more assignments when using online learning with a percentage of 36%. The third-place students objected because the credit was expensive with a percentage of 20%. The fourth place is that students answer other questions with a percentage of 5%. The fifth place is students objecting because the time is too long when using distance learning (online) with a percentage of 2%. The percentage is presented in Figure 1 below.
Based on the results in table 1, it shows that students, in terms of material content, still have difficulty understanding the material. This is because it is not common to learn online. Teachers as teachers and educators are also still not used to presenting material online. As a result, the material presented is not optimal for students because the ability to master technology is still not maximally mastered by the teacher. Learning is felt to be still not effective because of several influencing factors, including a lack of parental supervision\(^{(11)}\).

</tbody>
</table>
The percentage can be presented in Figure 2 below.

![Figure 2. Student Response after Application of Distance Learning](image)

Table 2 above shows that after implementing distance learning (online), students enjoy learning through distance learning with a percentage of 40%. Furthermore, students feel difficulty with distance learning with a percentage of 26%. Then students act normal if distance learning is applied with a percentage of 34%. The impact of distance learning is felt by students in various kinds of responses obtained from students, including boredom, mediocrity, frustration, and anxiety\(^\text{(12)}\). Based on table 1 distance learning most students feel happy, but also not a few students feel normal. Several factors affect, including because distance learning is a new thing for students, students learning online using cellphones feel freer to use cellphones than usual days.

Based on Table 1 and Table 2 above, if it is associated with the four commognitive components, namely word use, routine, visual mediator, and narrative. Students are more likely to still need a visual mediator as a visible object to be used as a communication medium, its realization depends on the material context\(^\text{(10)(13)}\). Students need to communicate to ask questions related to material that has not been understood. So it can be said that visual mediators are important during online learning. This is following the opinion of Sfard and Kieran\(^\text{(14)}\) that defines communication as effective when differences in the speech from the interlocutor generate responses that are in line with the speaker’s metadiscursive expectations\(^\text{(15)}\). Besides, communication will be more effective if students discuss in small groups to solve problems\(^\text{(16)(17)(18)}\). So it can be concluded that the use of words and visual mediators is very important in learning mathematics in distance learning.

Visual mediators are objects that are acted upon as part of the communication. Whereas everyday discourse
is mediated mainly by pictures of concrete objects that exist independently of a particular discourse, in mathematics most symbols and other mediators are created primarily for communication purposes. Visual mediators in mathematics learning include algebraic symbols that mediate ideas such as numbers and written graphics, or other symbols such as those representing variables, coefficients, and equations\(^\text{(19)}\). The mediator used in communication often influences what can be said about the ideas being discussed. To illustrate, while solving equations in algebra, students often use graphs as visual mediators. Also, a visual mediator is a means used by the participants as a discourse to identify the object of their conversation and coordinate their communication. Mathematical discourse often involves symbolics that is used as a form of certain communication\(^\text{(20)(21)}\). For students to be able to receive and understand the material presented by the teacher in the online learning process, creativity, and special skills from the teacher are needed to present the material.

In the learning process, both direct learning and using online media, communication is needed in providing an understanding of the material to students. Communication takes a broader view and also considers non-verbal aspects such as visual mediators\(^\text{(22)(23)}\). Commognitive with visual mediators focuses on cognitive frameworks about making routines explicit, supported narratives, words, and visual mediators such as lectures\(^\text{(24)}\). Meanwhile, commognition is a socio-cultural approach that aims to provide an understanding of what is learned during the learning process.

However, the problem with distance learning is that some teachers are still not tech-savvy, making online learning a new thing for most teachers in Indonesia. Resources, and the limitations of educational technology, as well as the skills and quality of the teachers, are not sufficient\(^\text{(1)(25)}\). Learning in schools is carried out by WA, zooming, and often by giving assignments, learning in the form of videos downloaded on YouTube. Whereas distance-learning studies according to a commognitive view state that students are more likely to still need a visual mediator as a visible object to be used as a communication medium, its realization depends on the material context. Students need to communicate to ask questions related to material that has not been understood. So it can be said that visual mediators are important during online learning.

Some of the recommendations suggested based on the results of this study are to carry out proper schedule control to guide students learning step by step and increase their understanding of the material that has been studied, motivate students to interact via digital platforms so that students can clearly express the problems they have faced, and The use of visual mediators is still applied so that students can improve their understanding.

Age Estimation by the Morphometric Analysis of Sternal End of Fourth Rib

Aditi Bhatnagar¹, Nirupma Gupta², Rachna Rohatgi¹
¹Assistant Professor, ²Professor & Head, Department of Anatomy, SMS&R, Sharda University, Greater Noida, U.P.

Abstract

Estimating the age at death in the adult skeleton is problematic owing to the biological variability in age indicators and the differential skeletal response to environmental factors over an individual’s life. While the pubic symphysis and intracortical morphometry have provided successful results in estimating age at death, other methods and sites in the skeleton are needed to improve the accuracy of age estimation. Present study is an attempt to develop a new method for estimation of age from sternal end of fourth rib. Currently there are different parameters available to determine the age of a person like study of teeth, ossification of bones and other ancillary data, but the accurate reliability of these measures is only limited to a particular age group i.e. 25± 5 years. For the age beyond this, many workers in different parts of the world have done their studies to accurately determine the age of a person from the skeleton. A random study of 100 cases for age estimation from sternal ends of the fourth ribs were carried out to estimate the age after death with minimal error.

Keywords: Fourth rib, Age estimation, Morphometric analysis.

Introduction

Identification of any individual is the first step for assessing the dead body, as in the cases of sudden or unexpected death or in any unclaimed bodies.

The Identity of a person is done by using various parameters as Sex, Age, Stature, Genetic constituents, etc. Age is an extremely vital parameter in the personal identity of living subjects as well as skeletonized dead bodies.(1)

Age estimation of unknown skeletal remains is very important in medico-legal practice. The procedures for age determination are complex and involve the consideration of many factors. Changes related to chronological age are seen in both hard and soft tissue. Amongst the hard tissues, bones are important as they undergo a series of changes from prenatal to postnatal life and changes in their composition and structure continue into old age and even after death. Hence, bones form a reliable source of information regarding growth and growth changes.

Morphologic methods are fast and easy to use for purpose of age determination. The sternal ends of the ribs are a reliable method of age estimation from late adolescence to old age.

Metamorphosis at the sternal extremity of the rib has already been established as a reliable indicator of age at death. It was shown that an accurate estimation of age can be made by direct examination of the bone itself.(2)

Therefore we have used the sternal end of the 4th ribs to determine the age of the Individual. The sternal
end of the rib is chosen because it has been shown from earlier study by Iscan et al\(^{(2,3,4)}\) to be a perfect bone to show the advancement of age and the age can also be estimated by this method if the partial skeleton is found.

This study aimed to develop regression formulae for estimating age at death using a macroscopic feature of bone.

**Materials and Method**

The present study was conducted in the Department of Anatomy, S. P.M.C, Bikaner & SMS&R, Sharda University, Greater Noida on 100 samples of 4th rib taken from dead bodies brought for postmortem examination. Its particulars were recorded and age was noted and it was cross-checked from relatives by authentic ID proof. The research work was approved by the ethical committee. Before taking the sample from the deceased the consent form was filled & signed by the kin of the deceased.

The specimens were separated from the body by cutting the fourth rib at two points i.e. three centimeters inner to and five centimeters outer to costochondral junction using a rib cutter without damaging the costochondral junction.

Macroscopic measurement had been taken after the extraction of bone. All of the measurements were taken with a sliding caliper calibrated to the nearest 0.1mm. The following measurements were used to determine age:

1. **Maximum Superior Inferior Height (SIH)**: the maximum distance between the most superior and inferior points at the end of the rib
2. **Maximum Anterior-Posterior Width (APW)**: the maximum distance between the most anterior and posterior points at the end of the bone
3. **Maximum Pit Depth (PD)**: the maximum depth of the pit was measured with a depth caliper keeping the caliper perpendicular to the base of the pit.

All the readings were taken thrice and an average of the three readings was taken for better accuracy. After calculating the above measurements the linear regression analysis was applied.

**Observations & Results**

In present study total 100 cases were examined. Out of 100 cases males constituted 67 while females constituted 33 of the samples.

**Table 1: Age distribution of study sample (N = number of individuals)**

The age of all sample ranged between 15 and 62 years with a mean age of 32.73 years. The age range for males was between 15 to 60 years (mean age=34.38 years), while the females range was between 18 to 62 years (mean age=29.36 years).

For Age determination following parameters had been studied. Their descriptive statistics also calculated. (Table 2).

<td>0.74</td>
</tr>
</tbody>
</table>

For the calculated data for linear regression analysis SPSS 21.0 software has been used. Simple linear regression analysis was done. Data was charted in order to identify possible outliers. Regression analysis was undertaken in order to evaluate apparent trends for each of the three variables examined with actual age. For each variable the regression equation also has been derived after statistical analysis of data.

**Table 3:** Comparison between r value, r square, Standard error of estimate (SEE), t-value and significance level.

<td>0.493</td>
<td>0.243</td>
<td>11.037</td>
<td>5.608</td>
<td>0.0001</td>
</tr>
</tbody>
</table>

According to the Table 3, the simple linear regression analysis that is best related to age for this pooled sexes sample is the Maximum Pit Depth (PD). The coefficient of determination ($r^2$) for this formula is 0.243 and the standard error of the estimate is ±11.03 years.

**Table 4:** Simple linear regression Equation (single variable only)

<table>
<thead>
<tr>
<th>S. No.</th>
<th>Variable</th>
<th>Regression Equation</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SIH</td>
<td>Age Predicted = 12.046 + 14.898 (SIH)</td>
</tr>
<tr>
<td>2</td>
<td>APW</td>
<td>Age Predicted = 13.594 + 42.688 (APB)</td>
</tr>
<tr>
<td>3</td>
<td>PD</td>
<td>Age Predicted = 17.43 + 84.222 (PD)</td>
</tr>
</tbody>
</table>
From Analysis it is cleared that Maximum Superior-Inferior Height, Maximum Antero-Posterior Width and Maximum Pit Depth are all reliable factors. This indicates that these variables are easy to score and thus prove useful in age estimation techniques.

For better result Multivariate linear regression analysis has been done with same variables. In the multivariate analysis, the change in the coefficient of determination was noticed in comparison with the univariate analysis, with a slight improvement in the SEE.

</tr>
</tbody>
</table>

Morphometric Study: Measuring SIH (Image 1) and APW (Image 2).

The highest coefficient of determination was 0.562. The best standard error of the estimate for the multivariate analysis was ± 10.603 years (Table 5). This indicates that there is a slight improvement in the standard error of the estimate and also improvement seen when the coefficient of determination is taken into account.

The question that remains is whether it is more practical to use the complex multiple regression formulae or the simpler, and less tedious linear regression formulae to estimate age at death.

Discussion

There are various methods and various bones were examined for estimation of age but very few methods are based upon morphometric or morphological analysis of bone. Morphometric Analysis are easy, Feasible and result can be achieved very fast.

In the present study morphometric analysis of Fourth rib has been done on 100 study sample and regression
equation for age prediction was derived. More of the previous studies on sternal end of fourth rib for age estimation are mainly based on histological, osteometric analysis and radiological techniques but morphometric analysis based studies are very less.

Results of the present study showed that the age of a subject can be estimated from metamorphic changes in the sterna end of 4th ribs in all the age groups, as the t-values computed in all the cases were found to be significant.

Iscan et al (3, 4) concluded that age at death can be estimated from a rib within about 2 years in 2nd decade to about 7 years in the 5th and 6th decades of life and Singh et al (5) revealed that age can be estimated from sternal end of 4th rib with an accuracy ranging between ±2 years up to 3rd decade and about ±8 years in the older age which is slightly invariance with our study. Pankaj Gupta et al (6) concluded that in the age group 17-30 years, age can be estimated from sternal end of 4th rib with an accuracy ranging between ±8 years, in the second age group 31 to 44 years ±15 years and in the third age group 45 years and above again ±8 years.

However, from the present study, for the sexes pooled and in all age group we could analyze that PD is most reliable among all factors and for this SEE is 11.037 years. for the better result in present study we had done the multivariate regression analysis and result showed SEE is 10.603 years.

So still in the field of Forensic Medicine, we remain handicapped to exactly pinpoint the accurate age from one single factor, as metamorphic changes in the sternal end of the 4th rib alone are not sufficient to assess the accurate age of a subject.

Conclusion

Positive identification involves matching of an “unknown” individual to a “known” individual. The identification of skeletal and other decomposed human remains is very important for legal and humanitarian reasons.

Most research on estimating age-at-death using human skeleton material suggested that degenerative processes are good indicators for age estimates. However, these processes can vary among populations, depending upon factors such as biological affinity and relate to growth and development.

The objective of this research was to estimate the age by using the sternal end of the fourth rib. We selected specimens of known age and sex. It was possible to observe the relationship between morphological changes and known age. For the fourth rib the morphometric features included in this study were SIH, APW and PD had a significant relationships with age.

The results of the analysis suggest that we can estimate age at death but for more precise and accurate results one must include we are also of the opinion that unifactorial parameter to assess the age from the sternal end of the ribs for practical purposes is not completely accurate. So multifactorial parameteric/ comprehensive approach should be the hallmark for arriving to conclusion as regard to the age of the subject.

We hope that these results will promote the evaluation of methods for estimation of age-at-death and a more critical consideration of factors that influence human variation.

Acknowledgement: We would like to thank Department of Anatomy, SMS&R, Sharda University for providing support throughout the research. We would like to thank Mr. Neeraj Pal Singh, Biostatistician, SMS&R for helping in statistics work. We would like to extend our sincere thanks to Dr. Pooja Rastogi (Associate dean, SMS&R.) for valuable advice and suggestions. We Sincerely thanks & are very grateful to Dr. Manisha Jindal (Dean, SMS&R, Sharda University) who assisted immeasurably with her feedback and support.

Isolation and Identification of *Streptococcus pyogenes* from Patients and Objects in Hospital Environment in Thi-Qar City in Iraq

AdyanNafee Abbas¹, Qasim Hassan Wida²

¹Research Scholar, Corresponding Author, College of Science, University of Thi-Qar, Iraq, ²Professor, Biology Department, College of Nursing, University of Thi-Qar, Iraq

**Abstract**

This study aimed to screen *Streptococcus pyogenes* in the hospital and investigate the incidence of this bacteria. The genotypes of the *S. pyogenes* in the study samples will be determined using 16Sr RNA and some virulence factors (*emm, scpA, speA* genes). The majority of the samples (74.1%) were isolated from patients at the emergency room and (25.9%) were from hospital environment (objects). The current study showed that the total of 215 patients with pharyngitis were included 118 (55%) males higher than 97 (45%) females. The patients’ ages ranged from 2 to 62 years, which were divided into four categories. The majority of patients 65 (30.1%) of patients from 3 to 6 years old, 54 (25%) of patients less than 3 years, 51 (23.6%) from 7 to 11 years old, and 46 (21.3%) more than 12 years. Six isolates sent for sequencing were after that submission in NCBI-GenBank database. The results of nucleotide sequence alignment of the isolates revealed that there are multiple point mutations, four of them appeared as a single nucleotide polymorphism (SNP) and two appeared in duplicate. Polymorphic sites (Mutations) of 6 *S. pyogenes* isolates.

**Keywords**: GAS, 16S rRNA, Pharyngitis, *Streptococcus pyogenes*

**Introduction**

(Group A Streptococcus (GAS) is a gram-positive bacterium that grows in pairs or chains and causes complete, or B -hemolysis when cultured on sheep blood agar (1). *Streptococcus pyogenes* is an important extracellular species of gram-positive, spherical and non-spore species, *S. pyogenes* is a facultative anaerobic bacterium, which is present in chain form. This bacterium is a conditional and opportunistic pathogen, which is always in search for suitable environment to cause a disease, this bacterium built colonies in the skin or throat and causes a wide range of complexes (2,3). The most common site of GAS infection is the oropharynx, and this presence is usually considered a prerequisite for the development of rheumatic fever, the leading cause of preventable childhood heart disease in the developing world, while GAS is mainly an extracellular pathogen, data over the past decade have shown that the organism can invade epithelial cells and live within them, GAS proliferation in the oropharynx triggers the signs and symptoms of pharyngitis (4). A number of virulence factors that contribute to the infectious process are created by GAS. One of the major virulence factors is the M protein, encoded by the *emm* gene, which promotes evasion of phagocytic killing (5). In *S. pyogenes* pathogenicity M protein shows its effect by facilitating adhesion, providing opsonophagocytosis resistance and contributing to the overall burden of GAS infections (6). Up to 11 different secreted superantigens can be produced by the human pathogen *Streptococcus pyogenes* that contribute to the features of cytokine-induced toxic shock.

E-Mail : adianalrekabyaa@gmail.com
during lethal, invasive infections such as necrotizing fasciitis. However, invasive diseases, manifested as pharyngitis, tonsillitis and childhood exanthem scarlet fever, are rare compared with symptomatic non-invasive disease that occurs in the nasopharynx, indeed, the throat and tonsils constitute the largest source of *S. pyogenes* in human populations carriage (7).

**Materials and Methods**

(Two hundred and ninety samples collected from hospital environment (75) and throat of patients(215) suffering from acute pharyngo-tonsillitis based on the symptoms and which the diagnosis by physicians with age range from 2 years to 60 years. The samples were collected in AL-Nassiriyah City. Selected samples were labeled and cultivated on blood agar and azide blood agar for 24 hours or 48 hours for better growth at 37°C in incubator. Any *S. pyogenes* suspected from samples make subculture on blood agar. Depending on morphological features of the B-haemolytic colonies and microscopically examination with gram’ stain, the pure cultures were prepared for biochemical tests and API-20 Strep to distinguish *S. pyogenes*. Polymerase Chain Reaction technique used for the amplification of specific genes belonging to *streptococcus* that is suspected to be present in both human pus. PCR products for 16S rRNA were sequenced by Macrogen Company (South Korea). The samples were sent through Iraq biotechnology and according to the requirements of the company including 15μl for each forward and reverse the PCR products and 50 μl (10pmoles/μl) for each forward and reverse prime. Each samples was labeled with a number and name identical to the number that sent to company and samples were sent in a cool box containing cool gel pack.

**Results**

(The total number of patients (215) who have symptoms were included 118 (55%) males and 97 (45%) females, where it was significant difference between them depending on frequency of different ages in males and females. The age ranged from 2 to 62 years old in a total 215 patients. The typical appearance of *S. pyogenes* colonies is dome – shaped with a smooth or moist surface and clear margins on blood agar after 24 hours of incubation at 37°C, and the most important feature is the hemolysis zone around the colonies. They display a white –greyish colour and have diameter of > 0.5 mm as shown in figure (1-A). Out of 61 beta haemolytic *Streptococci* isolates tested, 30 (49.2%) were bacitracin sensitive, the appearance of *Streptococcus pyogenes* produces inhibition zone around the disc on the blood agar, following 24 h of incubation under anaerobic conditions as shown in figure (1-B).

![Figure (1): (A) : Hemolysis of *S. pyogenes* ; (B): Bacitracin disc test →](image-url)
A total of twenty five isolates of *S.pyogenes* which identified by conventional methods such as; morphology of colonies, microscopic examination, biochemical tests and API 20 strep. Were subjected to DNA extraction and PCR assay for presence of *16S rRNA* gene. The results demonstrated that 25 (83.3%) of the isolates had *16SrRNA* gene with band 1500pb, as in figure (2). Twenty four isolates gave positive for each *emm* gene, *speA, scpA* gene as shown in figure (3), (4) and (5).

Figure (2): Conventional PCR for detection of *16S rRNA* gene (bp), in *Streptococcus pyogenes* isolates.

Figure (3): Conventional PCR for detection of (*emm*) gene.

Figure (4): Conventional PCR for detection of (*speA*) gene.
The results of nucleotide sequence alignment of the isolates revealed that there are multiple point mutations, four of them appeared as a single nucleotide polymorphism (SNP) and two appeared in duplicate, where a substitution of the nucleotide G instead of A occurred at site 262 as shown in, and AIX of G at site 849 of the sample gene segment with MW0425850 Accession number, also the nucleotide G was replaced by the A at site 363 of the links with MW0425846, there are double mutations that occurred at site 199 and 200 of sample MW0425847 where the nucleotides are CC instead of TT, and the same mutation was seen at site.

**Discussion**

*S. pyogenes* has remained a significant human pathogen for centuries, it causes a wide variety of infections in humans, which vary from mild upper respiratory and skin infections to non-suppuratives sequelae like Acute Rheumatic Fever and Rheumatic Heart Disease. The majority of patients were range (2-63 years) these results are similar to a study reported by (9), and also similar to another study reported by (10). The Samples were from (97) females (45%) and (118) males (55%), the males were predominant more than female, these results are agreement with results of study conducted by (11-13) and disagree with studies showed by (14,15), as shown in these result there is no big difference in the sex of patients. The results of the present study displayed that the occurrence of *S. pyogenes* was 25/290 isolates (6.8%), and this result disagree with a study in Thi-qar revealed by (16) who documented a high emergence of isolates from patients with tonsillitis, but similar to a study revealed by (17). Nosocomial transmission of GAS infection into patients in the hospital environment has been described in the medical literature, the range of transmission has been limited to small numbers of health care workers (18). The current study revealed that is no presence of *Streptococcus spp.* especially *S. pyogenes* and this result disagree with a study reported by (19) who showed that the rate of Streptococcus species is (2.75) and a high rate of *Staphylococcus aureus* (41.28). The results appeared 25 of the isolates were positive for 16S rRNA and 24 were positive for emm gene, these results are similar to a study reported by (6), who showed a similar DNA sequences of the 16S rRNA gene region of GAS isolates. The isolates appeared genetically close according to their sequence in the tree, as they are different in terms of the common ancestor, so we see them in the tree in the form singleton. Two isolates appeared in common with the ancestor, due to the presence of a high genetic similarity that appeared between them. In general, the isolates of the study were performed in the tree by their participation with one of the common ancestors, but it confirms the genetic changes that occurred in the isolates of the study, where a genetic bond was found with the isolates taken from the database NCBI. Phylogenetic tree analysis based on the partial 16S ribosomal RNA gene sequence that used for confirmative detection.
of *Streptococcus pyogenes* isolates, the analysis involved 6 nucleotide sequences, include (MW425845, MW425846, MW425847, MW425848, MW425849, MW425850). The resulting sequence were compared with worldwide reference sequence through NCBI BLAST, showed there is closely identical relationship between them (CP043530.1, CP049800.1, CP049799.1, CP047120.1, CP036531.1, CP031635.1) which were an isolates from USA (NCBI base). Sequence were aligned and edited using blast aligner.

**Conclusions**

High genetic variations were detected in *S.pyogenes* isolates. These genetics variations may make *S.pyogenes* more virulent and resistant to antibiotics.

Management of Pyogenic Granuloma (Clinicopathological Study)

Afrah A. Kh. Aldelaimi¹, Tahrir N. Aldelaimi²

¹Senior Lecturer, Oral & Maxillofacial Pathologist, Department of Oral Diagnosis, College of Dentistry, ²Professor & Consultant, Department of Oral & Maxillofacial Surgery, College of Dentistry, University of Anbar, Ramadi Teaching Hospital, Ramadi City, Anbar Province, Iraq

Abstract

Background: Pyogenic granuloma is a common oral cavity reactive lesion of. Injuries, calculus and hormonal changes are the common causative factors. It is often arises in the second decade of life as exophytic smooth lesion, mostly bleeds on simple probing. The study aimed to evaluate clinicopathological findings of pyogenic granuloma.

Materials: A total of 54 patients (including 40 male and 14 female) have been enrolled in this study subjected to surgical excision of pyogenic granuloma by diode laser 940nm. All the specimens were undergo a standard tissue processing procedure subsequently the paraffin embedded blocks were sliced in 5µm thickness into a clean glass slide and prepared to H & E staining and all slides were examined using light microspore. All cases in this study undergone surgical excision of pyogenic granuloma aged from 8 to 53 years (mean= 27 years) with the peak incidence of occurrence (44.5 %) in the (11-20 years) age group.

Conclusions: Pyogenic granulomas were most prevalent in male (74%) than female (26%). Oral pyogenic granuloma is a very common oral cavity occurring reactive lesion, mostly painless benign growth. Surgical excision with removal of etiological causes is the major treatment.

Keywords: pyogenic granuloma, oral pathology, oral lesion, oral tumors, benign tumors

Introduction

Pyogenic granulomas are common benign, non-neoplastic, localized, soft tissue lesions that misnomer as they neither represent a true granuloma nor infection with pyogenic micro-organisms¹. Anyhow, pyogenic granuloma has been retained in the literature since coined by Hartzell in 1904 because of its historic significance²,³. In pathological sciences pyogenic granulomas are known as granuloma gravidarum, granulation tissue-type haemangioma, lobular capillary haemangioma, eruptive haemangioma, or pregnancy tumor⁴,⁵. Pyogenic granulomas occur anywhere in oral cavity, head and neck region, trunk and extremities⁶. Scientifically many monographs proposed that low-grad injury from physical trauma or infection or chronic irritation from retained roots and/or dental calculus was the principle etiological factor in evolution of pyogenic granulomas⁷,⁸,⁹. Indeed, other studies offering certain drugs such as cyclosporine and hormonal alterations during puberty or pregnancy as causative factors in the development of the lesions¹⁰. Although numerous lesions resemble clinically with pyogenic granuloma arising in the oral
cavity but a detailed history reinforced with proper treatment plan and careful histopathological examination will be useful to accurately identifies the lesion 11. Pyogenic granuloma extirpation is correct treatment of choice, plenty alternative therapy such as lectrosurgery, sclerotherapy, cryosurgery, corticosteroid or ethanol injection and laser therapy have been declared to be effective 10,12. The abundant vascular nature of pyogenic granulomas required careful excision to avoid profuse bleeding. The excision by laser offer great advantage than conventional surgical excision in controlling bleeding through the surgical procedure 11,12. Pyogenic granuloma has an extremely increased recurrence rate with simple surgical ablation 13. Perfect treatment of pyogenic granuloma required correct removal of whole lesion to prevent its recurrence 12. The study aimed to evaluate clinicopathological findings of pyogenic granuloma in Iraq

Materials and Methods

A total of 54 patients (14 female and 40 male) have been enrolled in this study subjected to surgical excision of pyogenic granuloma in Ramadi Teaching Hospital, Razi Private Hospital and Private Dental Clinic in the Province of Anbar. This study was approved by Department of Scientific Affairs at College of Dentistry and was approved by Ethical Approval Committee at University of Anbar under Ref no. (6) On 24th of January, 2021. The patient consent form was obtained prior to surgery and the detailing of laser procedure was elucidated to the patients. Demographical information including patient`s name, age, sex, medical condition, past dental history and clinical examination of the features of the lesion (site, size, duration, color, texture of the lesion) were recorded and analyzed. The treatment plan included oral prophylaxis by preoperative intraoral antisepsis with Listerine mouth wash for about 30 seconds and safety goggles were worn for patients and surgical teams as eyes should be safeguarded. The lesions were excised completely as one piece by Diode laser 940 nm applies 1.4W Power, 100 milliseconds pulse duration with fiber optic delivery system. All patients had undergone the same surgical technique that achieved under local anesthesia (2.2 ml cartridge containing 2% lidocaine with epinephrine 1:80.000).

The lesions were cut carefully by moving the laser fiber tip in a sweeping motion on the surgical site to accomplish coagulation and prevent bleeding. The wounds were left without suturing for healing with secondary intention (Figure 1&2). Thereafter, 10% formaldehyde solution was utilized to preserve the specimens for histopathological investigation.

All the specimens were undergo a standard tissue processing procedure subsequently the paraffin embedded blocks were sliced in 5µm thickness into a clean glass slide and prepared to H & E staining and all slides were examined using light microspore. Cephalexin (250mg -500mg ) and paracetamol (500mg) as analgesic ( if necessary) were given to the patients postoperatively; the dose was determined according to the age and weight of each patient, each patient was motivated to enhance their oral hygiene practice by Listerine mouthwash with softly brushing, mushy food were recommended and all cases were followed up for about 3 days then after 1-2 weeks to assess the healing process and keep follow up for 6 months to reveal any possibilities of recurrence. For the study, all patients were requested to revealed opinion and complete the questionnaire chart and digital photos for documentation.

Results

A total of 54 patients (14 female & 40 male) have been enrolled in this study undergone surgical excision of pyogenic granuloma aged from 8 to 53 years old (mean age= 27 years) with the peak incidence of occurrence ( 44.5 % ) in the (11-20 years) age group. Pyogenic granulomas were most occur in male (74%) than female (26%), the male : female ratio was 3:1 .(Table 1)

Regarding site of the lesions, upper gingiva was the most frequently involved in 18 cases (34%) followed by lower gingiva in 14 cases (26%), tongue and buccal mucosa were equally involved in 6 cases (11%) while palate and lower lip were equally involved in 4 cases (7%) whereas the least occurrence site was upper lip in 2
cases (4%). In general the lesions manifested as smooth, painless masses, pedunculated or sessile, red to reddish-purple in color depending on duration of the lesion that often bleed easily because of vascular intensity. Most of the collected cases had intact surface 42 cases (78%) and ulcer was present in 12 cases (22%) and varied in size from 5mm - 3cm. (Table 2)

Histopathological examination reveals highly vascular proliferation tissues admixed with numerous blood vessels enriched with red blood cells, non-lobular pattern was seen in 48 (89%) while lobular pattern seen in 6 (11% ), diffuse inflammatory cells infiltrate found in both pictures. The intervening fibrous stroma is infiltrated with inflammatory cells and large collagenous bands seen in aged lesions. The surfaces were mostly non-ulcerated stratified squamous epithelium with hyperplasia and ulcerated surfaces were coated with fibrinoid necrosis (Fig. 3&4). Diode laser application given optimum integration of hemostasis and clean tissues cutting. The patients were satisfied and comfortable with the procedures. The wounds were completely healed within 10-14 days after surgery and no post-operative complications were observed.

Figure 4 (40X) Histopathological View
Discussion

Oral pyogenic granuloma can be evolved in any decades of human life. The current study revealed that the second decade was the most affected age group (45%)\(^{13,14,15}\). Although most of the researchers reported that females were highly affected by oral pyogenic granuloma in relation to males but our finding on the contrary, the male:female ratio was 3:1 and this difference was attributed to diversity in sample collection and nomadic factor associated with neglecting oral hygiene that resulting to calculus accumulation, trauma and oral tissues deterioration by promoting gingival inflammation\(^{14,16,17,18}\). Our clinicopathological study declared that maxillary gingiva was commonly affected site\(^{1,13,14}\). Clinically, most of collected cases presented as mass\(^{10,16}\), where the surface of the lesion becomes ulcerated with pedunculated base. Short duration oral pyogenic granuloma much more easily bleed as a result of less collagen fibers as well as high vascularity; in contrast the older lesion have more collagen and less vasculature\(^{18,19}\).

It is important to mention the clinical presentation of oral pyogenic granuloma during pregnancy was similar to non-pregnant. The socioeconomic status and oral hygiene practice play an important role in the up growth of the lesion in this clinicopathological trial, as urban people less complaining from in comparison to rural residents. The size of the lesion of oral pyogenic granuloma in this clinicopathological study was ranged from (0.5 – 2.5) cm in diameter, the small lesions arise within (7–21) day; while the larger sized lesion need a much more time (4–6) month which give indication about the growth of oral pyogenic granuloma was grow slowly\(^{14,18,20}\). Simple surgical excision by diode laser 940nm bonded to the lesion base of the oral pyogenic granuloma including about (2 mm) of the surrounding health tissue and curettage deeply up to bare bone was applied by precised roots planning of the surrounded teeth to ensure causative agents removal i.e. retained roots, overhanging filling and calculus. Follow-up of treated patients is mandatory to ensure there were no chances for recurrence in operated cases. Recurrence was attributed to inadequate lesion removal as well as causative agents’ persistence\(^{14,15,16}\); and thus; (2 mm) of the surrounded normal health tissue was ablated to have good prognosis.

Etiology of oral pyogenic granuloma is still not very clear but it has been concluded that it is considered to be a reactive lesion to multiple low-degree irritation or stimuli i.e. aggressions, repeated trauma, hormonal factors or even certain drugs and there is increased incidence during pregnancy is attributed to raised levels of progesterone and estrogen\(^{1,3,6}\).

Histopathological examination of the ablated oral pyogenic granulomas showed infiltration of vascular granulation tissue by inflammatory cells and macrophages, i.e distinguished vascular growth suggesting angiogenesis of a strong performance that may develop at any age but are more frequently seen in adolescents and young adults as well as current study showed no radiographical sign of bone resorption linked to lesion growth\(^{2,5,6,9,11}\).

Oral pyogenic granuloma is a non-neoplastic tumor growth that affects oral tissues. It is considered as one of the most common type of hyperplasia in oral cavity. Histopathological examination of the ablated lesions were in harmonies with hyperplastic inflammatory lesions that have granulation tissue proliferation with inflammatory infiltrate with increases angiogenic capacity; for that, vascular neoformations of assorted diameter are normally raised which exhibit abrupt onset and completion within the tissue with no sign of bony resorption linked to the lesions\(^{9,10,19,20}\). The laser is a rapidly developing technology that become a much standard tool in removal of oral pathological lesion. Hence, it becomes important for the surgeon as well as the pathologist to acquire knowledge about its applications more effectively and efficiently\(^{17,22,23}\).

The Role of Silver Nanoparticles Against Amoxicillin/Clavulanate-Induced Liver Damage in the Female Rats

Afyaa Sabah Nasir1, Basheer Sadoon Taher2
1Assistant Professor, 2Research Scholar, University of Kufa, Faculty of Science, Department of Ecology

Abstract

The current study was designed to evaluate the protective effect of silver nanoparticles against toxicity induced by amoxicillin/clavulanate acid. Number of rats in the experiment are nine divided into three groups each group has three rats. The first group is kept as control group and administrated normal saline, the second is administered amoxicillin/clavulanate acid at dose 80 mg/kg and third group is administered amoxicillin/clavulanate acid at dose 80 mg/kg and silver nanoparticles at dose 50 mg/kg for 30 days. The results show significant increase (p<0.05) in the liver aminotransferase levels (AST, ALT and ALP), total protein and albumin in addition significant increase (p<0.05) in the lipid profile total cholesterol TC, triglyceride TG, low density lipoprotein LDL, very low density lipoprotein VLDL and significant decrease (p<0.05) in the high density lipoprotein HDL in compare with control group. In conclusion: silver nanoparticles has beneficial effect against side effects induced by amoxicillin/clavulanate acid in rats.

Keywords: Amoxicillin/Clavulanate acid, Silver Nanoparticles, Liver Damage

Introduction

Medication prompted liver injury is getting mainstream around the globe. Anti-microbials are known as one of the reasons for liver injury, because of its high openness rate (1, 2).

Amoxicillin/clavulanic corrosive (AC) is an oral Broad-range antibacterial compound composite of an anti-infection semi-manufactured penicillin (amoxicillin) and an inhibitor of β-lactamase (potassium clavulanate). It has been viably utilized for more than 20 years in the treatment of different bacterial contaminations (3).

Despite the fact that AC has gotten one of the anti-microbials most regularly recommended, the organization of the medication may be corresponded with cholestatic and hepatocellular liver injury, which seemed, by all accounts, to be essentially due to the clavulanate part (4). demonstrated to have amazing cell reinforcement properties of the decrease responsive oxygen species (ROS, for example, superoxide anions, hydrogen peroxide, hydroxyl revolutionaries and hypochlorous corrosive (5).

Nanomaterials (1–100 nm materials) have been drawing in much consideration in the previous few decades in numerous fields, for example, biomedicine, catalysis, energy stockpiling, and sensors, because of their special physicochemical properties when contrasted with their mass structures. Silver nanoparticles (AgNPs) have gotten extraordinary interest, particularly in biomedicine. AgNPs are popular for their wide range and exceptionally productive antimicrobial and anticancer exercises (6). Other natural exercises of AgNPs have been likewise investigated, including advancing bone recuperating and wound fix, improving the immunogenicity of immunizations, and hostile to diabetic impacts. Unraveling the organic components

and possible cytotoxicity of AgNPs will encourage their better clinical applications\textsuperscript{(7)}.

The current work was planned to assess the scavenging antioxidative bioactivities of silver nanoparticles on oxidative stress related injury of liver in experimental rats poisoned with amoxicillin/clavulanic acid.

**Materials & Methods**

Using nine female rats (Rattus norvegicus) weighting 200-250 gm were obtained from the animals house in the faculty of science/university of kufa. the animals were kept under standard environment condition for one week (temperature 25-28 C° and 12 hr light-dark cycle) and allowed access to standard laboratory diet and water for acclimation after the animals were divided into three groups each group contain three animals : group one received orally amoxicillin/clavulinac acid at dose 80 mg/kg, group two received orally amoxicillin/clavulinac acid at dose 80 mg/kg with silver nanoparticles at dose 50 mg/kg and the last group as control group received distal water and standard diet for one month. At the end of experiment. Each animal was anaesthetized by the mixture of xylazine 0.1 ml and ketamine 0.5 ml and they were scarified\textsuperscript{(8)}.

**Determination of lipid profile activity**

Total cholesterol kit for quantitative determination of total cholesterol in serum was supplied by Biolabo SA, France, Serum HDL (High Density Lipoproteins), Cholesterol level and Triglycerides Kit was supplied by Biolabo, France, Very low density lipoprotein (VLDL) were measured by using the following formula: VLDL = TG (mg/dl) / 5 , Low density lipoprotein (LDL) were measured by using the next formula: LDL=TC(mmol/l)-VLDL(mmol/l)-HDL(mmol/l).

**Determination of Serum Transaminase Activity Transaminases – Kits**

Alanine Transaminase (ALT)& Aspartate Transaminase (AST) activity were determine by colorimetric method according to the biolabo kit, france and ALP according to biomerieux kit

**Statistical Analysis**

Data were presented as means ± S.E. and statistically analyzed using (ANOVA) test followed by least significant difference (L.S.D.) analyses at 0.05% probability of levels. Using computerized SPSS program.

**The Results**

According to table (1), the current study showed a high significant decrease in the levels of liver enzymes (AST, ALT, ALP) in the group treated with amoxicillin 80 mg/kg + silver nano. 50 mg/kg. The present study also revealed that there was a significant decrease in serum albumin (g/dl) total protein (g/dl) bilirubin (g/dl) in the group treated with amoxicillin 80 mg/kg + silver nano. 50 mg/kg as shown in table (2). Regarding table (3), the current study showed a high significant decrease in the levels of lipid profile (TC, TG; HDL, LDL, VLDL) in the group treated with amoxicillin 80 mg/kg + silver nano. 50 mg/kg.

Discussion

Our information uncovered a critical upregulation in the degree of complete cholesterol also, fatty oils in amoxicillin/clavulanate corrosive gathering which are steady with the investigation (9). The raised levels may demonstrate an unsettling influence in fat digestion because of the peroxidation of films and adjustment of the cell structure because of harmfulness portion of amoxicillin/clavulanate corrosive just as overproduction of free revolutionaries (10). The aftereffects of our investigation are in amicability with the past reports that indicated an elevated level of absolute cholesterol, fatty substances, low thickness lipoprotein and low thickness lipoprotein after amoxicillin clavulanate treatment. Such change in the degrees of absolute cholesterol, fatty oils, low thickness lipoprotein and low thickness lipoprotein prompted shift in the film porousness (11).

The degrees of lipids profiles, that is, plasma all out cholesterol, HDL cholesterol, LDL-cholesterol and fatty substances were high in the treated gathering. Examinations on layer lipids demonstrated that cholesterol/phospholipids molar proportion combined with different boundaries are the main determinants of film ease. The outcome may recommend a reduction in film ease and could bring about adjusted layer work (12).
The current examination uncovered a huge rise (P<0.05) in serum cholesterol, Triglyceride, LDL, VLDL and critical lessening (p<0.05) in HDL level in female rodents controlled amoxicillin at portion 80 mg/kg when thought about a benchmark group.

These discoveries are in concurrence with that expressed by (13). A few investigations affirmed that an ascent in fat eating regimen utilization in creatures prompted hypercholesterolemia. Past investigation proposed that for dynamic appropriation and digestion of the lipids, the lipoprotein was most essential. the elevated cholesterol in the eating routine causes down guideline in LDL receptors. So that, this examination was described that the plasma LDL fixation raised in rodents. Accordingly, the ascents in LDL-C show more cholesterol in the blood that speaks to the danger of coronary illness(14).

Some new investigations clarified the reduction of HDL level after admission amoxicillin. This investigation affirmed that the HDL decreased because of the increase in HDL creation chiefly in the liver and halfway in the small digestive tract. HDL molecule is comprised generally from ApoAI and apoAII Apo lipoproteins, which was impacted by nourishing impedance. What’s more, HDL is normally named as “great cholesterol” since significant levels of (HDL) speak to an ascent in the vehicle of cholesterol from fat tissue to the liver, where it is adjusted (15). So that, this expansion in HDL diminishes the danger of cardiovascular sicknesses and hypertension (16).

These discoveries were in concurrence with the past investigations. Past examination recommended that in light of the fact that the capacity of amoxicillin to diminish of LDL, it was utilized as the primary pharmacological treatment of dyslipidemia (17).

The evaluation of liver harm by xenobiotics and drugs, which are passing and processed into poisonous intermediates in hepatic cells. The serum boundaries identified with liver capacities which have been concentrated in the current work uncovered that intense dosages of amoxicillin-clavulanate actuated critical expansion in the degree of AST, ALT, ALP, egg whites and absolute protein. Comparative discoveries were seen that amoxicillin-clavulanate corrosive organization prompted liver injury (18). AST, ALT and ALP are ordinarily situated in mitochondria, cytoplasm or microsomes of hepatic cells; their expanded serum levels may show a harm in the hepatic cells and thusly liver harm (19). The expanded serum level of such proteins may likewise be ascribed to changes in the cell layer penetrability and expanded/diminished catabolism of aminotransferases and it was accounted for in conditions including rot of hepatocytes (20). Also, the expansion in egg whites and all out protein saw in the current examination are not in assent with different discoveries that demonstrated decreased degrees of egg whites and aggregate protein instigated by amoxicillin-clavulanate harming (21).

Then again, our information concurred with those acquired by Agbafor and his team (22) when their trial creatures were given anti-microbials, for example, ofloxacin and ciprofloxacin. They ascribed the unaltered or raised egg whites and complete protein level to the liver which keeps its typical capacities inside the given portions of the anti-toxins. We concur with the previously mentioned creators that the exploratory portions of anti-toxin utilized were not sufficiently able to cause broad hepatocytes harm to down control the blend of proteins, along these lines keeping the protein levels as high as would be expected in solid liver.

Liver is a primary site of collection of AgNPs along with spleen (23). Park and his co-workers found that oral organization of 1mg/kg of AgNPs in mice prompted diminished degrees of AST and ALT in both male and female mice with increment of ALT in female mice just and didn't show histopathological changes in the liver (24). El Mahdy et al. exhibited histopathological changes in the liver after intraperitoneal organization of various portions of AgNPs (1000 and 4000 mg/kg) in pale skinned person rodents every day for 28 days (25). Then again Cho and his co-workers indicated that the intraperitoneal organization of little estimated AgNPs (10 nm) in mice prompted huge lessening in AST.
with a diminishing inclination in ALT. While Qin and his co-workers detailed that lone AST was essentially diminished in rodents after oral organization of a 0.5 and 1 mg/kg AgNPs every day for 28 days notwithstanding minor histological changes in the liver and kidneys. As opposed to our outcomes, Pourhamzeh and his co-workers, found that oral organization of AgNPs orally to test rodents for 28 days didn’t show impressive changes in the serum level of AST and ALT when given in various portions\(^{26}\). These outcomes might be because of the utilization of huge estimated nanoparticles (78.59 nm) than that utilized in our test study.

**Conclusion**

In conclusion, our results suggest that silver nanoparticles have a hepatoprotective effect on liver dysfunction caused by amoxicillin-clavulanate acid and this effect is attributed to its antioxidant properties and this could be clinically beneficial to reduce the hepatotoxic adverse effect of amoxicillin-clavulanate acid. It was found that silver nanoparticles has beneficial effect against side effects induced by amoxicillin/clavulanate acid in rats regarding liver enzymes, proteins, bilirubin, and lipid profile.

A Multilevel Empowerment Approach to Prevent Relapse and Improve Quality of Life of People with Mental Disorders

Agustin Widyowati1,2, Bhisma Murti3, Aris Sudiyanto4, Suminah2

1Lecturer, School of Health Sciences Ganesha Husada, Kediri, East Java, 2Doctoral Student Program in Community Development and Empowerment, Universitas Sebelas Maret, 3Professor, Masters Program of Public Health, Universitas Sebelas Maret, 4Lecturer, Department of Psychiatric Faculty of Medicine, Universitas Sebelas Maret

Abstract

The global health problem that increases significantly every year is psychiatric disorders. Decrease in the quality of life of people with mental disorders, error in the recurrence rate suffered. This study aims to see the effectiveness of holistic family-centered mental health care in preventing recurrence and improving the quality of life of people with mental disorders in Kediri Regency, East Java Province. The research design used RCT (Randomized Control Trial). The population in the study was people with mental disorders. The research sample consisted of 38 groups of respondents and 38 control groups with the multistage random sampling technique. Dependent variables were disease recurrence and quality of life for people with mental disorders. Variable independent is a family-centered holistic mental health care. The instrument uses a questionnaire that has been tested for validity and reliability. Data analysis used an independent t-test using STATA 13. The t-test results showed that the increase in the average increase in the treatment group after being given the intervention “family-centered holistic mental health care” while the control group did not change significantly. Holistic, family-centered mental health care with a multilevel approach in this study is effective in preventing relapses and improving the lives of people with mental disorders. It is hoped that it can be used to help improve the quality of life for a wider range of people with mental disorders.

Keywords: disease recurrence, empowerment, family-centered, mental health care, quality of life

Introduction

One of the global health problems that increase significantly every year is psychiatric disorders. The decline in the quality of life for people with mental disorders is influenced by the high rate of recurrence. The impact of mental disorder client recurrence can result in drug resistance, progressive brain structure damage, personal distress, difficulties in the client’s rehabilitation process, anxiety, non-compliance with treatment due to lack of knowledge, and side effects of treatment(1). Meanwhile, the impact on the family and society, namely injuring themselves and those around them, going berserk, and destroying objects around them. Globally, the recurrence rate of mental disorders can reach 50-92% due to non-compliance in treatment or lack of support and stress-prone living conditions, a stigma in the surrounding community(2).

Many programs have been carried out by the Indonesian government to improve the health of people with mental illness so that they have a better quality of life. The real manifestation of the government in protecting and caring for people with mental illness is contained in Law No. 36 of 2009 concerning Health Articles 148 and 149 which states that “People with

Corresponding Address:
Agustin Widyowati

Phone number: +6285735399728
mental disorders have the same rights as citizens and are required to receive treatment and care in health care facilities” and Law No. 18/2014 on mental health article 86 states that “The act of shackling people with mental illness is an act which is prohibited and punishable by crime”. Besides, the government is also trying to tackle people with mental illness through the “Indonesia free from “pasung 2017” program, the formation of the Community Mental Health Implementation Team, and mental health integrated service post. However, lack of knowledge, low support, negative community stigma, and inadequate resources have resulted in the program not providing optimal results for sufferers and caregivers.

Although many kinds of research with psychoeducation interventions in families can prevent relapse, there is also a need for increased knowledge and mindset in the community, increased health personnel, and professional volunteer so that they can provide positive support and stigma to caregivers and sufferers. The stigma that exists in society is that people with mental disorders are someone who must be shunned because they are scary, something that must be shunned. Therefore, people with mental illness who live in a society that has a negative stigma will be hampered in the healing process because people tend to avoid or do not want to assist\(^3\). Someone who has the support of friends and family allows them to have greater resources to coping with stressful events, thus enabling them to see the event as a problem less\(^4\), thus serving as a preventive strategy to reduce stress, stress and its negative consequences\(^5\).

Kakuma state that it is necessary to involve mental health volunteer who coordinates with health workers to solve problems and improve public health, especially mental health. The synergy of family, friends, community, and health workers is expected to provide mental health care for caregivers and sufferers. This study aims to determine the effectiveness of family-centered holistic mental health care in preventing disease recurrence and improving the quality of life of people with mental disorders\(^6\).

Method

The research was conducted in Kediri Regency, East Java Province in 2019. The research design used RCT (Randomized Control Trial). Sampling was carried out by multistage random sampling technique, consisting of 76 respondents, 38 respondents in the treatment group and 38 respondents in the control group. The dependent variables of this study were disease recurrence and quality of life for people with mental illness. Recurrence of disease is a patient who experiences an increase in symptoms of abnormal behavior. The quality of life for people with mental illness is the level of a person’s health that is perceived by the individual itself, including physical, psychological, social, and environmental relationships. Variable independent is a family-centered holistic mental health care. Family-centered holistic mental health care is an intervention or support from various levels of society provided to families (spouses, children, son-in-law, parents, or siblings) who have emotional bonds, love each other, and are responsible for caring for sufferers so that they can prevent recurrences. The intervention given to the treatment group using a multilevel empowerment approach: a) Community level: 1) health professionals (mental health) provide education and training to health workers and volunteer, form mental health posts, 2) socialization to caregivers, families, neighbors, communities, local village government / religious leaders/community leaders so that there is increasing knowledge and changes in mindset to reduce negative stigma and help caregivers and sufferers if needed, 3) involve sufferers in community activities according to their abilities 4) active role of the local village government through financial support, facilities, and infrastructure informing mental health volunteer and mental health posts. b) Individual level: psychoeducation to caregivers and families, conducting home visits/ caregiver assistance in caring for sufferers. The data collection instrument used a questionnaire. The disease recurrence questionnaire was adapted from the BPRS (Brief Psychiatric Rating Scale) and the quality of life questionnaire was adapted from WHOQOL-BREF. Data analysis using a t-test with the help of STATA13 was
used to determine the effectiveness of the application of a family-centered holistic mental health care model on disease recurrence and quality of life for people with mental disorders in the control group and the treatment group. Before testing the hypothesis, the normality assumption test is fulfilled.

**Results**

The results include the characteristics of research respondents, variable measurement characteristics, and t-test.

Table 1 above, based on the age of the respondents, data shows that almost half of the respondents (48.7%) or as many as 37 people with mental disorders aged 26-45 years and 46-65 years, only 2 people with mental disorders (2.6%) were 12-25 years old. Mental disorders can be experienced by all types of ages, the younger a person experiencing mental disorders will experience a decrease in IQ, psychomotor abilities, the greater the verbal memory which can affect the quality of life of people with mental disorders. Based on gender, data was obtained that most of the people with mental disorders (73.7%) were male, 56 respondents, and a small proportion of people with mental disorders (26.3%) were female as many as 20 respondents. Men have a greater risk of experiencing mental disorders because the head of the family is the support for the household so that they experience greater life pressure and are less able to accept life situations than women. Based on the duration of illness, it was found that almost all respondents (85.5%) experienced people with mental disorders > 5 years as many as 65 people. The duration of illness is a description of the disease course of people with mental disorders starting from the acute phase, experiencing recurrence, stability, and even worsening mental health conditions.

Disease recurrence in the intervention group experienced recurrence, 18 respondents (23.7%) and in the control group experienced recurrence, 21 respondents (27.6%). The more frequent recurrences, the worse the prognosis for people with mental disorders. Quality of life for people with mental disorders in the intervention group had a low quality of life for people with mental disorders, 27 respondents (35.5%) and the control group had a low quality of life for people with mental disorders, 26 respondents (34.2%). One of the problems caused by people with mental disorders is the disruption of the quality of life of people who do not have mental disorders.

Table 3 shows that the recurrence of disease before the intervention “Family-Centered Holistic Mental Health Care” shows that the mean is not much different and is still in the same range, the control group mean is 35.61 (Mean = 35.61; SD = 11.61) and the intervention group mean is 34.45 (Mean = 34.45; SD = 12.07). So it can be concluded that both groups had the same disease recurrence in people with mental disorders (p = 0.671).

After receiving the intervention “Family-Centered Holistic Mental Health Care” showed a different mean, the intervention group had a lower result, 17.03 (Mean = 17.03; SD = 11.16) compared to the control group of 36.42 (Mean = 36.42; SD = 14.09). So it can be concluded that there was a decrease (rarely) of disease recurrence after receiving the intervention “Family-Centered Holistic Mental Health Care” (p <0.001).

<td>8.36</td>
<td></td>
</tr>
</tbody>
</table>

Table 4 shows that the quality of life of people with mental disorders before the intervention “Family-Centered Holistic Mental Health Care” shows that the mean is not much different and is still in the same range, the control group mean of 52.74 (Mean = 52.74; SD = 5.95) and the mean of the intervention group of 53.16 (Mean = 53.16; SD = 5.58). So it can be concluded that both groups have the same quality of life for people with mental disorders (p = 0.751). After receiving the intervention “Family-Centered Holistic Mental Health Care” showed a different mean, the intervention group had a higher result, 62.82 (Mean = 62.82; SD = 8.36) compared to the control group of 52.53 (Mean = 52.53; SD = 6.09). So it can be concluded that there is an increase in the quality of life of people with mental disorders after receiving the intervention “Family-Centered Holistic Mental Health Care” (p <0.001).

Discussion

The effectiveness of “Family-Centered Holistic Mental Health Care” against disease recurrence

Mental disorders affect patients and their families. people with mental disorders will experience disruption of daily activities, interpersonal relationships, roles, and social. Families experience rejection, stigma, helplessness, anxiety, fatigue, decreased personal needs, and the development of personal resources(7). This burden makes the family depressed which has an impact on people with mental disorders nursing or people with mental disorders healing(8). Caregiver/family involvement can reduce patient recurrence(9) so that caregivers need support in dealing with the chronic
phase of the disease\textsuperscript{(10)}. Support can be obtained from formal support (health workers and volunteers) and informal support (family, friends, neighbors) in caring for people with mental disorders. The individual level is psychoeducation to families and caregivers. Psychoeducation can have a positive impact on people with mental disorders, namely accelerating the recovery process\textsuperscript{(11)} and preventing recurrence\textsuperscript{(12)}. In line with research conducted by Kusumawaty, psychoeducation assistance can improve caring caregiver behavior for people with mental disorders\textsuperscript{(13)}. Community-level, namely health workers and volunteers, peers, neighbors, and the community. Social support from the surrounding environment, both from family, friends, neighbors, and the surrounding community are needed by caregivers in facing difficulties\textsuperscript{(14)}. Health workers have an important role in treating people with mental disorders through caregivers involving mentally healthy volunteers\textsuperscript{(15)}.

The effectiveness of “Family-Centered Holistic Mental Health Care” on the quality of life of people with mental disorders.

Mental disorders account for the largest proportion of the burden of disability or year lived with disabilities (YLDs) so that it affects the quality of life. Basic needs in the form of self-care that are not fulfilled will have an impact on the quality of life of people with mental disorders. Such as physical impacts, including susceptibility to various diseases of the skin, oral mucosa, and nails. Psychosocial impact in society, namely disruption of social interaction in daily life activities, people with mental disorders will be rejected by the community because of poor personal hygiene, people with mental disorders have low self-esteem, especially in terms of identity and behavior, people with mental disorders considers himself unable to overcome his shortcomings\textsuperscript{(16)}. People with mental disorders often don’t care about self-care in their life. This causes people with mental disorders to be isolated in the family and society. Nearly all patients with mental disorders had self-care deficits. This is due to ignorance and helplessness related to circumstances so that there is a self-care deficit\textsuperscript{(17)}. Their daily independence has decreased, especially in carrying out their roles and functions, such as taking care of themselves, attending school or work, and other functions. Therefore, people with mental disorders need help from other parties, especially families to survive and improve their quality\textsuperscript{(18)}. Combination therapy will be effective if accompanied by optimal family support\textsuperscript{(19)}. Without the support and care provided by family members to people with mental disorders, they can’t remain in the community and improve their quality of life\textsuperscript{(7)}. This study is in line with the research of Javadpour\textsuperscript{(20)} which states that psycho-educational interventions together with patient support systems in the treatment of bipolar mental disorder are effective in improving quality of life and reducing recurrence. Based on a literature review conducted by Puolakka\textsuperscript{(21)}, it was found that there was the effectiveness of psychosocial interventions (family intervention, health education, skills training on the quality of life of schizophrenic patients. Research conducted by Puspitosari\textsuperscript{(22)}, also resulted in Community-Based Rehabilitation being carried out. by health workers, volunteers, and sub-district social welfare workers, it is effective to improve the quality of life for schizophrenics in the community.

Conclusion

Holistic family-centered mental health care with a multilevel approach in this study proved effective in preventing relapses and improving the quality of life for people with mental disorders. It is hoped that it can be used to help improve the quality of life for people with a wider range of mental disorders. Future research can be more devoted to one mental disorder.

Acknowledgment: I would like to thank the respondents who participated.

Conflict on Interest: There is no conflict of interest to be declared

Source of Funding: None

A Review on COVID-19 and Current Repurposing Treatment Strategy

Ahalya S P1, Priyadharshini A1, Dhivya D2, Nila G2
1Assistant Professor, 2Pharm.D Student, SRM College of Pharmacy, SRM Institute of Science and Technology, Kattankulathur

Abstract
A recent outbreak was caused by SARS-CoV-2 was named Coronavirus disease- COVID-19. The first case was detected in China. It continued to spread globally and later was declared as a pandemic by WHO. Pneumonia like symptoms was observed which later led to respiratory illness, renal impairment, and death. Closed contact, respiratory droplets through cough, and sneeze are the mode transmission. Symptoms generally occur 2-14 days after infection. PCR is performed using various samples collected from infected patients and is the standard method of diagnosis. Chest X-ray, CT, and the symptoms observed generally show the extent of progress of the disease. Although there is no effective cure, currently symptomatic treatment and supportive care are available to reduce pneumonia-like symptoms and to decrease the severity of the condition. Preventive measures proposed by the WHO is to maintain proper personal hygiene, social distancing, and the use of the mask.

Keywords: SARS-Cov-2, RNA virus, Symptoms of Covid, Respiratory illness, Treatment strategy, Repurposing.

Introduction
Numerous cases of pneumonia were detected in Wuhan city, Hubei province, China, and reported to the WHO on 31 December 2019. By the end of the year, cases were reported in all continents to expect Antarctica. The factors that determine the cumulative incidence variation by states were possible, population density, demographics, migration, the extent of testing and reporting, mitigation strategies, etc. The main clinical complication was found to be respiratory illness and renal failure. The causative agent for the pandemic Coronavirus disease (COVID-19) is found to be the newly discovered strains of the Coronavirus.1

History
The history of the human coronavirus traces back to 1965, a virus named B814 was discovered by Tyrrell and Bynoe. Parallelly Hamre and Procknow succeeded in growing a virus with an unusual property named 229E. McIntosh et al while working in the laboratory found multiple strains of organ culture(OC- ether sensitive agents) virus. The three decades that followed encountered large exclusive studies related to human strains OC43 and 229E. There was an outbreak during 2002-2003, namely the SARS infection.

Infections were reported in 29 countries. It accounted for 8098 individuals with 774 SARS – related fatality. The entry of the virus in the human population was then unclear. In 2012, Saudi Arabia identified the first case MERS- CoV. The recent outbreak with unexplained LRTI was seen in the largest metropolitan area, Wuhan in China. The cases were first classified as “pneumonia of unknown etiology”. The CDC of China organized an investigation program. The results suggested that the
etiology attributed to the coronavirus (CoV) family. The WHO, on February 11th, 2020 announced the disease as “COVID 19” (acronym of coronavirus disease 2019).²

Objective:

The main objective of the article was to review the available information regarding COVID 19 virus. It also explains its origination, the epidemiology, pathophysiology of the disease, methods of diagnosis, existing treatment options, and the prognosis of the disease.

Epidemiology:

It was found that the coronavirus infection occurred more often in a temperate climate. The pediatric and the geriatric population are more prone to infection by the coronavirus. These viruses present in the healthy carriers are accounted to be responsible for 5% to 10% of acute respiratory infections. To date, the cases are found to be in 215 countries. Today the number of COVID-19 cases is estimated to 20,824,419. And the number of recovered cases is 13,721,180. The mortality has arisen to a rate of 7,47,503.¹

MORPHOLOGY AND STRUCTURE OF CORONA VIRUS:

Coronaviruses are single-stranded RNA viruses (60-140 nm in diameter), with spike-like projection on the surface, enveloped with projecting glycoprotein that surrounds a core consisting of a matrix protein within a single strand of positive-sense. The glycoprotein present in the envelope plays a crucial role in the attachment to the host cell and transport of the major antigenic epitopes. They were identified as transmissible spherical, pleomorphic particles 132 nm in diameter.¹

GENOMIC STRUCTURE:

Single-stranded RNA organization approximately 30 kb in length. These RNA viruses are the largest ever known. They have a 5’ – cap structure and 3’- poly-A tail.¹

ETIOLOGY:

- FAMILY- Coronaviridae
- SUBFAMILY- Orthocoronavirinae
- GENERA- Alphacoronavirus (alphaCoV), Betacoronavirus (betaCoV), Deltacoronavirus (deltaCoV), Gammacoronavirus (gammaCoV)

BetaCoV genus is further divided into five subgenera or lineages. Genomic characterization suggests that possibly bat and rodents are the sources of the gene of alphaCoVs and betaCoVs. Contradictory to this, the deltaCoVs and gammaCoVs seem to have their gene sources from avian species. The family of coronavirus is found to cause respiratory, enteric, hepatic, and neurological disease and is found to affect camels, bats, cattle, cats, and humans. Infection in humans is caused by seven human CoVs.⁴

TRANSMISSION:

Analysis of the cases and their spread suggested that close contact (6 feet or 1.8 meters) between individuals is essential for transmission. Statistical data suggests that 80% of the COVID-19 transmissions are asymptomatic in individuals. Studies show that the coronavirus can contaminate surfaces like plastic (virus stays up to 3 days), stainless steel (2-3 days), cardboard (24 hours), copper (up to 4 hours). In the first investigation conducted by the Chinese CDC indicated that symptoms would be observed within 12.5 days. On average the incubation period is 2-14 days and the patient infected with the virus begins to show symptoms from the 14th days.

PATHOGENESIS OF SARS-CoV-2 INDUCED PNEUMONIA:

The data available indicates that an excessive immune reaction is produced by the host due to the viral infection. Sometimes the whole reaction that takes place is named “cytokine storm”. The condition ultimately results in extensive tissue damage with dysfunctional coagulation. Recently Italian research insinuated the term MicroCLOTS (microvascular COVID-19 lung
vessels obstructive thrombo-inflammatory syndrome) concerning viral injury in lungs associated with microvascular pulmonary thrombosis and inflammation. The protagonist of the cytokine storm is Interleukin 6 (IL-6). Also, other cytokines like Tumor Necrosis Factor α (TNF-α), IL-1β, IL-8, IL-12, Interferon-gamma inducible protein (IP10), Macrophage inflammatory protein 1A (MIP 1A), and Monocyte chemoattractant protein phase 1 (MCP 1) are implicated in pathogenic cascade. Activated leukocytes produce IL-6 and exhibit its action on a large number of cells and tissues. IL-6 has pro-inflammatory properties and also anti-inflammatory effects.

**CLINICAL FEATURES:**

**Common symptoms:**

Fever, Dry cough, Tiredness, Ache and pain, Sore throat, Diarrhea, Emesis, Conjunctivitis, Headache, Loss of taste or smell, A rash on the skin, or discoloration of fingers or toes – COVID toes.\(^1\,^2\)

**Serious symptoms:**

Dyspnea, Chest pain or pressure, Loss of speech or movements.

**COMPLICATION:**

ARDS, Acute heart injury, Secondary infection, Neurological manifestation, Ocular surface infection, Arrhythmia, Impaired renal function, Abnormal liver functions.

**DIAGNOSIS:**

Cases may be symptomatic or asymptomatic. A suspected case is confirmed with a positive molecular test. Samples of an oropharyngeal swab, nasopharyngeal swab, sputum, endotracheal aspirates, bronchoalveolar lavage are collected and specific molecular tests are performed on them. Detection of virus can also be present in stool and blood in extremely severe cases.

**Laboratory observation:**

Usually, low WBC count is observed. Lymphopenia (lymphocyte<1000) is linked to the severe diseased condition. Platelet count is normal or depressed in some cases. Elevation in C-Reactive protein and ESR is observed. However, procalcitonin levels remain normal. Elevation in the procalcitonin level indicates CoV-infection. Severe conditions lead to an elevation in Alanine aminotransferase / Aspartate aminotransferase, prothrombin time, serum creatinine, D-dimer, creatinine Phosphokinase, and lactic acid dehydrogenase is noted.

**Chest X-ray:**

Show bilateral infiltrates which may be normal in the initial stage.

**Computed tomography (CT):**

It is considered highly sensitive and specific. It shows infiltrates, ground-glass opacities, and subsegmental consolidation.

**Nucleic acid reverse transcription-polymerase chain reaction (PCR):**

Currently, PCR is adopted to be the standard method of diagnosis for SARS-CoV-2 infection although there are limitations to the accessibility and availability of PCR test kits.

**Serological tests:**

Qualitative detection of the virus is based on the presence of IgM / IgG antibody. These tests comprise of ELISA technique, rapid chromatographic tests, and other similar tests. IgM antibodies are seen within 7 days of initial infection. The IgG antibody is found after 14 days of infection.

**TREATMENT:**

There are no specific vaccines or treatments are available for COVID-19. Clinical trials are being conducted for evaluating potential treatments. Currently, there are treatments to relieve the patient from symptoms and to prevent severity.
**Repurposed or off-label drug:**

**Hydroxychloroquine:**

DOSE: 400 mg BD on day 1 followed by 400mg daily for the next 4 days.\(^1\)

**Drugs currently in use**

1. **DRUG NAME:** CHLOROQUINE/HYDROXYCHLOROQUINE  
   CATEGORY: Anti-malarial  
   MOA IN COVID-19: The drug changes the Ph of endosomes and prevents viral entry and transport

2. **DRUG NAME:** FAVIPIRA VIR  
   CATEGORY: Anti-viral  
   MOA IN COVID-19: the drug inhibits the RNA-dependent RNA polymerase of RNA virus

3. **DRUG NAME:** INTERFERON BETA  
   CATEGORY: Immuno-modulator  
   MOA IN COVID-19: The drug decreases the viral load

4. **DRUG NAME:** LOPINAVIR/RITONAVIR  
   CATEGORY: Protease inhibitors  
   MOA IN COVID-19: blocks viral cellular entry by inhibiting protease

5. **DRUG NAME:** REMDESIVIR  
   CATEGORY: Adenosine nucleotide analogs  
   MOA IN COVID-19: inhibits viral application

6. **DRUG NAME:** RIBAVIRIN  
   CATEGORY: Antiviral  
   MOA IN COVID-19: inhibits viral RNA synthesis and mRNA capping

7. **DRUG NAME:** GALIDESIVIR  
   CATEGORY: adenosine analog  
   MOA IN COVID-19: disruption of viral RNA polymerase

8. **DRUG NAME:** TOCLIZUMAB  
   CATEGORY: Monoclonal antibody  
   MOA IN COVID-19: The drug decreases the pneumonia-like symptoms such as ARDS/ALI

**Drugs under trial**

1. **DRUGS NAME:** BEVACIZUMAB  
   CATEGORY: Monoclonal antibodies  
   MOA IN COVID-19: The drug prevents from ALI/ARDS in COVID-19 through suppression of pulmonary edema.

   PHASE OF CLINICAL TRIAL: Phase 3

2. **DRUGS NAME:** INTRAVENOUS VITAMIN C  
   CATEGORY: Ascorbic acid  
   MOA IN COVID-19: When sepsis happens, the cytokine surge caused by sepsis is activated, and neutrophils in the lungs accumulate in the lungs, destroying alveolar capillaries. Vitamin C can effectively prevent this process.

   PHASE OF CLINICAL TRIAL: Phase 2

3. **DRUGS NAME:** AZITHROMYCIN  
   CATEGORY: Macrolide antibiotics  
   MOA IN COVID-19: This drug helps in the treatment of bacterial infection caused by pneumonia which is a serious complication of COVID-19

   PHASE OF CLINICAL TRIAL: Phase 2

4. **DRUGS NAME:** NANOGENRETINIDE  
   CATEGORY: Retinoid  
   MOA IN COVID-19: NanoFenretinide shows inhibitory effects on sars-cov-2 virus replication
PHASE OF CLINICAL TRIAL: Phase 1

5. DRUGS NAME: NICLOSAMIDE

CATEGORY: Anti-helminthic

MOA IN COVID-19: Niclosamide inhibits SARS-CoV2 replication and abolishes viral antigen synthesis

PHASE OF CLINICAL TRIAL: Phase 2

Stem cells:

Athersys Inc. began a phase II/III clinical trial in the United States that will examine whether the company’s stem cell treatment could potentially benefit people with acute respiratory distress syndrome (ARDS). Mesoblast has also developed a potential stem cell treatment for ARDS.1

Blood plasma transfer:

A study on CP therapy shows a potential therapeutic effect and low risk in the treatment of severe COVID-19 patients. One dose of CP with a high concentration of neutralizing antibodies can rapidly reduce the viral load and improve clinical outcomes.2

Immunosuppressants:

In people infected with COVID 19 large amounts of cytokine is released by overactivity of the Immune system. Several Immuno-suppressants including Baricitinib (usually prescribed for rheumatoid arthritis), CM4620-IE (a drug prescribed for pancreatic cancer) and IL-6 inhibitor are tested under clinical trial to check whether theses drug can curb cytokine storm and minimize the severity of ARDS.1

Monoclonal antibody:

Monoclonal antibodies trigger the immune system and attack the virus. Tocilizumab is an antibody that is under clinical trials and is believed to improve the symptoms and repress deterioration of severe COVID-19 conditions.1

SNG001:

(Synairgen Research’s SNG001)

It is an inhalational drug that is tested in clinical trials to treat coronavirus induced conditions like asthma, COPD, and LRTI. SNG001 is a formulation that naturally occurs as Interferon-β. Administered via nebulizer1.

Ayurveda:

1. AYUSH-64: 02 tablets twice a day.1
2. Agasthya Hareetaki: 05 gm twice a day with warm water.11
3. Anuthaila/Sesame oil 02 drops in each nostril daily in the morning.4

Siddha:

Figure 1 Source: Effective treatment of severe COVID-19 patients with tocilizumab, pnas.org

A-C: Plaque-like and ground-glass opacities before the treatment

D-F: Diffuse infiltration in both lungs, but the lesions were absorbed after the treatment with
1. Nilavembu Kudineer/Kaba Sura Kudineer—decoction.

**Homeopathy:**

Various medicine which found to be effective in treating flu-like illness are

1. Arsenicum album
2. Bryonia alba
3. Rhus toxico dendron
4. Belladonna Gelsemium
5. Eupatorium perfoliatum

Vaccines under trials:

1. PLATFORM: Non-Replication Viral Vector
   TYPE OF VACCINE: Adenovirus Type 5 Vector
   DEVELOPED BY: CanSino Biological Inc./Beijing Institute of Biotechnology
   STAGE OF CLINICAL EVALUATION: Phase 2

2. PLATFORM: RNA
   TYPE OF VACCINE: LNP - encapsulated mRNA
   DEVELOPED BY: Moderna/NIAID
   STAGE OF CLINICAL EVALUATION: Phase 3

3. PLATFORM: Inactivated
   TYPE OF VACCINE: Inactivated
   DEVELOPED BY: Wuhan Institute of Biological Products/Sinopharm
   STAGE OF CLINICAL EVALUATION: Phase 3

4. PLATFORM: Inactivated
   TYPE OF VACCINE: Inactivated
   DEVELOPED BY: Beijing Institute of Biological Products/Sinopharm
   STAGE OF CLINICAL EVALUATION: Phase 3

5. PLATFORM: Inactivated
   TYPE OF VACCINE: Inactivated + alum
   DEVELOPED BY: Sinovac
   STAGE OF CLINICAL EVALUATION: Phase 3

6. PLATFORM: Non-Replication Viral Vector
   TYPE OF VACCINE: ChAdOx1
   DEVELOPED BY: University of Oxford
   STAGE OF CLINICAL EVALUATION: Early phase 1

7. PLATFORM: RNA
   TYPE OF VACCINE: 3 LNP-mRNAs
   DEVELOPED BY: BioNTech/Fosun Pharma/Pfizer
   STAGE OF CLINICAL EVALUATION: Early phase 1

8. PLATFORM: DNA
   TYPE OF VACCINE: DNA plasmid vaccine with electroporation
   DEVELOPED BY: Inovio Pharmaceuticals
   STAGE OF CLINICAL EVALUATION: Phase 1

9. PLATFORM: Inactivated
   TYPE OF VACCINE: Covaxin
   DEVELOPED BY: Bharath Biotech; NIV
   STAGE OF CLINICAL EVALUATION: Phase 2

**PREVENTION:**

- Covering mouth and nose with flexed elbow or tissue when coughing or sneezing. Dispose of used tissue immediately. Avoid touching the face.
• Wash hands often with soap and water. Always wear a mask and practice social distancing.
• Take food rich in vitamin C like citrus fruits, vitamin D. Ensure proper hydration.

The Role of Forensic Medicine in the Criminal Justice Process in Jordan (Sexual Crimes)

Ahmad Alsharqawi
Faculty of Law/ Applied Science Private University/ Jordan

Abstract
This research aims to clarify the role of forensic medicine within the criminal justice method in Jordan. The study showed what’s meant by forensic medicine during investigation and its relationship to law and judicial procedures in Jordan and also the judge’s discretionary authority to require the rhetorical report’s particularly sexual crimes, the study reached to an appropriate conclusion.

Keywords: Forensic Medicine, Justice, Law, Jordanian Code of Penal Procedure, Sexual Crimes, Criminal Justice, Sexual Abuse.

Introduction
Forensic medicine contains a major role within the diagnosing of crime, and therefore the determination of the criminal act and its consequences. Therefore, it affects the course of analysis and therefore the legal learning of facts. This is often evident within the event of death, in wounds of varied forms and causes, and in sexual crimes and sex abuse. Forensic medicine contains a sensible and technical role in uncovering the rhetorical proof that results in the clues of mysterious crimes once the investigation fails to uncover the causes and therefore the perpetrators. In these axes, searches and investigations area unit applied so as to uncover the proof on that it depends. Either the suspect is condemned or guiltless of the charge against him.

Among the general public roles that the forensic medicine doctor performs throughout the investigation part, it discover him activity medical examinations on the impact part of the victim and stating the kind and outline of the injury, with a sign of its cause and also the date of its prevalence.

It may additionally confirm the kind of the assaulted sexual organic parts, additionally because the chance of the prevalence of a permanent incapacity, its assessment upon its stability, and its relationship to the perpetrated assault.

The forensic medicine doctor is responsible to conduct these examinations with believability and honesty, once he’s deputized for the help of him at the placement of the crime, i.e. the scene of the crime, so as to provide a study proving the examination. Additionally to the autopsy of the deceased in criminal cases, and in cases of the suspected reason for death, however and once it occurred, and also the relationship of death to the injuries that exist on the body; With the requirement to precise technical opinions associated with adapting accidents and errors, additionally to examining blood, its types, spermatozoon material, scrutiny hair, and examining samples taken from bodies to understand regarding diseases The assaulted sexual organic parts.

Discussion
Sexual assault is a sexual act that a person does not consent to, or is forced against, his desire, and it is a type of violence that includes rape (assault that includes penetration into the vagina, anus, or mouth), or other sexual abuse such as touching, forcibly kissing, or sexual persecution of a child, Or torture a person in a sexual manner. Sexual assault is a behavior that the victim does not consent to, and it is not uncommon for the victim to be free of physical injuries or signs of assault, and yet
this behavior remains a crime that can be reported like other crimes.

Often in sexual crimes, general traumatic manifestations are seen, whether in the body of the victim or the body of the accused as a result of resistance (the term general injuries means injuries to any part of the victim’s body except the genital area). The absence of injuries does not mean ruling out the crime of rape, as there are many reasons for not showing injuries such as: Subjugating the victim through emotional interaction with her or the threat of violence or murder, the violence used by the perpetrator or the victim’s resistance is not sufficient to cause the injuries, the bruises may not appear before 48 hours have passed from the moment of the assault, and they may not appear at all, the victim’s delay in reporting the crime may lead to the disappearance or recovery of the injuries threat or coercion.

There is no consent if sexual intercourse occurs under threat or coercion, for example. Threatening a woman with a tool to kill her, her child, or the like and threatening her with pictures taken of her or messages she had previously written.

When the forensic doctor deals with rape crimes, he must bear in mind that:

1- The aim of the forensic medical examination is to document injuries and evidence so that it facilitates the prosecution of the case against the perpetrator or the acquittal of the accused in the case of a false allegation of rape.

2- Respecting the modesty of the plaintiff and not scratching it by making her completely naked during the examination.

3- It is possible for the plaintiff to be unaware of some of the injuries that occurred in her body as a result of the assault, so the forensic doctor must examine the whole body of the plaintiff using a strong light source and a magnifying lens (if necessary). And natural body openings such as the inner surface of the lips and the scalp.

Sexual violence can take many forms and occur in different settings. The violation may occur before one or more individuals (such as gang rape); this event may or may not be pre-planned suddenly and without planning. Although sexual violence often occurs in the victim’s home (or the perpetrator’s home), it does happen also in many other places such as workplaces, schools, prisons, cars, and streets, and open places (such as parks or farms). The perpetrator may be on a date with the victim, having a personal acquaintance with her, a friend or a member of the victim her family members, intimate partner, or former intimate partner may be unknown strangers of the victim, but more commonly it is someone known to the victim. There is no typical culprit. The perpetrators of Sexual violence come from all backgrounds of society, whether from the rich or the poor or from the educated or otherwise educated, religious or non-religious. Perpetrators may be persons with privileged positions or powers with respect and trust (such as police officers, doctors, teachers, tour guides, and pastors) and it is unlikely that sexual violence has been committed.

Evidence of the occurrence of sexual violence on the adult female victim depends on the time period between sexual activities and medical examination, as evidence disappears over time, or in the event that the victim changes her clothes or bathes, on the experience, knowledge and skill of professionals in the medical, psychological, social and police sectors in Interview with the victim, about the type of sexual activity the girl was exposed to, about the potential consequences of sexual violence such as sexually transmitted diseases or pregnancy.

It is not possible for the forensic medical examination to be the only reference to prove sexual violence against the girl, as it is very important and important, but the result is not complete except with a police investigation and a psychosocial evaluation.

Objective injuries to the labia majora or labia minora, their occurrence depends on the intensity of violence accompanying sexual activity, and usually in
the form of bruises or tears in the posterior spinal cord (the posterior region connecting the labia majora), and in very rare cases the injury is somewhat severe, as it extends a tear from the external genitalia to the perineum (the area between the anus and the vulva).

External sexual acts, including interviewing the genitals and licking the penis, are not expected to have an inevitable impact. Controlling the swabs to check for animals, sperm and genetic fingerprint take place within a few days of contact, and there is no point in controlling these areas after that.

When a criminal offence is committed, members of the judicial police, the general public prosecuting attorney and also the specialists move to the scene of the crime, so as to reveal its details, the causes and also the circumstances encompassing it. However, members of the judicial police, the general public prosecuting attorney and also the decide could face some scientific or technical problems that can’t be encompassed because of their data of specific judicial and legal competencies among the boundaries of their authority and specializations. Therefore, the Jordanian lawmaker allowable the Jordanian Code of Criminal Procedure No. nine of 1961 and its amendments, However, the court and also the prosecuting attorney could look for the help of forensic medicine to reveal what’s ambiguous and troublesome for the court or the general public prosecution to grasp, supported Article twenty of an equivalent law, that states that if someone dies by murder or unknown causes that make to suspicion, the general public prosecuting officer can look for the assistance of 1 or a lot of doctors to arrange a report of the causes of sexual abuse and also the condition of the victim body.

Forensic medicine is of particular importance with respect to criminal cases, particularly regulatory offence, whether or not at the first investigation stage or at the trial stage, and it depends on the forensic medical proof generally the accused’s conviction or final judgment. Opinions differed so as to work out the legal nature of the expertise. Means that forensic medicine report proof and supported elements: proof of the incidence of the crime and also the attribution of this crime to its perpetrator. Another side went up to now on say that it’s how to assess the proof that the decide uses to succeed in the truthfulness, and he cannot use it within the event that he’s not glad for him and that we support this opinion.

After that, the forensic doctor prepares his expertise report, and therefore the professional report is that the essence of the professional method, as through it the forensic doctor presents the results of his analysis that represent the required technical and scientific components that profit the choose or investigator in instructive the reality and provides him with the chance to create his judgments within the light-weight of it. The professional opinion includes a press release of proof and a detail of its elements, then a proposal from a medical and scientific purpose of reading of the worth it will have in proof, and an application of the principle of judicial conviction, the choose shall have the discretionary power to assess its price as is that the case with the remainder of the proof that the court appreciates once it’s mentioned by the litigants and in an oral application and confrontation within the trial, the court could or might not be convinced of the forensic doctor’s report because it deems applicable, consistent to the conscience principle stipulated in Article 174 of the Jordanian Criminal Procedures Law as long because it is that the solely proof.

In the implementation of this, the Jordanian Supreme Court dominated in its call No. 96/2000: that though the trial court’s conviction of proof isn’t subject to the management of the Court of Cassation, this court has the correct to observe it in terms of whether or not or not the proof is legal proof as a result of this issue is said to legal applications and not from realistic matters and to the decide That his conviction is within the proof contained within the case while not being sure by a particular means or a particular sort of proof, and this is often what the Jordanian lawgiver confirmed within the text of Article 86/2 of the act of Civil Procedure that the expert’s opinion doesn’t prohibit the court and also the decide is absolve to take proof once he reassures his conscience and might be excluded proof if he’s not
Conclusion

The criminal investigation could be a struggle between the investigator and also the criminal, the primary aims to achieve reality, and also the second try to obscure it, so as to flee the penalty. The investigation in its general sense is to require all legitimate measures and means to result in uncovering the reality. The road, and guides a way to walk and look for proof.

Forensic medication could be a term that consists of two portions: medicine and law. As for medication, it’s the science that’s involved with everything associated with the material body, whether or not alive or dead, and Sariah law suggests that the law that separates disputes between persons. Forensic medicine isn’t restricted to writing medical reports or examine the victims, it’s a living science in its title, the importance of that comes in terms of keeping pace with recent and fast developments and advanced theories in analysis and identification.

The opinion of the forensic doctors doesn’t prohibit the court, and also the choice is totally unengaged to take proof once he’s glad together with his conscience, and the proof is excluded within the event that they are not glad, so it’s become necessary to style a special programmer for criminal sciences for law students in Jordanian universities in an exceeding manner per the legal mentality.

The Criminal Liability of the Forensic Doctor as a Judicial Expert According to Jordanian Law

Ahmad Mohammad El-refaie¹, Ahmad Hussein Alsharqawi¹
¹Faculty of Law/ Applied Science Private University/ Jordan

Abstract
The judicial expert forensic doctor in Jordan, with his knowledge and experience he has possess, to provide assistance and to the judge on a specific point, which helps him in resolving the dispute before him, especially since the latter is difficult to get acquainted with the various types of medical sciences, and it is not permissible for him to makes a judgment and judge his personal work On the other hand.

The forensic doctor expert is not immune or far from criminal prosecution if he receives a bribe, commits fraud, betrayed trust, or took a false oath, discloses a secret or submits a false report, and this criminal responsibility finds a legal basis for it in Jordanian law

Keywords: Criminal Liability, Judicial Expert, Forensic Medicine, Jordanian law.

Introduction
A judicial expert is a person with scientific and practical competence and who possesses special technical know-how, who is familiar with some aspects of science, and he harnesses all the sciences, knowledge and experiences he enjoyed to serve the judiciary facility and achieve justice, after seeking his assistance from the judge in charge of a particular dispute. Among the issues that are presented to the judiciary and in which the judge does not have sufficient knowledge and expertise, such as time, abuse, sexual crimes and others, he shall resort to a judicial expert, who is the forensic doctor¹.

Forensic medicine is a branch of approved medicine that specializes in the application of medical sciences, serving many judicial matters that the judge cannot decide on apart from him. The forensic doctor is familiar with all branches of medical science, as well as matters of the judiciary and the law, even in general terms. On his observations and report, the fate of many people depends on because one of the most important things presented to the forensic doctor is the assault on individuals, and whatever the nature of this assault and its consequences, the doctor here has to rely on his skill and experience and above that on his conscience and impartiality².

And the forensic medical experience is important for the victim and the accused and at the court, so the victim always seeks revenge against the accused and endeavors to hold him moral and material responsibility, and its importance for the judiciary and justice lies in the fact that the medical experience directs the case in a specific direction and relieves the conscience of the judiciary that works so that his position is not tainted by any defect. Public and above it the authority of conscience and the authority of the judiciary. And courts often resort to forming medical committees to look again in some cases.

Discussion
The forensic doctor is the one who determines the severity of the injury, the presence of the impairment and the value of the resulting disability, detects cases of poisoning, and assesses the age of individuals, especially those wanted for civil jobs and the service of knowledge, for the accused. Sexual crimes on which the honor of
the individual and the family stands, and it identifies unidentified individuals, corpses and body parts, inspect the corpses, victims of assault, and sometimes seeks to exhume and dissect them to determine the cause of death, and examines vital spots: blood, semen, urine, leftovers, and establishes or denies paternity.

The forensic doctor, in his capacity as a judicial expert, submits a report to the court, which is an explanation and interpretation written with medical-technical expertise that the expert carries out at the request of the judiciary or his representative, and it relates to the causes of an accident, so its circumstances and results are shown.

Because the forensic doctor report is of great importance in establishing the truth or acquitting the accused, and in order for the forensic doctor to carry out his duty to the fullest. The Jordanian legislator, in the Penal Code of 1960 and the Code of Criminal Procedure of 1961, has regulated criminal responsibility that rests on experts during the performance of their mission, and this responsibility also includes the forensic doctor in his capacity as a judicial expert.

Code of Criminal Procedure stated in Article (39):
1. If discrimination of the nature of the offence and its conditions ceases to be based on knowledge of some arts and crafts, then the public prosecutor must accompany one or more of the artists and craftsmen. 2. The court may take urgent measures to ascertain the health condition of the injured or the defendant or to verify the validity of the medical reports submitted in the lawsuit, without summoning the litigants.

Article (40): If a person dies by murder or for unknown reasons that give rise to suspicion, the public prosecutor shall seek the assistance of one or more physicians to organize a report on the causes of death and the condition of the dead body.

Article (41): 1. The doctors and experts referred to in Articles (39 and 40) must take an oath before starting their work to perform the task entrusted to them honestly and honestly. 2. The public prosecutor sets a date for the expert to submit his report in writing, and if he fails to submit it on the specified date, the public prosecutor may decide to recover all or part of the wages received by the expert and replace this expert with another expert.

Article (170) of the Penal Code stipulates that every employee and every person assigned to public service, whether by election or appointment, and every person assigned to an official mission such as an arbitrator, expert, and bondholder, who requests or accepts for himself or others a gift, promise, or any other benefit in order to do a right act by virtue of his position, he shall be punished with imprisonment for a period not Less than two years and a fine equivalent to the value of what was requested or accepted from cash or two.

Article (218) of the same law also states 1. An expert appointed by the judicial authority in a legal or penal case and asserting a matter contrary to the truth or interpreting it with incorrect interpretation of his knowledge of his truth shall be punished with imprisonment from three months to three years, and he is forbidden to be an expert afterwards. 2. Temporary employment shall be adjudicated if the expert’s assignment is related to a criminal case.

The importance of the judicial expert, the forensic doctor, lies in the judiciary by assisting in the process of adjudicating the case, as the need for the expert if it arises during the course of the criminal case is a technical issue on which the determination of the case depends, especially if the judge is not able to decide an opinion on it, because that requires jurisdiction Technically he does not have it, and among the most important issues in which he asks the forensic doctor to express an opinion: sudden deaths, unknown cause, especially among healthy people who are not of advanced age, suspicious deaths or that follow a violent act or a specific accident, deaths of prisoners and judicial detainees, exhumation of the grave Determining the cause of death, especially when claiming to cause death, those physically injured after an assault, traffic accidents, and work accidents, in issues of determining age, determining paternity, in cases of rape, homosexuality and criminal abortion, studying a
person’s mental status or civil capacity, and laboratory analyzes of vital spots, And to detect some of the poisoning substances. Because it is not permissible for the court to rule with its personal knowledge, especially in technical matters, especially if a person dies by murder or unknown causes that give rise to suspicion, so the public prosecutor will seek the help of one or more doctors to organize a report on the causes of death and the condition of the dead body.

The judicial expert also plays an important and positive role in the case, so there is no doubt that as an impeccable person, he may fall into the forbidden, as he commits acts that harm him and harms the right, justice and the judiciary, so it is not excluded that he commits what is considered financial crimes and non-financial crimes.

Article (170) of the Penal Code states that every employee and every person assigned to public service, whether by election or appointment, and every person assigned to an official mission, such as an arbitrator, expert, and bondholder, who requests or accepts for himself or others a gift, promise, or any other benefit in order to do a right act by virtue of his position, shall be punished by imprisonment. A period of not less than two years and a fine equivalent to the value of what was requested or accepted from cash or two. For example, asking for a bribe from one of the litigants, or forging the documents that were handed over to him, or destroying or altering one or more documents he received. He shall be punished by imprisonment for a period of no less than two years and a fine equivalent to the value of what he requested or accepted from cash or two.

In this, we find that the felony of bribery stipulated in Articles (170 and 171) of the Penal Code, for its occurrence, requires the following elements:

1. To be submitted to an employee or his authority.
2. That this employee requests or accepts for himself or for others the gift (or promise).
3. Or any benefit to perform an unlawful act or to abstain from the work that he must do, which is known as the material corner. That the work he will do or refrain from doing is part of his job.
4. Availability of the criminal intent.

The crime of forgery is based on several elements, namely:

First: Actus Reus.

Its basis is to distort the truth in one of the ways stipulated by the law. This is based on two elements. The first is based on a distortion of the truth:

Distortion of the truth is the criminal act carried out by forgery, and then if there is no distortion of the truth, forgery is denied, as there is no perpetration of the crime without a criminal act, and the distortion of the truth does not mean that all the data are false, but rather that the law is satisfied with the lowest share of the truth. For the truth, and the rest of his data are correct, this is considered sufficient for the occurrence of forgery. A fortiori, forgery is available if some of the data differ from the truth and others are identical to it. As for the second element on which this is based, it is the means stipulated by the law with which criminal activity (methods of forgery) are investigated. Where the legislature specific methods of tangible forgery in Article (262) of the Penal Code, which are:

A - Forged signature, a forged seal, or a forged fingerprint.
B - Making a deed or manuscript.
C - Deletion, addition, or change in the content of an instrument or manuscript.

While the legislator specified methods of incorporeal forgery in Article (263) of the Penal Code, which are:

A - The defendant’s abuse of using a white signature entrusted to him.
B - Writing articles or statements other than those issued by the contracting parties or those they hope for.
C - Proving false facts to be true.

D - Evidence of unrecognized facts as being recognized.

F - Forgery by omission or abandonment.

Therefore, the tangible change is what the sense perceives and the eye falls on, whether it is an increase or deletion in an existing editor from the original or by creating a new editor.

Second: The object of the crime:

It is the document or the manuscript that has the power to prove. The legislator has expressed the subject on which the distortion of the truth is focused, as the facts and data that are to be proven by a document or manuscript to be used as evidence.

The criminal subject matter of forgery is multi-component on the one hand, it must be in writing, and the legislator expressed this in Article (260) of the Penal Code, stipulating that it be a document or manuscript. On the other hand, this writing must have a legal value that the legislator outlined in its requirement that it be considered a document in the legal meaning, and the distortion of the truth must deal with the data that the purpose of this writing was to prove.

The document that is correct to be subject to the crime of forgery is every written statement that includes signs that give a coherent meaning that is transferred from one person to another upon reading it and that is suitable for being used in indicating an incident of legal effect.

Third: The Damage:

The damage means every infringement of a right or interest protected by law, that is, a waste of a right and a breach of a legitimate interest recognized by the law and which guarantees protection for it, and that such damage is achieved whether the harm is actually occurring or is likely to occur.

Fourth: The criminal intent (mens rea):

Falsification crimes are intentional in which the law requires the availability of the criminal intent, which consists of knowledge of the elements of the crime and the will to commit them, and the perpetrator must have a special intention to use the forged document for what it was forged.

The criminal intent in forgery has been defined as (Intentionally changing the truth in a document that would cause harm and the intention to use the document while changing the truth for its sake).

Article (218) of the Penal Code: 1. an expert appointed by the judicial authority in a legal or penal case and asserting a matter contrary to the truth or interpreting it with incorrect interpretation of his knowledge of his truth shall be punished with imprisonment from three months to three years, and he is forbidden to be an expert afterwards. 2. Temporary employment shall be adjudicated if the expert’s assignment is related to a criminal case. Such as submitting a false experience report in the case, or giving false testimony about his experience report, or not depositing the experience report or case highlights, or disclosing the experience report to one of the litigants before it is deposited to the court that assigned him the expert, or failure to comply with the court’s decision regarding attendance for the purposes of discussion in the report The expertise provided by him.

We find that the offence of asserting an order contrary to the truth by the expert in accordance with the provisions of Article 218/1 of the Penal Code requires the following elements for criminal accountability:

1. Actus Reus: It is the act or abstinence by which the crime unfolds and its body is complete, which is represented by the behavior of the perpetrator, a specific result and a causal relationship between them, and here is the performance of experience before the court.

2. Mens Rea: It consists of two components (knowledge and will), which is the departure of the perpetrator’s will to commit the crime with knowledge
of its legal elements (criminal intent).

**Conclusion**

This research deals with the criminal liability of the judicial expert, the forensic doctor, within the framework of Jordanian law\(^{10}\). The forensic expert is not immune or far from criminal prosecution if he receives a bribe, commits fraud, betrayed trust, or took a false oath, discloses a secret or submits a false report, and this criminal responsibility finds a legal basis for it in Jordanian law in Articles 218 or 170 of The Jordanian Penal Code and its amendments of 1960.

Efficacy of Clinical Palpation to Detect Cervical Lymph Node Metastasis of Oropharyngeal Cancer

Ahmad Naeem Mahdi¹, Sabah Abdulaziz Issa², Saif Saadedeen Abdulrazaq³
¹Al-Kindy Teaching Hospital, Department of Oral and Maxillofacial Surgery, Baghdad/Iraq, ²Ghazy Al-Hariri Hospital for Surgical Specialties, Medical City, Baghdad/Iraq, ³Department of Oral and Maxillofacial Surgery, College of Dentistry, University of Baghdad, Iraq

Abstract

Background and Objectives: Before excision of the primary tumor in oropharyngeal cancer, a decision must be made to treat the cervical lymph nodes (LN) or not. The study aimed to assess the role of clinical palpation (CP) for preoperative detection of LN metastasis.

Methods: Twenty patients with oropharyngeal squamous cell carcinoma (OSCC), managed by excision of the primary tumor and neck dissection. The histopathological examination results compared to the preoperative assessment of the nodes by CP.

Results: There were 20 patients involved, 11 males and nine females. The mean age was 54.5 years. Twenty neck dissections were performed; there was 14 LN metastasis as proved by histopathological examination. On CP, true positive was 12, false negative was two, true negative was two and false positive was four.

Conclusion: Clinical palpation performed preoperatively is highly advised as it has high diagnostic capabilities to reach a decision to do neck dissection or not.

Keywords: oropharyngeal cancer; lymph node metastasis; neck dissection; squamous cell carcinoma.

Introduction

The deformity results from the management of oropharyngeal cancer is the main concern facing the head and neck surgeon during the treatment plan. In addition to this esthetic concern, there are functional problemssuch as speech and mastication. These factors make oropharyngeal cancer management differs from other types of cancer, also differs from the management of benign tumors⁴⁻⁷.

The first correct step of the treatment plan to manage patients with oropharyngeal cancer is an early diagnosis, which eventually decreases morbidity and mortality⁶.

Before the definite diagnosis of the excised primary tumor and its associated LN by histopathological examination, clinical examination by palpation and different imaging techniques provide a provisional or almost definite diagnosis especially if they are handled by an expert surgeon⁵⁻⁷.

More than 95% of oropharyngeal cancer is squamous cell carcinoma (SCC)⁸. The prognosis of the SCC depends on the size, site, thickness, and histopathological staging of the primary tumor. However, the most significant prognostic factor is the metastasis to the cervical LN⁹⁻¹⁰. Metastasis to cervical LN reduces the five years survival rate by 50%¹¹⁻¹³. The controversy of managing N₀ neck probably goes with elective neck dissection as the risk of occult metastasis is higher than 20%¹².

Although the clinical examination of the neck may be difficult especially after radiotherapy or patients with a short neck, it acts as a first screening tool to detect LN metastasis, this is why a well-trained and experienced
surgeon who can differentiate between reactionary and metastatic LN must do the examination. However, a decision to operate on the metastatic LN has to be made for all patients whether they are palpable clinically or not\(^{(1,13)}\).

The aim of the study was to assess the validity of the CP to reach a definite diagnosis by comparing the results with the histopathological examination of the excised nodes.

**Methods**

The study involved 20 patients; all of them were presented with OSCC. The data were collected over two years. Staging of the primary lesion and neck was according to the American Joint Committee on Cancer\(^{(14)}\).

Inclusion criteria included patients with OSCC who required both surgical excision of the primary tumor along with neck dissection. Exclusion criteria included patients who required only excision of the primary tumor without neck dissection, patients previously treated by surgery, radiotherapy and/or chemotherapy, and patients who presented with inoperable tumors (beyond surgery).

**Clinical Examination of the Neck**

All the levels of the neck were examined systematically on both sides. If there was palpable LN (Fig 1), the assessment of its site, size, consistency and tenderness or any associated signs and symptoms were recorded. The criteria to consider the node as metastatic on CP were palpable, firm to hard and/or fixed node, while the criteria to consider the LN reactive were soft, tender or when there was a history of inflammation.

Fig 1: Enlarged (palpable) left submandibular and supraclavicular lymph nodes (black arrows).
Radiographic Examination

As a protocol, patients were examined by CT (with contrast/2mm sections) of the neck from the base of the skull to the clavicle.

Preparation For Pathological Examination

During surgery, the neck dissection specimens were divided into levels and sublevels; each level must be cautiously labeled and presented in a separate container to provide better information for the pathologist.

Statistical Analysis

Clinical palpation findings were compared with the histopathologic results. The outcomes were presented in terms of sensitivity, specificity, accuracy, positive and negative predictive values. IBM SPSS statistics for windows, version 24.0 was used for statistical analysis (P < 0.05 considered statistically significant) [15].

Results

There were 20 patients involved, 11 males (55%) and nine females (45%). The age range was 25-79 years, the mean age was 54.5 years, the sixth decade (50-59) was the most commonly involved (35%), the male to female ratio was 1.2-1. The most common site of the primary lesion was the tongue (45%) (Fig 2). The most frequent histopathological grade was well-differentiated SCC (60%). The most common size of the primary tumors was T4 (65%). Stage IV was the most common stage (Table 1).

Discussion

There is a debate about the role of the CP before the definite diagnosis of LN metastasis is given by histopathology, those who go with high sensitivity and specificity and those who conclude that there is a “not sufficient” sensitivity and specificity for the clinical and imaging examination to predict the LN metastasis\(^{(1,11)}\).

Oropharyngeal cancer is a disease of elderly; the peak incidence is usually during the sixth and seventh decades. The probable explanation is that the activity of the natural killer cells falls with increasing age. The incidence of cancer in the younger age group is uprising due to the diet that poor in antioxidant, genetic factor and exposure to different types of carcinogen\(^{(16)}\). In our study, the peak incidence was in the sixth decade\((35\%)\) and 25% for the younger age group 30-39.

Most of the patients (16 patients, 80%) were in stage IV this is mostly due to ignorance of patients to seek treatment of the primary tumors (delayed diagnosis). This will allow the tumor to increase in size and metastasize to the LN.

The cervical LN metastasis occurs in a successive pattern except in the tongue, floor of the mouth, and anterior area of the oral cavity\(^{(17)}\). When the nodal stage increases the prognosis decreases, overall the rate of cure is halved with the nodal spread\(^{(18)}\).

The sensitivity of CP in our study was 85.7%, which is comparable to various studies\(^{(19,20)}\). While the accuracy of CP in our study was 70%, which is in line with previous studies\(^{(19,21)}\).

Conclusion

It is hard to conclude whether a diagnosis of cervical LN metastasis based on CP can be compared with histopathology because histopathological examination can show metastatic involvement as small as 1mm, which cannot be detected by CP or by imaging techniques. However, the CP can provide a cornerstone role in taking a decision to do or not an elective neck dissection.

Abstract

\textbf{Aim:} This study aims to apply the Intervention Mapping protocol and Social Cognitive Theory in the development of an infection prevention and control education program aimed at critical care nurses.

\textbf{Background:} Education programs have been widely used to improve awareness toward infection prevention and control, but the development of an integrated theory- and evidence-based education program tailored to critical care nurses has not yet been discussed.

\textbf{Subject and Methods:} Data are from the Hospital Universiti Sains Malaysia infection control records. The 6-step Intervention Mapping protocol and the Social Cognitive Theory were used to develop an infection prevention and control education material tailored to critical care nurses. The educational material was also influenced by Previous literature, hospital infection control committee, and in-charge nurses of intensive care unit.

\textbf{Results:} The educational material was tailored to target knowledge, self-efficacy, and risk perception that identified as the individual determinants of critical care nurses health behavior during assessment phase. In addition to physical environment and organizational support that determined as external determinants. A matrix of change objectives was mapped out for each health behavior determinant, teaching methods, and their practical applications.

\textbf{Conclusion:} Applying the Intervention Mapping protocol and the Social Cognitive Theory is effective in developing educational material tailored to critical care nurses to improve their self-confidence and promote knowledge-based practice in infection prevention and control.

\textbf{Background}

Intervention Mapping (IM) protocol is a framework that facilitates the development of an evidence-based education materials for an intervention program in health promotion and disease prevention fields and grounded on health behavior theories and enhance...
their implementation (1, 2), and used to bridge the gap between the behavioral theories and their application in health promotion interventions (2). Although the IM protocol is widely used in the development of health promotion programs, it can also be used in the development of any intervention requiring change in behaviour (3). The significance of the application of the IM Protocol is to describe the intervention developed and the effects of health behaviour theory adopted to promote the achievement of the objectives identified. In addition to developing strategies to ensure sustainability of the intervention program. The adopted health behaviour theory is Social Cognitive Theory (SCT), a multidimensional model that focuses on enhancing self-efficacy, perception of actions consequences, and environmental factors in order to achieve the desired change in individual’s behaviour (4). The application of IM protocol based on SCT to develop an education material for Infection prevention and control (IPC) intervention program that satisfy the needs of critical care nurses to reduce healthcare associated infections (HAIs) has not been addressed before.

HAIs are critical health problem defined as an infection that the patient acquires after 48 hours of being hospitalized (5). The World Health Organizations (WHO) estimates that hundreds of millions of patients worldwide are affected by HAIs annually and indicated high risk in the developing countries, with 10% of hospitalized patients acquire at least one HAI at any time compared to 6-7% in developed countries (6). The impacts of HAIs can be described as increased mortality and morbidity rates, prolonged length of stay, developing of multidrug resistant organisms (MDROs), and increased economic burden (7, 8).

Patients who are admitted in intensive care units (ICUs) are at high risk to acquire HAIs which is associated with their critically ill conditions, the need for invasive devices in their care (urinary catheters, endotracheal tubes, and central venous catheters), comorbidities, and impaired immune system (9). According to the WHO healthcare-associated infections fact sheet, the HAIs in intensive care units is 2-3 times higher in low and middle-income countries compared in high-income countries (10). The largest portion of care in ICUs are provided by the critical care nurses who are known to be the vast majority of the healthcare team who have a daily direct contact with patients. Many studies have touched upon the important role of nursing staff in the transmission of HAIs (11-13). An IPC program targeting critical care nurses at the ICU will help in preventing HAIs and improve the quality of health care (14). Low knowledge level is a major contributor to high HAIs rates worldwide (8, 15). And the need for educational programs is now critical to improve the knowledge and practice levels of IPC among nurses (16).

Various studies conducted in Hospital Universiti Sains Malaysia (HUSM) have identified the need for an IPC program to tackle the HAIs problem. One study reported that 74% of HUSM healthcare professionals in critical care units have more than 50 colony-forming units (CFUs) of microorganisms on their hands and concluded that there is a need for a program to promote effective hand hygiene techniques (17). Another study revealed the need to update the IPC protocols of HUSM and emphasized on the need for post-operative follow-up system to prevent SSI, especially in high risk patients who had open heart surgery and diabetic patients (18). And as the development of MDROs, especially in ICUs, is a critical health issue, a study reported that 13.6% of the total mortality rate in critical care units in HUSM were related to Carbapenem Resistant Acinetobacter (CRA) (19), which is make the development of an effective and comprehensive education program to understand the proper use of antibiotics is a crucial need.

The majority of the studies conducted educational programs to improve the awareness in one or more competencies of IPC (e.g. hand hygiene) (20-22), but studies that focus on the development of an integrated educational program that covers multicomponent of IPC competencies, in addition to the fundamentals to understand IPC and satisfying the requirements of critical care nurses are very limited.

The contribution of this paper is to describe the
development of tailored educational material for an intervention program directed at critical care nurses at HUSM. Another contribution of this study is to expand the scope of IM protocol application to include the development of education materials to be used in an IPC intervention program and the use of Social Cognitive Theory (SCT) to improve critical care nurses awareness and their compliance toward IPC.

Materials and Methods

The education material has been developed in conjunction with the WHO’s guidelines on health education (23) and using the Intervention Mapping (IM) protocol (1). In addition to Social Cognitive Theory (SCT) that enhances health behaviour change by applying theory-based teaching methods.

Step 1: Needs Assessment

The education material will be used in an intervention program aimed at adult critical care nurses at HUSM and, thus, in order to identify the needs and capacities of the hospital and the target group, the assessment phase consisted of three strategies:

First strategy: Assessment of HUSM infection control system

The assessment of HUSM infection control system was performed by using the Centers for Disease Control and Prevention (CDC) IPC Assessment Tool for Acute Care Hospitals (24). The assessment tool focused on assessing the applied infection control program and infrastructure.

Second strategy: Healthcare-Associated Infections Prevalence Rates

The hospital infection control records were reviewed and a one-year prevalence rates of HAIs were obtained and analyzed from 1st of January 2019 to the 31st of December 2019 for HUSM adult ICUs (neuro ICU, medical ICU, surgical ICU, and cardiothoracic ICU).

Third strategy: Cause and Effect Analysis of the Problem

A cause-and-effect is a method used to identify potential causes of the problem under study, which can then be organized in a structural format called the “fishbone diagram” (25). This method is unique in that it encourages both creative thinking and brainstorming in the process of breaking down the problem to find its solutions.

The assessment phase findings were discussed with the Hospital Infections and Epidemiology Control Unit staff and the ICUs infection control link nurses who were invited to brainstorming sessions to identify the main and sub-causes of the problem in the ICUs at HUSM.

Step 2: Setting of objectives

The aim of step 2 of the IM protocol is to establish a framework for the development of the proposed education material that will be used in an intervention program by determining what will improve as a result of the intervention (1). This step is achieved by working on the overall objective of the education material which is to increase knowledge and practice levels toward IPC among critical care nurses to reduce HAIs. A set of performance objectives (POs) was then identified from the overall objective and established on the basis of the findings of the needs assessment (step 1) and taking into consideration the viability of carrying out the IPC education program activities with the available HUSM resources. After determining the POs, a matrix of change objectives (COs) was created to link the POs to the identified determinants of critical care nurses behavior.

Step 3: Program design

The third step of IM protocol involves the identification of the theory-based instructional methods that can contribute to the attainment of behavior change objectives and the practical applications that can operationalize these methods (1).

The methods to be applied to different aspects of the developed education material have been based on Social Cognitive Theory (SCT), a commonly used theory of behavior change that has been applied in health
promotion and disease prevention (4, 26, 27). The SCT is a multidimensional model wherein beliefs in individual abilities act together with objectives, perceptions of the outcomes of particular action, and environmental factors in determining individual’s behavior (4).

Step 4: Program development

The fourth step of IM protocol concerns on the development of the educational material. In this step, the teaching methods and their practical applications which addressed in step 3 will be used for attaining the objectives identified in step 2 to ensure development of the education material that suits the critical care nurses and meet their needs which determined in step 1 (1). The educational material resources were based on web-based content published by CDC, WHO, Malaysian Ministry of Health (MMOH), and the Association for Professionals in Infection Control and Epidemiology (APIC). In addition to literature on relevant topics.

Step 5: Program implementation

The fifth step in IM protocol focuses on how to adopt, implement, and sustain the education-intervention program (1). It is a crucial step that should be properly considered during the development of the education material in order to ensure that it will be translated into practice and to fulfill the purposes of the program.

Step 6: Evaluation plan

In step 6, the IM protocol focuses on developing an evaluation plan for the process and effectiveness of the education program (1).

Process evaluation

The Hospital Infections and Epidemiology Control Unit and the Nursing Department were engaged in the development of the education material and the outcomes of each step were discussed and evaluated with them.

Effectiveness

The main goal of the developed education material is to improve the knowledge and practice levels of critical care nurses toward IPC. We determined the interventional study design, and the data collection and analysis methods to assess the effectiveness of the education material to the target group.

Results

Step 1: Needs Assessment

In this phase, High HAIs prevalence rates confirmed the need to develop an IPC education material aimed at critical care nurses to improve their awareness and practice. The brainstorming sessions, taking into consideration the findings of the qualitative studies reviewed, the HUSM infection control assessment, and HAIs prevalence analysis, ended in the description of the causes of the study problem in the fishbone diagram (Figure 1).

![Figure 1 Fishbone diagram of the study problem](image-url)
The changeable determinants of IPC practices that identified in needs assessment phase and as supported in the qualitative studies (28-33) were knowledge, self-efficacy, and risk perception at the individual level. Whereas at the external level, changeable determinants were physical environment, and organizational support. The resulting information served to determine the needs to develop an education material for an intervention program to counter the HAIs in HUSM.

The needs assessment findings were summarized into logic model of the health problem (HAIs), shown in Figure 2. This model outlined the causes of the HAIs identified by the needs assessment and the key determinants of behavior related to individual and external levels (1).

Figure 2: Logic model of the health problem (HAIs) based on needs assessment

Step 2: Setting of objectives

The education material objective is to increase knowledge and practice levels toward IPC among critical care nurses to reduce HAIs. This objective has been subdivided into POs(Table 1). The POs were formulated on the basis of the WHO’s guidelines on health education (23) and debated with the HUSM infection control committee. To change the behavior of critical care nurses, a matrix of change objectives (COs) was established by combining the POs with the relevant important and changeable determinants of behavior

Step 3: Program design

The appropriate theory-based methods, based on the adopted SCT, for each of the individual and external determinants are then determined through discussion with the Hospital Infections and Epidemiology Control Unit at HUSM to ensure that they fit the education material context and characteristics of the critical care nurses. The determined theory-based methods included: consciousness raising, persuasive communication, advance organizers, tailoring, modeling, feedback, empowerment, facilitation, and developing new organizational network linkages

Step 4: Program development

The education material named as Nursing Guide to Infection Prevention and Control and it consists of three main constructs explained over six different chapters (Table 1). A glossary of IPC terminology that was added at the beginning of the developed material and arranged alphabetically. For learners to construct knowledge, they require to integrate new knowledge with knowledge that are in their cognitive structure (34), so that the educational material developed based on the results of critical care
nurses needs assessment in step 1\(^{(1)}\). And in order to facilitate understanding and building new knowledge, the educational material takes the form of contextual strands that are strongly integrated in such a way as to ensure tackling complex tasks in IPC.

After developing and designing the needed material, the topics were discussed with the Hospital Infections and Epidemiology Control Unit at HUSM to ensure its suitability and applicability to the critical care nurses. Then, the material was reviewed by the research team in terms of content’s relevancy and clarity, spelling, and using of infographics.

</tbody>
</table>
Step 5: Program implementation

To optimize adoption and implementation, an introductory meeting will be scheduled prior to commencement of the education program with the higher management of the HUSM, Hospital Infections and Epidemiology Control Unit, and Nursing Department. This meeting will be arranged to provide a brief overview of the education material and its' components, the role of the higher management, Hospital Infections and Epidemiology Control Unit, and Nursing Department, and to facilitate communication and collaboration between them and the research team. Another vital element of any education-intervention program, once implemented, is to improve its’ sustainability (1). So that, in coordination with the Hospital Infections and Epidemiology Control Unit, and Nursing Department, the education-intervention program will be part of continuous nursing education (CNE) program and the participants will be granted continuing professional development (CPD) points, in addition to adopting the educational material as a part of periodic validation of IPC competencies for critical care nurses.

At the critical care nurses level, to improve adoption, the HUSM represented by the Nursing Department and Hospital Infections and Epidemiology Control Unit will inform the participants about the education program and the importance of their participation, and an attractive posters will be designed that will briefly explained the education program. In addition to the participant consent form that will contain description of the education
program and its’ effects on improving their knowledge and practice toward IPC and how that will improve the quality of health care and protect the health of patients, healthcare workers, and visitors, and scope of critical care nurses participations. The consent form will be distributed on critical care nurses to sign and grant their agreement to participate in the education program. The program instructor will motivate the participants during the program sessions to improve implementation. In order to improve sustainability by the critical care nurses, counselling via email or telephone will be provided by the instructor and the Hospital Infections and Epidemiology Control Unit.

To ensure adoption and implementation of the developed education material to be used for an intervention program in the way that fulfill the purposes of what it designed for and to ensure participation of all critical care nurses, a guideline for the implementation of the education program is mapped out and will be provided to the Hospital Infections and Epidemiology Control Unit, and Nursing Department.

Step 6: Evaluation plan

Process evaluation

The developed educational material was discussed and reviewed with the Hospital Infections and Epidemiology Control Unit and Nursing Department and they affirmed that the development process adopted resulted in the appropriateness of the education material to be used as an education program with respect to the objectives defined in step 2 and the assessment findings (step 1) of critical care nurses’ needs and the implemented infection control system.

Effectiveness

According to the education material development objective, which determined on the basis of the needs assessment in step 1, the hypothesis will test whether the knowledge and practice toward IPC among critical care nurses improved after applying the education program compared to before the program.

The effectiveness of the developed education material will be evaluated in one group pre- and post-test quasi experimental study. The total of 138 adult critical care nurses of medical ICU, surgical ICU, neuro ICU, and cardiothoracic ICU will be included in the study. A closed-ended and valid questionnaire which developed according to the WHO IPC precautions will be used to assess the impact of the educational material as an intervention program on the knowledge and practice of the targeted group. It will be assessed two times, before and 3 months after the implementation of the education program.

The difference between pre- and post-test will be analyzed through repeated measures ANOVA. The analysis will be done by using the Statistical Package for the Social Sciences (SPSS) Ver 26 with CI-95% and P value ≤0.05.

Discussion

IM protocol is now widely being used to plan, implement, and evaluate interventional programs for disease prevention, and that will increase, significantly, the uptake of these programs (2).

This study is one of the few focusing on the development of education material for an intervention program in the field of IPC at healthcare setting targeting critical care nurses. It describes the development, implementation, and evaluation of an educational material to be used for an intervention program to improve the levels of IPC of critical care nurses based on evidence-based knowledge, using the IM protocol (1).

Our study has come out with results that assure the usefulness of IM protocol for designing IPC education material. The significance of IM protocol arises from identification of individual and external determinants of IPC practice which was the start point of developing education material. The needs assessment indicated the importance of individual factors such as having adequate knowledge, self-efficacy, and risk perception as well as external factors that reflected by the physical environment and organizational support in changing
their behavior and promoting their compliance with IPC precautions. Taking these determinants into account, it helped in developing the *Nursing Guide to Infection Prevention and Control* material which aims to enhance the self-confidence of critical care nurses by acquiring evidence-based knowledge for practice of IPC and clarifies the risks of incompliance with the precautions of IPC. The developed education material also focuses on the role of suitability of hospital environment and providing of organizational support on facilitating the IPC practice. For example, in order to clarify the individual determinants, the critical care nurses role in the prevention of MDROs development as a result of incorrect prescription of ineffective antibiotics can be viewed as having confidence to review the prescribed antibiotic in the light of the results of culture and sensitivity test and the confidence to discuss with the attended physician in case of incorrect prescription of antibiotic. The self-efficacy of critical care nurses is based on their knowledge in microbiology of infection and their perception of the risk of developing MDROs. Clear understanding of the microbiology of infection reflects on enhancing implementation of IPC practices and ensuring patients and healthcare workers safety (35). The external determinants can be described, for example, as the suitability of the hospital environment and availability of IPC supplies at the point of care in addition to the motivation of critical care nurses to minimize the stress of work to ensure better practice of IPC precautions.

The findings of the needs assessment (step 1) were consistent with the barriers that many studies concluded to IPC compliance by healthcare staff (28-33).

IM protocol recommends that the development of an education material for an intervention program should be on the basis of health behavior theory to plan and implement the education-intervention program (1). Health behavior theory helps to determine the teaching methods to be applied to ensure achievement of performance objectives (POs) and change objective (COs) and suit the target group and ensure their adoption and implementation of the education-intervention program. Consciousness raising, persuasive communication, advance organizer, tailoring, modeling, feedback, empowerment, facilitation, and developing new organizational network linkage were the planned teaching methods to be used in implementation of the *Nursing Guide to Infection Prevention and Control* which were extracted from the Social Cognitive Theory (36).

The usefulness of Social Cognitive Theory (SCT) in *Nursing Guide to Infection Prevention and Control* material development and implementation is in consistence with the results of many studies. One systematic review study revealed that the SCT was the most frequently used framework in driving healthcare practice behavior change (37). In our study, the focus is to improve the critical care nurses belief in their ability to execute IPC precautions that based on cognitive (personal) factors of acquiring evidence-based knowledge through well-developed education material, and this is supported by SCT (36). The SCT focuses on understanding of individual behavior as the function of their perceptions that affected by variant cognitive variables which include knowledge, perception of threats, expectations of outcomes, motivation, and social pressure (38).

The strategies that have been used to ensure adoption, implementation, and sustainability of the education-intervention program depend on keenness of the research team to involve the higher management, hospital infections and epidemiology control unit, and the critical care nurses in the process of development the education material. At the critical care nurses level, they will be encouraged by the Nursing Department and the Hospital Infections and Epidemiology Control Unit to participate in the education-intervention program as it will be adopted as periodic validation program of IPC competencies, and the importance of the education-intervention program will be explained through attractive posters and the distribution of participant consent forms that contains description of the program and its importance, in addition to motivating them during the implementation of the program by the research team.
Conclusion

In this study, IM protocol facilitate understanding of actual critical care nurses needs and the barriers to compliance with IPC precautions. And It is effectively enhancing the development of an integrated educational material that satisfy the needs of critical care nurses across three interlinked contextual strands, including: fundamentals to understand IPC, principles of IPC, and specific IPC.

The teaching methods that extracted from the adopted SCT, facilitate the development of education content that will enhance achievement of the desired individual’s behaviour change. The application of IM protocol based on SCT was successfully guide the development of critical care nurse-oriented, feasible, and an integrated education material to be used in an intervention program to improve awareness and increase compliance with IPC to reduce the HAIs.

Ethical Approval

The study has been approved by the Human Research Ethics Committee of HUSM (approval code: HUSM/JEPeM/19070440) and carried out in compliance with the research ethics guidelines outlined by the 1964 Helsinki Declaration.

Acknowledgments

The authors gratefully acknowledge the higher management of HUSM and the health care staff of HUSM represented by Hospital Infections and Epidemiology Control Unit and Nursing Department, and the academic staff of health campus of HUSM represented by microbiology and parasitology and medical education departments at school of medical sciences and interdisciplinary health department at school of health sciences for their collaboration and rich contribution in making the success of this study.

Competing Interest

The authors declare no competing interest. This study was funded by Research University (Individual) Grant (RUI grant No.: 1001.PPSK.8012373) of USM. The funder had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript, or in the decision to publish the results.

The Correlation Study between Some Biochemical Parameters of 256 Covid-19 Cases Considering Diabetes

Ahmed Ab. Jabbar
Lecturer, Medical Laboratory Techniques Department, Erbil Technical Health College, Erbil Polytechnic University, Erbil, 44001, Iraq

Abstract

Background: Diabetic Mellitus is an independent risk factor in patients with coronavirus disease 2019 (COVID-19), but data on the association of diabetes, acute kidney injury, and COVID-19 severity are limited to Middle East populations.

Materials and Methods: This cohort study aimed to investigate these associations in 256 patients sequentially admitted between June 2020 and November 2020, at Emirati Hospital/Erbil. The investigation included some main biochemical parameters including liver and kidney function tests. Data analysis was processed by SPSS and the Pearson correlation pathway using log-converted data.

Results: Diabetic patients showed the highest correlations between measured parameters, of which glucose level showed a positive correlation coefficient (0.13**) with C-reactive protein and other biochemical parameters. Based on the glycemic status, COVID-19 patients were found in 3 groups, euglycemia group with an abundance of 148 (57.81%), hyperglycemia patients were 67 (26.17%), and 41 of them were diabetics (16.01%).

The Diabetic group showed a significantly (0.0002) increased level of C-reactive Protein and Glucose in comparison with hyperglycemia [CRP 15.38 mg/dl vs 10.09mg/dl, glucose 429.75 mg/dl vs 160.62mg/dl] with a Significantly (0.00374) higher mortality rate (29.26%) than that (10.44%), and (6.75%) of hyperglycemia, and euglycemia, respectively.

Conclusion: Male COVID-19 cases showed higher correlations between the estimated parameters than female cases. Diabetes was significantly associated with elevation of almost all kidney and liver function parameters. Finally, diabetes followed by COVID-19 disease was related to severe complications and higher mortality rates than nondiabetic COVID-19 cases.

Keywords: Biochemistry, COVID-19, Diabetes, Kidney and liver injury, correlations

Introduction

A new viral infection known by the coronavirus (COVID-19) has invaded Wuhan, China, in December 2019. Zoonotic exposure led to the transmission of coronavirus (COVID-19), resulting in the current pandemic disease. After one year, since the first case announcement, the total COVID-19 cases in December 2020, has reached 75 million reported cases and 1.6 million deaths of Novel COVID-19 disease.

Diabetic disease is considered a chronic disease that results from either complete lack of insulin (type 1 diabetes) or resistance to insulin (type 2 diabetes). Diabetics are more vulnerable to multiple infectious diseases, eventually, damaging to their immune system.

Corresponding author: Ahmed Ab. Jabbar
ahmed.abuljabbar@epu.edu.iq
and even causing organ failure, resulting in higher mortality rates as in COVID-19 patients. In addition, the death incidence of 27955 Italian diabetes by COVID-19 was 31.1%. This has risen in another survey in the UK, the prevalence death of 23804 British diabetes by COVID-19 was 32%. While another study showed 22% of death occurrence of diabetes with confirmed COVID-19 cases among 52 intensive care unit patients in China.

Acute kidney injury (AKI) incidence in COVID-19 disease was varied as evidenced by Chinese, invasion of COVID-19 virus into kidney tissue, clinical epidemiology of COVID-19–associated acute kidney injury (AKI) across our health system later also has been reported. A rapid increased serum urea and creatinine levels caused a hypercatabolic state in which understanding the causes will help as a marker for disease severity, predicting pulmonary or kidney outcomes. Previous study published different incidence rates of AKI from only 0.5% among 1099 patients, to 22.2% in 3908 patients with a 75% mortality rate. A recent cohort study on 3200 patients with COVID-19, showed that closely half of them had AKI and acute dialysis. Therefore, exploring the biochemistry of COVID-19 patients with diabetes will aid the physicians to reduce the incidence of severity. A retrospective study on 256 COVID-19 after confirmation by Real-time polymerase chain reaction (PCR) in one hospital was made and the correlations between estimated biochemical parameters were discussed.

**Materials and method**

**Data collection**

A total of 256 Admitted patients between June 2020 and November 2020, at Emirati hospital/Erbil, were enrolled in this study. After confirmation of Real-time polymerase chain reaction positivity for COVID-19 infection, the patients were separated into males (157) and females (99). Based on the glycemic status, COVID-19 cases were divided into 3 groups, euglycemia group (had normal blood sugar level before and during hospitalization), hyperglycemia group (increased blood glucose during hospitalization with no history of diabetes but their blood sugar normalized after hospital discharge), and Diabetes group had Elevated blood glucose level with a history of using diabetic treatments. Blood Samples were taken to the laboratory for examination of high sensitive C-reactive protein (hs-CRP), alanine aminotransferase (ALT), alkaline phosphatase (ALP), aspartate aminotransferase (AST), total bilirubin (TBILL), Direct bilirubin (DBIL), Urea, and Creatinine by the biochemical auto analyzer (Cobas - Roche C 311, Hitachi company, Japan).

**Statistical Analysis**

Data processing was made by SPSS (0).21 (IBM, Armonk, NY, USA). The Undistributed data were converted into a log 10 scale. The relation between the parameters was found by the Pearson correlation pathway using log-converted data.

**Results and Discussion**

The Data analysis in Table 1. shows that among the 256 included cases of COVID-19, 157 of them were males (63.33%) with an average age of 56.13 years, and 99 of them were female (38.67%) with an average age of 53.62 years. As illustrated in (table 2), from a total of 256 COVID-19 patients, 148 of them were euglycemia (57.81%), 67 of them were hyperglycemia (26.17%), and 41 of them were diabetics (16.01 %). the average age was higher in diabetic patients (55.68 years) than those of euglycemia (48.12years) and hyperglycemia (51.08years), respectively. Males have outnumbered females with no significant differences on the estimated parameters. Diabetes was associated with significantly higher mortality rates (29.26%) than that of hyperglycemia (10.44%), and euglycemia(6.75%), respectively (Table 2), (Figure 1). The displaced laboratory results in (Table 1) show that the levels of Urea, creatinine, AST, ALT, TBILL, DBILL, ALP, and CRP were higher nonsignificantly in male COVID-19 cases than that of female cases.

</table>

Note: Mean ± standard deviation in COVID-19–positive patients.

Data analysis in Table 2. showed significantly (p-value =0.002) higher urea values in diabetes 58.75 (27.3-132.4)mg/dl than that of 49.03(23-151) mg/dl, 37.09(17-104)mg/dl, for Hyperglycemia and euglycemia, respectively. Creatinine was significantly (p-value=0.00236) higher in the diabetic group 0.807 (0.5-3.3)mg/dl than that of 0.60 (0.3-2.9)mg/dl, 0.57 (0.3-2.7)mg/dl for Hyperglycemia, and euglycemia, respectively. The Diabetic group showed significant (0.0002 and 0.001) differences in the level of CRP and Glucose, respectively, in comparison with hyperglycemia [ CRP 15.38 (3.1-25.8) vs 10.09 (1.8-17.1), glucose 429.75(276-580) vs 160.62(120-213)] mg/dl and euglycemia group [ CRP 15.38 (3.1-25.8) vs 8.33 (1.6-16.3), glucose 429.75(276-580) vs 91.49 (54-115)]mg/dl. Insignificant changes existed in other tested parameters, such as AST, ALT, TBILL, DBIL, and ALP levels.

</table>

Data are shown as medians and interquartile ranges.

In male COVID-19 patients, the analyzed data anticipated the positive correlation coefficient (r-value) between urea (0.69), AST (0.37), DBIL (0.22), and CRP (0.039). While DBIL had a positive correlation with Urea (0.22), creatinine (0.21), and TBILL (0.28), and negatively correlated with the AST (-0.02) and ALP (-0.03). CRP values showed significant relations with the Urea (0.39) and creatinine (0.40) numbers, Table 3. The measured parameters showed fewer correlations in the female cases, which only AST had a significant correlation coefficient (r-value) with the Urea (0.21) and creatinine (0.21) numbers. And, ALT was significantly correlated with ALP (0.22) and AST (0.64) as shown in table 4.

*< 0.05; **< 0.01. The Bold values represent statistically significant findings. The first line shows the r values, the second line for p values, and the third line is for patient numbers in all correlations included.

Diabetic patients showed the highest correlations between measured parameters, of which glucose value had positive correlation coefficient (r value) with urea (0.22**), creatinine (0.17**), AST (0.19**), ALT (0.03*), DBIL (0.02**), ALP (0.05**), and CRP (0.13**) levels. CRP values showed significant correlations with the Urea (0.32**), Creatinine (0.27**), AST (0.31**), and ALT (0.15*) levels. ALP was significantly associated with creatinine and Urea (0.24**), AST (0.23**), and ALT (0.19*). No significant relationship was detected between TBILL and other chemical parameters (except for DBILL). And finally, Creatinine values were found to be negatively correlated with the TBILL values (-016*), Table 5.
Table 5. Correlation findings detected in the Diabetic patients.

*< 0.05; **< 0.01. The Bold values represent statistically significant findings. Gender discrimination did not consider, the first line shows the r values, the second line for p values, and the third line is for patient numbers in all correlations included.
Coronavirus is a multiorgan inflammatory disease, specialized from another virus of their family, by its rapid spreading, highly contagious, and more vital to the respiratory system with higher mortality rate than previous virus outbreak. Our data showed that the biochemical parameters did not change significantly based on gender. The same was found by other researchers.

Men were more common in all three glycemic groups. Our results showed that men COVID-19 patients had higher correlations between their biochemical parameters, specifically urea and creatinine values, which in severe cases may lead to acute kidney injury. By our outcome, previous reports also concluded that regardless of age, men are at higher risk for more severe results with a higher incidence of death than women.

Based on the glycemic status, the current work showed significant differences in the levels of CRP, glucose, and kidney function parameters (Urea and creatinine) between the three tested groups, in which the values were significantly higher in groups with higher sugar levels (Hyperglycemia and diabetics) in compare with euglycemia COVID-19 patients. This may explain the elevated mortality (29.26%) in diabetic group in our data analysis. Such an increased mortality rate in diabetic patients is following a previous study, which proposed a mortality rate of diabetes with COVID-19 disease between 20-32% in different countries according to COVID-19 severity and poverty status.

Studies showed that increased glycemic status is an independent risk factor of mortality and in the case of COVID-19 patients, causing severe complications because of increased releasing of glucocorticoids and catecholamines into circulation. also led to an increase in the glycation end products and worsened prognosis. Another study showed that increased ACE2 (Angiotensin-converting enzyme2) receptors in hyperglycemia and diabetic patients facilitate COVID-19 virus adherence to the pancreatic cells leading to decreased insulin secretion by β-cells and thus raising

Figure 1. Shows the mortality rate in the COVID-19 group according to the glycemic levels.
the severity of COVID-19 infection in those patients 24,25. Another reason behind the high mortality rate in diabetes may be due to impaired leukocyte function of phagocytosis leading to increased viral infections. In addition, increased cellular binding affinity, decreased viral clearance, reduced T-cell function, and increased susceptibility to hyper-inflammation, and renin-angiotensin-aldosterone system (RAAS) activation are other causes behind the high mortality rate of diabetes following COVID-19 disease 25. The abundance of Dipeptidyl Peptidase-4 which degrades incretin 25 and furin 26 in diabetic patients, is another entry enhancement for coronavirus. Diabetes also has different lung volumes and pulmonary diffusing capacity that also affects their severity level of COVID-19 disease 27.

Our data analysis showed that the level of urea and creatinine positively correlated with the CRP and almost all other estimated parameters without gender discrimination. Diabetes had significantly higher levels of urea and creatinine than those of the euglycemia and hyperglycemia groups. The same result was found by the previous researchers 28. Previous studies also showed kidney dysfunction and acute kidney injury (AKI) occurrence in a range of 3-9% with 3-fold higher odds of death than COVID-19 without AKI 29. Studies on hospitalized patients with COVID-19 disease reported that 44%, 30 and 63% 31, of them had proteinuria and significantly increased serum creatinine and blood urea nitrogen levels. Thus, AKI is considered as an independent risk factor of death with or without COVID-19 30. A recent study considered the kidney as a target organ of the COVID-19 virus after successful isolation of the virus in the urine sample of an infected patient 32. Pathogenesis between the current virus and AKI may be also due to sepsis occurrence heading to cytokine storm syndrome 33.

**Conclusion**

The COVID-19 pandemic still has many unraveled sites that need to be undertaken. As shown from our results that the gender has no significant effect on the severity and progression of COVID-19 disease, although more correlations between biochemical parameters were found in males than in females. The presence of Diabetic Mellitus followed by COVID-19 disease will increase the odds to possess severe complications of liver and kidney organs. C-reactive protein and glucose levels of diabetic COVID-19 patients were positively correlated with almost all estimated biochemical tests, which could be the reason behind the higher mortality rates of diabetes than those of euglycemia and Hyperglycemia COVID-19 patients. The severity of COVID-19 and increased levels of CRP was associated with increased levels of urea and creatinine regardless of gender or glycemic status, which may be referred to an important indications of acute kidney injury. Due to data limitations, some laboratory tests were not included. More elaborate research trials are still required to anticipate other postulates related to correlations between COVID-19, diabetes, and acute kidney injury.

Psychological Distress among Caregivers of Children with Down Syndrome at Al Najaf Province

Ahmed Burhan Abdulameer¹, Arafat Hussein Al-Dujaili²

¹Research Scholar, Faculty of Nursing, University of Kufa, Iraq, ²Professor, Faculty of Medicine, University of Kufa, Iraq

Abstract

Psychological Distress has recently been shown to have a negative impact on caregivers, but there has been little longitudinal research on this subject. A sample (61) caregivers of children with Down Syndrome have been selected Al-Najaf Province centers. The researcher adapts and modifies the questionnaire to fulfill the study’s objectives. The results of the study revealed that caregivers of children with DS have severe level of psychological distress (38.7%). There is a significant relationship (P < 0.05) between Psychological Distress and some of the socio-demographic characteristics (child age, family member and trainings about down syndrome). The present study recommends providing families with Educational programs to increase parents knowledge about etiology, signs and symptom and treatment of stress and Providing scientific booklet, publication and journal about stress. In addition to increasing schools and institutes specialized in educating children with Down syndrome, as they are few in the province of Najaf, and some of them are far from their places of residence.

Keywords - Psychological Distress, Caregivers, Children, Down Syndrome

Introduction

Globally, mental health disorders have emerged as major public health concerns; disabilities, physical mortality and morbidity, and poor social functioning can all result from psychiatric disorders; furthermore, psychological issues can exacerbate the social burden and economic insecurity in a variety of societies around the world (¹). Psychological distress (PD) is a form of emotional turmoil marked by a blending of depression and anxiety symptoms (²). In Europe and the United States, the prevalence of psychological distress among parents of children with chronic diseases is as high as 50% (³), and there are 8.27 individuals with down syndrome for every 10,000 people in the United States (90 % UI, 6.14-10.62) (⁴). Psychological distress is broadly defined as an emotional state characterized by symptoms of depression (e.g., loss of interest; sadness; hopelessness) and anxiety (e.g., restlessness; tenseness); these symptoms may be linked to somatic symptoms (such as insomnia, headaches, and a lack of energy), PD is viewed as an emotional disturbance that may impact on the social functioning and day-to-day living of individuals (⁵). Down syndrome (DS) is the most common chromosomal anomaly which is associated with intellectual disability (ID), typical physical features, and health problems. The incidence of DS is about 1–1.5 of every 1000 live births. DS is the most frequent genetic cause of mental retardation (MR). People with MR have behavioral, emotional, and psychiatric problems more often than the general population. DS exhibits distinctive neurodevelopmental, neurocognitive, and psychopathological patterns when compared to other genetic syndromes leading to ID, albeit higher than the general population. A 28.9% of the children with DS have psychiatric comorbidity (⁶). Caregivers of children
with DS are often distressed, many of the children have unmet needs that are not being addressed by services, and the degree of unmet need is related to caregiver distress; these high levels of anxiety are likely to have an effect on the parents’ health and ability to care for their children (7). Due to a child’s disability, parents may be required to pursue educational and recreational accommodations to ensure that the child has the same opportunities as a child who is not disabled, caring for a child with a chronic condition (such as a child with Down syndrome or DS) causes caregivers to experience additional stress, which may lead to caregiver distress (8). The main person with complete or greater responsibility for the care given to the person being cared for is the family caregiver, and there is no financial reimbursement for the care provided (9,10). Parents are the most common caregivers, since they look after their children in all aspects of their lives (11). The majority of family caregivers are women who perform time-consuming and demanding activities such as personal care, aside from the physical, emotional, and financial effect, there are also limitations in social and recreational activities (12).

Materials and Methods

A descriptive (correlational) quantitative design study was carried throughout the present study to identify the psychological distress among caregivers of children with Down Syndrome. During the period from 15th September 2020 to 15th April 2021. A non-probability sampling technique (purposive sample) of (61) caregivers of children with Down Syndrome are included in the study. The General Health Questionnaire-12 (GHQ-12) is a tool for assessing current mental health that has been used in the current study.

The Kessler Psychological Distress Scale (K10) was used as indicator of psychological symptoms.

Results

The caregivers in this study are within ages of 37 and 46 (39.3%), female caregivers (75.4%), mother’s age (49.2%), child age (57.4%), those are graduated in institute and college (27.9%), those with barely sufficient monthly income (54.1%), those who are married (86.9%); those who are housewives (52.5%); those who live in urban areas (85.2%); those who are freehold owning their houses (78.7%); those who were not trained for down Syndrome (78.7%); those with no physical disorder (73.8%); those with no psychiatric disorder (93.4%).

Discussion

Psychological distress (PD) is a popular community mental health problem,\(^{(14)}\). The influence of caregiver stress, which can lead to distress, on caregivers’ mental wellbeing has been well recorded, caregivers of people with a range of physical and psychological disabilities have higher rates of anxiety and depression than noncaregivers, and caregivers are twice as inclined to seek mental health treatment emulated with noncaregivers\(^{(15)}\). Globally, mental health problems accounted for 13% of the overall burden of disease, and 31% of all years lived with disability.

The analysis of findings revealed that most of sample were married mothers of children with down syndrome, fall in the age group (37- 46) years old, graduated from institute or college(27.9%) with barely sufficient monthly income . These findings have revealed that parenting of DS children fell overwhelmingly on the hands of mothers more than fathers; these mothers are responsible for their children’s care. Fathers generally play a secondary role in the care for children or sometimes no role at all, leaving the primary caregiver responsibility to the mother. This finding was backed up by Rodrigue and his colleagues, who found that mothers accounted for 74% of all parents. Peishi Wang and his colleagues discovered that 59.2 percent of parents were mothers, which provided additional support. Also this approves with study of\(^{(16)}\), The study results indicate that the more caregiver is the mother’s(74%), \(^{(17)}\) mention that (53.8%) of caregivers were mothers.

The results showed that the majority of the subjects’ job (52.5%) are house wife , In the point of view that is in our culture, fathers spend most of their time in work and had provider responsibility, and mothers have the responsibility for household and child care, so mothers spent all her time for their children . This finding comes along with \(^{(18)}\) who found that (70%) of samples are housewives. Supplementary support was found by \(^{(19)}\) the study that show (71.4%) of samples are housewives .

Concerning the training cycle, the results show that caregivers without a training cycle account for the largest percentage of those with training. This result agrees with \(^{(16)}\). Table (1) reveal that the majority of caregiver have (moderate) level of general health assessment (60.66%) ; while (37.7%) of them have (good) level of general health assessment.

This result accords with Dijkstra-de Neijs& his colleagues (2020) whose studies show that most of parents of children with chronic disabilities suffer from disturbance in mental health and well-being .Furthermore, the results were in line with those of Sangeetha, et al. (2017), who found that (40 %) caregivers are experienced moderate to severe level of general health assessment , Depression was detected in (63%)and (53.8%) of The caregivers’ psychological well-being was clinically disturbed.

Table (2) and Figure(4.3) assert that the majority of caregivers have severe disorder (24) of K10 Scale assessment(38.7%). It is clear that some of individual who participated in the study have severe disorder, this may be due a history of anxiety and depression as a result of stressful situations .This result is consistent with previous research that indicates chronic illness or a negative self-evaluation of one’s health is related to increased psychological distress. This result is agree with \(^{(17)}\) the study assures that (57.7%) of caregivers have psychological distress, \(^{(20)}\) who found that (39.6%) of caregivers had GHQ score suggesting severe level of psychological distress. Additionally supporting was done by \(^{(21)}\) who reported that (60.5 %) of caregivers experience elevated level of psychological distress .

Tables (3) display that there is a significant relationship between psychological distress among caregivers of DS children and child’s age. This result may be due to the fact that children of this age (8-13 years) have more mobility and their needs are more than the youngest and older children. This result almost agree a study by Johnson and his colleagues, (2013) who found that the majority of children(7.7 to 8.8 years ) with chronic conditions contribute to increase distress of their parents . The current result agrees with Gilbert, (2009) he revealed that there is a significant association between
age of the child and psychological burden. They are positively correlated and the child’s age increases with the increase in respondent’s burden.

Conclusions

The researcher has reached the following conclusions based on the discussion and analysis of the study findings: The study concluded that most of the caregivers were to have moderate psychological distress. Psychological distress was statistically significant among females. Family member, child age and Training about Down Syndrome were statistically significant while other parameters regarding socio-demographic characteristics of caregivers were not significant. The caregivers were under the age of fifty, and more than three quarters of the caregivers’ children were females (mothers). The majority of the subjects were married, had a high degree of education, and had a meager income.

Evaluation of the Antioxidant and Antibiofilm Activities of *Rosmarinus Officinalis* Essential Oil Extract

Ahmed H. Al-Azawi¹, Kais Kassim Ghaima², Noor Saad Latteef³, Alaa Aziz Abdulhassan⁴

¹Associate Professor, ²Professor, ³Lecturer, ⁴Research Scholar, Institute of Genetic Engineering and Biotechnology for Postgraduate Studies, University of Baghdad, Baghdad, Iraq

Abstract

Biological activities of essential oils from various plants, including Rosemary, have been attributed to the presence of specific chemical compounds with antimicrobial, anti-inflammatory and antioxidant activities. The aim of this study is to estimate the antioxidant and antifungal activity of *Rosmarinus officinalis* essential oil extract. The study included the extraction of essential oil using a Clevenger apparatus. The chemical compositions were evaluated by GC-MS and High Performance Liquid Chromatography (HPLC). The rosemary essential oil extract was tested with regard to antioxidant utilizing 2, 2-diphenyl-1-picrylhydrazyl (DPPH) assay. Microtiter plate Assay used to determine the antifungal and antibiofilm activity. The result showed that the GC-MS analysis revealed that the major components determined in *R. officinalis* essential oil were linalool (17.09 %), L- Borneol (11.92 %), Verbenone (8.52 %), camphor (5.30 %), Eucalyptol (4.79 %), while the chemical compositions identified by HPLC shows four phenolic acids were identified in the essential oil, Rosmarinic acid, Caffeic acid, p-Coumaric acid, 4-hydroxybenzoic acid, and lignans (medioresinol), while Isorhamnetin was the only flavonol detected. The free radicals scavenging activity increased gradually with the increase in the concentration of essential oil which was 81.59 % when compared with BHT and V.C (92.34 and 97.42) respectively. The results of the antifungal activity revealed that Minimum Inhibitory Concentration of *C. albicans* and *C. krusei* was 3.125%, while the MIC of *C. glabrata* was 12.5% in contrast with the highest MIC which recorded for *C. tropicalis* at 25% of rosemary essential oil. The current results revealed that the reduction of biofilm formation among *C. albicans* and *C. krusei* was obvious at the lower concentration (1.56%), where the percentage of biofilm formation in *C. albicans* was (91.25%) and *C. krusei* was (84.25%), while *C. tropicalis* exhibit (86.32%) for biofilm reduction at the concentration (12.5%) of rosemary essential oil, also it was found that the effect of essential oil on *C. glabrata* biofilm formation was at the concentrations 3.125% and 6.25%. The findings of this study indicated to the significant effect of rosemary essential oil against the growth and biofilm formation of the important pathogenic yeast *C. albicans* at low concentrations.

Keywords: *Rosmarinus officinalis*, Essential oil, GC-MS, HPLC, Antioxidant, Antibiofilm

Introduction

The use of traditional herbs and medicinal plants has recently become very popular because they contain large amounts of natural products with biological properties. Medicinal plants extracts possessed strong antioxidant and antimicrobial activities against pathogenic organisms. Medicinal and aromatic plants have been used for their bioactive compounds with potential applications in food industry, nutraceuticals, cosmetics and perfumes. Also, some plants from the Lamiaceae family are very rich in phenolic compounds, such as flavonoids, phenolic acids and phenolic diterpenes, and possess high antioxidant activities. These compounds...
can delay or inhibit the oxidative damage caused by free radicals and can protect us against major diseases such as coronary heart disease and cancer in human (4, 5). Also it was found that the extracts and essential oils of Rosmarinus officinalis show inhibitory effects against cyanobacteria (6).

Rosemary (Rosmarinus officinalis L.) is a spice and medicinal herb widely used around the world. They are also used as flavouring agents in foods (7). Additionally, various pharmacological studies have demonstrated the analgesic, anti-inflammatory, and anti-ulcerogenic properties of R. officinalis (8, 9). Many compounds have been isolated from rosemary, including flavones, diterpenes, steroids, and triterpenes. Of these, the antioxidant activity of rosemary extracts has been primarily related to two phenolic diterpenes: carnosic acid and carnosol. The main compounds responsible for the antimicrobial activity are α-pinene, bornyl acetate, camphor and 1, 8-cineole (10, 11). Thus, the purpose of this research is to estimate the antioxidant, antifungal, and antibiofilm activities of Rosmarinus officinalis essential oil extract

Material and Methods

Chemical reagents

The chemical reagents DPPH (2,2-diphenyl-1-picrylhydrazyl), Butylated hydroxytoluene (BHT), ascorbic acid, gallic acid monohydrate (3,4,5-trihydroxybenzoic acid) and sodium carbonate were purchased from Sigma aldrich chemicals (St. Louis, USA). Folin Ciocalteu reagent was purchased from Merck (Darmstadt, Germany), Resazurin dye (Himedia, India), Sabouraud’s dextrose broth (Himedia, India) and crystal violet (Pro-Lab, Canada).

Candida spp. isolates

The isolates of Candida spp. (C. albicans, C. glabrata, C. tropicalis and C. krusei) were obtained from specialist hospital in Baghdad, Iraq, from female patients with Vulvovaginitis and identified by Vitek2 system.

Plant material

Fresh leaves of Rosmarinus officinalis plant were procured from the greenhouse in Baghdad, Iraq. Authentication and identification of the plant were carried out by the specialist, Department of Biology, College of Science, University of Baghdad.

Extraction of the essential oil

Air-dried leaves of the Rosmarinus officinalis plant was subjected to steam distillation for 4 h using a Clevenger apparatus. The essential oil was kept at −4°C in an amber glass airtight container.

Fourier transform infrared (FTIR) assay

FTIR stands for Fourier Transform Infrared, the preferred method of infrared spectroscopy. In infrared spectroscopy, IR radiation is passed through a sample. Some of the infrared radiation is absorbed by the sample and some of it is passed through (transmitted), the resulting spectrum represents the molecular absorption and transmission, creating a molecular fingerprint of the sample. Like a fingerprint no two unique molecular structures produce the same infrared spectrum, this makes infrared spectroscopy useful for several types of analysis. The FTIR spectrum was recorded between 4000 and 400 cm−1 (12).

Gas chromatography mass spectrophotometer analysis

Analysis of the Rosmarinus officinalis essential oil was carried out on GC-MS equipment. The experimental conditions of the equipment are: HP-5MS ultra inert capillary non-polar column, dimensions: 30 mm × 0.25 mm; ID: 0.25 mm, film thickness: 0.25 μm. The flow rate of mobile gas: 1.0 ml/min. The oven temperature for the gas chromatographic part was 50°C raised to 300°C at 7oC/min for 10 min. The nature and structure of compounds were identified by the mass spectrometer. The spectrum of unidentified components was compared with the spectrum of identified components stored in the national institute standard and technology (NIST) library (13).
High-Performance Liquid Chromatography (HPLC) Analyses

HPLC analysis was performed for analysis of Rosmarinus officinalis essential oil extract. The HPLC analysis was carried out according to Adham (2015) (14) the separation was performed in reversed-phase ODS-C18 column (250 mm×4.6 mm i.d); the mobile phase consisting of 80% methanol as solvent (a) and 20% (water with 0.1% acetic acid) as solvent (b). A flow rate was set at 1 ml/min for 10 min, detected by UV at 320 nm.

Determination of total phenolic contents

Total phenolic content of Rosmarinus officinalis essential oil extract was determined spectrophotometrically using the Folin-Ciocalteu method described by Jayaprakasha et al. (2001) (15), 2 ml of Folin-Ciocalteu reagent (diluted 10 times) was mixed with 1.6 ml of 7.5% sodium carbonate solution and 0.4 ml of the essential oil extracts. The volume was completed to 5 ml by adding distilled water. The tubes were covered with parafilm for 30 min. at room temperature, and then the absorbance was read at 760 nm spectrophotometrically. The total phenolic content was calibrated against gallic acid standards and expressed the results as mg gallic acid equivalents (GAE)/g extract. The test was performed in triplicate.

DPPH assay

The DPPH free radical scavenging activity of Rosmarinus officinalis essential oil extract was determined following the method described by Kedare and Singh, (2011) (16), 5ml of a freshly prepared 0.004% of 2,2-diphenyl-1-picrylhydrazyl (DPPH) in methanol was mixed with 50 μl of different concentrations (0.312, 0.625, 1.25, 2.5 and 5) μg/ml of the essential oil, then the mixture was left to stand for 30 min. The absorbance was measured at 517 nm. Butylated hydroxytoluene (BHT) and ascorbic acid were used as a positive control. All tests were performed in triplicate. The percentage of DPPH reduction was calculated as:

% Reduction = (Abs DPPH – Abs Dil.) / Abs DPPH × 100

Where: Abs DPPH = average absorption of the DPPH solution, Abs Dil. = average absorption of the three absorption values of each dilution.

With the obtained values, a graphic was made using Microsoft Excel. The EC50 of each extract (concentration of extract or compound at which reduced 50% of DPPH) was taken from the graphic.

Determination of the antifungal activity

Antifungal activities of the rosemary essential oil towards Candida spp. (C. albicans, C. glabrata, C. tropicalis and C. krusei) were determined by the Resazurin Microtiter plate Assay (broth dilution method) (17). Fifty microliters of the essential oil was two-fold serially diluted (0.19-100%) with Sabouraud’s dextrose broth in a microtiter plate. Fifty microliters of the Candida suspension was added and mixed with the oil. Candida cultured in the broth without the tested agents served as a positive control and the mixture of broth and the tested agents without microorganism served as a negative control. The plates were incubated for 24 h, at 37 °C. Then Candida growth was examined and the lowest concentration of the tested agents which inhibited the visible growth of the yeast was recorded as the minimum growth inhibitory concentration (MIC). All experiments were repeated on two of each species of Candida and three separate occasions, with triplicate determinations on each occasion.

Biofilm formation of Candida spp.

Biofilm formation was determined by crystal violet assay (18). After the growth of Candida spp. (C. albicans, C. glabrata, C. tropicalis and C. krusei) with serial dilutions of sub-inhibitory concentrations of Rosemary essential oil (0.78-25%) in the wells of microtiter plate, the content of each well was carefully removed and the plate was washed five times with sterile saline solution to remove any unattached cells. Pure methanol (200 μL) was added to each well and incubated for 15 min.
Methanol was removed, the plates were thoroughly dried at room temperature, and 200 μL of 0.5% crystal violet was added for 15 min. Then, the stain was removed and the wells were washed in tap water and dried. Two hundred microliters of 95% ethanol was added to each well. Finally, the absorbance (OD450) was read using a microplate reader.

Inhibition of biofilm was determined from the formula described by Jadhav et al. (2013) (19).

\[
\% \text{ Inhibition} = 100 - \left( \frac{\text{OD450 nm sample}}{\text{OD450 nm growth control}} \times 100 \right)
\]

**Results and Discussion**

**Fourier Transform Infra-Red (FTIR)**

Figure (1) shows the infrared spectra of the *Rosmarinus officinalis* essential oil, the results revealed that the presence of different functional groups such as phenolic–OH group stretching, C-H stretching, C≡C stretch, Aromatic C=C, P=O stretch, N-O stretch and Aliphatic C–O (Table 1).

Abdullah *et al.* (2010) \(^{(20)}\) mention the GC analysis revealed that the major components determined in *R. officinalis* essential oil were 1,8-cineol, camphor, α-pinene, limonene, camphene and linalool, while Christiane *et al.* (2016) \(^{(21)}\) revealed the major components of the essential oil indicated three compounds: cineole, camphor and alpha-pinene. The variation in the chemical compositions of *R. officinalis* essential oil across countries might be due to different ecological conditions. Our results are in agreement with the findings of Jan *et al.* (2017) \(^{(22)}\) that also identified eucalyptol, α-Linalool, Camphor, L- Borneol, Verbenone, Caryophyllene, etc. as major components of *R. officinalis* essential oil.

*R. officinalis* is an aromatic plant popularly known as rosemary which has important biological properties, especially due the phenolic and the essential constituents, such as carnosol, carnosic acid and rosmarinic acid present in the extract of rosemary and α-pinene, bornylacetate, camphor and eucalyptol present in the essential oil of this species \(^{(23)}\).

**High-Performance Liquid Chromatography (HPLC)**

Individual phenolic compositions of *R. officinalis* essential oil were analyzed by HPLC method. Figure (3) shows that the essential oil of *R. officinalis* contains 16 polyphenolic compounds, and 6 compounds were identified depending on retention time according Hossain (2010) \(^{(24)}\), Romo-Vaquero (2012) \(^{(25)}\) and Meziane-Assami *et al.*, 2013 \(^{(26)}\), the result shows four phenolic acids were identified, Rosmarinic acid (compound 1), Caffeic acid (compound 2), p-Coumaric acid(compound 4), 4-hydroxybenzoic acid(compound 6), and lignans (medioresinol), while Isorhamnetin was the only flavonol detected.
Total phenolic content of *Rosmarinus officinalis* essential oil extract

Phenolic compounds are a class of antioxidant agents which act as free radical terminators and their bioactivities may be related to their abilities to chelate metals, inhibit lipoxygenase and scavenge free radicals \(^{(27)}\).

The results of total phenolic content in the *Rosmarinus officinalis* essential oil were (30.52, 41.80 and 54.47 mg/g) in (50, 100 and 200 µg/ml) respectively as shown in (Table 3).

**Table (3): Total Phenolic content of *Rosmarinus officinalis* essential oil**

<table>

\(^{**} (P\leq0.01).\)

Genena *et al.* (2008) \(^{(28)}\) mention the amount of phenolic compounds content ranged from 7.45 to 13.51 g of TAE/100 g of extract, with an overall mean of 10.06 g of TAE/100 g of extract. Phenolics are a class of compounds, which act as free radical scavengers and are responsible for the antioxidant activity in many medicinal plants \(^{(29)}\).
Determination of Antioxidant Activity Using (DPPH) Radical Scavenging Method

The antioxidant activity of essential oil was assessed by the DPPH (2, 2-diphenyl-1-picrylhydrazyl) free radical scavenging method. The free radicals scavenging activity increased gradually with the increase in the concentration of essential oil as shown in Table (4). Furthermore, the antioxidant activity is expressed as an effective concentration (IC50). The half-maximal effective concentration (IC₅₀) often refers to the concentration of a drug, toxicant, or antibody which induces a response halfway between the baseline and maximum after a specified exposure time is commonly used as a measure of the potency of a drug. (30) In this study, the radical scavenging capacity (IC50) of vitamin C and BHT were (0.2 and 0.4 µg/ml) respectively, while the essential oil was (1.8 µg/ml) as shown in Figure (4). Lee et al. (2007) (31) confirmed if the IC₅₀ value of the extract was less than 10 µg/ml it indicates the extract is an effective antioxidant. In this study, the IC₅₀ value of Rosmarinus officinalis essential oil is less than 10 µg/ml this indicates the extract was effective antioxidant.

Elansary et al. (2012) (32) revealed monoterpenes hydrocarbons are known to have noticeable antioxidant activities. Our study was higher than study presented by Benyoucef et al. (2018) (33) which concluded that R. officinalis essential oil showed the greatest antioxidant activity with an IC50 of 2.6 mg/L.

Figure 4: IC₅₀ of Rosmarinus officinalis essential oil
Determination the antifungal activity

In this study, the antifungal activity of rosemary essential oil was evaluated. The minimal inhibitory concentrations (MICs) of rosemary oil against four species of Candida were detected by Resazurin Microtiter plate Assay as showed in Figure 5.

![Figure 5: Minimal inhibitory concentration of serial dilutions of rosemary oil against four species of Candida by Resazurin Microtiter plate Assay](image)

The results revealed that MIC of C. albicans and C. krusei was 3.125%, while the MIC of C. tropicalis was 12.5% in contrast with the highest MIC which recorded for C. tropicalis at 25% from rosemary oil. The findings of the current study indicated to the significant effect of rosemary oil toward the important pathogenic yeast C. albicans at low concentrations. Fu et al. (2007) (34) investigated the antimicrobial activity of the essential oils from rosemary (Rosmarinus officinalis L.) and studied the Minimum inhibitory concentrations (MICs) against three Gram-positive bacteria, three Gram-negative bacteria and two fungi were determined for the essential oil The essential oil possessed significant antimicrobial effects against all microorganisms tested, where the MICs of rosemary oil ranged from 0.125% to 1 % (v/v).

In a previous study by Abdulaziz et al. (2015) (35), the diameter of inhibition zone with rosemary essential oil was (11.8±2.8) and the serial two-fold dilutions of the tested essential oil showed exhibited antifungal activities even at very low concentrations. In a study by Tavassoli and Emamdjomeh (2011) (36) the antimicrobial activity of rosemary leaf extract against some of bacteria, Saccharomyces cerevisiae, and Candida krusei was determined by MIC measurements and the results indicated that the rosemary extract had a stronger inhibitory effect against the bacteria.

The mechanism of action of essential oils is related to changes in cell membrane permeability. The liposoluble nature of essential oils and their constituents facilitates their interaction with cellular structures that
have lipid components, resulting in increased membrane permeability, which in turn can cause electrolyte imbalance and cell death \(^{(37)}\). It was found that the antifungal action of the \textit{M. alternifolia} essential oil against \textit{C. albicans}, \textit{C. glabrata} and \textit{Saccharomyces cerevisiae}, is related to the changing in the permeability and membrane fluidity of these fungi \(^{(38)}\).

The effect of rosemary essential oil on the biofilm formation of the local isolates of \textit{Candida} spp. was investigated as showed in table 5.

**Table 5: The percentages of biofilm reduction by rosemary oil against four \textit{Candida} spp at different sub-inhibitory concentrations**

</tbody>
</table>

*The reduction of biofilm included 3 isolates of each species.

The current results revealed that the reduction of biofilm formation among \textit{C. albicans} and \textit{C. krusei} was obvious at the lower concentrations (1.56%), where the percentage of biofilm formation in \textit{C. albicans} was (91.25%) and \textit{C. krusei} was (84.25%), while \textit{C. tropicalis} exhibit (86.32%) for biofilm reduction at the concentration (12.5%) of rosemary essential oil, also it was found that the effect of essential oil on \textit{C. glabrata} biofilm formation was at the concentrations 3.125% and 6.25%. The local study of Raheem and Ghaima (2021) \(^{(39)}\) revealed that the Nystatin had the inhibitory activity against \textit{C. albicans} at the concentrations 6.25 and 12.5 μg/ml, while the highest antibiofilm activity by Nystatin were demonstrated at the subinhibitory concentration 50 μg/ml with biofilm eradication percent (75.80%).

As the findings of the present study, Cavalcanti \textit{et al.} (2011) \(^{(40)}\) found that the essential oil of \textit{R. officinalis} had an anti-adherent effect on \textit{C. albicans}, where the oil at the concentration 2.25 mg/mL caused significant cell disruption and inhibition of adhesion and the intermediate effect was observed at 1.12 mg/mL. The rosemary essential oil was found to be more active against the gram-positive pathogenic bacteria and drug-resistant mutants of \textit{E. coli}, similarly, it was found to be more active toward nonfilamentous, filamentous, dermatophytic pathogenic fungi and drug-resistant
mutants of Candida albicans. The results of the previous study revealed that R. officinalis extract provided a significant biofilms reduction after 5 min treatment, with rates of 99.96 ± 0.07% for C. albicans; 67.84 ± 12.05% for S. aureus; 77.64 ± 15.67% for E. faecalis; 79.32 ± 7.34% for S. mutans; and 98.23 ± 2.17% for P. aeruginosa. In the biofilm of C. albicans with S. mutans was also observed reductions of 92.04 ± 5.24% and 64.55 ± 15.12%, respectively.

Rosmarinus officinalis essential oil when coated to nanoparticles strongly inhibited the adherence ability and biofilm development of C. albicans and C. tropicalis to the catheter surface, as shown by viable cell counts and scanning microscopy examination and the sub-inhibitory concentrations of these substances resulted in a reduction of the amount of sterol extracted as well as the capsule size, suggesting that they play an important role, in particular by causing the cell wall destruction and membrane irregularities, the presence of vesicles and cell wall thickening in C. albicans.

Conclusion

The phytochemical constituents present in the essential oil extract of Rosmarinus officinalis showed twenty-four constituents such as Eucalyptol, Linalool, Camphor, Borneol, Verbenone, and Caryophyllene and contains 16 polyphenolic compounds with 6 compounds were identified. The free radicals scavenging activity increased gradually with the increase in the concentration of essential oil and it was found that the essential oil was effective antioxidant. The findings of this study exhibited that the essential oil has antifungal activity against pathogenic C. albicans isolates at low concentrations. Also, the current results revealed that the reduction of biofilm formation among C. albicans and C. krusei was obvious at the lower concentrations.

Abstract

An accurate diagnosis of ovarian cysts is of utmost importance to determine the timely treatment to preserve fertility. We sought to determine the effectiveness of ultrasonography and MRI modalities for diagnosing the most common ovarian lesions and differentiate between benign and malignant lesions in order to guide patients to appropriate treatment. This study was conducted on 94 women, the age group between 14-70 years, in the period of January 2020 to October 2021. Were all women suffering from abdominal pain, swelling, nausea or vomiting and bleeding and irregular menstrual cycle. Was suspected clinically in the presence of lesions in the ovary was confirmed by tests of ultrasound and magnetic resonance. The entire cases were subjected to transvaginal and transabdominal ultrasound and magnetic resonance imaging to assess ovarian lesions in terms of content (somatic, cystic solid), nodules, septal characteristics, wall thickness, vascular lesion and ascites. In USG, there were 16% cases of malignant ovarian lesion and 84% cases had benign lesions. MRI reports showed that 10.6% cases had malignant ovarian lesions and 89.4% cases had benign lesions. Findings of USG with HPE have 100.0% sensitivity, 89.1% specificity and 91.07% diagnostic accuracy. In MRI findings with HPE have 100.0% sensitivity, 100% specificity, and 100.0% diagnostic accuracy. MRI had high specificity and more accuracy value in terms of diagnostic performance than USG. The ultrasonography diagnostic value in case of characterization of adnexal mass lesion was significantly lower than in the MRI.

Keywords: USG, MRI, histopathology, adnexal lesions, ovarian cyst, adnexal masses.

Introduction

One of the common disorders in gynecology is ovary cysts, also known as adnexal masses or ovarian masses. Ovarian masses pose a dilemma for gynecologists since the diagnosis of variation is complex and difficult. Among the most serious types of gynecological cancer are ovarian malignancies, which are characterized by a late onset and poor response to therapy. Adequate surgical management of ovarian cancer remains as the cornerstone treatment for possible malignancy of the ovary and minimal invasive surgery (i.e. laparoscopy or laproectomy) if the tumor is benign. One of the routine gynecological investigation and primary diagnostic in cases of suspected a lesion and identification ovarian mass is an ovarian ultrasound. Where the mass in adnexal region is recognized as undefined on ultrasound when it couldn’t be surely located into either the malignant or benign tumor, even after thorough examination including evaluation by the Doppler, or for which the location of source, from the uterus, ovary
or other structures of the pelvis, stays to be decided (3). When findings of the ultrasound are equivocal or nondiagnostic, the magnetic resonance imaging can be solve the problem, an auxiliary method of assessing lesions in adnexal region, appropriate for even providing information on surgical readiness with avoiding the radiation exposure. Magnetic Resonance Imaging (MRI) can be used specifically to provide accurate details of fat, collagen, and hemorrhage (5-7). Also, it can detect several kinds of masses in the pelvis and distinguish between malignant and benign ovarian tumors with high accuracy ranging from 88-93% (1, 7). MRI due to its higher contrast to the soft tissue and high spatial resolution abilities can improve characterization and definition of normal anatomy pelvic organs with diffuse and focal conditions of the uterus. MRI has the advantage of a noninvasive test, without radiation risk, less operator-dependent and not need anesthesia (8). Characteristics of benign tumors are more indicative, a wall thickness smaller than 3mm, completely cystic consistent, a diameter smaller than 4cm, absence of inner structure and the lack abdominal fluid (as cites), adenopathy or disease of peritoneal (9). MR imaging has become an essential device in the valuation of patients with adnexal lesion, and its role continues to develop. Some benign structures can be diagnosed by magnetic resonance imaging with a high grade of sureness, such as endometriomas, simple and hemorrhagic cysts, fibromas, and hydrosalpinx (10). In cases of malignant tumors, MR imaging may be more exact than other modalities for staging, lesion characterization, and follow-up (11). Most significant morphological characteristics of ovarian masses at significant risk involve (a) the lesions is solid or solid / cystic with a high diameter greater from 4 cm; (b) The appearance of unequal, non-fatty, Solid avascular zones larger than 28 mm in diameter (c) In a cystic lesion, the existence of papillary bump and thick wall and septa larger from 3mm (12, 13).

In this study, we aimed to investigate the effectiveness of ultrasound and magnetic resonance imaging (MRI) for diagnosing the most common ovarian lesions. In addition, we studied the cases to determine the precision of ultrasonography (USG) and magnetic resonance imaging (MRI) in ovarian cyst characterization to differentiate between benign and malignant lesions in order to guide patients to appropriate treatment.

**Patients and Methods**

Ninety four consecutive patients, with age group (14–70) years; the mean age was 39.13 years diagnosed with adnexal lesions by ultrasound and MRI in the department of radiology in Al-Hakeem in Najaf teaching hospital, the women present with variation of symptoms include abdominal swelling, irregular cycle, abdominal pain, bleeding, incidental. MR imaging was achieved on 1.5T unit of MR to do T1-weight edimages(T1W), T2-weighted images, and fat-suppression image T1-weighted pre and post intravenous MRI contrast agent (gadolinium). Ovarian cysts have features that include shape, size, content (solid - cyst), nodal or vascular septum, and reinforcement. In addition, other features appeared includes peritoneal disease, enlarged lymph nodes and ascites. We differentiate surgical and pathologic findings with the image features. On all MR imaging features, multiple logistic regression analysis was performed without clinical details. They were classified as benign or malignant, according to the image features that were differentiated to the pathological findings and surgical.

**U/S and Doppler Protocol**

The systems used were the PhilipsHD11xe and GE Vivid E9, and GE volusion E6. All devices had a transabdominal probe of about 2–5 MHz and an endovaginal probe with 5-7 MHz. All devices had both pulsed Doppler and colorability. Where U/S and Doppler of the abnormality in ovarian may have been endovaginal performed, transabdominal Doppler U/S of the abnormality may have been used for non characterization outcomes. Before menstruation of females were arranged for the USG in eight days to the beginning their menses.
The protocol of MR Imaging

MR imaging was performed on 1.5-T units (Siemens Medical Systems). For imaging the pelvic, we used the multi-coil array, while for imaging the abdomen, we used body-coils. The sequences used to females pelvis was transverse T2-weighted sequence fast spin-echo (5,100–6,100/104–128 (TR msec/TE msec)) with a number of echoes acquired in given TR (ETL) of 15, a thickness of slice 4–10mm, and gap 1–2.5mm. 256 × 256 matrix size with twain signals obtained. These series recurred as seen in sagittal and coronal sequences. A transverse T1-weighted image sequence (510-810/12-20) with T2-weighted sequence similar to spatial resolution was then accomplished. After injections intravenous (10-15) mL of gadolinium, the T1W images recurrent. By an axial fat-suppressed T1W spin-echo sequence and an axial T2W fast spin-echo sequence, the residue of the pelvis and abdomen were imaged. There was 16 of an echo train length, an 5-9mm thickness of the slice, and a gap 1-2.5-mm in the T2-weighted sequence (4,100/101-125). The matrix was 256 or 256×192 by 2 to 4 signals obtained, in the planes of coronal and sagittal, this sequence was repeated. The sequence of T1-weighted (400–610/12–21) an 4–8-mm thickness of slice with a gap 2-mm. The two signals with a matrix o 256×128–192.

Discussion

The study was achieved on 94 females who had clinically suspected ovarian lesions who were primarily investigated with U/S then by MRI. The last diagnosis was confirmed by histopathological (HPE). Age patients ranged from 14 to 70 years; the mean age was 39.13 years. Most cases (91.5%) had unilateral lesions while 8.5% had bilateral lesions. These bilateral lesions were confirmed as malignant. 16% cases were suffered with multiple presentation, 62.7% abdominal pain, 4.3% cases were with abdominal swelling, 8.5% cases were with abnormal bleeding and 58.5% cases were suffered with irregular cycles of menstruation (figure 2). Also, this study showed most of the benign lesions are simple cysts, thin wall of cyst with absent vegetations, nodules, or a solid component and without of significant contrast enhancement. Whereas, typical characteristics of ovarian lesion in MRI which pointed to a malignant pathology were, thick wall, present enhancing, septations, vascularity, solid areas, ascites, present nodules this agree with Arun Prasad et al. (14).

USG findings showed most lesions were cystic in nature 80 (85.1%) than solid cystic 14(14.9%), Nodules was absent in 93(98.9%) cases and nodules was seen in 1 (1.1%) case. Ascites was absent in 89(94.7%) cases and present in 5(5.3) cases, 85(90.4%) cases absent with Septum while 9(9.6%) cases had with septum, vascularity was absent in 85(90.4%) and present in 9 (9.6%) as shown in table 1.

MRI findings of this study stated that most lesions were cystic in nature 82 (87.2%) than solid cystic 12 (12.8%) Nodules was absent in 90(95.7%) cases and nodules was seen in 4(4.3%) cases. Ascites was absent in 89(94.7%) and seen in 5(5.3%) cases, septum was absent in 84(89.4%) and septum was seen in 10(10.6%), vascularity was absent in 85(90.4%) and present in 9 (9.6%) as shown in table 1.

Also, on USG there were 15(16%) cases of malignant ovarian lesion and 79(84%) cases had benign lesions. MRI results showed that 10(10.6%) cases had malignant ovarian lesions and 84(89.4%) cases had benign lesions. Those results are roughly in agreement with Chinta Vittal Prasad et al. (15).

The comparison of findings of USG with HPE: The sensitivity of US results in diagnosis of malignant ovarian cyst was (100.0%) that mean ultrasound was able to diagnosed all patients with malignant ovarian correctly. The specificity of US results in diagnosis of benign ovarian cyst was (89.1%) that mean ultrasound was able to diagnosed (89.1%) patients with benign ovarian correctly. Positive predictive value (PPV) was (66.7%) that mean those diagnosed as malignant ovarian cyst by US was (66.7%) being malignant ovarian cyst by histopathology and negative predictive value (NPV) was (100.0%) that mean all those diagnosed as benign ovarian cyst by US being diagnosed as benign ovarian cyst by histopathology and overall accuracy was (91.07%) as shown in table 2. The sensitivity of MRI results in diagnosis of malignant ovarian cyst was (100.0%) that mean MRI was able to diagnosed all patients with malignant ovarian correctly. The specificity of MRI results in diagnosis of benign ovarian cyst was (100.0%) that mean MRI was able to diagnosed all patients with benign ovarian correctly. Positive predictive value was (100.0%) that mean those diagnosed as malignant ovarian cyst by MRI was (100.0%) being malignant ovarian cyst by histopathology and negative predictive value was (100.0%) that mean all those diagnosed as benign ovarian cyst by MRI being diagnosed as benign ovarian cyst by histopathology and overall accuracy was (100.0%) as shown in table 3. In this study ultrasound sensitivity was same as that MRI, however specificity and accuracy was more on MRI with small percentage difference in detecting malignancy in adnexal lesions that agree with Sadowski, E. A. et al. (16) and disagree with Chinta Vittal Prasad et al. (15) and Yasmeen Usmaniet al. (17).

Conclusion

In USG, there were 16% cases of malignant ovarian lesion and 84% cases had benign lesions. MRI reports showed that 10.6% cases had malignant ovarian lesions and 89.4% cases had benign lesions. The comparison
of findings of USG with HPE has 100.0% sensitivity, 89.1% specificity. 66.7% PPV, 100.0% NPV and 91.07% diagnostic accuracy. In comparison of MRI findings with HPE have 100.0% sensitivity, 100% specificity, 100% PPV, 100.0% NPV and 100.0% diagnostic accuracy. The results conclude that MRI had high specificity, accuracy value than USG. MRI is dominant in diagnosis and characterization of ovarian cystic lesion than ultrasonography. MRI is superior to ultrasound and can be used in difficult or equivocal cases.

Abstract

In this study, thirty patients complaining of bruxism at night and hyperactivity masseters muscle causing TMJ disk changes, TMJ clicking sound and all selected patient complaining of gingival inflammation as included criteria, and 50-unit botulinum toxin type A were injected in both side of masseter muscle. Regarding to T.M.J clicking sound there were three intervals of PRP injection for 3 months. The levels of IL-6 in the blood samples measured by ELISA technique, this study proposed to investigate the plasma IL-6 level in patient with early changes of T.M.J disorder and role of repetitive intraarticular PRP injection on the T.M.J clicking sound and the effect of decreasing stress force microtruma of masseter muscle on gingival score in previously diagnosed bruxism patient with gingival inflammation whether of causative factor of gingivitis. The mean difference of plasma IL-6 in between patient and control (25.6 ± 4.2 and 23.8 ± 1.8) respectively. There were highly significant differences in gingival index score of all sided of oral cavity after botox intramuscular injection. Force stress muscle microtruma of bruxism patient considered a contributory factor that increased gingival inflammation these fact suggested by botulinum toxin injection to decrease this force, and highly statically difference on gingival score after injection and also, the intraarticular injection of PRP in T.M.J disorder patient statically not affected on the clicking sound of joint as well as suggesting in our research for further studies to appear the role of IL-6 in early joint changes locally as an experimental study.

Keywords : Gingival Inflammation, IL-6, TMJ, botulinum toxin, PRP , Bruxism

Introduction

Bruxism is defined as non-desirable upper and lower teeth contact that causing in clenching or grinding of teeth due to repetitive, unconscious tightening of the masster and temporalis muscles (¹). One of the biggest problem faced the dentist in the daily work is the fracture of dental restoration, many dentists forget the force from excessive teeth contact as in bruxism that causes teeth wearing, fracture, tooth cracking and gingival, periodontal damage and tooth mobility (²).

The etiology of temporomandibular joint disorder stilled unknown, but many factors included, one of these factors occlusal interference that contributed in masster muscle over contraction and spasm and these microtrauma that causing temporomandibular disorder and pain was considered the most obvious symptoms.

Proinflammatory cytokines play an important role in inflammation and dysfunction of the joint and associated structure as well as muscle of mastication especially lateral pterygoid muscles and masster. Interleukin-6 (IL-6), IL-1 and TNF-a, have been important roles implicated in pain and tenderness by developing and maintenance of muscular hyperalgesia and also

Research Scholar, University of Kufa, Faculty of Dentistry, Iraq,
increased level of proinflammatory cytokines leading to express psychological stresses and depression in patient with TMJ disorder (3).

Parafunctional habits have been thought to cause TMJ microtrauma or masticatory muscle hyperactivity; however, these habits are also common in asymptomatic patients. Although parafunctional habits may play a role in initiating or perpetuating symptoms in some patients, the cause-and-effect relationship remains uncertain. There is some evidence to suggest that anxiety, stress, and other emotional disturbances may exacerbate TMJ disorders, especially in patients who experience chronic pain. It is not clear which symptoms are more common in which TMJ disorders; however, it is generally assumed that joint clicking or grating signifies intra-articular derangement whereas headache, neck pain (4). Clicking sounds (a single sound) have energy concentrated in a short time interval (10–100 ms), while crepitus (a series of sounds) is longer in duration (0.1–1 s). Various attempts to characterize TMJ sounds have been made. Watt described waveforms of clicks and crepitus based on the oscillographic display of the analog sound recordings. Reduction of the articular disc has been suggested as one of the major causes of TMJ clicks (5).

Methods

In this study, thirty patients complaining of bruxism at night and hyperactivity masseters muscle causing TMJ disk changes, TMJ clicking sound and all selected patient complaining of gingival inflammation as including criteria, all of those patient diagnosed in private clinic of oral medicine specialist in Najaf City private dental center in period from 25/4/2020 to 15/2/2021.

All of patients informed the purpose of study and taking her consent, intraoral examination has been done and all of the gingival index score were obtained by specialist of dental prevention in this center, after extra and intraoral examination and including criteria that all selected patient without any sign and systemic disease were approved 50-unit botulinum toxin type A diluted in 2 ml distilled water and injections of 5 unit of diluted botox in each one of 3 marked point one the masseter muscle in both side below the line from angle of mouth to tragus of ear, botulinum toxin prevented release of acetylcholine neurotransmitter in neuromuscular junction and resulting in muscle paralysis and decrease of muscle tone, after 15 days of botulinum toxin injection gingival index score were also measured.

Temporomandibular joint clicking sound were hearing by stethoscope for each patient, all of patient injected by platelet rich plasma (PRP) made from 5 ml Venus blood in PRP tube as described by Mazzocca et al. (6).

The buffy coat was resulted from centrifugation at the superior surface of fluid in PRP tube and red blood cell at the bottom, the procedure was finished and 2/3 of poor plasma from platelet removed by syringe and late about 15 minute to insure the buffy coat was linked and dissolved after gentle shaking the tube in the area of visible gel. Finally, 1ml of PRP aspirated by syringe. Aspirated PRP injected in the TMJ joint in point below 2mm under the 10 mm line drawing from tragus to canthus of the eye. This procedure of PRP injection was done after aspiration to avoid auriculotemporal artery injection (7,8).

Three interval of injection for 3 month and joint sound were evaluated at the end of two weeks from last month. ELISA assays were performed to determine expression levels IL-6 in the blood samples, according to manufacturer instructions (BT LTD company Research Institute). Limitation of present study difficulty in patient follow-up the research begun with thirty patients and dropped to 25 patients in 3 months.

**Discussion**

It has been suggested that trauma from occlusion in the presence of periodontal inflammation may be an important contributory factor in the pathogenesis of periodontal disease (9,10). Thus, occlusal forces may alter the path of spread of gingival inflammation and thereby facilitate direct penetration into the periodontal ligament enhancing angular bone resorption and infra bony pocket formation (11,12).

Therefore, in our study highly significant differences in gingival inflammation after botulinum toxin injection in masseter muscle suggesting decrease level of force applied on teeth by muscles botox injection lead to decrease spreading and penetration of gingival inflammation as well as the considering bruxism as causative factors or contributory factor in gingivitis and needing further studies in futures.

The importance of IL-6 in OA is also supported by previous results. It was shown that IL-6 concentrations in synovial fluid were considerably higher in patients with cartilage defect or OA than in donors without joint pathology. Follow-up study showed that increased serum concentrations of IL-6 were associated with articular changes observed in radiographs (13).

In present study there is no significant in plasma IL-6 level in patient with T.M.J changes as a clicking sound and our suggestion that local changes of cytokines in early stage of T.M.J disorder and changes occur without developing pain response that result agree with previous research (14).

Pain is one of the common sensations which usually indicates tissue damage as a consequence of various external or internal factors. From the results of previous report, it seems that masticatory muscles are capable to adapt to minor occlusal changes and chronic stress without developing the changes in pain response, but when this two proposed etiological factors work together they cause a higher pain response (14).

In the present study, similarly to pain response results, there was a lack of significant changes in both tissue and plasma IL-6 levels between the chronically stressed animals and rats with occlusal interference in comparison to the control group, while masseter IL-6 significantly increased in animals submitted to combination of experimental procedures. These results suggest that only the combination of occlusal interference and chronic stress leads to a strong local inflammatory reaction characterized by the alteration in masseter IL-6 level. Results of other studies showed increased levels of IL-6, prostaglandins, serotonin, and growth factors in muscle tissue after the contraction and muscle damage (15). Also, cytokines (IL-6, IL-1, IL-8, TNF-a) and prostaglandins, when locally injected, influence nociception causing hyperalgesia (16).

Contrary to positive association between pain response and masseter muscle IL-6 level found in this study, in most plasma samples the IL-6 level was below the detectable limit of the assay and there were no differences in plasma IL-6 levels between groups as well as no correlation with pain. Although not significant, there was a negative correlation coefficient between the pain and blood IL-6 level. Low level of blood IL-6 found in this study, especially in the group with combination of occlusal interference and chronic stress and negative correlation coefficient regarding to pain response point to the difference between local and systemic cytokine response. It has been suggested that blood IL-6 level does not depend on its local level and in contrarily to local proinflammatory reaction, the systemic cytokine response might be directed towards suppression of inflammatory reaction (17).

After 3 intervals of PRP injection there were no significant differences statically in between group and that came in agreement with previous studies stated that the joint sound was evaluated using VAS scale (18) other studies it was calculated on joints affected by sound or crepitus, (19) and in another two number of patients reporting sound was scored (20). In all of the
works analysed joint sound was found to improve during follow up. But remained results were not statistically significant, nevertheless an improvement was noticed (20).

**Conclusion**

force stress muscle microtrauma of bruxism patient considered a contributory factor that increased gingival inflammation these fact suggested by botulinum toxin injection to decrease this force, and highly statically difference on gingival score after injection and also, the intraarticular injection of PRP in T.M.J disorder patient statically not affected on the clicking sound of joint as well as suggesting in our research for further studies to appear the role of IL-6 in early joint changes locally as an experimental study.

Comparison between 3 Different Types of Mouthwash on the Healing Process of Periodontal Diseases

Ammar Alwan Ali¹, Zainab Kasim Mohammad¹, Abeer Isam Abdulhameed¹

¹Researcher, High Diploma in Periodontics / Dental Health Specialist Center in Sheikh Omar / Baghdad, Iraq

Abstract

Dental plaque is the principal etiological agent for the development and progression of gingival and periodontal diseases. Three different mouthwash types were compared in this study for the periodontal healing process based on the results. For all bacterial strains, the culture type collection is used. The serial dilution process is used for preparing every mouthwash and adding it to the tubes with a specific dilution. In certain microorganisms of the respective mouthwash, the last tube dilution that does not show any turbidity will be considered MIC. The three types of mouthwashes were compared in terms of the ability to inhibit microbial growth. Twenty-four hours after the agar was solidified and the colony forms (CFU) units counted, the plates were incubated. This study showed that bacterial growth inhibition might occur in the three types of mouthwash. Both, Behsa and Kimgingival mouthwashes had a significant difference in their antimicrobial effect. This study showed that they were unable to perform s after 24 hours of in vitro incubation while the bacterial count was lowered after two weeks of in vivo use in the boht washings. Continuous exposure to bacteria may be necessary to wash the mouth, especially for Behsa and Boht. It is difficult to remove all bacteria from the mechanical plaque controls; antibacterial mouthwash can cause additive. In the current study, three types of mouthwash have compared antimicrobial effects. The results showed only that bacterial counts are affected by mouthwash. Based on this study’s results, Boht mouthwash is more effective than Kin Gingival and Behsa mouthwash for oral microorganisms, but further clinical studies are necessary to confirm our findings.

Keywords: Dental plaque, Periodontal diseases, Mouthwash, Bacterial, Boht, Behsa, Kin-gingival

Introduction

A variety of microorganisms, mainly bacteria, can be colonised and developed through the mouth; one influence factor in teeth and periodontal tissue destruction is bacterial plaque (1). The primary etiological factor for tooth decay, gingivitis, and periodontal disease is dental plaque. Dental and periodontal conditions are diseases associated with the prevention of biofilm. Dental plaque is the primary etiological agent in gingival and periodontal disease development and progression (2). Dental and periodontal susceptibility varies according to risk factors, including genetics, systemic factors and oral hygiene (3).

The primarily mechanical removal of plastic plaque through regular tooth brushing is used to prevent different periodontal diseases’ development and progression (4). The use of mouthwash to control plaque bacteria is about 5000 years long when the Chinese suggested that urine for children be used to prevent gingivitis (5). Various bacterial and fungal communities integrated into a highly specialised extracellular matrix are present in oral biofilms. The decrease in oral biofilm accumulation (dental plates) and the control/reduction of dental disease risks are essential for good oral care practices (6).

The primary effect of Mouth rinses on the supragingival and marginal plaque is limited due to tight gingival contact with the tooth in healthy persons (7). It
must always be used in conjunction with mechanical plaque control measures but should never be used solely as a means of oral hygiene. Mouth washing can help prevent oral infections, reduce inflammation, decrease halitosis and local fluoride prevent caries. Mouth washing has several preventative and therapeutic purposes. Usually, mouthwash is based on anecdotal evidence instead of on-the-counter (OTC) scientific evidence.

The use of mouth washing and chemical cleansing of teeth is typically to reduce dental accumulation. It can even be used as oral care only for patients who cannot brush their teeth either after surgery or due to the motor or cognitive constraints. Chlorhexidine (CHX) is long considered a short-term gold standard of action for bacteria, spores and fungi, including many antiseptic components of oral mouth washing. Mouthwash is a safe and effective anti-plaque and antimicrobial agent, which prevents adhesion, colonisation, metabolic activity and bacterial proliferation. Due to the variety of antibacterial efficacy, cytotoxicity and kinetics of different solutions, it isn’t easy to decide whether to use a particular mouthwash. In decreasing oral microbial counts, CHX is regarded as the gold standard.

In preventing periodontal illnesses, mechanical plaque control measures (tooth brushing and flossing) are essential. Benzydamine chloride can also help avoid periodontal diseases by chemical plaque control measures, such as utilising only 0.12 or 0.2 per cent mouthwashes preparations with chlorhexidine. If there is unevenness between the host defence and the bacterial niche, periodontitis may occur. The primary aetiology of the gingival tissues and the paradental attachment is the bacterial plaque. Mechanic removals of the plaque or calculus and topical antimicrobial agents that can inhibit periodontal pathogens are commonly used in periodontal therapy. Moreover, in current periodontal and other applications, extracts from plants have been offered as anti-plaque agents.

Body rinse can produce a therapeutic effect on the tooth’s entire surface, including interproximal areas where toothpaste is very effective. Although it is effective in plaque control, chlorhexidine cannot be used for a long time because of some of its unpleasant side effects after a long time. The use of mouthwash in oral hygiene is ancient, in contrast to the popular notion. The use of mouthwash originates from religious codes of behaviour such as the outdated Manu laws of India that must rinse their mouths after a meal. This study aimed to compare three different mouthwash types for the periodontal healing process based on the findings.

**Methodology**

This study aimed to determine the effect of three types of mouthwash on the treatment of periodontal disease. The impact on Kin Gingival, Behsa and Boht are assessed on the selected bacterial. Thus, minimum inhibiting concentrations (MIC) were used. The collection of culture type is used for all bacterial strains. The serial dilution method has been used to prepare every mouthwash with specified dilution and added to the tubes. The last tube or the last mouthwash dilution not showing turbidity is considered the MIC in certain microorganisms of the respective mouthwash. In terms of the ability to inhibit microbial growth, the three mouthwash types’ MIC was compared. The tubes without turbidity (transparent) were then transferred to a solid media after 24 hours of incubation, which showed bacterial growth inhibition with the respective mouthwash and evaluated for the microbial growth to determine the MBC of mouthwash. In terms of the solid medium culture, the last tube, which was negative, indicated the minimum concentration (MBC) of bactericidal fluid.

For all bacterial strains, this procedure was done. 0.5 ml diluted samples have been transferred in empty plates for counting bacterial colonies. The agar was cooled to 50°C and poured into each plate. The pouring of the agar was done into each plate. The plates were incubated 24 hours after the agar had solidified and the colony forms (CFU) units counted. On dilute samples collected before the patients’ used mouthwashes or water, the zone of growth inhibition test was done in vitro. On the agar surface with the swab, bacteria were streaked. The filter
paper impregnated disks were then placed at the centre of each section and slightly pressed to the agar with the water and mouthwash. The plates were then incubated for 24 hours at 37°C inverted positions. The inhibition zone was measured after 24 hours.\(^{(10)}\)

**Results**

![Figure 1: The MIC and MBC effect of the three mouthwash on the selected bacteria](image1)

![Figure 2: The effect of the three mouthwash on the zone of inhibition in selected bacteria](image2)
**Discussion**

This study showed that the three types of mouthwash could cause bacterial growth inhibition. The antimicrobial effect of Boht, Behsa and Kin, gingival washes of the gum, were significantly different (Figure 1). The SM growth inhibition areas in the three study groups are shown in Figure 2. Two-week use of Boht, Behsa and Kin gingival mouthwash, before and after periodontal patients, is summarised in Figure 3. In patients with periodontal disease, the summary of bacterial counts is also presented in Figure 3 before and after two weeks.

Mueller Hinton Agar was the artistic medium of this study, used as a growth speciality for those bacteria in procedures commonly conducted for aerobic and optional anaerobic bacteria (neogen.com). Therefore, it would appear logical to assume that both aerobic and optional bacteria cultivated on agar plates were actual.

The results of this study demonstrated a difference in the antibacterial effects shown by Behsa and Boht, as they were unable to make s after 24 hours of in-vitro incubation, while boht washings showed a reduced bacterial count after two weeks of in-vivo use. The culture medium was treated only once and then after 24 hours in inhibition tests with mouth washing. At the same time, bacteria were repeatedly exposed to the effect of mouth washing for the in vivo testing for two weeks. The results were obtained after 24 hours only. It may require continuous exposure to mouth washing, especially for the Behsa and Boht, to reduce bacterial counts. Mechanical plaque controls are difficult to remove all bacteria; antibacterial mouthwashes may help additives to this effect. Antimicrobial effects were compared in three types of mouthwash in the current study.

The role of bacterial plaques was demonstrated by dental caries aetiology and by periodontal diseases. The mechanical methods of plaque inhibition are limited; this problem is proposed to chemical methods for plaque inhibition (6). Therefore, the utilisation of mouth washing as disinfectants can help mechanically...
reduce plaques. Mouth washing takes place in few ways, including apoptosis, bacterial growth inhibition, metabolic inhibition of cells, and bactericidal inhibitions based on their concentration \(^{11}\).

A great deal of study has shown that washing chlorhexidine’s mouth is the best way to wash the mouth. The supremacy of most studies comparing mouthwashes, with only a few studied products competing in antibacterial characteristics with chlorhexidine, has been demonstrated. Streptococci are the primary etiologic agent for tooth decay \(^{18}\).

Removal of streptococci prevents plaque formation and disease spreading. In the study of S. mutans susceptibility to mouthwashes, Jarvinen et al. showed that S. mutans is resistant to antimicrobial agents. S. mutans have the highest mouthwash strength and even greater varnish resistances \(^{19}\).

We also have confirmed that S. mutans are somewhat resistant to chlorhexidine. The most significant anti-caries effect of fluoride chlorhexidine was achieved using a study comparing Behsa polyphenol extracts with fluoride washes, showing its synergistic effect on microorganisms \(^{20}\).

A study comparing oral-B with other mouthwashes has demonstrated greater efficacy in reducing the S. mutans by washing Boht in plaques around orthodontic brackets, indicating high antimicrobial activity mouth \(^{14}\). Kin Chlorhexidine Gingspace effectively eliminates Streptococci causing decay and beneficial antimicrobial and anti-gingival effects, as they support initial plaques in these microorganisms. Studies have shown that a higher concentration of the antimicrobial effect. The main impact on the microorganism concentration is Kin gingival mouthwash \(^{20}\).

The first microorganisms to develop dental caries are lactobacilli and chemical or mechanical removal. The differences between the chlorhexidine compound may lead to previous studies since different combinations have other products \(^{21}\).

Streptococcus mutans are the primary etiologic agent for dental caries. It may adhere to the acquired film as the first step in plaque formation. By eliminating this bacterial species, I prevent plaque formation and caries development \(^{7}\). Mechanical methods of plaque inhibition have several limitations; dental plaque inhibition techniques have therefore been suggested. The use of disinfectants to wash the mouth can help to reduce plaque. The effect of Behsa mouthwash on SM inhibition has been evaluated and compared with Boht and Kin Gingival mouthwash’s effectiveness \(^{22}\).

The results showed that all three washers could inhibit SM’s spread with the highest Boht-inhibiting effect. Many oral studies in microorganisms have shown that Boht is the most appropriate gold standard for chemical treatment with SM and dental cavities. The study showed the inhibition by Boht containing mouthwash and Total Care Kin gingival of the formation of the plaques by various Streptococci species \(^{23}\). They also say Boht’s mouthwash is more efficient than Total Care Kin’s gingiva mouthwash. Dental caries and pathology decreased, damaging the innocent bacterial species that competed with SM effectively inhibited by washed-in \(^{1}\).

Boht’s positive effect on reducing the SM and Lactobacillus colonies has been described in the literature. Boht is a large anode and adsorbs the tooth, plaque and mucus surface and increases adsorption to the above characters by its cationic nature. The extracellular polysaccharides cause the absorption of this antibacterial mouth washing \(^{24}\).

However, previous authors, contrary to this study, have shown a better effect on the Kin gingival mouthwash plankton and biofilm bacteria than Boht (diluted). Boht also decreased the number of plaques and gingivitis, but no antibacterial activity existed when Boht was diluted. In its antimicrobial activity, Boht concentration appears to play a vital role \(^{2}\).

Another discovery of this study was Behsa mouthwash’s best, higher, antibacterial effect than Kin Gingival mouthwash. The essential oils available are kin gingival. The antimicrobial activity of Kin gingival against oral microorganisms has already been evaluated and has been confirmed \(^{2}\).
The main flavonoids in tea are epigallocatechin-3-Gallate and epicatechin. The catechin’s anti-cancer activity may be attributed to a direct anti-bacterial effect on SM inhibition adherence to tooth surfaces. Behsa purifies the oral cavity, and reduced dental caries affects people who drink large quantities of Behsa (8). The combination of several antibacterial agents in a single product is one way of increasing anti-plaque efficiency. In Behsa mouthwashes, the higher antibacterial effect is higher than that of Kin gingival, given confirmations from various studies on the impact of Behsa extract and Kin Gingival mouthwashes in SM (25).

The positive effect of Behsa extract on the decrease in SM and Lactobacillus colony figures has previously been demonstrated in line with this study. Contrary to current research, the use of Behsa extract mouthwash has been shown to reduce the number of oral Kin Gingival-like micronutrients and have similar implications for both mouthwash types (17). The differences in the concentration of active agents in the formulation of mouth washing can be due to the study results. Unfortunately, the manufacturer’s Behsa concentrations in the Kin gingiva mouthwash have not been reported, and studies’ attention is not similar (26).

Therefore, Boht may be used every day as the natural component is present in Behsa and the tooth’s lack of dental colour potentials (5).

**Conclusion**

The results showed just that mouthwash affects bacterial counts. Since the oral cavity for commensal species has nevertheless played a positive part, there is still discussion of the need to maintain a constantly low number of bacteria within the mouth. This study demonstrated that three types of mouthwash could reduce the number of bacteria in the oral cavity. The S. mutans proliferation was more efficient than Kin gingival due to the Behsa containing a mouthwash. But Boht was less potent than both types of mouthwash. This study helps doctors to select the best antimicrobial agent on the market. Based on this study’s findings, boht mouthwash is more effective for oral microorganisms than Kin Gingival and Behsa mouthwashes, but further clinical studies are required to confirm our findings.

Histological Evaluation of Effect of Combined Local Application of Vitamin D3 and βeta-Tricalcium Phosphate on Bone Formation in Rabbits

Noor Abdulkareem Razouki1, Ban A.Ghani Jamil2
1Assistant Lecturer, AL-Rafidain University College, Baghdad- Iraq, 2Professor, Department of Oral Diagnosis, College of Dentistry, University of Baghdad, Baghdad- Iraq

Abstract

Bone, a hard and rigid constituent of the skeleton of vertebrates is composed primarily of calcium salts and connective tissue. Osteogenesis, or bone formation, is the process by which new bone is formed. Beta-Tricalcium phosphate (β-TCP) is alloplastic biomaterials, multiple studies conducted on the β-TCP and bone interaction, that histological examination shows an initial bone neoformation in inter granular areas and in the porous surfaces that helps guided for new bone formation. Calcitriol is active form of Vit.D3, can affect human osteoblast growth and differentiation stimulating bone formation and mineralization. The aim of study is evaluation of effect of β-TCP alone and combined with vitamin D3 on bone deposition in induced bone defect. Twenty-four adult male New Zealand rabbits weighting an average of (1.5 – 2 kg) used in this study. three intra bony holes created in both tibias (right tibiae for experimental groups and left for control group) of each animal which will be divided as follows: Group I(C): Bone defect left to heal spontaneously as control. Group II(TCP): Bone defect filled with β-TCP. Group III(TCPD): Bone defect filled with combination of β-TCP and Vit.D3. Animal scarification was done for the healing durations (7 and 21days). Routine processing and sectioning technique was performed for histological evaluation. Histological and Histomorphometrical findings at 7 days revealed new bone entrapping osteocytes and enclosed bone marrow in TCP and TCPD groups. TCPD group after 21 days showed defect area filled with dense bone trabeculae entrapping osteocytes and rimmed by osteoblasts. Haversian canals started to develop and reversal lines between new and old bones were also noticed. The highest mean value of osteoblasts, osteocytes and trabecular area were recorded in (TCPD) group. Trabecular number and osteoclasts recorded highest mean value in (TCP) group at 21days healing period. Conclusion: Within the limitations of this study the observed histological results indicated that local Vit.D3 with β-TCP application may accelerate new bone formation.

Keywords: Beta-Tricalcium phosphate, Vitamin D3, bone formation.

Introduction

βeta-Tricalcium Phosphate β-TCP( has been utilized in bone reconstruction as a scaffold that may successfully regenerate bone over critical sized bone defects in an in vivo model (1). β-TCP is reabsorbed in progressive manner, leaving area for bone neoformation (2) Multiple studies conducted on the β-TCP and bone interaction, that histological examination showed an initial bone neoformation in inter granular areas and in the porous surfaces that guided for new bone formation. Unlike hydroxyapatite, β-TCP is continuously and totally reabsorbed, thereby discharged calcium and phosphate ions that participate actively in the new osseous tissue formation (2, 3). It’s a challenge to Repairing large bone defects using osteoconductive biomaterials alone, because osteogenic cells are not probable to be enrolled in the center of large defects without osteogenic property, and lack of absorbability, there remain substantial impediments. Therefore, biomaterials used to repair burdened bone defects should...
have osteoconductive and osteoinductive properties. \(^4\). Calcitriol is active form of Vit.D3, can affect human osteoblast growth and differentiation stimulating bone formation and mineralization \(^5\). Calcitriol significantly accelerated the production of mature matrix vesicles in the pre-mineralization. It directly accelerates osteoblast-mediated mineralization via increased production of mature matrix vesicles in the period prior to mineralization. The accelerated deposition of mature matrix vesicles leads to an earlier onset and higher rate of mineralization. These effects are independent of changes in extracellular matrix protein composition \(^6\).

**Materials and Methods**

Twenty-four adult male New Zealand rabbits weighting (1.5 – 2 kg) were used in this study. The general anesthesia given by intramuscular injection of xylazine 20mg(Arendonk, Belgium) (0.2 ml/kg-B.W.) plus ketamine HCL 50 mg (Holland) (20 mg/kg B.W.) \(^7,\ 8\). The operation site was the proximal tibia metaphysis of the right limb \(^9\). Exposure of tibia and initial intermittent drilling was done by small round bur (no.010) and fissure bur (no.010) with speed 1500 rpm and vigorous irrigation by normal saline ,the drilling accomplished by round and fissure bur (no.012) to diameter of about 3mm and depth 4 mm. Intra bony holes were created in both tibias of each animal divided as follows:

1- Group C: Bone defect left to heal spontaneously as control.

2- Group TCP: Bone defect filled with \(\beta\)-TCP (Portugal) only.

3- Group TCPD: Bone defect filled with combination of \(\beta\)-TCP and Vit.D3 (Calcitriol) (Turkey) in a ratio of 1:1 \(^10\).

Animal scarification done by over dose of general anesthesia and specimens immediately stored in 10% freshly prepared formalin(Tedia, U.S.A) for fixation

Bone decalcification done by 10% formic acid then processed to paraffin blocks as a bone defect faced outside of block toward microtome knife. Tissue sections of 5 \(\mu\)m thickness were prepared followed by Hematoxylin and Eosin staining procedure, histological and histomorphometrical evaluation using light microscope (OpticaB-350, Italy). The following microarchitectures were measured

1- Osteoblast cell number (OB/ \(\text{mm}^2\)).

2- Osteocyte cell number (OC/ \(\text{mm}^2\)).

3- Osteoclast cell number (OCL/ \(\text{mm}^2\)).

Trabecular and bone marrow area:

1- Trabecular area(\(\text{mm}^2\)).

2- Bone marrow area (\(\text{mm}^2\)).

3- Trabecular number(\(\text{mm}^2\)).

Measurement of trabecular and bone marrow area was performed by software program (ImageJ. exe). Statistical analysis of recorded data was done by (ANOVA) test, least significant difference (LSD) test.

**Results**

**Histological and Histomorphometrical findings:**

Histological findings at (7 days) duration of defect area in control group shows blood islets and osteoblasts rimming newly deposited bone spicules also osteocytes entrapped in bone are noticed Fig.(1 A). \(\beta\)-TCP group shows osteoblasts at the periphery of new bone that entrap osteocytes and encloses bone marrow and also areas of remaining \(\beta\)-TCP material are illustrated Fig. (1 B). While bone defect area filled with \(\beta\)-TCP and Vit. D3 (TCPD group) shows new bone matrix deposition, rimmed by osteoblasts and entrapped osteocytes Fig. (1 C).
Histological View at (21 days) duration in control group shows bone marrow with progenitor cells, osteoblasts rimming bone and osteocytes embedded Fig.(2 A). Defect area of TCP group shows bone trabeculae rimmed by osteoblasts, numerous osteocytes trapped inside trabeculae and reversal line demarcating new bone from the old one, fat cells and progenitor cells also seen Fig.(2 B). TCPD group after 21 days shows defect area filled with dense bone trabeculae entrapping osteocytes and rimmed by osteoblasts. Haversian canals start to develop and reversal lines between new and old bones are also noticed Fig.(2 C).
Regarding histomorphometrical analysis, the mean values of trabecular number, bone marrow area, trabecular area, osteoblasts, osteocytes and osteoclasts showed highly significant difference in all groups in both durations (7days and 21days). All measured parameters in both durations had increased mean value with time except for bone marrow area and osteoblasts decreased in all groups, the highest mean value of osteoblasts, osteocytes and trabecular area were recorded in (TCPD) group. Trabecular number and osteoclasts recorded highest mean value in (TCP) group at 21days healing period. Bone marrow area showed the highest values in (C) group. In 7 days healing period revealed highly significant difference between groups for studied parameters. Regarding 21days duration high significant differences were estimated in all bone parameters in different groups, except trabecular number there was no significant difference between C and TCPD experimental group Fig. (3 and 4).

Figure (3): Histomorphometrical analysis of bone architecture parameters at 7 days

Figure (4): Histomorphometrical analysis of bone architecture parameters at 21 days.
Discussion

This study was designed to evaluate bone healing after application of osteoconductive graft material (β-TCP) and active form Vit.D3 in experimentally induced bone defects in rabbit’s tibiae. Rabbits are potentially, manageable, not overlooked species for bone healing experiments (11). The beneficial effects of Vit.D3 in bone metabolism and regeneration is experimentally and clinically evident, but no consensus exists regarding the applicable benefit of local application in bone defect healing which still controversy. The Vit.D3 receptors (VDR) are principally involved in mineral metabolism, is expressed in osteoblasts and studies didn’t found the corresponding clinical or microscopic side effects after local calcitriol application to concure the previous evidence (12, 13). The choice of β-TCP in present study as bone substitutes and carrier for Vit.D3 was for the following reasons:

1- The microporous geometric topography of β-TCP gives allocation for osteoblasts differentiation.

2- β-TCP is useful as a growth factor carrier and scaffold for bone augmentation. That habitat standard and control releases of Vit.D3 over time (14).

In the current study, histological examination at 7 days duration of some bone sections showed residues of β-TCP material surrounded by new bone deposition , mean values of trabecular area and trabecular number were higher in TCP and TCPD groups with high significant difference for all bone microarchitectures in agreement with Luvizuto,2011 (15) who found that β-tricalcium phosphate presents very promising osteoconductive properties, including the defect closure with new formed bone.

At 21days duration , bone trabeculae surrounding β-TCP were seen with signs of bone maturation, in accordance with the findings reported by Hirota et al., 2009 observed that β-TCP could be a good scaffold material for bone regeneration when used in combination with osteogenic materials (16). The aforementioned results of histomorphometric analysis of induced bone defect at both 7 and 21 days healing periods which showed higher mean values of different studied microarchitectures of TCPD and TCP groups in line with Sivolella et al.,2013 who explained main purpose of the use delivery system at the defective bone site is to ensure adequate concentrations for as long as it takes to enable the regenerative cells to migrate, proliferate and differentiate. In histological examination of TCP and TCPD groups, remnants of β-TCP material were noticed in some sections which may be attributed to:

1- It biodegrades relatively slowly occurs through osteoclastic activity, which is generally recognized to be in association with bone formation (17, 18).

2-It’s restorability allows a gradual biologic degradation over a period of time and a progressively replaced by a natural host tissue, pure β-TCP may be completely resorbed at skeletal sites over 24 weeks’ duration (19).

Vitamin D3 suppresses bone resorption through VDR in osteoblast-lineage cells and that the role of Vit.D3 in stimulating osteoblast development through exerting anti-apoptotic effects (20) which may support results of this study regarding TCPD groups as compared to control group in 7 and 21 days healing intervals.

Conclusion: Within the limitations of this study the observed histological results indicated that combined local Vit.D3 and β-TCP application may accelerate new bone formation.

Assessment of Serum Ferritin, Folate, Vitamin B12, C-reactive Protein, D-dimer and Homocysteine in Patients with Severe and Critical Covid-19 Infection

Nawar Mazin AL-Alwan¹, Zainab A. Razak Al-Sharifi², Abbas Hashim Abdulsalam³

¹Postgraduate, ²Assistant Prof. dr. University of Baghdad, College of Medicine / Department of Biochemistry/Iraq, ³Assistant Prof. dr. University of AL-Mamoon/Iraq

Abstract

Background: Corona virus disease 2019 (COVID-19) pandemic need urgent measurement and correlation of laboratory parameters in severe and non-severe cases. Serum ferritin, folic acid, vitamin B12, C-reactive protein, D-dimer and homocysteine was measured in patients who were infected with COVID-19.

Aim of the Study: To evaluate the usefulness of serum ferritin, folate, B12, C-reactive protein, D-dimer and homocysteine level as biomarkers for prediction of patients with severe and critical COVID-19 infection.

Subject, Material, Method: A cross sectional study was conducted at AL-Kindy hospital, Baghdad, Iraq from October 2020 to December 2020. Serum ferritin, folate, Vitamin B12, C-reactive protein, homocysteine and blood D-dimer were measured in 88 patients who suffered from COVID-19 infection, 50 cases with severe infection and 38 with non-severe infection. The age range of patients between 20-59 years old. Samples were collected from AL-Kindy hospital, Baghdad.

Result: Serum folic acid was significantly low in severe group than in non-severe group, while serum ferritin, CRP and blood D-dimer were high in severe group than in non-severe group.

Conclusion: In this study, measurement of serum ferritin, CRP and blood D-dimer were important in follow up of patients who infected with the novel virus as the level of them were higher in severe than in non-severe cases. Folic acid has role in determining the severity of COVID-19 infection because level was low in patients with severe than non-severe infection.

Footnote: COVID-19, folic acid, vitamin B12, C-reactive protein, D-dimer, ferritin and homocysteine.

Introduction

Corona viruses infect humans and animals, in general human corona viruses (HCoVs) cause 15-30% of common colds. Any animal reservoir corona viruses can however be transferred to humans, causing outbreaks in the human population, these zoonotic viruses infect both humans and animals, unlike HCoVs, and cause serious respiratory diseases such as acute respiratory distress syndrome (ARDS) and pneumonia, resulting in death¹.

90 % of patients with COVID-19 have irregular chest radiographs, In serious and critically ill patients, lymphopenia is common, and in patients with mild symptoms, it is uncommon, COVID-19’s chest computed tomography features include bilateral opacity of ground glass, consolidation, and local or bilateral patchy shadowing, In COVID-19 patients, GI symptoms are common, and a meta-analysis has shown that these symptoms occurred in 17.6% of infected patients and are more common in serious patients².

Respiratory tracts are the primary focus of SARS-CoV-2, contributing to clinical symptoms such as fever, dry cough, fatigue and dyspnea, in 10-20% of patients,
the disease usually progress into a serious type, requiring hospital admission or even intensive care unit (3).

Ferritin levels were high in patients who died from COVID-19 upon admission to hospital and during the hospital stay (4). In COVID-19 infection, pregnant women who classified as severe and critical were less than non-pregnant women, The factor protecting these patients against SARS-CoV-2 infection may be folic acid supplementation during pregnancy(5).

A significant modifiable risk factor for COVID-19 morbidity and mortality in the elderly and those with diabetes mellitus could be vitamin B12-folate-homocysteine dependent biochemical reactions that are crucial for wide-ranging aspects of DNA synthesis, cellular regulation and body repair(6).

In most patients with COVID-19, elevated serum C-reactive protein (CRP) levels were observed(7).

Elevated D-dimer and the increased rate of poor prognosis-related conditions, and the initiation of anticoagulant administration identified with D-dimer as a potentially useful method to avoid complications and have a beneficial effect on the course of corona virus disease 2019 (COVID-19)(8).

Aim of the Study

To evaluate the usefulness of serum ferritin, folate, B12, CRP, D-dimer and homocysteine level as biomarkers for prediction of patients with severe and critical COVID-19 infection.

Subject, material, method:

Across sectional study was conducted at Al-kindly hospital in Baghdad/Iraq, from October 2020 to December 2020, where 88 patients with COVID-19 infection documented by polymerase chain reaction (50 patients with severe symptoms who need hospitalization and 38 patients with non-severe criteria), the age of the patients range from (18-59) years old.

The permission was obtained from Al-kindly hospital, the blood samples were drawn from the patients after their agreement.

Whole blood samples were collected in a clot activator tube, centrifuge the sample after clotting for 5 minutes at 3000 rpm, clear serum was obtained which is divided into five eppendorf tube (1ml each eppendorf tube). Then the serum was frozen at -50°C. Repeated freeze-thaw cycle were avoided.

For measurement of D-dimer, human whole blood was needed and the test must be done within 24 hours.

Serum level of ferritin was measured by Vidas ferritin is an automated quantitative test for measurement of human ferritin in human serum or plasma using Enzyme Linked Fluorescent Assay (ELFA).

Serum level of folic acid, vitamin B12 and homocysteine were measured by Enzyme Linked Immuno-sorbent Assay (ELISA) for quantitative measurement of human serum.

Serum C-reactive protein was measured by NycoCard which was a diagnostic test for quantitative determination of C-reactive protein in human.

D-dimer was quantitatively measured by Fluorescence immune-assay (FIA).

Statistical Analysis

Data translation was done in computerized database, SPSS version program 25 was used to do analysis, p value less than 0.05 was statistically significant results.

Result

Study conducted on 88 patients who suffer from COVID-19 infection, split into two groups (50 patient with severe infection and 38 patients with non-severe infection).

The most frequently observed category Male ($n = 26, 46.43\%$) and ($n = 30, 53.57\%$) for non-severe and severe groups.
Table 1: Gender distribution of patients according to severity of COVID-19 infection:

<table>
<thead>
<tr>

</table>

In non-severe COVID-19 patients, the most frequently observed category of age was 40 - <50 years (n = 13, 34%). As compared with 50 - <60 years (n = 40, 80%) for Severe cases. Age had an average of 53.24 ± 6.60, and Median was 55.5 in severe group. For non-severe, the average of age was 42.66 ±10.14 years, and median was 44 years.

Figure(1): Age distribution in patients with COVID-19 infection.

The most frequently observed category of biochemical parameters in severe and non-severe patients with COVID-19 infection show that the folic acid was significantly lower in severe group than in non-severe group (p<0.05).

There was significant difference in vitamin B12 between the Covid-19 patients’ groups, p < 0.05. Severe group was significantly lower than non-severe group.

There was significant difference in homocysteine between Covid-19 patients groups p < 0.05. Patients with
Severe infection was significantly lower homocysteine level than non-severe group.

There was significant difference in D-dimer level in blood between Covid-19 patients groups $p < 0.05$, Patients with Severe infection was significantly higher level than non-severe group.

### Discussion

Serum folic acid level was lower in severe group than serum folic acid in non-severe group, the results agree with (Elias J, *etal*, 2020) which was found that Pregnant women seem to have a lower risk of contracting COVID-19 infection, and those who infected were more likely to be asymptomatic. Pregnant women from ethnic groups with low folate RBC concentrations due to genetic factors and/or who do not receive folic acid supplementation, have a higher hospitalization rate$^{(9)}$.

Serum vitamin B12 levels were normal in patients with severe and non-severe COVID-19 infection. In non-severe COVID-19 infection, mean of serum vitamin B12 level in severe group was higher than non-severe group. These results were disagreeing with (Dalbeni A, *etal*, 2021) which was found that Excess serum B12 level has been linked to a rise in mortality rates$^{(10)}$.

Serum homocysteine levels were normal in non-severe COVID-19 infection patients, while serum homocysteine levels were low in severe COVID-19 infection. The results were disagree with (Ponti G., *etal*, 2020) which show that plasma homocysteine must be measured on a routine basis as a potential marker for severe disease in SARS-CoV-2 patients$^{(11)}$.

Serum ferritin levels were significantly increased in patients with severe COVID-19 infection in comparison with non-severe COVID-19 infection. These results were agree with (Henry B, *etal*, 2020) and (Cheng L., *etal*, 2020). Who show that severe group had substantially higher serum ferritin levels than non-severe also they
recommend that serum ferritin must be used to monitor COVID-19 patients’ prognosis\(^{(12)}\)\(^{(13)}\).

Serum C-reactive protein showed significantly high levels in patients with severe COVID-19 infection. These results were agree with (Liu F., etal, 2020). Their research looked into the connection between CRP and COVID-19 and discovered that patients with CRP levels greater than (41.8 mg/L) were more likely to develop serious disease\(^{(14)}\).

D-dimer levels showed significantly high levels in patients with severe COVID-19 infection while the in patients with non-severe COVID-19 infection was within normal range. The results were agree with (Li Y., etal, 2020) which show that patients with severe COVID-19 infection had a higher D-dimer than non-severe infection in the patients without cardiovascular disease\(^{(15)}\).

**Conclusion**

1- High Serum ferritin, C reactive protein and whole blood D-dimer levels were important to confirm the severity of the patients with COVID-19 infection.

2- Low serum folic acid level was associated with severe COVID-19 infection.

3- Serum vitamin B12 level was not affected by the severity of the COVID-19 infection.

4- Serum homocysteine level had no role in detection of the severity of COVID-19 infection because it was affected by drugs which were received as a protocol for COVID-19 treatment.

**Recommendation:**

1- A large sample size of patients are needed, follow up of patients until they discharged from the hospital in addition to calculate the mortality rate.

2- Two groups of patients with severe COVID-19 infection, first group receive folic acid tablet and the other group receive placebo then follow up to the patients.

3- Measurement of other parameters in COVID-19 infection such as lactate dehydrogenase, troponin and procalcitonin to detect the severity of infection.

4- Measurement of serum ferritin, C-reactive protein and whole blood D-dimer levels before intake of vaccine.

The Effect of Acute Bronchitis on Blood Pressure

Haider Noori Dawood
Dr. FIBM, FABM, FIBM (Resp.)/ Consultant of Internal Medicine and Respiratory Diseases/Iraq

Abstract

Background: Acute bronchitis is one of the top 10 conditions for which patients seek medical care. Acute bronchitis is a clinical term implying a self-limited inflammation of the large airways of the lung. A possible link between inflammation and elevated blood pressure has been suggested by several cross-sectional and longitudinal studies.

Objective: To assess the effect of acute bronchitis on the blood pressure.

Patients and Methods: The cross sectional study was carried out in Baghdad. 100 patients with acute bronchitis, their age group of 17-76 years were included in the study. Blood pressures (systolic and diastolic) for the patients were taken in sitting position on the right arm during the attack and after improvement (five to seven days later).

Results: 100 patients with acute bronchitis were enrolled in the study. Mean age was 45.51±15.46. Female were 54 (54%), and 46 (46%) were male. There was 42 (42%) have history of hypertension. Only 15 patients (15%) have history of smoking. Mean arterial pressure (MAP) during attack was normal in 58 (58%), and high in 42 (42%). MAP after improvement was normal in 84 (84%), and 16 (16%) remain high. About clinical features, 100% have cough, 71% sputum, 36% dyspnea, and 6% hemoptysis. Systolic, diastolic blood pressure, and mean arterial pressure during the attack were higher than after improvement with highly statistically significance (P value < 0.001). There was no statistically significant effect for the history of hypertension and smoking on blood pressure during the attack and after improvement (p value 0.441, 0.309 respectively).

Conclusion: Systolic, diastolic blood pressure, and mean arterial pressure during the attack of acute bronchitis were higher than after improvement.

Key words: Acute bronchitis, systolic blood pressure, diastolic blood pressure, mean arterial pressure.

Introduction

Acute bronchitis is one of the most common diseases. (1) It affect approximately 5% of adults per year, and although they occur throughout the year, the incidence is higher in the autumn and winter (2). The usual causes of acute bronchitis are viral infections of the upper airways including influenza A and B, parainfluenza, coronavirus (types 1-3), rhinovirus, respiratory syncytial virus, and human metapneumovirus (3). However, reports indicate that more than 60 to 90 percent of patients with acute bronchitis who seek care are given antibiotics (9, 10).

Cough constitutes the most prominent manifestation of acute bronchitis(6). It is a self-limiting upper respiratory infection that takes about two to three weeks to resolve, however, a cough can last to a maximum of 6 weeks (7). Initially, the cough is non-productive, but after about a week there is an increase in mucus production, and in the second week, the colour of the sputum often changes from grey-white to purulent. Despite being a self-limiting condition, most patients with acute bronchitis seek medical advice, mainly because of bothersome cough (8).

Acute bronchitis is thought to reflect an inflammatory response to infections of the epithelium of the bronchi.
Epithelial-cell desquamation and denuding of the airway to the level of the basement membrane in association with the presence of a lymphocytic cellular infiltrate have been demonstrated after influenza a tracheobronchitis. (9)

In patients with acute cough and sputum production suggestive of acute bronchitis, the absence of the following findings reduces the likelihood of pneumonia sufficiently to eliminate the need for a chest radiograph: 1- heart rate > 100 beats/min; 2- respiratory rate > 24 breaths/min; 3- oral body temperature of > 38°C; and 4- chest examination findings of focal consolidation, egophony, or fremitus (10).

High blood pressure is a major public health epidemic in the United States. There are 76.4 million adult Americans with hypertension as defined by a blood pressure “140/90 mm Hg or greater (11). The WHO’s 2016 Global Health Observatory (GHO) data estimated that high blood pressure would cause 7.5 million deaths, about 12.8% of the total of all deaths (12).

Within Europe, high blood pressure is particularly an issue as it has been shown to have an increased prevalence of 60% when compared with the U.S. and Canada – two prominent non-European developed countries (13). Angiotensin converting enzyme (ACE) is an endogenous regulator of blood pressure that is highly expressed in the lung and has been linked to risk for acute respiratory distress syndrome (ARDS) (14).

The mean arterial pressure (MAP) is a term used to describe an average blood pressure in an individual. It is defined as the average arterial pressure during a single cardiac cycle (15). MAP may be used similarly to Systolic blood pressure in monitoring and treating for target blood pressure. Both have been shown advantageous targets for sepsis, trauma, stroke, intracranial bleed, and hypertensive emergencies (16).

Patients and Methods

Setting and study design:

The cross sectional study was carried out in in Baghdad. 100 patients with acute bronchitis (history of cough for two weeks or less with or without sputum, dyspnea, hemoptysis), their age group of 17-76 years were included in the study. From May 2018 to May 2019.

**Inclusion criteria:** 1. Adult patients 2. With clinical features of acute bronchitis

**Exclusion criteria:** 1. Patients complaint of fever as it can cause tachycardia which may increase blood pressure. 2. Heart rate > 100 beats/min; 3. Respiratory rate > 24 breaths/min; 4. Chest examination findings of focal consolidation, because not all patients did chest x ray (10), and 5. Patients who did not come for fellow up.

**Definitions of the outcomes:**

Self-administered questionnaires on age, respiratory symptoms (cough, sputum, dyspnea, and hemoptysis) were performed. History of hypertension, smoking were assessed by self-report for all patients.

Blood pressures (systolic and diastolic) for the patients were taken in sitting position on the right arm, by Mercury Sphygmomanometer.

The patients had two visits, during the attack and after improvement (five to seven days later). With each visit asked about respiratory symptoms, and blood pressure measured.

MAP can be estimated from measurements of the systolic pressure P sys and the diastolic pressure P dias. MAP = P dias + 0.33(P sys – P dias) (18)

**Statistical Analysis**

The statistical analysis of this prospective study performed with the statistical package for social sciences (SPSS) 21.0 and Microsoft Excel 2013. Categorical data formulated as count and percentage. Chi-square test describe the association of these data. Numerical data with normal distribution were described as mean and standard deviation, independent sample t-test used in comparison between two groups. The lower level of accepted statistical significant difference is bellow or equal to 0.05.
**Results**

100 patients with acute bronchitis were enrolled in the study. Mean age was 45.51±15.46. Female patients were 54 (54%), and 46 (46%) were male. There was 42 patients (42%) have history of hypertension, while 58 (58%) have not. 15 patients (15%) have history of smoking, while 85 (85%) have not. Mean arterial pressure (MAP) during attack was normal in 58 (58%), and high in 42 (42%). MAP after improvement was normal in 84 (84%), and high in 16 (16%). As in table 1.

**Discussion**

In this study patients with history of hypertension was 42%, this was higher than that of Cathleen study (19) in which the overall age-adjusted prevalence of hypertension among persons aged ≥18 years was 29.6%, however in the later study there is race /ethnicity difference which showed that Hispanic blacks had a higher rate of hypertension (41.3%) than non-Hispanic whites (28.6%), so prevalence of hypertension may be different from country to other depend on factors like race, and our study took small number if compared that study.

The history of smoking in this study was 15%, while according to the WHO 2015 (20) data, there was 21.5 % in Iran, 19.9% in United Kingdom, and in United States of America 19.5%, but no data available from Iraq. However again the number in our study is small to detect prevalence.

In this study all patients were have history of cough, 71% have sputum, 36% have dyspnea, and only 6% have hemoptysis. In Boldy study (21) the cardinal symptom was the acute onset of cough (100%), usually productive (90%), wheezing was noted by 62% of patients. Transient bronchial hyper responsiveness appears to be the predominant mechanism of the bothersome cough of acute bronchitis (22). Acute purulent bronchitis is characterized by infection of the bronchial tree with resultant bronchial edema and mucus formation. Because of these changes, patients develop a productive cough and signs of bronchial obstruction, such as wheezing or dyspnea (23).

In this study the systolic blood pressure, diastolic blood pressure, and mean arterial pressure during the attack of acute bronchitis were higher than after improvement with highly statistically significance (P value < 0.001). This may be explained by fact that inflammation of the bronchial epithelium in acute bronchitis, this inflammation causes the bronchial and tracheal mucosa to thicken as well as epithelial-cell desquamation and denuding of the basement membrane airway (9, 24). Inflammatory processes are important participants in the pathophysiology of hypertension and cardiovascular disease (25). Tissue expression and plasma concentrations of inflammatory markers and mediators are increased in patients with cardiovascular disease, those molecules include CRP (26). Furthermore, the CRP level is positively associated with systolic blood pressure, pulse pressure, and hypertension (27).

Other inflammatory mediators are increased in patients with essential hypertension and in experimental models of hypertension include, interleukin (IL)-6,IL-1 (28), tumor necrosis factor-a(TNF-a) (29), monocyte chemotactantprotein-1(MCP-1), intercellular adhesion molecule-1(ICAM-1) and vascular cell adhesion molecule-1(VCAM-1) (26), and have been linked to the activation of the nuclear factor kappa B (NF-kB) system (30). So in both acute bronchitis and hypertension inflammation play important role in the pathogenesis.

There is a strong association between smoking and cardiovascular disease, acute tobacco consumption is only associated with a temporary rise in blood pressure per cigarette consumed – a rise which subsides after 30 minutes. (31). However, chronic tobacco consumption causes arterial stiffness that can persist for years after
smoking cessation \(^{(32)}\). Further, heavy consumers have increased incidence of hypertension \(^{(33)}\). In this study there no statistically significant effect for the history of hypertension and smoking on blood pressure during the attack and after improvement, this indicate that the effect of acute bronchitis on blood pressure is independent from history of hypertension and smoking.

**Conclusion**

During the attack of acute bronchitis blood pressure (systolic, diastolic blood pressure, and mean arterial pressure) may be elevated, and may decreased after improvement of the bronchitis without need for antihypertensive drugs. So just need fellow up the blood pressure during the attack and after improvement.

Common complications of Behcet’s Disease in Baghdad Teaching Hospital

Barq Wameedh Azeez¹, Atta AH Al-Sarray², Ali H. Al-Hafidh³

¹Post Graduate, ²Professor Dr. Middle Technical University/Iraq, ³Lecturer Dr. Middle Technical University/Iraq

Abstract

Background: Behcet’s disease is multi-systemic vasculitis, which usually is frequent oral & genital ulcerations as well as eye and skin lesions.

Objectives: To determine the proportion of complications of BD & associated epidemiological variables.

Patients and Methods: A cross-sectional study was conducted and performed in the Baghdad teaching hospital’s Rheumatology unit and Dermatology and Venereology Center, involving (116) patients over the course of six months, beginning November 2nd and ending April 2nd, 2020.

Results: The patients ranged in age from 13 to 64 years old at the time of the study. The mean age and SD was 35.08±10.46 and 70.7% from male while 29.3% from female. Recurrent oral ulceration, Recurrent genital ulceration, Eye lesion, Skin lesion, and Joint symptoms were the most common clinical manifestations of Behcet’s disease, with 96.6 percent, 37.9%, 67.2 percent, 62.1 percent, and 75.9%, respectively. The most common Behcet’s disease complication was ocular complication (34.5 percent), and the first major symptom of BD (94 percent) was oral ulcer. The age at onset of disease at (20-29) years with higher frequency (38.8%).

Conclusion: Higher percentages of study sample had ocular complications (83%) while the lower percentage (2%) had gastrointestinal complication.

Recommendations: More research is required to determine the etiology, enhance diagnosis precision, and develop new therapeutic strategies. To prevent visceral and ocular involvements, early diagnosis and treatment with the help of a dermatologist with extensive experience is essential.

Keywords: Behcet’s Disease, common complications, Iraq, Baghdad

Introduction

The disease is defined as a chronic, relapsing, multisystemic idiopathic inflammatory problem characterized by an episodic occlusive retinal vasculitis with no specific treatment¹. This ubiquitous disorder exhibits a distinct geographic variation and is endemically higher particularly in Turkey, Iraq, Iran, Korea and Japan, the population derived historically from the ancient Silk Road that was used for centuries as a trade-making passage from the East to the West (²). Behcet’s disease is an inflammatory multisystem disease of unknown etiology with unpredictable exacerbations and remissions. The disease was first described in 1937 by the Turkish dermatologist Hulusi Behcet as a trisymptom complex, characterized by recurrent oral ulcers, genital ulcers and uveitis (³).

Behçet’s disease usually starts around the third or fourth decade of life (⁴). Epidemiological surveys suggest that sex distribution is roughly equal. However, there are some exceptions. BD shows male predominance in some Middle Eastern and the Mediterranean countries, and female predominance in Japan and Korea (⁵).

There is no standard test for diagnosing of Behçet’s disease, there are multiple criteria sets in use up until 1990. The first evidence-based criteria for Behçet’s
disease were introduced by the International Study Group (ISG) in 1990. In most cases, a combination of local and systemic therapy is used. Immunosuppressants, corticosteroids, and colchicine are some of the medications used.

**Objectives of the Study**

To determine the proportion of complications of BD & associated epidemiological variables.

**Patients & Methods**

**Study Design**: A cross sectional study.

**duration of the study**: The data collection continued for the period of 6 months starting on 2nd of November 2019 ending to 2nd of April 2020.

**Place of Study**: The place of this study was performed in the Rheumatology unit & Dermatology and Venereology Center in Baghdad teaching hospital.

**Inclusion and Exclusion criteria of study:**

**Inclusion criteria**: All patients with BD attending to Baghdad teaching hospital in during the period of study

**Exclusion Criteria**: Patients with Behcet’s disease who visit the Rheumatology unit or Dermatology and Venereology Center in other hospitals in Baghdad and other governorates, as well as patients who visit other hospitals in Baghdad or other governorates.

**3.11 Statistical data analysis**

Analysis of data was carried out using the available statistical package of SPSS-25 (Statistical Packages for Social Sciences- version 25). Data were presented in simple measures of frequency, percentage, mean, standard deviation, and range (minimum-maximum values). The significance of difference for different percentages (qualitative data) were tested using Pearson Chi-square test (c²-test). Statistical significance was considered whenever the P value was equal or less than 0.05.

**Results**

**Table 1**: The higher percentages of patients (96.6%) in both genders have recurrent oral ulceration while the lower percentages (3.4%) had gastrointestinal lesions and the P value of gender with clinical manifestations show not significant (P value >0.05) except gender with recurrent genital ulceration which find significant (p value = 0.04).

Discussion

Regarding the clinical features of patients, this result show a high percentage of patients with oral ulcers (96.6%). This result agree with the results of those published studies (82.1% by (8) in oman; 96.3% by (9) in china; 91.2% by (10) in japan; 100% by (11) in magnolia; 99% by (12) in korea). Regarding the relationship between gender and oral ulcer. this study which finds that females had oral ulcers more than males. this result similar with results of those published studies (13) in Russia; (9) in china & (10) in japan. This study show (37.9%) of patients with recurrent genital ulceration. this result similar with the result Omani study (8) which shows (40%) of patients with genital ulceration and also similar with another study conducted in Iran (14) that find (47.4%) of patients with genital ulcer. Another study in china (9) that results show differ from this study which finds that (71.2%) of patients had a genital ulcer. The explanation of This difference were probably due to differences in geographic regions, genetics or diagnostic criteria. Regarding the relationship between gender and genital ulcer. This study finds that males had genital ulcers more than females. This result agree with the results of those published studies (13) in Russia; (15) in Finland). Another study in china (9) differ from this study which found that female more than genital ulcer than male. The explanation of This difference were probably due to that the difference in hormonal balance influences the development of clinical manifestation of BD with gender like genital ulcer. Some previous studies conducted in turkey (16; 17) have reported the possible influence of sex hormones such as testosterone and androgen on BD. Regarding the ocular lesions in this study demonstrated
(62.1%) of patients with ocular manifestations. This result similar with results of those published studies (57.1% by \(^8\) in Oman ; 58.1% by \(^{18}\) in Iran ; 54% by \(^{13}\) in Russia ; 63.1% by \(^{11}\) in magnolia). This study show relationships between ocular lesion with gender. This result find that male had more than female , this result similar to the results of those reported studies (\(^{13}\) in Russia ; \(^9\) in china ; \(^{10}\) in japan ; \(^{19}\) in Greek ; \(^{11}\) in magnolia). Regarding the cutaneous manifestation, this study shows (62.1%) of patients with skin lesions. This result agree with the results of those published studies (63.1% by \(^{20}\) in china ; 64.4% by \(^{18}\) in Iran ; 71.7 % by \(^{21}\) in brazil). Regarding the cutaneous lesion with gender, this study show the male more than female with a skin lesion. this result similar to the results of those reported studies (\(^{13}\) in Russia ; \(^{21}\) in brazil & \(^9\) in china). This study found (75.9%) of patients with joint symptoms. These result agree with a results of another reported studies ( 63.2% by \(^{12}\) in korea ; 87.3% by \(^{22}\) in southeast America ; 72.4 % by \(^{23}\) in Serbia ; 79.5 % by \(^{24}\) in turkey ). This result disagree with Another results of those reported studies (4.1% by \(^{25}\) in Iran ; 28.4% by \(^{20}\) in china ). The probably explanation of this difference that a high frequency of joint involvement might be speculated, because they used the questionnaire to obtain the information regarding joint symptoms, and they also employed a broad concept, “arthropathy”, rather than inflammatory arthritis. In addition, the reason why there is hesitation to use arthritis among the primary criteria, to us, may be because complaints about joints in society are very common, and therefore, investigators hesitate to consider these complaints and findings among the symptoms of the illness.

Regarding the joint manifestation with gender, this study shows the female more than male had joint symptoms. this result agree with the results of those published studies (\(^{26}\) in Korea ; \(^{21}\) in brazil ; \(^{24}\) in turkey ). This study show (3.4%) of patients with a gastrointestinal lesion. This result similar with the results of those published studies ( 3.8% by \(^{26}\) in Korea ; 7.1% by \(^{27}\) in turkey ; 3.3 % by \(^{20}\) in china ; 7% by \(^{18}\) in Iran. Regarding the neurological involvement, this study shows (6.9%) of patients with neurological symptoms. This result agree with the results of those reported studies (6.1 % by \(^{28}\) in turkey ; 9.6% by \(^{20}\) in china ; 10.6 % by \(^{18}\) in Iran ; 3% by \(^{14}\) in Iran ; 10.2% by \(^{29}\) in turkey ; 7.8% by \(^{30}\) in turkey). This study show (6.9%) of patients with a vascular lesion. This result agree with the results of those published studies ( 9.4% by \(^{10}\) in japan ; 6% by \(^{31}\) in japan ; 9.1 % by \(^{18}\) in Iran ; 8% by \(^{32}\) in japan ). The complications of Behcet’s disease in this study in general according to the clinical manifestations of patients that find the higher percentages of is an ocular complication (34.5%) of the complicated cases. There was no previous study on the general complications of Behcet’s disease in Iraq. This study show the relationships of complications with ( family history of BD and family history of immune mediated disease ) and the associations between them show non significance (P value >0.05). There was no previous study on the complications of BD with family history of BD & immune mediated disease in Iraq.

**Conclusion**

Higher percentages of study sample had ocular complications (83%) while the lower percentage (2%) had gastrointestinal complication.

**Recommendations:** More research is required to determine the etiology, enhance diagnosis precision, and develop new therapeutic strategies. To prevent visceral and ocular involvements, early diagnosis and treatment with the help of a dermatologist with extensive experience is essential.

Clinical Manifestations with Different Treatment Protocols for Iraqi Patients with Wilson’s Disease

Fadwa Ghassan Hameed¹, Inam Sameh², Mohamed Mahmood³, Hala Sameh⁴

¹Post graduate, Department of Pharmacy, Al-Kitab University, Kirkuk, Iraq, ²Ass.prof., Department of Pharmacology and Toxicology, College of Pharmacy, University of Al-Mustanseriah, Baghdad, Iraq, ³Ass.Prof. Department of Clinical Pharmacy, College of Pharmacy, University of Al-Mustanseriah, Baghdad, Iraq, ⁴Prof. Department of Pediatrics, College of Medicine, Al-Nahrain University, Baghdad, Iraq

Abstract

Wilson disease (WD) is an autosomal-recessive disorder of copper metabolism caused by mutations in the ATP7B gene. ATP7B is also essential for biliary excretion of copper when cytoplasmic levels are high. Dysfunction of ATP7B therefore leads to accumulation of copper in the liver giving rise to cellular damage and disease, and the release of non-ceruloplasmin bound copper into the systemic circulation. Clinical presentation of Wilson disease can vary widely; therefore diagnosis is not always straightforward. Wilson disease is not just a disease of children and young adults, but may present at any age. The key features of Wilson disease are liver disease and cirrhosis, neuropsychiatric disturbances, Kayser–Fleischer rings, and acute episodes of hemolysis, often in association with acute liver failure. Diagnosis is particularly difficult in children and in adults presenting with active liver disease. None of the available laboratory tests is perfect and may not be specific for Wilson disease. To overcome the diagnostic challenge, several clinical signs (Kayser–Fleischer rings(KF.), neurologic symptoms) and laboratory features (copper in serum, urine, liver; serum ceruloplasmin; genetic testing) are scored 0 (absent) to 2 (present) and the Leipzig score is calculated. If the score is >4, the diagnosis of Wilson disease is very likely. For asymptomatic siblings of index patients, mutation analysis is the most reliable approach.

Keywords: WD.(Wilson disease), ATP7B gene, Kayser–Fleischer rings(KF); toxicity; Iraqi patients

Introduction

Wilson disease (WD) is an autosomal-recessive disorder of copper metabolism caused by mutations in the ATP7B gene. It presents in childhood, adolescence or adulthood with a wide range of clinical manifestations. The disease prevalence has previously been estimated as 1 in 30,000 (3,4), but some recent analyses have suggested a genetic prevalence of 1 in 7,000 (5,6).

Copper is absorbed from the stomach and duodenum, taken up by the liver, and secreted by the liver into the systemic circulation bound to ceruloplasmin. ATP7B transports copper through the trans-Golgi network in hepatocytes before it is incorporated into apoceruloplasmin which is secreted as holoceruloplasmin. ATP7B is also essential for biliary excretion of copper when cytoplasmic levels are high. Dysfunction of ATP7B therefore leads to accumulation of copper in the liver giving rise to cellular damage and disease, and the release of non-ceruloplasmin bound copper into the systemic circulation.

Copper also accumulates and is associated with cellular damage and disease in other organs, most notably the brain. The extent to which disease in the brain relates to high levels of free circulating copper and/or underlying dysfunction in neurons, which also express ATP7B, is not clear.

Originally referring to this condition as progressive lenticular degeneration, Samuel Alexander Kinnier Wilson first described the combination of neurologic disease with cirrhosis in 1912. He recognised that psychiatric manifestations were common but stated that the cirrhosis was rarely symptomatic during life.
Barnes and Hurst subsequently reported in 1925 that WD can present with symptomatic liver disease in the absence of neurologic features \(^{(11)}\). It is now accepted that symptomatic involvement of the liver or brain can occur in isolation or in combination at presentation. Asymptomatic, or pre-symptomatic, liver and brain disease in siblings can be identified and studied through family screening \(^{(12)}\).

A working party at the 8th International Meeting on WD in Leipzig in 2001 revised the phenotypic classification and differentiated cases into neurologic (N), hepatic (H) or other (O) presentations \(^{(14)}\). Any patients in whom neurologic and/or psychiatric symptoms are present at the time of diagnosis are classified as a neurologic presentation. They are then subdivided into those with (N1) or without (N2) symptomatic liver disease, or not investigated for liver disease (Nx). This classification requires a detailed neurologic examination to exclude neurologic symptoms at diagnosis and a liver biopsy to confirm the absence of marked liver disease. Hepatic presentations are subdivided into acute (H1) or chronic (H2) depending on the presence of acute jaundice due to hepatitis and/or hemolysis in a previously healthy subject (H1), or any type of chronic liver disease, with or without symptoms (H2). The presence of any biochemical evidence of liver disease indicates a hepatic (H), as opposed to other (O), presentation.

The relative frequency of neurologic and hepatic presentations has been examined in several large cohorts over the last three decades. The proportion of patients that would, under the 2001 classification, be referred to as neurologic, either N1 or N2, ranges from 37% to 80% \(^{(13)}\). While there is likely to be some variation in phenotype between individual populations, comparing these cohorts may be problematic for other reasons.

Firstly, selection bias may affect the relative frequency of different presentations in individual cohorts; centres of excellence for neurology are likely to report a higher number of cases with neurologic involvement. Secondly, neurologic and hepatic features may be subtle or identifiable only through specific investigations. The classification of presentations may therefore have been inconsistent in some cohorts, especially before the introduction of rating scales for WD such as the Unified Wilson’s Disease Rating Scale in 2008 and the Global Assessment Scale in 2009 \(^{(15,16)}\).

The majority of neurologic presentations consist of a movement disorder associated with bulbar symptoms. The movement disorder is usually characterized by tremor, dystonia or parkinsonism. These ‘core’ movement disorders often occur in combination and may initially be subtle. Bulbar symptoms consist of dysarthria, drooling and/or dysphagia. There are a range of additional neurologic features, including cerebellar dysfunction, chorea, hyperreflexia, seizures and cognitive impairment, which can also co-exist.

**Material and Methods**

A total of 42 Iraqi patients diagnosed with Wilson disease (20 males and 22 female) with age range between 10 – 20 years, who attended the Rare Disease clinic of the Al-Imaamin AL-Kadhmiyan medical city Hospital – Baghdad/Iraq. The diagnosis of WD was established by clinical features, low serum ceruloplasmin and copper and increased 24 h urinary copper excretion, Liver function tests.

**Inclusion Criteria**

- Patients age from 10-20 years old.
- Asymptomatic patients with WD with hepatic involvement diagnosed by screening method.
- Patients referred for unexplained elevation of liver enzymes and have Leipzig scale score.
- Patients with positive family history of Wilson disease.

**Exclusion Criteria**

- Patient >20 years old.
- Patients with other co-moribids.
- Pregnancy and breast feeding.
- Patients allergic to any of the study medications.
The eligible 42 patients were allocated into three groups:

**Group (1)**; include 23 asymptomatic Iraqi patients with WD and hepatic involvement diagnosed by screening method treated with Dietary Supplement: **Zinc acetate** (100-150 mg/d) in 2-3 divided dose for 90 days.

Blood tests will be performed (before and after the treatment): ALT, AST, ALP, Ca., s.Albumine, Total Albumin, PT, IRN, s.Copper, s.Ceruplasmine, 24-hr. urine copper.

**Group (2)**; included 10 Iraqi Patients referred for unexplained elevation of liver enzymes and (+ve) Leipzig scale score treated with **d-PCA** (20mg/kg/d for Ped., 750-1500 mg for adult) for 90 days.

Blood tests will be performed (before and after the treatment): ALT, AST, ALP, s.Albumine, Total Albumin, PT, IRN, s.Copper, s.Ceruplasmine, 24-hr. urine copper.

**Group (3)**; included 9 Iraqi patients referred for unexplained elevation of liver enzymes and (+ve) Leipzig scale score treated with **Trientine** (20mg/kg/d for Ped., 1500-2500 mg for adult) for 90 days.

Blood tests will be performed (before and after the treatment): ALT, AST, ALP, s.Albumine, Total Albumin, PT, IRN, s.Copper, s.Ceruplasmine, 24-hr. urine copper.

**Results**

Patients in this study were classified according to clinical manifestations into the following groups: pre-clinical (pre symptomatic, identified by family screening), hepatic manifestations (H1: acute hepatic WD; H2: chronic hepatic WD) and neurological manifestations (N1: associated with liver disease; N2: not associated with WD) as mentioned in table (1). No significant p.value were identified between these three groups.

Discussion

Patients in this study were classified according to clinical manifestations into the following groups: pre-clinical (pre symptomatic, identified by family screening), hepatic manifestations (H1: acute hepatic WD; H2: chronic hepatic WD) and neurological manifestations (N1: associated with liver disease; N2: not associated with WD). The clinical presentations of patients with WD can involve multiple organ systems and vary from subtle to life-threatening. Diagnostic testing for WD is essential for patients of any age with unexplained hepatic, neurologic, or psychiatric abnormalities. Diagnostic testing algorithms for WD, the Leipzig scoring system because of its quantitative, systematic nature (17). Pre symptomatic patients identified through genetic screening: Chelators and zinc have been proven effective in preventing development of symptoms or laboratory test abnormalities of WD in pre symptomatic patients identified by testing for WD in a pro band’s first-degree relatives. Zinc is preferred treatment, based on its low cost and minimal adverse event profile (18). Patients with hepatic manifestations: WD patients with acute liver failure, notably those with classic Wilsonian acute liver failure, do not spontaneously recover and require urgent liver transplantation for survival (despite occasional single patient reports to the contrary) (19,20-22). These patients must be transferred to a transplant center for management. In contrast, WD patients with or without evidence of advanced hepatic WD should be treated with a chelating agent (23). Such patients typically respond to therapy in the first 2-6 months, and progressive improvement can continue for up to 12 months. Responses often include improvement of complications of portal hypertension in cirrhotic patients. Thus, whenever possible, patients with decompensated cirrhosis should be observed for evidence of a therapeutic response to chelation prior to performing liver transplantation (22). Patients with neurologic signs and symptoms: The initial goal of chelation or zinc therapies is elimination of excessive total body copper causing end-organ dysfunction. The subsequent goal is to prevent re accumulation of toxic concentrations of total body copper using maintenance therapy. Rapid removal of excessive copper from the central nervous system must be avoided, as it can worsen symptoms and result in irreversible neurologic deficits (18). In contrast, gradual removal of copper from the central nervous system, achieved by using lower doses of D-penicillamine or Trientine, has a higher probability of resolving signs and symptoms long term. Patience in using lower doses and de coppering slowly is key. Improvement in neurologic symptoms is a slow process and may require up to 3 years after starting chelation therapy. Unexpectedly, zinc therapy has also been implicated in the worsening of neurologic WD. A recent series reported neurologic worsening in 9.1% of patients treated with D-penicillamine, 8.8% on Trientine, and 7.3% on zinc salts (19). Approximately 10% of WD patients treated with either D-penicillamine or zinc had neurologic worsening during the first 6 months of therapy (24). Since liver transplantation rapidly restores biliary copper excretion in WD, it also markedly accelerates depletion of total body copper. Thus, liver transplantation is relatively contraindicated for active neurologic WD prior to removal of substantial amounts of brain copper. In selected patients with neurologic WD, liver transplantation has reversed the neurologic deficits (25).

Conclusion

The WD clinical phenotype includes hepatic, neurologic, and psychiatric manifestations that can present with a wide range of severity and can be combined in unpredictable ways. Copper accumulation in WD is due to a genetic defect affecting the hepatic copper transporter ATP7B, the Wilson ATPase, but clinical and experimental evidence indicates that genetic mutations are just one component of the pathogenesis and clinical presentation of WD. Specifically, two types of evidence indicate there are likely other factors that can affect disease presentation: first, the lack of convincing genotype-phenotype correlation; second, several case reports indicating that homozygous twins with the same ATP7B mutation can present with different phenotypes. Diagnostic tests include serum ceruloplasmin, neurologic exam, and slit-lamp examination for Kayser Fleischer rings. However, additional testing for basal 24-hour urinary copper excretion, hepatic copper concentration...
or sequencing of the ATP7B gene may be required for diagnosis. Family screening is recommended for first-degree relatives of patients and may detect the disease prior to the appearance of signs or symptoms. With improved methods of diagnosis, WD has become an important disease in childhood. The hepatic manifestations are varied, and the neuropsychiatric manifestations may be subtle or nonspecific. Treatment needs to be individualized; comprehensive follow-up is important for all patients. Scoring systems may assist with diagnosis or clinical decisions relating to need for liver transplantation.

Clinical presentation may be chronic liver disease, acute liver failure with distinctive features (ALF-WD) or it may be “silent” liver disease. A broad spectrum of neurologic or psychiatric conditions can occur in childhood or adolescence. While hepatic presentation is more common than neurologic in the pediatric population, manifestations of WD are characteristically multi systemic. WD can resemble autoimmune liver disease clinically. Particularly when there is inadequate response to immunosuppression therapy in autoimmune hepatitis, every effort must be made to ensure that a diagnosis of WD is not being missed. Current management includes chelators like D-penicillamine or trientine; zinc has multiple effects exclusive of chelation. As an oral chelator, D-penicillamine is specified as a first-line drug for use in symptomatic WD patients according to recommendations published by the European Association for the Study of Liver (EASL) (Grade II-1, B, 1) and the American Association for the Study of Liver Diseases (Class I, Level B).

Abstract

Objectives: Although multiple drugs administration mostly increase therapeutic effect, some combinations lead to adverse drug-drug interactions and increased morbidity. This study was designed to identify the types, frequency, severity, and significance of drug–drug interactions (DDIs)

Methods: This retrospective cross-sectional study was conducted from September 2018 to February 2019 in Al-Fayha’a teaching hospital in Basrah, Iraq. The data of 186 patients were collected from hospital patients case sheets. The type and significance of DDIs were analyzed using “Medscape drug Interaction Checker.

Results: At least one to two DDI are noticed in about three quarters of the patients, about 30% cases have three to nine DDIs and 15% of them have ten or more DDIs. According to their severity, there are 85 (11.5%) of serious or potent DDIs. The largest percentage of reported interactions 544 (73.5%) were moderate were close monitoring required. Out of 740 documented DDIs, 65.1% were pharmacodynamics and 19.5% were Pharmacokinetic interactions, in addition, there were 15.4% of DDIs due to Unknown mechanisms. Most of the major potential DDIs occur with the antibiotic ceftriaxone and blood thinning medications (heparin and warfarin).

Conclusion: The findings of this study revealed a high prevalence of drug-drug interactions in hospitalized patients particularly in patients with cardiovascular disease. Potential DDIs in this study sufficiently high to alert health care providers to pay more attentions in order to prevent or decrease their adverse effects on patients.

Keywords: Drug interactions; pharmacokinetics drug interactions, pharmacodynamic drug interaction

Introduction

Drug-drug interactions (DDIs) widely occur in hospitalized patient especially in patients use long list of medications. A drug interaction occurs when the pharmacological effects of the one medication alters the intensity of the other concomitant drug. When two or more medications are taken together, there is a chance of an interaction among the drugs that could be manifested as an increase or decrease in the therapeutic effects or lead to serious unwanted effects which may change the clinical outcome of the patients [1]. Polypharmacy and increased age are significant risk factor for these interactions [2,3]. DDIs generally classified as pharmacodynamic and pharmacokinetic interactions that sub-classified according to mechanism of interactions into absorption, distribution, metabolism and elimination [4]. Potential DDIs are one of the preventable mechanisms of adverse drug events and health damage [5]. Frequency of potential DDIs markedly increase in prescriptions for hospitalized patients [6]. The clinical outcome of a possible DDIs is usually unknown [7]. Studies show that the patients may expose to one or more major or moderate DDIs during hospitalization especially in internal medicine wards and the probability these interactions increased when use more than 6 drug items [8-10]. Although DDIs are common in the hospitalized patients, but there are few data reporting these interactions clinically. It is difficult to remember all the known important DDIs.
However, knowledge of the vital types of medications that are more likely to be involved will be useful alert while prescribing [11]. Predicted theoretical drug-drug interactions may not lead to noticeable toxicity or therapeutic failure, therefore clinical intervention do not always needed. However, any clinically significant DDIs should be identified and discussed with health care team and kept under monitoring. Therefore clinicians should have a sufficient knowledge about the potential drug interactions. Product monographs, info graphics, health information technologies and drug interactions software programs would help in alerting healthcare providers about the possible DDIs [12]. In recent years, many programs have been developed to detect potential DDIs. Numerous online drug interactions databases are available which is either free such as “Drugs.com” and “medscape.com” or copyrighted databases (e.g., Micromedex) [13]. The use of these applications could enhance patient safety by minimizing the incidence of DDIs, and also help in educating trainers [14]. In this study DDIs were checked using Medscape free online application (https://reference.medscape.com/drug-interactionchecker).

Materials and Method

The present study held in Al-Fayha’a teaching hospital based in Basrah, southern of Iraq. This hospital provides medical services for large number of population in Basrah city and receive both in- and outpatients from all age groups. The study designs as retrospective cross-sectional study was conducted from September 2018 to February 2019. This study was approved by the ethical committee of the college of pharmacy/ university of Basrah. Patients admitted with different diagnosis were included in this study. Hospital permission was obtained to access the patient’s medical files during hospital stay for research purpose. Medications prescribed during the hospital admission were allocated from medical reports. Patient’s age, sex, length of hospitalization period, causes of admission, morbidities and associated comorbidities, and details of medication therapy collected from hospital patients case sheets. The type and significance of DDIs were evaluated using “Medscape Drug Interaction Checker”. It grades DDIs into three categories: minor (no change required), moderate (monitor closely), and potent DDIs (use alternative). Data analysis performed by Medcalc® software v12.

Results

Demographic Data

Demographic characteristics had shown in Table 1. A total of 186 patients’ case sheets were studied. The mean age of the patients was 56.4 ± 19 years, most patients were in age range of 60-80 years. With 51% being males. Most patients were received more than 3 medications. The length of stay was at least one week for most patients, few percentage stay more than seven days. Table 1 also showed the medical conditions and comorbidity of the patients included in the study.

Types of drug-drug interactions (DDIs)

Details of the DDIs were reported in Table 2. At least one to two DDI are noticed in about three quarters of the patients. About 30% cases have three to nine DDIs and 15% of them have ten or more DDIs. According to their severity, there are 85 (11.5%) of serious or potent DDIs. The largest percentage of reported interactions 544 (73.5%) were moderate were close monitoring required.

The documented DDIs were mostly pharmacodynamics 482 (65.1%) (increase or decrease effects of medications). Pharmacokinetic interaction about 144 (19.5%) with most of them were due to change in metabolism (enzyme induction or inhibition). In addition, there were 114 (15.4%) of DDIs due to Unknown mechanisms.

Potential interactions (alternative medications should be tried)

The serious interactions are about 85 (11.5%) of total interactions (780). The frequencies and potential risk of these interactions are shown in table 5. The most common interaction has been seen with ceftriaxone-heparin and ceftriaxone-calcium (19, 9) respectively. The potential interactions with blood thinning drugs like heparin, warfarin, aspirin and clopidogrel also frequently seen in this study.

Discussion

Drug-drug interactions are common preventable health risk. The present retrospective study analyzes the type and number of DDIs in hospitalized patients using data from 186 patients case sheets in Al-Fayhaa Teaching Hospital in Basra- Iraq. There are various methods for identification of DDIs. In this study Medscape drug interaction checker program is used.

The prevalence of DDIs is especially high in hospitalized patients, and the incidence of DDIs is usually associated with polypharmacy and patient age\cite{15,16}. The mean age of patients included in this study are [56.4 ± 19] and most of them in age range 60-80 year. This compatible with previous studies that correlate DDIs with age\cite{17}. This result explained by fact that most elderly patients have multiple comorbidities as shown in table [4] that illustrate the significant increase in DDIs with increasing comorbidities especially cardiovascular disease. This agree with other studies which conclude that patients with cardiovascular disease have additional risk for DDIs\cite{18,19}. Additionally, the present of polypharmacy medication in hospitalized patients are very important factor that explain the high rate of DDIs recorded in this study. Table 1 show that most patient take three medications or more and about 22(11.8%) take more than nine medications. Similar conclusion found by Assefa et al who show a higher incidence of potential DDIs in elderly people with polypharmacy and cardiovascular disease\cite{20}. The length of hospital stays also among the factor that lead to high rate of DDI\cite{21,22}. In the present study most of the studied patients were hospitalized about three to seven days [111(59.7% of cases)] and some of them stay more, as seen in table 1.

In the present study most patients (about 75%) experience at least one interaction during hospitalization. The total number of interactions are 740 DDIs identified from 186 case with average (3.9) interaction per case. Similar study found that 78.2% of the cases had at least one potential DDI\cite{23}. Lower rate of interactions, about 46% and 26% had been seen in other studies\cite{24,25} respectively. The heterogeneity in the results of various studies may reflect differences in the conditions of the included patients and level of care, as well as the various methodology used, especially the software used to identify these DDIs\cite{26}.

Most of DDIs in the present study occur due to pharmacodynamic mechanism482 (65.1%), followed by pharmacokinetic 144(19.5%) and about is occur by unknown mechanism 114 (15.4%). Moderate interactions are frequently found in the present study and 544 (73.5%) respectively. This agree with other studies which shows that moderate DDIs were highly incident\cite{27,28}.

The mild interaction is about 111 (15%). The mild and moderate DDIs may not associated with potentially harmful effects, however its need careful monitoring and adequate management. Serious DDIs or X- interactions is about 85 (11.5%) in our study and they are considered high compare with Shetty V. et al study that report 3.02% of X-interaction\cite{19}. Unfortunately, these interactions would cause clinically significant adverse effects on patients. Serious interactions reported in the present study include interactions blood thinning drugs with ceftriaxone and/or other medications and in most cases result in increasing the potential risk of bleeding. Another potential interaction seen in this study, is decrease the efficacy of clopidogrel by co-administration with omeprazole. This pharmacokinetic interaction occurs due to enzyme inhibition action of omeprazole on cytochrome p450. Instead of omeprazole, other proton pump inhibitor, pantoprazole not inhibit with the enzyme and not interfere with clopidogrel action.

Many potential interactions preventable adverse effect that need pharmacological knowledge. These DDIs not well documented and many of them unnoticed by health care organizations. Even in developed countries like united states, there is a study shows that DDIs did not recognize and/or adequately treated\cite{30}. Therefore, health care provider in our society, especially clinical pharmacists, should be encourage to use electronic based software for checking DDIs and discuss them with specialists for modification and or monitoring their clinical outcomes.

There are some limitations in the present results including that its retrospective study so the adverse
effects of these DDIs not followed clinically. DDIs are checked and recorded using Medscape drug interaction checker hence its needed identify real clinical interactions from theoretical one. Inaddition, the performance of drug-drug interaction software is different in their sensitivity and specificity.Finally, the data are collected from one hospital and we need further studies in multiple hospitals or health centers to shed light on true percentage of DDIs in our society.

Conclusion

There are many potential drug interactions in hospitalized patients especially who have cardiovascular comorbidities. The serious DDIs were unfortunately high in the studied patients and its sufficiently high to alert health care organization to pay more attention toward these avoidable adverse effects on patients. There is a need to provide health care team and clinical pharmacists with the useful software to check and monitoring the significant drug interactions in order to prevent or at least minimize their adverse effect on patients.

Abstract

Background: Lateral sinus augmentation and simultaneous insertion of dental implants is a highly predictable procedure and associated with high rate of implants success.

Aims: To evaluate implant stability changes following maxillary sinus augmentation utilizing deproteinized bovine bone alone or mixed with platelet-rich fibrin.

Materials and Methods: A total of 34 lateral sinus augmentation procedures were performed and 50 dental implants simultaneously installed. The lateral sinus augmentation cases were allocated randomly into 3 groups: Group A comprised 13 procedures and 21 dental implants utilizing solely deproteinized bovine bone. Group B involved 10 cases and 16 dental implants using deproteinized bovine bone mixed with leukocyte and platelet-rich fibrin. Group C included 11 operations and 13 dental implants employing deproteinized bovine bone mixed with advanced platelet-rich fibrin. Resonance frequency analysis test was performed immediately after implant installation and 24 weeks postoperatively for the measurement of the implant stability.

Results: Implant stability quotient values increased significantly for all study groups 24 weeks after dental implants installation (P= 0.001). The implant stability quotient at T1 (day of implant installation) was 56.93 ±12.01 for group A, 58.34 ±12.82 for group B, and 61.35 ±8.47 for group C. The implant stability quotient at T2 (24 weeks after implant insertion) was 69.17 ±5.10, 69.43 ±5.32, and 68.50 ±7.44, respectively.

Conclusion: The addition of leukocyte and platelet-rich fibrin or advanced platelet-rich fibrin to the bovine bone for sinus floor augmentation did not increased the implant stability quotient value in comparison to the bovine bone alone.

Key Words: bovine bone, implant stability quotient, maxillary sinus augmentation, platelet-rich fibrin.

Introduction

Bone remodelling after tooth extraction and maxillary sinus pneumatization often create a clinical challenge for dental implant (DI) placement in the posterior maxilla (1,2). Several surgical approaches have been adopted to increase bone height in the posterior maxillary region for the insertion of DI. Two main techniques were reported for maxillary sinus augmentation; the crestal and lateral approaches (3).

Maxillary sinus augmentation through lateral approach (LSA) with concomitant insertion of DI is highly predictable procedure for gaining bone volume in atrophic posterior maxilla and associated with high rate of implants success (4,5).

Different types of biomaterials have been used for LSA including autograft, allograft, xenograft, alloplastic, and growth factors (6,7). The clinical suitability of deproteinized bovine bone (DBB) for maxillary sinus augmentation has already been proofed by many studies.
Biomaterials with osteoinductive properties, such as platelet-rich fibrin (PRF), which are rich in growth factors were introduced as additional or replacement materials in bone augmentation procedures, aiming to stimulate angiogenesis, enhance new bone formation, improve graft maturation and recovery period (10,11).

One of the most important criteria for implant success is osseointegration. Dental implant stability is an indirect indication of osseointegration, it is a measure of the anchorage quality of an implant in the alveolar bone. Implant stability can be defined as the combination of both primary (mechanical) and secondary (biological) stability (12,13).

Several methods are used for the measurement of implant stability. Resonance frequency analysis (RFA) devices are claimed to be more objective and superior to other methods in measurement of implant stability (13,14). It provides the clinician with valuable information about the present state of bone-implant interface at various times. Furthermore, it used as a guide for timing of implant loading (15,16).

The objective of the present study was to monitor the changes in DI stability after LSA with simultaneous placement of DI utilizing demineralized bovine bone (DBB) alone or mixed either with leukocyte and platelet-rich fibrin (L-PRF) or with advanced-PRF (A-PRF) as a grafting material during the first six months of healing.

Materials and Methods

Study sample

This randomized prospective clinical study was conducted at the Dental Implant Unit/Department of Oral and Maxillofacial Surgery/College of Dentistry/University of Baghdad, from January 2019 to August 2020. Twenty-five patients (15 females and 10 males), with a mean age of 51.5 years (ranged 25-72 years). A total of 34 cases with atrophic posterior maxilla who met the eligibility criteria and were suitable candidates for this research.

The LSA cases were randomly allocated into three study groups according to the type of the graft material which was inserted in the created subantral space: Group A comprised 13 procedures and 21 DI, utilizing solely deproteinized bovine bone (DBB) with particle sizes 0.5-1 mm (BEGO OSS, mebios GmbH, Germany), group B involved 10 operations and 16 DI, using DBB mixed with L-PRF, and group C included 11 LSA and 13 DI, employing DBB mixed with A-PRF.

Randomization was performed by drawing lots to distribute the grafting materials according to the study groups. The protocol of the study was approved by the Ethical Committee of the College of Dentistry/University of Baghdad (No. 035118). All patients were informed about the nature of the study and they signed a written consent form for their participation in this study.

Patients were selected according to the eligibility criteria: Healthy individuals without any systemic disease/local pathological lesion at the sinus zone, patients age ≥ 18 years, residual bone height (RBH) ≥ 3 ≤ 6 mm with residual bone width (RBW) ≥ 5mm, and healed implant insertion site at least 6 months after tooth extraction.

Radiological examination

Panoramic radiograph was obtained preoperatively for preliminary evaluation of the residual alveolar ridge. Preoperative CBCT scan was recommended when the candidates were selected for sinus augmentation to provides more informative preoperative assessment of the RBH, RBW, and maxillary sinus anatomy.

Surgical procedure:

One hour prior to the commencement of the surgical procedure, the patient received one capsule of Cefixime 400 mg orally and gargled with 0.2% chlorhexidine mouth rinse for 2 minutes. All surgical procedures were accomplished by an experienced surgeon with this sort of operations. Surgeries were performed under local anesthesia using lidocaine 2% with adrenaline 1:80,000 (Septodont, France). Three-sided flap was performed, followed by reflection of a full thickness mucoperiosteal flap to expose the lateral wall of the maxillary sinus. A lateral window approach was accomplished using conventional drilling technique with round diamond bur.
Gentle elevation of the Schneiderian membrane (SM) using Frios Sinus Set elevators (Dentsply Friadent, Germany). Preparation of implant insertion sites using NucleOss T6 surgical kit (Turkey). Undersized drilling protocol was done in an attempt to achieve optimal primary implant stability.

In all study groups, barrier membrane (GENOSS, South Korea) placed directly below the elevated SM and extended outside to cover the lateral window. Partial augmentation of the created subantral space with one of the optional graft materials according to the groups. Installation of the DI (NucleOss T6, Turkey) into the prepared osteotomy site. Finally complete the augmentation of the created space.

**PRF preparation:**

Preparation of PRF was performed by collecting 10 mL of autogenous venous blood which was poured into 10 mL plain glass tube and immediately centrifuged. Centrifugation was performed according to the following two protocols: either at 2700 rpm for 12 min for preparation of L-PRF, or at 1500 rpm for 14 min for preparation of A-PRF (17,18). Placing the PRF clot in a jar to be cut in small pieces with scissor and mixed with 1-2 cc DBB and being ready for sinus augmentation with one of these mixtures according to the study groups (B or C).

**Implant stability measurement**

Implant stability was measured by resonance frequency analysis test using Osstell ISQ device (Ostell; Gothenburg, Sweden) immediately after implant installation for baseline record (T1) and 24 weeks postoperatively (T2) before implant loading, as illustrated in figure 1. Two consecutive measurements, one from bucco-palatal and the other from mesiodistal direction for each implant were recorded. The mean of the two ISQ values was considered as the final primary ISQ (T1).

![Image of Osstell ISQ device](image.png)

**Figure 1: Osstell ISQ device for measurement of:**
(A) Primary implant stability (T1). (B) Secondary implant stability (T2).

Change in implant stability = Secondary implant stability (T2) - Implant stability (T1). Change in implant stability (%) = Change in implant stability (T2-T1) × 100% / Implant stability (T1).

**Statistical Analysis**

The new edition of IBM® SPSS® 24 was used for statistical analysis. The histogram revealed that the data was not distributed normally. The data is provided in the form of a mean and standard deviation. Kruskal-Wallis test was used to compare the mean stability of the groups. Wilcoxon Rank U test was used to assess changes within each category. The Mann-Whitney test is used to compare two different groups statistically. P value was considered not significant at \( P > 0.05 \), significant at \( P \leq 0.05 \) and highly significant at \( P < 0.01 \).

**Results**

Distribution of inserted dental implants according to the study groups
A total of 34 LSA procedures and simultaneous installation of DI (one-stage technique). The total number of DI installed concomitantly with the LSA for all study groups were 50 DI. Twenty-nine DI (58%) of which with a diameter of 4110 mm. Forty-six DI (92%) out of 50 DI were inserted in molar region (tables 2).

DI, dental implants.

Dental implant stability and study groups

Table 3 illustrates that the ISQ value increased significantly for all study groups from T1 to T2 (P= 0.001). For groups A and B, the statistical increase in stability was relevant with the increase in clinical ISQ scale (from low to medium stability, according to ISQ scale). In contrast, the significant increase in DI stability for group C was irrelevant clinically (within the medium ISQ scale).

Discussion

The implant stability quotient (ISQ) value ranges from 1 to 100. In general, ISQ values for successful implants are reported from 57 to 82 ISQ \cite{13,14}. The ISQ > 70 represents high stability, ISQ between 60 and 69 exemplify medium stability, and ISQ < 60 ISQ considered low stability \cite{19}.

In the present research, the results were considered clinically significant or not dependent on the number of DI that remained in the same level of ISQ-scale or changed to another level. This clinical analysis of the data illustrated and confirmed that not all the statistically significant results essentially being clinically relevant. This idea is supported by Guller in 2008 \cite{20} who declared that statistically significant differences may be of no clinical relevance whatsoever”.

The implant survival was 100%. For all study groups, there was a significant increase in ISQ value from 58.78 ±11.1 ISQ (low stability) at T1 to 69.03 ±5.95 ISQ (medium stability) at T2 with a mean change of DI stability (10.16 ISQ), in which it was statistically significant and clinically relevant.

For study groups A and B, there was a statistically significant increase in stability from T1 to T2 which was harmonious with the clinical outcome (increase of ISQ values from low to medium stability level). In contrast, the statistically significant increase in ISQ value for group C was not associated with clinical relevance (ISQ values remained within medium stability level).

The statistically significant increase in stability from T1 to T2 for all study groups might be related to the increase in osseointegration. This outcome is supported by Sennerby et al. in 2005 \cite{21} who claimed that the increased ISQ values might be attributed to the successfully osseointegrated implants.

Undersized drilling protocol was accomplished in the maxillary posterior region to gain the requested primary implant stability. This method was enforced by several studies which proved that when DI were inserted in underprepared osteotomy sites using smaller diameter drills, maximum bone volume preservation and enhanced bone density were achieved as stated by Turkyilmaz et al. in 2008 \cite{22}, Tabassum et al. in 2010 \cite{23}.

No statistically significant difference (P > 0.05) noticed in ISQ values between the 3 study groups at T1, T2 and in mean change (T2-T1). Nevertheless, it was higher in groups A and B, 12.24 ISQ and 11.09 ISQ, respectively, when compared to group C (7.15 ISQ). However, it did not reach the level of statistical significance (P = 0.45).

In addition, it has been found that the addition of L-PRF and A-PRF to DBB for the study groups B and C, respectively; did not provide an enhancement to the ISQ value superior to the DBB alone in group A. This result comes in line with Pichotano and co-workers in 2019 \cite{24}, who found that the ISQ values at loading did not differ according to the grafting materials, following a split-mouth design, in which the right maxillary sinus was augmented using L-PRF mixed with DBB and the left side was filled with DBB alone. In contrast, Călin et al. in 2016 \cite{25} claimed that the use of the combination of A-PRF and bovine bone in sinus lift technique speeded healing time by approximately 50%. However, the authors in their study relied the assessment of implant osseointegration on clinical examination and panoramic radiograph and they did not measure the DI stability.

Relation of implant stability to patient-related variables

For all study groups, and from a statistical point of view, there was a highly significant increase in the ISQ value for gender and age variables from T1 to T2. The speculation might be related to the normal remodeling process during osseointegration in which the stability increased during time depending on primary stability and other factors as bone remodeling and implant surface conditions as proclaimed by Sachdeva et al. in 2016 \cite{14}.

Relation of implant stability to surgical-related variables

In this research, the effect of some factors on implant stability were standardized by operating on the same region (posterior maxilla), standard surgical technique (LSA), the same implant system (geometry
and surface characteristics) utilized for all cases, the same surgeon, undersized drilling technique that is to reduce the confounding factors that might influence implant stability.

There was a statistically significant increase in ISQ value for each surgical-related variable (RBH, DI insertion site, and DI diameter) from T1 to T2. This was ordinarily related to the normal sequelae of healing process and osseointegration since stability of DI increased in all surgical-related variables.

The RBH < 4 mm demonstrated a statistically significant increase in implant stability versus RBH ≤ 4 mm at T1 and T2. This result is supported by several studies which concluded that primary implant stability is influenced by quality and quantity of the residual bone, and the secondary implant stability in its turn affected by the primary stability (12,16,26).

**Conclusion**

There was a significantly increase in ISQ value for all of the DI 24 weeks after their installation irrespective to the type of graft material utilized to augment the sinus. Moreover, the addition of L-PRF or A-PRF to the bovine bone for sinus floor augmentation did not increased the ISQ value superior to the bovine bone alone.

Evaluating the Effect of Air Abrasive Polishing on Friction and Surface Micromorphology of Ceramic Brackets Using Different Wires

Ahmed R. Mohammed Hassan¹, Shahbaa A. Mohammed²
¹Master Student, ²Assit. Prof. ; Department of Orthodontics, College of Dentistry, University of Baghdad, Baghdad/Iraq

Abstract

Objectives: The aim of this in vitro study was to evaluate the Resistance to Sliding (RS) provided by ceramic (Perfect clear) sapphire ceramic brackets using round 2 types of orthodontic wires (Fiber-Reinforced Polymer Composite (FRPC) and Epoxy fully coated Stainless-Steel), before and after the use of sodium bicarbonate airborne particle abrasion, in an experimental model with 3 non levelled brackets and to evaluate the surface micromorphology of these brackets by means of scanning electron microscopy.

Materials and Methods: One commercial brands of ceramic brackets were evaluated. The forty specimens were divided into two groups (n = 20) according to the two type of arch wires and each group was divided into four subgroup of five specimens according to the application or not of sodium bicarbonate airborne particle abrasion for (5, 10 and 20) seconds. A device adapted to a universal testing machine was used to simulate the movement of retraction in sliding mechanics, measuring the traction force needed to slide 10 mm of the wire over the test specimen brackets. The test speed was 5 mm/min. The data were analyzed by two-way analysis of variance (ANOVA) and Tukey test.

Conclusions: It may be concluded that it is not recommended to apply airborne particle abrasion on the slots of ceramic.

Key Words: One commercial brands of ceramic brackets were evaluated.

Introduction

With the advent of increasing adults’ number opting for the orthodontic treatment, the development of the orthodontic appliances with ample emphasis on the aesthetics coupled with the optimum performance has become an exceedingly essential object or rather necessity of the day [1]. It has been partially resolved by the introduction of aesthetic brackets manufactured of ceramic or composite [2].

The ceramic brackets available nowadays are made of alumina either in poly-crystalline or mono-crystalline forms. The manufacturing process of mono-crystalline brackets results in a purer structure, a smoother surface, and a considerably harder substance than the fabrication of polycrystalline brackets [3].

Ceramic brackets currently represent an aesthetic alternative, although their use is limited. They abrade the enamel, and fracture more easily, and they have a higher coefficient of friction, increasing resistance to sliding [4].

However, most arch wires are still made of efficient, albeit un aesthetic, metal alloys such as stainless steel (SS) and nickel-titanium (NiTi) so that an aesthetic arch wire is highly desired to complement aesthetic brackets in clinical orthodontics [5].

Coating metallic arch wires by plastic resin materials was the main solution to offer aesthetic characteristics to the wires of metallic or silver colour appearance [6]. As the patients favor that shiny metal arch wires were not as apparent as opaque, an alternative could be wires with transparent or translucent features [7]. Moreover,
aesthetic coating of alloy arch wires are not durable clinically and tends to dehisce over a period of time [8]. Through composite technology, an aesthetic arch wire has been developed from continuous fibers and polymer matrix, giving rise to the fiber reinforced polymer composite (FRPC) arch wire [9]. The translucent nature of the polymer matrix confers the aesthetic property to this wire, while the fiber content gives the flexibility, overcoming the inherent problem of brittleness [10].

Friction is defined as a force that retards or resists movement related to two objects in contact. In sliding mechanics, friction is determined by the type of arch, type of bracket, and type of ligature.[11] Although orthodontic treatment provides the functional and aesthetic correction of teeth, one of its inconvenient aspects is that the brackets (whether they are made of metal or ceramics) and other accessories allow a greater accumulation of residues and consequently, the formation of dental plaque, especially around the brackets. Professional prophylaxis must be performed to correct the patient’s deficient tooth brushing, particularly with the use of sodium bicarbonate abrasion, a system that releases controlled jets of air, water, and sodium bicarbonate particles. It was introduced at the end of the 1970s as a fast and easy mechanism to remove dental plaque,[12]

Consequently, professional tooth cleaning could be extremely important for the maintenance of oral health, especially when patient compliance is inadequate or when dexterity is poor.[13] Compared to professional tooth cleaning with rubber cup and pumice, air-polishing devices are more effective for removing dental plaque, and in addition they promote less operator fatigue due to reduced working time.[14]

With regard to alterations to the dental substrate, it has been shown that the use of sodium bicarbonate airborne particle abrasion does not cause surface alterations in healthy enamel, but it does affect and change the micromorphology of dentin and cementum. Therefore, the use of the sodium bicarbonate airborne particle abrasion is an efficient and safe method for removing dental plaque from healthy enamel, but its use on exposed dentin and cementum must be avoided. [12,14–17].

Many studies evaluated the factors that could influence the frictional resistance, such as proprieties related to bracket and wires materials,[18–23] type and force of ligation,[20,24–26] and biological variables.[27,28] However, little research has been conducted to evaluate the effect of sodium bicarbonate air abrasive polishing on frictional resistance at tooth alignment and levelling phase of orthodontic treatment. Therefore, the aim of this study was to evaluate in vitro the frictional resistance (static friction) provided by Perfect Clear Sapphire brackets, using 2 types of aesthetic orthodontic wires size 0.018 inch (Fiber-Reinforced Polymer Composite (FRPC) arch wire and Epoxy fully coated Stainless-Steel arch wire) before and after the use of the sodium bicarbonate airborne particle abrasion, in an experimental model with 3 non levelled brackets and surface micromorphology of the brackets before and after applying sodium bicarbonate airborne particle abrasion, by means of scanning electron microscopy.

**Materials and Methods**

The study samples included 0.018 inches upper preformed round arch wires from two commercial brands . The first one was Fiber-Reinforced Polymer Composite (FRPC) arch wire manufactured by (Dentaurum, Germany.) and the second was Epoxy fully coated Stainless-Steel arch wire manufactured by IOS® (Tooth Tone® arches, Ortho Technology, USA).

The distal end of wires were cut into (5 cm.) length and investigated with one type commercial brand Sapphire Ceramic brackets {Perfect Clear® sapphire brackets from Hubit Co. (South Korea)}. Frictional resistance of 40 samples in this study was obtained from grouping the samples into 2 groups (n = 20) according to the type of arch wire and each group was divided into four subgroup of five specimens according to the time of air powder abrasive application.

In this present study, we used an experimental model with 3 non levelled brackets to assess the frictional forces generated during the dental alignment process. To
prepare the samples, 120 upper first premolar Sapphire ceramic edgewise brackets.022”(MBT prescription with a 0.022x0.028 inch slot with torque of (-7) and angulation of 0) were employed. Sapphire ceramic brackets were used because they are more aesthetic than stainless steel brackets and made from mono crystal alumina because the manufacturing process of mono-crystalline brackets result in pure and clear structure, smoother and harder surface than other type of ceramic brackets (Swartz, 1988).29

The samples were prepared by bonding 3 brackets on a preformed plastic block (37 mm length, 12 mm width, 10 mm height) made by Computerized Numerical Control (C.N.C), which was designed to simulate a non-aligned dental segment. The brackets were bonded with cyanoacrylate adhesive (Gucex star 502, china) and the bonding procedure was standardized by using the (C.N.C) plastic design and positioner showed in [Figure 1]. The end of the arch wire with a dimension of 0.018 inch cut into 5 cm and ligate with ligature elastic to brackets specimen.

[Figure 1: A-from the left to the right (C.N.C) plastic design, block and positioner. B-precisely bonding of a non-aligned brackets .C-standardized application of air abrasive powder.]

The vertical discrepancy between the brackets was set at 1 mm to simulate a non-alignment situation in the segment of dental arch to be studied. The inter bracket distance was set at 11mm, according to a previous study.30

The brackets and wires were washed in 95% ethanol and air-dried, and then one wire segment of 5 cm was positioned on the brackets slots for each sample. Several studies have documented that a high force generated by a tight ligation will cause an increase in the measurement of frictional force.31 To reduce the potential for such bias, all ligations were done by the same operator using a needle holder in a standardized procedure. The ligatures used in this study were elastomeric modules (Super slick clear) IOS® (International Orthodontic Services, Stafford, USA)).

During the frictional force tests Static Friction (SF) and Kinetic Friction (KF) readings were performed. SF readings were obtained by determining the peak force (N) at the first 2 mm of wire displacement.

The test specimens were submitted to the tensile test in the mechanical testing machine computerized universal testing machine (Instron H50KT Tinius Olsen testing machine with 10 N load cell). Figure 2 shows the device and the bracket/wire positioned in the universal
testing machine. A maximum load of 5 kgf was used under dry conditions. Tensile force needed to slide 10 mm of the wire over the test specimen brackets for 2 minutes, at a speed of 5 mm per minute, was measured, and the maximum tensile force value obtained during the range of motion of each bracket was also measured. The data were obtained Newtons.

The sodium bicarbonate airborne abrasion was performed with a sodium bicarbonate appliance using AIR-N-GO Classic sodium bicarbonate polishing powder based in raspberry natural fresh flavour (Satelec A Company of Acteon Group, French). After each air abrasion session for every bracket the remaining powder was discarded and a new (15 gm) of powder were poured into the tank of Prophy-Mate neo polishing system airflow hand piece (NSK Company, Japan) to prevent the level of powder from reaching below 50% of the tank in accordance with Parmagnani and Basting (2012).

The airborne abrasion was applied perpendicularly to the brackets at a distance of 5 mm for 10 seconds with a 2.3 bar pressure.

Surface micromorphology of the brackets was examined by scanning electron microscopy before and after application of sodium bicarbonate air abrasive polishing visualized at (50X, 500X, 1000X, 2000X) magnification is shown in figure 3 to figure 5.

**Results**

According to Table 1, it was observed that mean resistance was higher in the group that received airborne particle abrasion, regardless of the type of wire.

Epoxy fully coated Stainless-Steel arch wire showed a higher mean resistance than the Fiber-Reinforced Polymer Composite (FRPC) arch wire, both in the control group and after airborne particle abrasion.

Surface micro-morphologies of the brackets before and after jet application are shown in Figures 3 to 5. For the ceramic brackets, there was no surface alteration both at (50X, 500X, 1000X, 2000X) magnification.

Discussion

The sliding of the brackets along the arch wire results in frictional forces that prevent the supporting tissue from attaining the optimal force level required for tooth movement [33]. Therefore, to overcome the friction at the bracket-arch wire interface, it is important to understand the orthodontic force so that a proper magnitude of force can be used to produce optimal biologic tooth movement, as well as understanding the tooth movement affected by a combination of biological and mechanical factors [34].

There are several ways to reduce friction by improvement of the material surface of the arch wire [35]. With ion implantation, the measured frictional losses ranged from 23.4 to 45.9 per cent [36]. The influence of the bracket material with regard to friction caused by the wire during sliding mechanics has been assessed, and it was found that ceramic brackets show higher friction than those made of stainless steel, not only due to the type of material, but particularly due to the irregularities on ceramic bracket surfaces [31,38,39].

In the present study, mono-crystalline ceramic brackets were used. In general, the surface roughness of ceramic brackets is similar to that of a block of concrete in comparison with stainless steel brackets, which has a porous, irregular, and polyhedral surface, and this was observed in the scanning electron microscopy images in the present study, retaining a larger amount of sodium bicarbonate particles after the airborne particle abrasion and therefore, increasing friction. On the other hand, the sodium bicarbonate airborne particle abrasion did not cause surface alterations on ceramic brackets because the ceramic material hardness was greater than that of the metal material.

Therefore, it must be considered that jet application on the bracket slot should be avoided, and if it is done, abundant washing with water must be performed to remove the residues, which occurs mainly in the ceramic brackets due to their greater surface irregularity.

Conclusions

Sodium bicarbonate air abrasive polishing is not recommended because the airborne abrasion of the brackets promoted a significant RS increase when the 2 types of wires (FRPC and the Epoxy fully coated Stainless-Steel) were used. Concerning the Epoxy fully coated Stainless-Steel wire, the airborne abrasion effect on RS seems to be greater due to these material’s properties.

Regardless of the type of wire tested, mean resistance was higher in the group that received sodium bicarbonate airborne particle abrasion.

The micromorphologic analysis showed that the airborne particle abrasion caused no changes on the surface of the ceramic brackets.

The application of airborne particle abrasion on the slots of ceramic brackets is not recommended.

Angulation and Height of Canine in Different Type of Malocclusion

Iman I. Al-Sheakli¹, Muthanna I. Ali²

¹Professor, Department of Orthodontics, College of Dentistry, University of Baghdad, Iraq,
²M.Sc. Student, Ministry of Iraqi Health, Baghdad, Iraq

Abstract

Background: Canines are unique teeth because they have certain characteristics and responsibilities. They are located in the corner of the mouth, assist the incisors in cutting and tearing food, help the posterior teeth by guiding the mandible during the action of mastication. The present study aim to determine the most common angulation and height of buccally malposed canine and determine the gender difference of the angulation and height of buccally malposed canine measured in each side and in total samples and to study the relation between the angulation and height and the relationship of the angulation and height with the side of buccally malposed canine and with the sagittal malocclusion of dental arch.

Material and Method: The present study was a population-based, cross sectional study based on the surveying of panoramic radiographs of 11-17 years aged patient with buccally malposed canine seek orthodontic treatment in Baghdad city- Iraq. For each case, determine age and gender of the patient, as well as determine affected side and sagittal malocclusion of the dental arch. And measure angulation and height of buccally malposed canine on panoramic radiograph. T-test and F-test were used to determine gender difference (for each side and for total samples), side difference and sagittal malocclusion difference. Person correlation were used to reveal the relation between angulation and height of buccally malposed canine. 

Result: The total samples is 71 sample, consist of 41 female and 30 male. The gender difference was not significant in right and left sides and in total samples. No significant difference in angle and height between the sides, as tested by t-test. F-test reveal no significant difference among different sagittal malocclusion in angulation and in height. The Angulation and Height of buccally malposed canine in total samples show normal distribution of samples with median, mode and mean close to each other. The person correlation between the angle and height was (-0.552) with p-value (0.000) that reveal highly significant reverse relation

Conclusion: No gender difference found in the buccally malposed canine in the right and in the left side, so the gender difference can be measured in the total samples as one unit High frequency of buccally malposed canines was reported in female than in male. The side difference was not significant in total samples, High frequency of buccally malposed maxillary canines was found in class I & II sagittal occlusion more than class III. The sagittal malocclusion difference was not significant. The Angulation and Height of buccally malposed canine in total samples show normal distribution of samples so the mean was represent most common angulation and height of buccally malposed canine. There are highly significant reverse relation between height and angulation, so the buccally malposed canine be more vertical as it came close to the occlusal plane

Keywords: Canines are unique teeth because they have certain characteristics and responsibilities.

Introduction

Human beings have four pointed teeth one on each side of the dental arch called canine or cuspid. Each canine represents the third tooth from the median line after the central and lateral incisors forming the key stone or the corner stone of the dental arch (¹).
They are the longest teeth in the mouth; the crowns are usually as long as those of the maxillary central incisors, and the single roots are longer than those of any of the other teeth. The middle labial lobes have been highly developed incisally into strong, well-formed cusps (Nelson and Ash, 2015). The shape and position of the canines contribute to the guidance of the teeth into the intercuspal position by “canine guidance” (2).

Development: The calcification of crown of the permanent canine begins to take place early in life i.e. at the age of 4 to 5 month, and by the end of the first year it can be seen high in the maxilla above the bifurcation of first deciduous molar and below the floor of the orbit. From this position to the occlusal plane the path of eruption is more tortuous and difficult than any other tooth, as the root begins to form approximately at 7 years of age the canine moves towards the occlusal plane, the crown lying in close proximity to the root of the lateral incisor and emerging into the mouth at the age of 11 and 12 years. By 12 years the canine has usually reached occlusion, the lateral incisor has been.

Importance: The positions and forms of the permanent canine and their anchorage in the bone, along with the bone ridge over the labial portions of the roots, called the canine eminence, have a cosmetic value. They help form a foundation that ensures normal facial expression at the corners of the mouth. Loss of all of these teeth makes it extremely difficult, if not impossible, to make replacements that restore that natural appearance of the face for any length of time. It would therefore be difficult to place a value on the canines, and their importance is manifested by their efficiency in function, stability, and aid in maintaining natural facial expression. In function, the canines support the incisors and premolars, since they are located between these groups. The canine crowns have some characteristics of functional form, which bears a resemblance to incisor form and also to the premolar form (3).

Iteology: Sachan, Chaturvedi, (4) summarized the etiological factors of ectopic canines as followed: Early loss of deciduous teeth, Crowding of the permanent successor, Tooth size and overall arch length, High developmental position and long path of eruption and tortuous movement, Prolonged retention of the deciduous tooth, Failure of primary canine root resorption, Small or congenital missing permanent lateral incisor, Reduced in the length of the adjacent lateral incisor root, Ankylosis of permanent canine, Alveolar cleft, Malposed tooth germ, Hereditary factors, Endocrine deficiency, and Febrile diseases.

Many studies have been performed in Iraq to study the problems of the canines. Some of them took the maxillary canine as a part from the survey (5-9). Other Iraqi studies was study impacted canine (11, 12). Some of them concern with canine specifically. Kinaan (13) study the management of buccally malposed canine. Ghaib, (14) and Aziz, (15) study the prevalence of buccally malposed canine. Saloom, (16) and Al-Ani (17) concern with eruption course and eruptive anomalies of canine. Al-Fahdawi (18) and Aziz, (19) study the problems of the maxillary canine in Iraqi people. Al-Dabagh, (20) study buccally malposed mandibular canine in Iraqi Kurdish population.

This survey was conducted to study the angulation and height of the canine in deferent type of malocclusion.

Material and Method

The present study was a population-based, retrospective cross sectional study based on the surveying of panoramic radiographs.

The study sample The samples of present study are derived from any patients seeking fixed appliance orthodontic treatment in dental hospital of university of Baghdad / collage of dentistry and private practices in Baghdad city.

Age was considered according to the last birthday giving an age range from 11 years to 17 years.

Selection criteria: The sample specification for present study are: Patient indicated for fixed appliance orthodontic treatment who have unilateral or bilateral buccally malposed canine, have complete set of maxillary permanent dentition with/without the third molars, have no extracted or congenitally missed lateral incisor or premolar, no massive interproximal caries or
restoration, and no crown or bridge restoration.

Characteristic of radiographs: Digital panoramic radiography was carried out using PM 2002 CC Proline apparatus (Planmeca, Helsinki, Finland) using imaging values between 58–68 kV and 4–10 mA, depending on the subject’s size. And the magnification factor was 1:1. All re-reported measurements were adjusted according to this factor.

The study variables: The variables of present study incorporated age and gender of the patients, sagittal malocclusion class, as well as side, angulation and height of buccally malposed canine.

Inter- and intra-examiner: All panoramic radiographs were investigated by two observers in two time interval to assess intra- and inter-examiner reliability

The anatomic measures:

1. Angulation of malposed canine: The measurement of angulation of malposed canine on panoramic radiograph will be done by measure the angle between the long axis of malposed canine and the occlusal plane (21). The occlusal plane will be determined by drawing a horizontal line from the medial point of the incisal edge of the central incisal to the mesiobuccal cusp tip of the maxillary first molar. (21) The angulation of the malposed canine will be measured lateral to the midline and recorded in degrees (22, 23).

2. The height of the malposed: Canine will be measured as length of perpendicular line extend from the occlusal plan to the cusp tip of the canine and recorded in millimeters.

Statistical analysis: Data were entered into a spreadsheet during the study period and analyzed using a commercially available statistical software package SPSS (Statistical Package for Social Sciences, version 11.0; SPSS Inc, Chicago, IL).

For statistical descriptions, means with standard deviations, were calculated and presented by gender, side and sagittal class. T-tast and f-tast use to test the difference between two and three variables, respectively. For all analyses, a P value less than (0.05) was considered statistically significant.

Result

Gender difference of the angulation and height of buccaly malposed canine measured in each side.

The samples were divided to angulation and height of buccally malposed canine in the right side and in the left side, and test gender difference in each side.

The gender difference was not significant in both sides (p >0.05), table 1

Gender difference of the angulation and height of buccaly malposed canine measured in total samples.

The total samples is 71 sample, consist of 41 female and 30 male. The mean of angle in female was slightly more than in male. The mean of height was slightly more in male than female. The gender difference was not significant in total samples (p >0.05), table 2

Angulation and Height of buccaly malposed canine with side different.

The sample consist of 32 sample with right buccally malposed canine and 39 with left. The mean of angle and the mean of height nearly similar in both sides. No significant difference in angle and height between the sides, (p >0.05), table 3.

Angulation and Height of buccaly malposed canine with sagittal malocclusion difference.

The samples consist of 26 sample with class I sagittal relation. 26 sample with class II sagittal relation and 19 sample with class III sagittal relation. F-test reveal no significant difference among different sagittal malocclusion in angulation and in height. (p >0.05), table 4.

Discussion

Angulation and Height of buccally malposed canine with gender difference measured in each side.

No gender difference found in the buccally malposed canine in the right and in the left side, so the gender difference can be measured in the total samples as one unit.

Angulation and Height of buccally malposed canine with gender difference in total samples.

High frequency of buccally malposed canines was reported in female than in male and this agree with (24). There is no significant difference between male and female in both angulation and height.

Angulation and Height of buccally malposed canine with side different.

High frequency of buccally malposed canines was reported in the left side more than the right, this agree with Al-Atabi, et al, (24), Al-Huwaizi (9) and Aziz (15), and disagree with Ghaib (14), Al-Fahdawi (18) and Al-Chalabi (10).

The side difference was not significant in total samples, and this agree with Al-Atabi, et al, (24).

Angulation and Height of buccaly malposed canine with sagittal malocclusion difference.

High frequency of buccally malposed maxillary canines was found in class I &II sagittal occlusion more than class III; because the dominance type of occlusion is class I & II, so it is reasonable to find a higher percentage of canine problems in class I & II, sagittal occlusion.

The sagittal malocclusion difference was not significant.

Angulation and Height of buccaly malposed canine in total samples.

The Angulation and Height of buccaly malposed canine in total samples show normal distribution of samples so the mean was represent most common angulation and height of buccaly malposed canine.

Relation between the height and angle of buccally malposed canines

There are highly significant reverse relation between height and angulation, so the buccaly malposed canine be more vertical as it came close to the occlusal plan.

Abstract

Background: This study was carried out to detect the distribution of *Streptococcus mutans* with dental caries in Iraqi’s patient samples. Out of 100 patient’s samples only (22) with age (3-17) years old were found to be effected with *Streptococcus mutans*. DNA was extracted amplified by Gradient PCR and then sequenced. vicR was showed highly conserved with no mutation while vicK showed that these were silent mutation and four isolates have missense mutation from eight isolate.

Material & Method: In this study, 22 from clinical *S. mutans* strains were isolated from caries- children to sequence the vicR, vicK and 16s rRNA genes. Genomic DNA was extracted from *S. mutans* strains and amplified using Gradient PCR. The PCR products were purified and then sequenced.

Result: The molecular study include vicR, vicK and 16s rRNA, genes by Gradient PCR. The result of sequencing appear that no mutation in vicR genes, although in 16s rRNA present transion and transverision mutation . Finally the sequencing of vicK gene appear silent mutation and four isolates have missense mutation from eight

Conclusion: the result of molecular study of vicR gene were appear no mutation in all isolates while 16s rRNA although have transition and transversion mutation, the Sequence of vicK gene that note more of mutation was silent mutation but some of them was missense mutation.

Keywords: Dental caries, molecular, *Streptococcus mutans*.

Introduction

Dental caries is a major common and common public health oral illness which hinders the attainment and safeguard of oral health in variation age groups (1). Dental caries is one of most important prevalent infectious disease of the human can be leads wastage tooth structure, there after changes in oral functions (2). Other define of dental caries is a bacterial disease of the dental hard tissue and happen in certain localized sites in the dentitions. In the iorder of frequency sites to attack “pits” and “fissures”, especially on the surfaces of the teeth, proximal contact of the surface, and “labial”, “buccal” and “lingual” surface of the dentition neighboring to the gingivae (3). So consider a complex disease caused by a physiological imbalance, between fluid and mineral dental biofilm (4). *Streptococcus mutans* is the plurality cariogenic pathogens in tooth decay. The highly acidogenic, industrialize short-chain acids which...
the soften hard tissues of dental. Three isoymes of glucosyltransf erases metabolize and catalyze; sucrose to industrialize insoluble extracellular polysaccharides, which increase attachment. The most isolated of significant from tooth caries samples are S. mutans (5) In the oral cavity Despite being ubiquitous, Streptococcus mutans spread often an indicates caries portability and no good oral hygiene. Streptococcus mutans is a gram positive cocci, food used not only for sticking to the dental, but also for synthesis, consequently detect acids. and allows low pH of the bacterium, preventing competitive bacteria from colonizing and eventually causing early decays (6). Usually, the appearance of S. mutans in the tooth cavities is followed by caries after 6-24 months (7).

In the bacteria, two component regulatory systems (TCRSs) are used as “molecular switches” in the response to ecology changes. Regulatory genes are essential for the bacterial adaptation, survival, and the virulence. Basically on the genome sequence, 13 TCRSs genes have been; identified in the S. mutans (8). One of these TCRSs, the vicRK signal transduction system, affects different virulence features of S. mutans (9). This system is consist of a histidine kinase sensor protein (vicK) located in the bacterial membrane and a cytoplasmic; response regulator protein (vicR). During phosphorylation reactions, extracellular signals is sensed via vicK, and then the vicK histidine kinase transmits the message to vicR, which is modulates gene expression (10). VIC genes regulate expression of several virulence associated genes that is affect produce and adhesion to polysaccharides, including gtfBCD, ffI, and gbpB. Furthermore it, compared with wild-type UA159 strain, strains without vicK form thumping biofilms, with a decrease rate of total format ion glucan (11). In addition, inactivation of vicK action a decrease level of lactic acid and best acid tolerance of S. mutans (10); a vicK knockout mutant have been present to be more sensitive to H2O2 than wild-type (12).

A vicR null mutation is present lethal to S. mutans. vicR acts directly on promoter regions of the gtfB, gtfC, and ffI genes. Over production of vicR transcript up regulates these genes (11). In addition, vicR binds specifically to; the comC gene, subsequently negatively affecting the transcription of comC, comDE, comX, and nlmC (13). The vicRK signal transduction system are basic for S. mutans by modulating gene expression. sequenced the vicR and vicK genes of the S. mutans strains isolated from; children with a distinct caries status to analyse effects of vicR and vicK polymorphisms on risk of Early childhood caries (ECC). Mutational analysis present that vicR in S. mutans plays an basic role in the viability vicR, vicK of this bacterium (11)."
Result & Discussion

Concerning the supposed 1353 bp PCR amplicons of *vicK* gene, NCBI engine has shown extremely high sequences similarities between the sequenced samples and this target. NCBI (http://www.ncbi.nlm.nih.gov) engine has indicated the presence of 99% of homology with the expected target that completely covered

| Table ( 1 ) analysis sequencing of *Streptococcus mutans* *vicK* gene |
|---------------------------------|-----------------|--------------------------|--------------------------|
| Type mutation                   | Nucleotide change          | Amino acid change        | Isolation                |
| silent mutation                 | AAA->AAG               | Lysine> Lysine          | All isolation            |
|                                 | GAA->GAG,               | Glutamic acid> Glutamic acid |
|                                 | AAT->AAC                | Asparagine> Asparagine   |
|                                 | ACC->ACT                | Threonine> Threonine     |
|                                 | GTA->GTT                | Arginine> Arginine       |
This table 1 appear that most of mutation was silent mutation in all bacterial isolates that mean the mutation change to the same amino acid change may well have little effect on the protein since the substituted amino acids are similar to the original (they are all hydrophobic amino acid) such as Lysine > Lysine AAA>AAG, Glutamic acid > Glutamic acid GAA>GAG, Asparagine > Asparagine AAT>AAC, Threonine > Threonine ACC>ACT, Arginine > Arginine GTA>GTT But four isolates (2,3 and 7) was give a missense mutation, Glycine > Arginine GGT>CGT, Asparagine > Lysine AAT>AAA, Glutamine > Histidine CAG>CAC, Glutamine > Arginine CAG>CGG, this mutation may be cause high biofilm product, (benefit mutation or positive mutation), mutation lead to decrease production biofilm.

### Detection of 16S rRNA gene

16S rRNA gene was used to increase the confirmation of bacteria *S. mutans* deposite begin diagnosis by GP 24 kit, vicK gene detected by electrophoresis Amplification was verified by electrophoresis 1.5% (w/v) agarose using a ladder(1500) as a molecular weight marker. An amplification of 16S rRNA from 22 isolates was performed to confirm bacterial identification, Identification of S. mutans isolates by using 16S rRNA is more accurate than bacteriological and biochemical assays. (15) demonstrate that 16S rRNA gene PCR was sensitivit, specific,and used for diagnosis of culture-negative bacterial Infections also useful for identification of bacterial pathogens in patients pretreated with antibiotics.

Figure 3: Analysis of 16S rRNA gene product was electrophoresis on agarose gel (1.5 %) at 70 volt. 1x TBE buffer for 1 hours. 16S rRNA product band size (1250 bp). Lane(N): DNA Marker sizer (1500) and lane 1-22 for sample dental caries.
Sequencing of 1250 bp amplicons of 16S rRNA gene

Ten samples was sent to Korea sequencing which had shown exactly 1250 bp The sequencing reactions indicated the exact positions after performing NCBI for these PCR amplicons. Concerning the supposed 1250 bp PCR amplicons of 16S rRNA gene, NCBI engine has shown extremely high sequences similarities between the sequenced samples and this target. NCBI(http:// www.ncbi.nlm.nih.gov) engine has indicated the presence of 98- 99% of homology with the expected target that completely covered.

In this appear 16S rRNA gene despite the emergence of mutations in all isolates they gave a ratio 98-99% S.mutans The sequence was blasted in NCBI against standard strain of S. mutans complete genome. The identifying result showed 98-99%.

Conclusion

The result of molecular study of vicR gene were appear no mutation in all isolates while 16S rRNA although have transition and transversion mutation but the percentage of similarity with NCBI (http:// www.ncbi.nlm.nih.gov) appear 98-99% that Streptococcus mutation partial 16S rRNA gene. While the Sequence of vicK gene that note more of mutation was silent mutation but missense mutation present in isolated that cause change in biofilm production.

Periotest Evaluation of Stability after Insertion of Temporary Anchorage Device

Hussain Jabar Kadhem¹, Akram Fasial Alhuwaizi²

¹Post graduate, ²Prof.; Department of Orthodontics, College of Dentistry, University of Baghdad, Baghdad/ Iraq

Abstract

Introduction: Skeletal anchorage devices was developed for absolute anchorage during orthodontic treatment. Because of immediate loading on orthodontic miniscrews, early stability became a essential requirement for loading forces on miniscrews.

Objective: The aim of this study was to evaluate the early stability of the miniscrews after two weeks of insertion and the effect of the length and the side of insertion of the miniscrews on its stability using Periotest device.

Material and Method: Thirty- three orthodontic patients in a collage clinic were recruited who required bilateral miniscrews for orthodontic anchorage. Under local anesthesia, each patient received two miniscrews in the maxillary buccal area (one side 1.6x8mm and the other side 1.6x10mm). after two week early stability measured using Periotest device.

Results: There was no significant different in stability of miniscrew between right and lift sides and between short and long miniscrews.

Conclusion: length of miniscrew and side of insertion do not affect the early stability of miniscrew.

Keywords: Periotest ; stability ; Insertion ; Temporary Anchorage Device

Introduction

Preparation of the anchorage is a extremely important part in the orthodontic treatment. The success of orthodontic treatment generally relied on the anchorage protocol planned for particular cases. Planning for anchorage and preparation before tooth movement is necessary to avoid inappropriate tooth movements and not to interfere with the orthodontic result (19). Absolute anchorage is defined as no movements of the anchorage segment as a result of the reaction forces applied to move the teeth (7). The success rates are reported to be 80-90%, which is to some extent inferior than that of miniplate and palatal screw (15). Miniscrews can simply be placed and removed with a uncomplicated procedure, can be loaded instantly, are commercially accessible in a number of sizes (width and lengths), and are relatively cost-effective (4).

Because of immediate loading on orthodontic miniscrews, early stability became a essential requirement for loading forces on miniscrews (12). It is considered as clinical condition of immobility of miniscrew and ability to resist loads in different directions (10).

The early stability of miniscrews is mostly held by mechanical retention between bone and miniscrew surface (18).

Early stability is controlled by factors such as overloading, bone density, cortical bone thickness , design of screw and root proximity (6,1). The Periotest measurements after implant placement are helpful in the assessment of early stability. Periotest® M is an electronic instrument comprised of a hand piece containing a metal slug that is accelerated towards a tooth/implant by an electro-magnet, the tapping rod strikes 16 times in 4
seconds. The contact duration of the slug on the tooth/implant is measured by an accelerometer. The software in the instrument is designed to relate contact time as a function of tooth mobility. The result is displayed digitally as Periotest® values (PTVs). The Periotest® values (PTVs), ranging from -8 to +50. 

Materials and Methods

Patient selection:

A total of Thirty-three patients undergoing orthodontic treatment who required miniscrew placement between second premolar and first molar teeth in the buccal side of dental arches bilaterally as part of their treatment plan at the Department of Orthodontics, College of Dentistry, University of Baghdad were recruited as study participants. Age range of the participants was between 18 and 28 years and all the participants were healthy, with no significant medical findings, or special needs. The study was reviewed and approved by the ethical committee of the University of Baghdad College of Dentistry.

Miniscrew installation protocol:

The miniscrews used in this study were a self-drilling, 1.6 mm in diameter, made of Titanium alloy (Hubit Company, Gyeonggi-do, South Korea). In one side an 8mm miniscrew was inserted and in the other side a 10mm miniscrew was used. The surgical procedure involved the following:

1. From the pretreatment OPG, the site of insertion was determined in order to reduce radiation exposure.

It was located interdentally in the buccal side of the posterior segment of the maxilla between the upper second premolar and first molar.

2. Infiltration local anesthesia approximately 0.45 mL (a quarter of acarpool) of 2% lidocaine with 1:100,000 epinephrine, was administrated into the alveolar mucosa above the miniscrew insertion site, in order to provide an adequate degree of anesthesia, while still permitting the patient feedback in case the miniscrew make contact with the periodontal ligament.

3. Miniscrews (8mm and 10mm length) were randomly assigned to right and left sides.

4. Miniscrews were inserted manually by a screw driver through the attached gingiva at an angle between 30 and 60 degrees. No mucoperiosteal flap was raised and no pilot hole was made.

5. A periapical x-ray was taken to confirm miniscrew position.

6. Post-operative care instructions were explained to the patient and given in a written sheet. Post-operative care instruction included:

   1. Gently brush mini-screw and use of soft bristle tooth brush.

   2. Don’t touch mini-screw with the tongue or finger.

   3. Avoid eating hart food during first two day of insertion.

   4. Don’t tap mini-screw head with toothbrush.

Figure 1: Miniscrew insertion.
Stability measurement

After two week of miniscrew placement, early stability was measured using Periotest® M (Figure 3). Measuring procedure achieved by holding the Periotest® M at right angle to the center toward the miniscrew head to be examined, the maximum deviation angle from the ortho-radial direction of percussion is 45 degree. In addition, the rod of Periotest® M and the test surface of miniscrew superstructure must maintain 0.6-2.5 mm distance according the (Periotest® M operating instructions), measurements were taken by placing the Periotest parallel and gingivobaccally to occlusal plane to head of miniscrew. Two repeated measurements were obtained for each implant and the mean of these two readings was taken. An audible sound will be emitted and the damping capacity was measured as a Periotest® M value (PTV), this value can range from -8 to +50, the lower the values represented the better the stability (Figure 3).
Inter examiner calibration

The inter examiner calibration was done to assess the standardization of the Stability values (Periotest M values), this calibration was done by the researcher and another examiner (A.G Msc oral surgeon who work on Periotest during Msc research) at same time on 20 TAD (10 patients) and non-significant differences were found between two readings as in Table 1.

Discussion

One of the most techniques to assess the stability of implant objectively and noninvasively is the Periotest Mentor. PTVs evaluates the miniscrew mobility indirectly to predict the early stability of implantation, the amount of osseointegration, and the prognosis of the implant (8).

Insertion of miniscrews with the self-drilling technique used, as proposed by the manufacturers, to leave out a hole of pilot drilling since the size of pilot hole and its depth have been found to control the early stability of mini-implants (3).

The results of this study showed that miniscrew length had no significant effect on early stability of miniscrew that agrees with (6) who compared the success rate of each miniscrew anchor in 51 patients with 151 miniscrew anchors. He used three types of titanium screws with different lengths and diameters (length, 6 mm, diameter 1.0 mm; length, 11 mm, diameter, 1.5 mm; length, 14 mm, diameter, 2.3 mm) and miniplates with 2 screws (diameter, 2.0 mm; length, 5 mm) and one of result of his study was lack of relationship between the miniscrew length with its stability if the miniscrew was longer than 5 mm. did not find that the length of the miniscrew had a significant correlation with implant stability clinically. (2) study stability of miniscrew experimentally. He also found that the miniscrew length does not have significant impact on their stability when measuring insertion torque. (16)

However, (14) found that the length of the inserted screws was an important risk factor. They used 8, 10, 12, and 14 mm miniscrews in the upper and lower jaws and left unloaded for 2 weeks. The authors findings emphasized that the miniscrews length was associated with their success rate, with higher success rates in the longer miniscrews. (17) suggest that the smaller diameter and shorter miniscrew had lesser survival rates than the longer miniscrews.

For side factor, the result of our study shown no significant different between right and left side. (13) studied 70 orthodontic patients with 140 miniscrews in the maxillary buccal bone between the first molar and second premolar the on both sides and divided them randomly into 2 groups: the first group received self-tapping miniscrew, and the second group had self-drilling miniscrews. They found that the left side with either method of placement had a higher success rate.
than the right side, but the differences between both sides were not statistically significant.\(^{(11)}\) also showed that the left side had higher rate of success and was more stable than the right side. The former two studies attributed to that hygiene on the left side of the dental arch is better by right-handed patients, who are the majority of the population. Better hygiene could decrease inflammation around the miniscrew.

Evaluation of Chlorhexidine Application on Shear Bond Strength in Different Brackets and Different Etching Techniques in Vitro Study

Bayan Ghdhban¹, Nidhal H. Ghaib²

¹Post graduate; ²Professor/College of Dentistry, University of Baghdad, Iraq

Abstract

Purpose of this study was to assess the etch enamel surface of teeth, affect “shear bond strength” in application chlorhexidine and the “adhesive remnant index” scores.

Material and Method: Eighty premolar teeth half of the samples (Groups A,B/metal bracket.C,D/ceramic bracket) were conditioned with using 37% orthophosphoric acid gel (SDI, California,USA) for 30s washed/dried. The other half of the samples (Groups E,F/metal bracket.G,H/ceramic bracket) were conditioned with Er:CrYSGG laser system, Power: 2W, Wave length: 2,780, energy: 250 mJ , Pulse duration: 140 μs Frequency: 20 Hz. , Cooling system: 90%:%80air-water spray , Mode of application: swiping motion (Waterlase,1 plus from Biolase USA) and then washed and dried. The groups(B,D,F,H) sealant was applied with CHX varnish.

Results: statistical analyses presented that SBSs of laser radiation were significantly difference than that of acid etching.

Conclusions: laser etched resulted the bond Strength accepted clinically in the metal, ceramic and could be an substitute to the acid etching .CHX sealant not significant affect in orthophosphoric acid etching but more weaker in laser etching.

Keywords: chlorhexidine application; shear bond strength; etching techniques; vitro study

Introduction

key to therapeutic success is get highly bond strength and less damage to the tooth surface. The bond strength between the bracket base and tooth surface should be sufficient to withstand the thermal and mechanical effect of the oral environment and have to provide sufficient resistance against stresses from arch wires and force of mastication(1,2),it is consider acid etching has been standard procedure for bonding orthodontic brackets .But the decalcified enamel surface after acid etching has the prospective disadvantage of making the enamel more liable to a caries attack . There is an urgent to found simpler clinical techniques with decrease enamel loss and provide clinically better bond strength. Lately, It has attracted significant attention to using laser radiation are Er:YAG, and Er,Cr:YSGG because it results in an irregular surface pattern which is similar to that of an acid etching pattern(3) and can remove the smear layer and it does not involve heat or vibration, It can be modifies crystalline and chemical structure of the tooth surface and more resistant to caries. (4). Fixed appliances difficulties maintaining proper oral hygiene, and easily dental plaque can accumulate therefore increase prevalence of plaque-induced diseases lead to a higher risk of rising gingivitis and decalcification (5). Prevention of dental caries plays a vital role in orthodontic treatment, strategies chemotherapeutic treatment regimens have received much attention and have presented satisfactory result. Chlorhexidin (CHX) as chemical antimicrobial substances are proficient of inhibiting bacterial adhesion, metabolic activity, and colonization by reducing the bacterial growth. CHX collective with thymol in a varnish have excellent adsorption to the tooth surface for long period, prevent its immediate loss, thus acting
as slow-releasing reservoirs\(^6\), this study has been established to evaluate and comparable the laser etching with acid-etching and to decide the suitability of these with chlorhexidine varnish.

**Materials and Methods**

Sample organization and preparation: The selected (82) upper premolar teeth intact enamel, no caries and cracks. The teeth were pumiced/ washed-dried for (10) s. The teeth embedded in acrylic resin and align the buccal surface of the tooth with mounting jig was used to be parallel to the force applied through shear test\(^7\). The power of laser output can be various from 0-6W determined the tissue to be cut. The power settings for laser groups had been selected on the basis dentinal studies and pilot study, the using 2 W power, the rate repetition pulse 20 pulses / second (20 Hz), a duration of the pulse 140 microseconds\(^8\),\(^9\),\(^10\). The Er,Cr:YSGG laser (Waterlase, I plus from Biolase USA ), is produces accurate cuts for hard tissue via interaction with water at the enamel surface. The air levels were 90% and water 80%, respectively. To standardized the distance, The beam of laser was a vertical to the tooth surface at a distance of 1 m\(^11\), a sweeping manner was moved by hand over an about 4*4 an acrylic resin with a gap, was retained on the enamel surface during an exposure time of 15 seconds\(^1\) (Fig:1-1). All specimens were randomly divided into:

- **Group A (10teeth):** Enamel etched with 37% orthophosphoric acid for 30 second, then rinsed/dried for 15 second then bonding metal bracket as control group.

- **Group B (10teeth):** Enamel etched with 37% orthophosphoric acid for 30 second then rinsed/dried for 15 second then bonding metal bracket with chlorhexidine sealant.

- **Group C (10teeth):** Enamel etched with 37% orthophosphoric acid for 30 second then rinsed/dried for 15 second then bonding ceramic bracket without chlorhexidine sealant.

- **Group D (10teeth):** Enamel etched with 37% orthophosphoric acid for 30 second then rinsed/dried for 15 second then bonding ceramic bracket with chlorhexidine sealant.

- **Group E (10teeth):** Enamel irradiated with the Er,Cr:YSGG laser at 2 W for 15 seconds then washed/dried for 15 second then bonding metal bracket without chlorhexidine sealant

- **Group F (10teeth):** Enamel irradiated with the Er,Cr:YSGG laser at 2 W for 15 seconds then washed/dried for 15 second then bonding metal with chlorhexidine sealant

- **Group G (10teeth):** Enamel irradiated with the Er,Cr:YSGG laser at 2 W for 15 seconds then washed/dried for 15 second then bonding ceramic bracket without CHX sealant.

- **Group H (10teeth):** Enamel irradiated with the Er,Cr:YSGG laser at 2 W for 15 seconds and bonding ceramic bracket with chlorhexidine sealant.

The two teeth were utilized for observation by “scanning electron microscopy” (SEM) to decide the morphology/topography of the etching enamel.

Adhesive preparation: The group B,D, F,H were incorporated, with CHX varnish has equivalent, thymol+CHX (1 mg of each/gm) ,two drops of CHX were added to every one drop of primer 2:1 and then mixed\(^12\). Thin uniform coat was applied to etched enamel surface from mixture Transbond XT primer and curing for 15 second all groups\(^13\).

Bonding Procedure: each group of the brackets were bonded to premolars utilizing primer / resin (3M Unitek,Monrovia, U.S.A),in the center of the facial surface of the tooth. Sufficient pressure “ 200 gm. load on the upper part of the vertical arm of the surveyor” to promote excess adhesive, which was removed by probe, and then brackets light cured for 10s;5s for each side. the intensity of light was 1200 m W/cm .later exposed to thermocycling 500 times in distilled water between 5uC and 55uC, with a dwell time in each bath of 30s and a transfer time of 15s. All specimens accomplished by using “Tinius `Olsen universal testing machine with 5 KN load cell and a crosshead speed of 1 mm/minute” \(^13\),as a result that the readings in newtons
Then, values were altered into megapascals (MP) via dividing the force on the base of bracket area (metal 10.50mm$^2$/ceramic10.75 mm$^2$). The facial surface of every tooth were inspected under a stereomicroscope (10X magnification) later debonded bracket for conclude the ARI score to define quantity of resin residual on the enamel surfaces was predominant site of bond failure [Artun and Bergland, 1984](14). ARI ranges between 0 - 3 (0: no residual resin covering on tooth; 1: less than 50% resin covering on tooth; 2: more than 50% residual resin on tooth; 3: 100% residual resin covering on tooth). Data were collected and analyzed using SPSS program version 25. The descriptive statistics included means, standard deviations, frequency distribution and percentage, while the inferential statistics included Shapiro-Wilk test, independent sample t-test and Chi-square test.

Results

SBS in descriptive statistics was expressed in (MPa) for 8 groups tested are existing in (Table:1/Fig:1). Anova revealed the existence of significant differences (P<0.0001) between laser etching/acid etching and Tukey test informed that with conventional acid etching, the highest SBS values were recorded than laser etching. Adding CHX as the sealant lowers SBS in laser groups, but no more effect in acid etching special in metal bracket (Table:2/Fig:1). Chi-square comparison of the ARI scores between entirely groups (Table:3/Fig:2) shown that the groups were significantly different. The minimum quantity of residual adhesive was found in laser groups. SEM analysis revealed the different etching patterns gained for every group.

Discussion

Acid etching is considered the well technique of attachment resins to tooth surface\textsuperscript{(15)}. But it is more susceptible to acid attack as a result of plaque accumulation nearby to the brackets especially when saliva contamination and air bubbles disturb the resin penetrance. Recently introduced laser etching as an alternative to the acid etching, because it decreases the caries risk by altering the calcium to phosphorus ratio. But the lased surface is fissured and less homogenous\textsuperscript{(1)}. We aimed to find the most suitable enamel preparing techniques for bracket attachment in terms of SBS, ARI, and SEM observations, with minimum caries risk by CHX application.
In present study, the laser parameters determine based on a previous studies and pilot study \(^{(8)}(9)(10)\). The results of present study revealed that SBS values of brackets bonded with laser etching were significantly lesser than that of acid etching in both (LM, LC brackets). Reynolds \(^{29}\) recommended the SBS ranged from 6 to 8 MPa clinically acceptable bonding. So, the SBS values for LM and LC groups in present study are still acceptable clinically strengths for bracket bonding. These results agree with the findings to \(^{(8,10,16)}\). But is different from Findings \(^{(17,9)}\).

Probably this Contradictory the findings relating they utilized more various power outputs of laser technique and varies nature curvature enamel structures or formed micro pores, craters in enamel and melted bubbles formed during laser etching or may be as result of the using sweeping motion by hand controlled of the laser beam during the etching may be reason a inadequately standardized etching pattern during the irradiated area. Further might standrazition be aid to solve this problem, Our results also agree with the findings of Nakamura et al \(^{(18)}\). Chlorhexidine such as in Cervitec plus (1% Chlorhexidine +1%thymol) has proved to be better antimicrobial agent, therefor using as the sealant with primer agent, to reduce minimal time application and does not rely on patient compliance. Also retained on to the oral surfaces by attaches to the glycoproteins by reversal electrostatic binding thus gets CHX releases slowly into the oral environment permitting for a prolonged antimicrobial effect \(^{(19)}\). Laser in CHX sealant commonly weaker this is probably causing a existence of micro cracks under close enamel particles, this may formed a weakened substrate, this is more susceptible to the happening of fractures during measured bond strength testing \(^{(20)}\). But is more acceptable in acid etching this agreement with Karaman \(^{(21)}\).

In acid etching more ARI score was found on facial surface resultant in decreased enamel fracture risk and final more “bracket bond strength”. These results were in agreement with Samruajbenjakul et al \(^{(22)}\). reduce ARI score was found in laser etching and sealant with CHX. This means a smaller quantity of adhesive remaining on tooth surface resulting in relatively reduced SBS. These results were comparable with studies showed via Sibi et al, \(^{(23)}\).

Different etching patterns achieved in SEM analysis, according to Silverstone et al \(^{(24)}\), the acid etched enamel shows cracks in some regions, and produced enamel surface resembled type 1 pattern of etching (Fig: 4).

![Fig.4: Scanning electron microscope image of an enamel surface etched with acid](image)

**Conclusions**

The results of the study point to that etching of tooth surface with an” acid etching with 37% orthophosphoric acid for 30s” is more predictable bond strengths than did “Er,Cr:YSGG hydrokinetic laser system”. But laser can be consider acceptable bond strength more practical and quicker than acid etching. CHX sealant did not influence bond strength in acid etching but not significant in laser etching.

Abstract

Background: Uniqueness of the current study at first time in Iraq specially, across the comparison the clinical parameters among Iraqi infertility females according the IVF program outcome: failures and success implantation. While, aspect were neglected in IVF field. Also, to difficulty of some parameters comparing with control.

Methods: This study done during (December 2019 to November 2020) on Iraqi infertile females with age range (19 – 45)ys. It included the two groups: success implantation and failure implantation females.

Result: The current study revealed to that , secondary infertility is a good marker in implantation success prediction. Central circumference increasing has been associated with implantation failure (P<0.05). When hormonal profile comparison among two groups. Failure implantation females have non-significant increasing in basic prolactin values. Also, E2, progesterone and LH values were higher significantly(P>0.001), among success implantation. The hCG values were highly significant in failure implantation (P>0.001). MII oocytes and G2 embryos were highly significant in success implantation. Our result support that no. of embryo cells have positive impact on IVF outcome. The S. TC and TG were significant increasing among failure implantation.

Key words: hormonal state, Infertility female, IVF, toxicity

Introduction

Implantation is phase at which the embryo adheres to the wall of the uterus¹. The implantation required the synchronism among the endometrium maturation and embryo(s) development². The clinical window of implantation (WOI) is the time frame; in which IVF embryo(s) must be transferred. The optimal period for WOI is known as the period (20-24) of natural cycles, or after 2 or 3 days of egg-retrieval in an IVF cycles³. After IVF, 25-30 % of the embryo(s) transferred to the uterus are successful in implantation⁴.

After birth, 1-2 million cells remain in the ovary; no new oocytes are formed. Follicle stimulating hormone (FSH) promotes the growth of multiple follicles at different stages of development⁵. Luteinizing hormone (LH) triggers follicle bursts and the release of ova into the fallopian tube. The corpus luteum(CL) is created, when luteinized granulosa cells combine with luteinized theca and surrounding the stroma in the ovary⁶. CL was a temporary endocrine organ that secreted the hormones progesterone and estradiol (E2). E2 causes uterine swelling, which may aid in pressing the blastocyst into the endometrium⁷. After ovulation, progesterone is released during the luteal phase. The endometrium cannot be prepared for implantation, if progesterone levels are insufficient. While, Human chorionic gonadotropin (hCG) functions to maintain of gestational yellow body and controls the development of progesterone and estrogen⁸.

The purposes of present study: Evaluate the hormonal and demographic state of Iraqi infertility women during IVF.
Materials and Methods

Study done over a ten months (December 2019 to November 2020), on 70 Iraqi infertile females during IVF, age range was 19 – 45 years. Samples collected from: the Kamal Al-Samurai hospital. Iraqi infertility females were assessed clinically by physician. IVF program was beginning 2-3 day of cycle. There are forms to determine the number and quality each of ova and embryo during IVF. The embryos were transferred, at two or three days after cleavage began.

Subject undergo to questioning for obtain some demographic and clinical information. Also, Subject divided into two groups according IVF outcome: Implantation failure group comprised 50 infertile Women. While, other group 20 subjects of implantation success. Serum lipid profiles were measured. Also, Serum hormonal profile tests done by VIDAS- auto analyzer as the following:

i. Basal hormonal profile (LH; FSH; TSH and prolactin) in the second day of menstrual cycle for normal ovarian reserve.

ii. E2 Follow- up of IVF to assessment of ovulation occurrence

iii. At embryo transfer (ET) (LH; Progesterone). Furthermore, β-HCG after 14day of ET to IVF outcomes reported.

Results

Current study described the demographic and clinical data of Iraqi infertility females. 58.57% have primary, 41.43% secondary infertility type (P>0.05). Also, the study recorded the highly significant increasing (P<0.001) of abnormal ovulation through 36 cases (51.43%), 19 cases (27.14%) have unexplained infertility. While, Uterine factor were seen in 10 cases (14.29%), only 3 cases (4.29%) and 2(2.86%) cases with endometriosis and tubal factor, at respectively. While, patients distributed according outcome of implantation:

Success implantation forms 28.57%, failure implantation 71.43% (P<0.001). Infertility duration distributed into four categories: 1-5 ys (37.14%), 6-10 ys (41.43%), 11-15 ys (15.71%) and >15 ys (5.71%) (P<0.01). Ages distributed between 20-25 ys (30%), 26-30 ys (34.29%) and >30 ys (35.71%) (P<0.05). While, BMI distributed significantly(P>0.05) into three categories: 18-24 Kg (21.43%), 25-30 Kg (54.29%) and >30 Kg (24.29%). Waist/hip ratio (WHR) (Kg) recorded lower significant (P<0.05) for group <0.85 (25.71%) than for group >0.85(74.29%).

The success of implantation strongly (P<0.05) in secondary infertility (60%) than primary Iraqi infertility females (40%) as following in table (1):

The current study recorded non-significant increasing (P>0.05) in LH and FSH basic in success implantation. While, non-significant decreasing of prolactin basic among the same group. E2 levels for success implantation had highest value (857.11±88.96) at (P>0.001).

At ET: There was non-significant increasing in LH among success implantation. Also, non-significant increasing in progesterone hormone among success implantation. But, the current study recorded highly significant increasing (P>0.001) in hCG values that were (41.60) in failure implantation than (12.05) in success, as shown table (3):

There are highly significant in total no. ova in success (12.40±0.97) than (7.58±0.62) failure implantation group of Iraqi infertility women during IVF (P>0.001). Also, highly significant (P>0.001) recorded in MII oocytes in success (7.95±0.88) than failure group (4.10±0.55). Total embryo(s) have highly significant increasing (P>0.001), among success implantation group. The mean were (4.65±0.48) in success, While it was (3.26±0.27) in failure implantation. Non-significant increasing of Grade 1 (G1) embryos (P>0.05). While, highly significant for Grade 2 (G2) embryos means, that were 1.25±0.39 in success and 0.26±0.08 of failure implantation. Mean embryo cells no. has significant increasing (P<0.01) in success implantation (6.80) than failure implantation group (5.44), as shown in table (4).

MI Oocyte(pre-ovulatory); MII Oocyte(mature); GV Oocyte(immature)

According the Table (5): The total cholesterol (TC) levels have highly significant increasing in failure than success implantation (P>0.001). The Means were 133.9±5.64 in failure, 111.9±5.77 in success group. Also, there was increasing significant for S. triglyceride and S. HDL between failure and success groups (P>0.05, P>0.01). Means were (95.4±6.33), (113.57±5.62) for S. triglyceride(TG) and (51.12±1.95), (42.75±2.78) for S.HDL at receptively. While, non-significant deference was reported in S.LDL among failure and success implantation. VLDL had highly significant (P>0.01), in implantation failure than success group.

Discussion

Infertility type has significantly effect on outcome of implantation among Iraqi infertile females. Current result agree with Hambartsoumian,1998 study(9). Also, the present result, can be contributed according the Moragianni, 2012 suggest, to the counseling and psychological support are required to enhance the IVF success (10). In present study: Gravidity means seem non-significant higher among failure than success implantation. This is back to non-significant increasing of abortion in failure than success group . Although the current study does not accept with significant lowering for gravidity and parity among infertility females as
compared to the control (11).

The present study found no effect of age on the implantation success, which agree with Abdalla et al. study (12). Also, Other study reported no significant relation for BMI and age means between primary infertility and control (13). Furthermore, the age means for infertile females and the control group included in the study were identical (14). There was highly significant increasing of success implantation rate in BMI<30 than >30(15). Central obesity lead to decrease the chance of implantation success according the current study. Central circumference is a tool to assess lipid excess and ART prediction of infertility women (16).

Through comparable hormonal profile of current study, among success and failure implantation during IVF. Current basic hormonal were similar to Tawfeek et al. for each of: prolactin; FSH and LH (14). Thyroid dysfunction associated to fertility decreasing (17). Other research suggests that infertility women with an abnormal menstrual cycle should have checked TSH (18). The current study agree with important of E2 for induction of implantation to improved IVF efficiency (19).

At ET: non-significant decreasing of LH between failure implantation women of current study. This can be supported by the report that refer to that, Luteal phase deficiency (LPD) is widespread among failed implantation females (20). The change in progesterone levels in LPD, leads to a rise implantation failure rate (21). For high significance of hCG among failure implantation group of this study; disagree with non-significant differences of implantation rates in higher or lower the hCG cycles (22). The current study matched with Strom et al. 2012 decreased of hCG levels through ET at cleavage stage in success implantation(23). Also, Other report refer to: high doses of hCG administration is associated significantly with decreased of implantation, (24). The current study showed non-significant increasing progesterone level, that comparable with previous studies; through the progesterone kept the fetus from the mother’s immune, during secretory phase of cycle (25).

This study agree with Khalaf Allah et al., 2020 through the oocyte no. is essential to be evaluated the IVF outcome (26). Also, The no. of eggs obtained has no impact on the probability of implantation (22). With increasing MII oocyte and G2 embryos among success group in current study. Other reports refer to non-association with in MII no. (27).

Present results suggest the lipid may be used as indicator of fertility. Other designs revealed to the TG, TC, LDL levels were highest, but HDL were lowers in un-explain infertility females than fertiles (28;29).

**Conclusion**

Although, afraid the couples of IVF outcome. But, There are many factors that effect in the implantation success rate during IVF. Specially, central obesity and hormonal profile. So, the control of these factors across the BMI , LH, Progesterone, E2, hCG balance, Oocyte pick up number and quality will lead to significant increasing in success implantation during IVF.

Study the Synergistic Effect of AgNPs with Antibiotics on Klebsiella Pneumoniae Isolates Which Diagnosed by Molecular Methods

Sura Saadoun Khalaf1, Hanaa Abdellatif Yassin2

1Post Graduate; 2Assist Prof Department of Biology College of Education For Woman University of Anbar/Iraq

Abstract

The current study was conducted to study the synergistic effect of AgNPs with anti-biotics on Klebsiella pneumonia isolates, where 50 samples were collected from different pathological conditions (wounds - burns - urine - ear - and excretion) on the Maconkey Agar. To the Klebsiella, it was diagnosed microscopically and biochemically and was also diagnosed by the Vitek2 device, whose results were identical with the biochemical diagnosis, and the isolates were also subjected to molecular diagnosis for confirmation by using the PCR technique based on the diagnostic gene 16SrRNA, which is characterized by being good, stable and low heterogeneity for a long time in the bacterial type. Ten types of antibiotics were selected and immersed in silver nanoparticles at a concentration of 20Mm, a test was conducted for the synergy between the silver nanoparticles AgNPs and the antagonists towards 12 isolates of Klebsiella bacteria, as they were applied to Muller-Hunton medium and after they dried up, the anti-saturated tablets were fixed with a silver particle solution, and after the expiration of the incubation period, the diameter of the inhibition area around the tablets was measured in mm. According to the standard results, the results of the statistical analysis showed that the interaction of silver nanoparticles with the antibiotics had a significant effect on increasing the sensitivity of the isolates towards the synergistic antagonists, as the general rate of inhibition diameters of the antagonists (Impenem, Gentamicin, Amikacin Ciprofloxacillin) was (32.59, 21.6, 18.98, 36.18), respectively. This activity is due to the ability of the nanoparticles to bind to the surface of the bacterial cell. The binding causes structural damage and changes such as permeability, which facilitates the entry of the antagonist into the cell and thus its death. As for the synergies with the antagonists Tetracycline, Vancomycin, Erythromycin did not show efficacy in the direction of Klebsiella isolates did not give good results of synergy as it has a weak effect towards negative bacteria and it is as a non-synergistic antagonist because it does not have effective binding sites for silver nanoparticles.

Keywords: molecular methods; health; death; toxicity; synergy

Introduction

Nanotechnology or nanoparticle technology, which is the science that studies the treatment of matter on the atomic and molecular scale. Nanotechnology is interested in creating new techniques and means whose dimensions are measured in nanometers, which is a thousandth of a micrometer, i.e. a part of a millionth of a millimeter, nanotechnology deals with measurements between 100-1 nanometer, i.e. it deals with atomic assemblies ranging from five to one thousand atoms, which are of dimensions much less than those of bacteria and a living cell (1). Silver nanoparticles are one of the most common types of nanoparticles known, with multiple applications, lower costs, and have antibacterial efficacy for a wide range of pathogenic and antibiotic resistance. As some antibiotics have become useless in the treatment of diseases, especially acute and pathogenic diseases, as increasing the dose beyond the required limit or the frequent use of antibiotics or cutting treatment without completing it allows the bacteria to become more resistant to those antibiotics, so it has become necessary to find alternative treatment methods to produce effective active substances. Health benefit without side effects, and these alternative solutions
include nanoparticles, including silver nanoparticles. One of the characteristics of *Klebsiella* is that it has a capsule, so its colonies are mucous and sticky, and it is also able to release large quantities of the mucous gel on the surface of the core of the components in it, where a strand of mucus can be observed when touching the colony with the object. One of the common diseases that this bacteria cause to humans are burn and wound. It also causes pneumonia, which causes inflammation of the air sacs in the lungs, if these sacs or vesicles are filled with liquid waste and pus and cause bronchitis and severe pneumonia. The genus *Klebsiella* spreads in humans in the form of throwing organisms in the nasopharynx and intestinal tract, as the bacteria are swallowed with food and drinks contaminated with bacteria or by contact and transmitted through the spray of respiratory patients from one patient to another. The ability of the bacterium to cause infection is due to its possession of many virulence factors that play an important role in causing disease and enable it to reduce and multiply within the host’s body, including the capsule and the adhesion factors that enable it to attach to the surface of the host cell. *Klebsiella* possesses virulence genes that have the ability to evade and mask the process of phagocytosis by large phages to enable them to resist antibiotics. Bacterial resistance to antibiotics is a real threat to patients, as some antibiotics have become preferred food for some types of bacteria and their activity increases. In addition to the agricultural environment, the reason for this resistance is due to the widespread and frequent use of antibiotics, and this problem is one of the most medical problems facing the world, which leads to lack of control of diseases, and from a genetic point of view there are genetic elements called plasmids, which are an important vector for genes responsible for factors Virulence in bacteria, such as biofilm and hemolysin production, is the main cause of bacterial cysts events.

**Materials and Methods**

**Sample collection**

30 samples were collected from different pathologies. The samples included 10 samples from urine, 5 samples from wounds, 6 samples from burns, 5 samples from the ears, and 4 samples from the exit. The samples were planted directly in the planning method on suitable agricultural environments such as the environment Acids for 24 hours at a temperature of 37 °C, and after the first transplantation of samples and purification of colonies, the samples were then diagnosed by biochemical and microscopic diagnosis, and *Klebsiella* was negative for the oxidase test, the indol test, the methyl red test, and positive for the Catalase test, and the Fox-Proscor test. Proskauer-Voges, also has the ability to ferment the sugar lactose.

Diagnosis was made based on the culture, microscopic and biochemical characteristics.

Molecularly diagnosed by PCR method

DNA was extracted and purified using a ready-made DNA extraction kit and according to the instructions of the American manufacturer Promega The concentration and purity of the DNA genetic material was measured using the Fluor meter Quintus device, which has high accuracy and sensitivity compared to the Nano drop, and then set and programmed the PCR device according to the optimum temperature of the mutant and correlation Prefixes and number of cycles. Then, 5 μL of the product of gene duplication was transferred to electrophoresis on an acarose gel. Where DNA loading was carried out in the gel pits and electrocuted on a horizontal surface. Then, 5 μl of the product of gene duplication was transferred to electrophoresis on an acarose gel. The antibiotics were used (Ciprofloxacin, Gentamicin, Tetracycline, Amikacin, Imipenem, Vancomycin, PiPeraciclin, Chloramphenicol is, Erythromycin) where these antibiotics were placed in sterile boxes of 8 boxes and the name of the antagonist was recorded on each carton containing a solution of silver nanoparticles at a concentration of 20 mM.

To test the synergy between silver nanoparticles and antibodies

The synergy test between AgNPS silver nanoparticles was tested against 12 isolates of *Klebsiella* pneumonia, as they were transferred (5-3) a pure colony into tubes containing5ml) of a physiological salt solution and the resulting suspension turbidity was compared.
with a standard McFarland turbidity of 0.5, after which a sterile cotton swab was submerged with the bacterial suspension and spread over Muller-Hunton’s medium. The plates were incubated at a temperature of 37 ° C for 24 hours, and then the diameter of the inhibition zone around the disks was measured in mm (mm) for the silver saturated nanoparticles, and then compared with the standard results.

Results and Discussion

After conducting biochemical tests for bacterial isolates isolated from Ramadi Teaching Hospital, 30 isolates of *Klebsiella pneumonia* were diagnosed out of 50 samples, which were isolated from different pathological conditions that included (wounds, burns, diuresis, ears, excretions) and diagnosed based on the culture, microscopic and biochemical characteristics as well as Use a Vitek2 device. As between the microscopy and staining with the Cram stain, they are negative bacilli of the Gram stain organized in the form of short chains, and the *Klebsiella* was characterized by rather large colonies and mucous in consistency because they contain the capsule fermented for lactose sugar, and the biochemical examination showed that it is negative for the indole test and negative for the Proaskaure Vogas test. Citrate utilization And it is positive for the Uerase test, and it was confirmed by the Vitek2 device, as it gave results identical to the results of the biochemical examination Sanders and Sanders, 1997 The number of *Klebsiella pneumonia* bacteria in urine samples was the highest rate of 33%, while the rates of wounds and burns were 20, 16% (16%) respectively, and this result is close to what the world reached (9) as the percentage of *Klebsiella pneumonia* in urine samples was 21.8. The reason for their prevalence in hospital environments is due to their ability to develop different methods of resistance to disinfectants and their possession of virulence factors that resist antibiotics, and the results obtained by the two researchers are also converging (10) Molecular identification, whereby all bacterial isolates were subjected to molecular diagnosis by using PCR technology based on the 16SrRNA diagnostic gene, which is good, stable and has little heterogeneity for a long time in the bacterial species. It is also the main key to identifying among several thousand genes inside the cell. Bacterial (11) The results of DNA extraction of *Klebsiella* isolates that were isolated from different pathological conditions, as 12 isolates were selected for molecular diagnosis, showed that there are clearly packages of the isolates after the DNA transposition extracted on the acarose gel, as the molecular diagnosis matched the biochemical diagnosis. The results of the current study are consistent with the findings of the researcher (12) who showed that the percentage of identical molecular diagnosis of *Klebsiella* bacteria was 98%.
The effect of overlapping silver nanoparticles with antibiotics against *Klebsiella pneumonia*

The results of the statistical analysis showed that the interaction of AgNPs silver nanoparticles with antibiotics had a significant effect on increasing the sensitivity of isolates towards antibiotics, as the general rate of antagonist inhibition diameters with AgNPs was reached (Cip-Ag, Imp-Ag, AK-Ag, GN-Ag) (32.59, 36.18, 21.6, 18.98 respectively)
While there was no significant effect of the interaction of AgNPs with the antagonists (Tet-Ag, Er-Ag,) the general rate of inhibition diameters was (Er-Ag 8.4 VA-Ag, 9.1 Tet-Ag, 8.5) as these antagonists did not show efficacy against isolates, because It has a weak effect against negative bacteria and is non-synergistic as it does not have effective binding sites that bind with nanoparticles. Many researches indicate the synergism between nanoparticles and antibiotics, and the increased sensitivity of bacteria to the effect of antibiotics mixed with nanoparticles. As the antibiotic molecules have many active groups such as hydroxyl and amide groups that easily interact with silver nanoparticles by chelation. The silver nanoparticles bind to the surface of the bacterial cell and this association causes damage and structural changes that affect the biological functions of the bacterial cell, such as permeability, causing gaps and pits that allow the antibiotic to penetrate the bacterial cell, leading to its death (13). As the researcher (2014) explained, The role of nanoparticles in enhancing antibodies), Amikacin Imipenem, towards Gram-negative bacteria, as it is one of the modern strategies in treating multiple bacteria resistant to antibiotics, as he found that the use of the antibiotic with silver nanoparticles is more efficient in killing bacteria, the particles also act as a carrier medium for antibiotics. The anti-synergistic antagonists with Imipenem Ciprofloxacin silver nanoparticles showed the highest significant effect ratio (32.50, 36.00), respectively, in the direction of K. pneumonia bacteria isolates. agrees with the findings of (14) indicating strong efficacy. Particles that are synergistic in inhibiting the growth of a group of multiple antibiotic-resistant bacteria, including (Salmonella typhi, Pseudomonas aeruginosa Klebsiella pneumonia), and he explained that the particles mixed with the antagonists behave an anti-bacterial behavior towards many types of negative bacteria by causing a defect in the cellular membrane correlation. Bigger for nanoparticles in bacterial cells. The synergistic effect of Chloramphenicol with AgNPs increased the susceptibility to infection of bacteria and its effect was clear against Pneumoniae K, as the study agrees with the results reported before. (15) who confirmed the increasing efficacy of synergistic antibiotics and explained this to the efficiency of silver nanoparticles in transporting the antibiotic to the inside of the bacterial cell to interfere with the protein synthesis mechanism to prevent bacterial growth.

Celiac Disease among Adults and Children in AL-Anbar Province West of Iraq: a Comparative Cross-Sectional Study

Yasin. Hamad Majeed
Assistant Professor University of Anbar, College of Medicine, Department of Internal Medicine/Iraq

Abstract

Background: gluten-sensitive Enteropathy is a public non-communicable, immune-associated disease which is activated by wheat (gluten) ingesting that occur in hereditarily susceptible individuals in initial childhood & elderly individuals with varied presentations whereas several studies have shown CD are predominant in adults. The purpose of this study was to compare the clinical presentation, serological, endoscopic, and histopathological features in adults and children with celiac disease at Al-Anbar province, west of Iraq. A total of 170 consecutive newly confirmed CD patients in AL-Ramadi teaching hospital, Gastroenterology Clinic during a period between August 2017 & Jun 2020 had been involved in comparative cross-sectional design research. Patients were divided into two groups: adults and children and each of them was also divided into two groups- classical and non-classical celiac disease based upon the clinical presentation. Clinical presentation, endoscopic findings were recorded in all cases gastrointestinal endoscopy & duodenal biopsy with Anti -TTG IgA had been determined & tested for the CD diagnosis. Histopathology results had been divided using modified Marsh taxonomy. Results had been examined through a suitable statistical test. Of 170 CD patients that include 97 (57.1%) adults CD and 73(42.9) children. Classical symptoms were predominant among 85.56% of adults while non-classical symptoms were more common among 45.2% of children. Bloating with abdominal pain and anemia were predominant among adults and children respectively. No significant differences in the Levels of anti –tTG among each of adults and a pediatric group of CD patients (P-Value 0.072). The most common endoscopic finding was scalloping 60.3%, 40.2% among children and adults respectively. Marsh grade G3A were predominant among adults [83 (89.2%)] versus [67 (95.7%)] among children of CD patients with anti-tTG IgA U/ml 10+1 and more levels. No statistical difference regarding marsh grade G3 frequency among adults and children CD patients (p 0.191).

Introduction

Celiac disease (CD), also named gluten–sensitive enteropathy, is a general chronic, the autoimmune disease that occurs due to long-lasting gluten intolerance in hereditarily sensitive persons [1].

CD distributes in 1-2% of the overall people of totally races & countries [2-4] CD was usually supposed to be a disease of children, unusual in adults. But, several reports in the previous decades have exposed that adults are also infected with CD some time more frequently than children as it could occur at every age in a lifetime & about 20% of patients are older than 56 years of life [5-7] In adult CD typically in a larvae mode with less intestinal appearances & nonappearance of Mal-absorption, & exhibition atypical forms described by public extra- digestive complaint’s & numerous associated environments, which make detection more challenging [8-10].

Classical CD in children is usually confirmed in the 2nd year of life, it is described by mal-absorption signs like permanent diarrhea, Steatorrhea, failure to thrive & loss of weight, stunted-growth, muscle wasting, loss of appetite, nausea & vomiting linked with lethargy & emotional stress [11-13]. Additional slighter abdominal signs are abdominal-pain, abdominal− distention, flatulence, irregular bowel habits, & perminant constipation [14].
The non-classical CD is frequently designated in young children & adolescents offering with extra-intestinal signs linked CD, as delay in puberty, unexplained permanent or ferrous deficiency anemia, non-responsive to supplementation, reduced bone mineralization (osteopenia/osteoporosis, dental enamel defects, irritability, chronic fatigue, neuropathy, arthritis/arthralgia, amenorrhea, unexplained elevated liver enzymes & repeated Aphthous stomatitis[12-14]. Also, monitoring & celiac prognosis can diverge dependent on the pediatric or adult stage. Aims of the Present study is to compare the clinical presentation, serological & endoscopical findings in adults & children suffering from CD at Al-Anbar province, west- of Iraq.

Patients and Methods

A total of 170 consecutive new confirmed CD cases at AL-Ramadi teaching hospital - Gastroenterology Clinic during a period from August 2017 & Jun 2020 had been comprised in a comparative cross-sectional study. Patients were divided into two groups: adults and children and each of them was also divided into two groups- classical and non-classical celiac disease based upon the clinical presentation. Clinical presentation, endoscopic findings were recorded. Four duodenal biopsies were taken from each case. Anti-TTG IgA were also taken from each patient.

In total cases, gastrointestinal biopsies in addition to serum anti-tissue transglutaminase (anti-tTG) were firm &confirmed for diagnosis of CD, histopathological results were divided through the use of "modified marsh taxonomy"[15][16]. Anti-tTG levels were determined by ELISA test. All Patients with IgA anti -tTG less than 10 iu /ml were considered as negative cases & IgA anti > 10+1 positive and it had a calibration range of 3 to 100 iu/ml. Gastroduodenoscopy was performed in suspicion of CD patients. Four duodenal biopsies from D2 had been obtaining, with duodenal endoscopic markers valuation such as a reduction in duodenal folds, visible mucosal vessels & fissures, scalloping, & mucosal nodularity. The specimen has been tested by an-experienced pathologist. Diagnosis of CD frequently depending on the sero-positivity of anti tTG antibodies [17] plus anti-tTG histopathological findings of intestinal mucosa [18]. From every patient. Family and patients who have written consent have been taken & from Anbar medical college, Iraq- ethics approval committee, the ethical approval had been taken.

Statistical Analysis

Data had been examined through IBM SPSS software version 22 using. The results had been offered in tables as descriptive statisticians results (mean, SD, frequency, percentage), Chi-square test had been used for comparing the CD frequency between groups. Means of scales of adults and pediatric groups had been compared using the independent sample T-test. A two-tailed P value has been used in overall analyses & a P value of less than 0.05 has been used to decide statistical significance.

Results

A total of 170 CD patients, 97 (57.1%) of them in the adult’s CD group of consist of ( 39 (22.94%) male and 58(34.12%) female with a mean age of 35.38 ±11.129 years and 73(42.9) of them in the pediatric group consisted of 42 (24.71%) males and 31 (22.24) females with a mean age of 10.81±4.020 years. As reported in Table 1A and Table 1B, Classical symptoms were predominant among adults 85.56% versus 54.79% among children which was statistically significant (p 0.000), while non-classical symptoms were more common among children 45.2% versus adults 14.5% which was statistically significant (p 0.000). Bloating and abdominal pain with a percent (34.0%) and (22.7%) respectively were more common among adults which were statistically significant (p 0.001), whereas anemia with a percent 24 (32.9%) was predominant among children’s which was statistically significant (p 0.046).

The most common endoscopic finding was scalloping 60.3%, 40.2% among children and adults respectively. No statistically, a significant difference of scalloping between children and adults followed by a reduction in duodenal folds 24.7%, 9.6% among adults and children respectively. There was a statistically significant difference in reduction in duodenal folds between adults and children (p 0.002), whereas Nodularity, Visible vessels, and mucosal fissures and Atrophy with visible vessels were less frequently among adults and children with CD. The normal endoscopic finding has significantly higher in the adult group [32 (33.0%)] compare with a pediatric group [15 (20.5%)] (P 0.013) as shown in table 3.

Histopathological evaluation of intestinal biopsies revealed marsh grade G3 were predominant among adults [83 (89.2%)] versus [67 (95.7%)] among children of CD patients with anti-tTG IgA U/ml 10+1 and more levels. No statistical difference regarding marsh grade G3 frequency among adults and children CD patients with anti-tTG IgA U/ml 10+1 and more levels (p 0.191). G3A (40.2%) were more common in adults while G3B (42.5%) and G3C (19.2%) were more common among children. There were 7 adults with marsh G2 as shown in Table 4.

Discussion

Our study shows the predominance of females in adult patients. This predominance was not significantly significant, this consistent with Oberhuber G et al. [16], maybe due to females may seek health advice more than males.

Regarding CD children there is boy predominance, this is similar to the study done by Rana et al. [19], this may be explained by better care and attention given for boys for that reason they brought earlier for health advice while in the western study there is no sex predominance [20].

Our study shows that the classical form of CD was predominant among adults 85.56% versus 54.79% among children, which was statistically significant (p 0.000), this is inconsistent with the study done by Poddar, 2013 [21] which shows the predominant of children. While non-classical symptoms are more common among children 45.2% versus adults 14.5%. which was statistically significant (p 0.000), this is inconsistent with the research prepared by Pooni et al. [20] that found the predominance of CD among adults.

The current study shows that clinical differences of a classical presentation at diagnosis in pediatric and adult groups, as bloating and abdominal pain being the most common symptoms in adults which were statistically significant (p < 0.001); while diarrhea was the predominant complaint in children this consistent with the study done by Sez-Rodrigo Luis et al. [22].

Regarding non-classical presentations, anemia was the most common findings among children 32.9% versus 12.3% among adults which was statistically significant (p 0.046), this inconsistent with Sez-Rodrigo Luis et al. [22].

Regarding endoscopic findings, scalloping was the most common finding in both age groups this consistent with Pooja Semwal et al. [23]. Our study shows no correlation between anti-tTG levels and marsh 3, this is similar to a study done by Ganji et al. [24] and inconsistent with another study that showed a statistically significant relation P < 0.001 [25]; this may be attributed to environmental and genetic variation.

Our study shows marsh 2 among adults 7.52% and 1.4% among children while marsh 1 1.07% only among adults, regarding Marsh G1 and G2 Type these lesions are well-matched with but nonspecific for CD, minimal intestinal lesions plus sero-positivity of anti-tTG point to CD diagnosis. whoever, least lesions can lead to additional causes, such as food allergies (such as cattle milk proteins), Crohn’s syndrome, lymphocytic colitis, bacterial infection & helminthic gastro-intestinal manifestation, like Giardia, public immunodeficiency, small intestinal microbial growth, NSAID, & Helicobacter pylori infection [26-28].

Normal histology [marsh 0] with positive serology was found in 2.15% Among adults versus 2.85% among children, this may be a latent type of CD [30]. Conclusion: Classical symptoms and bloating with abdominal pain were more common among adults whereas non-classical symptoms and anemia were predominant among children of CD patients. No difference in levels of anti –tTG in both groups. Scalloping is more common among both groups. marsh grade G3A more common in adults while G3B anG3C is more common among children.

Antibacterial Effect of *Lactobacillus acidophilus* and Silver Nanoparticles on Antibiotics Resistance *Klebsiella pneumonia* Isolates from Burn Infection

Maryam Hayder¹, Baydaa A. Hassan²

¹Mater Studern; ²Assist Prof. Dr./ University of Kufa-Faculty of Science-Department of Biology/Iraq

Abstract

This study was completed in laboratories of Biology Department in Faculty of Science. It explains the antibacterial effect of *lactobacillus acidophilus* and silver nanoparticles on antibiotics resistance *Klebsiella pneumonia* that isolated from burn infection patients in the province of Najaf. A total number of 130 samples were collected from patients with burn infection from Burn Center AL-Najaf Governorate, the results showed that inhibition zone of *K. pneumonia* increased progressively with increase the silver nanoparticles and *Lactobacillus acidophilus* concentrations in reaching a optimum inhibition in 80 µg/ml,0.7mg/ml respectively , also antibacterial activities of some resistance antibiotics included Amoxicillin, Ceftriaxone , ceftazidime and tetracycline exhibited that the presence of silver nanoparticles with *L. acidophilus* together with the resistance antibiotic resulting in decrease in the ability of the antibiotics to inhibit the *K. pneumonia* resulting in the occurrence of inhibition zone of *K. pneumonia* and insignificant compared with the presence of silver nanoparticles alone as well as less than the case of the presence of *Lacidophilus* alone with these antibiotic . The results showed that the *bla oxa* was detected in from the 30 (100%) isolates of *K. pneumonia* have *bla oxa* gene 22 (73.33 %) ,and 17 (56.66%) were have *ctx-m*

**Key words**: nanoparticles, inhibition, silver, *Lactobacillus acidophilus*

Introduction

Burn wounds are susceptible to an extensive array of colonization and infection by microorganisms, the granulation tissue in burn wound makes a rich culture medium for the growth of different organisms as the exposed skin is exchanged by a protein rich, avascular environment that generates an appropriate niche for microbial colonization ,the movement of immune cells is also hampered contributing to the septic process (1). The depression of local and systemic host cellular as well as humoral immune responses show an essential role in infectious complications of severe burn patients (2). Antibiotic resistance remained informed toward occur when a treatment misses its capability to prevent microbial growing efficiently, microbes change resistant’ also remain ‘to grow in the occurrence of healing stages for antibiotics, bacteria, after duplicates even in the occurrence of the antibiotics are known as resistant, bacteria, antibiotics become are typically active in contradiction of them, however when microorganism fewer sensitive or resistant, it needs a greater from the ordinary concentration of the identical treatment to need an influence (3)

Materials and Methods

Samples Collection and bacterial identification

A total number of 130 were collected from patients with burn infection (October , 2020 to January , 2021 ) . Sample collection after removal of old plaster of burns patients, the superficial of the burns wound was cleaned with normal saline to avoid contamination. All sample was collected by swabbing the wound by a disinfected cotton- tip swab staff. Circling the swab stick amongst the toes, the swab stick was moved across the whole wound external, the swab staff was rapidly place in carriage middle, Swabs were taken and close it until transported to advanced test center of Science College.
in Kufa University and culturing on diverse media for 24 hours at cultivate 37 °C for bacterial diagnosis. silver nanoparticles and lactobacillus acidophilus as antibacterial agent preparation of silver nanoparticles: according of (4) preparation of lactobacillus acidophilus: according of (5)

**Evaluation of the silver nanoparticles efficiency in the inhibition of the growth of antibiotic resistance bacteria that causes infection**

The preparation of Muller Hinton medium , it is sterilized in the autoclave and poured in petri dishes , then antibiotic resistance *K. pneumonia* isolates were streaked by sterilized swab on petri dish , antibacterial activity of the silver nanoparticles was determined using the agar well diffusion assay method , all the dishes were incubated at a temperature 37 °C for 24 h, and the plates were studied to indication of zone of inhibition, it seem as a pure zone about the pits , the width of inhibition regions was determined by a meter leader (6)

**Evaluation of the lactobacillus acidophilus in the inhibition of the growth of antibiotic resistance bacteria that causes infection :** This test is agreed in the same method described in paragraph excluding the use of *Lactobacillus acidophilus* (5)

**The relationship between silver nanoparticles, lactobacillus acidophilus and resistance antibiotics**

Muller Hinton Agar was poured in petri dishes , antibiotic resistance *K. pneumonia* isolates were streaked by sterile swab on petri dish ; then, the optimum concentration of silver nanoparticles and *lactobacillus acidophilus* were added , also, the resistance antibiotic powders were placed in each dish , then, all the dishes were incubated at 37 °C for 24 h and the diameter of inhibition zones were measured using a meter ruler

Bacterial DNA was detached through using a process of (7).

**Molecular Identification**

Gel electrophoresis was used to determine of DNA via UV trans illuminator , the primer was planned by Alpha DNA company, Canada .

**Results and Discussion**

The effect of different concentrations of sliver nanoparticle antibiotics resistance *K.pneumonia* isolates growth :

The results also directed that inhibition zone of *K.pneumonia* bigger progressively with increase the silver nanoparticles concentrations in attainment a finest inhibition in 80 µg/ml figure (1). A additional of science reports suggests that the antibacterial mode of action of silver nanoparticles is similar to the antimicrobial effects of silver ions, due to the life cycle of silver nanoparticles and their change to silver ions (10). Silver ions have ability connection for the specific transporter proteins and enzymes residing in the microbial plasma membrane, the sequence of proteins and enzymes carriage electrons also concurrently transfer protons from the cytoplasm for the periplasmic area making a concentration decline called the PMF, the electron transport scheme above the plasma membrane is the main producer of ATP through aerobic breathing in microbes, in addition the manner is named chemiosmosis, the one place protons have ability diffuse into the cytoplasm again is through the ATP formation compound, which effects in the creation of ATP in a redox response amid ADP and inorganic phosphate, also the electrons reaching the ending electron acceptor place, the last electron acceptor is melted oxygen in the situation of aerobic respiration, also mainly results in water or in minor concentrations of cytotoxic ROSs, which specific enzymes method (11;12).
Figure (1): Effect of Different Concentrations of silver nanoparticles in *K. pneumonia* growth

The effect of different concentrations of *lactobacillus acidophilus* in antibiotics resistance *K. pneumonia* isolates growth:

The results indicated that inhibition zone of *K. pneumonia* increased increasingly with rise the *lactobacillus acidophilus* concentrations in attainment a finest inhibition in 0.7 mg/ml figure (2). Specific investigators from advanced nations must reported significant in vitro inhibition of Gram negative and Gram-positive pathogenic microbes via *Lactobacillus acidophilus* class, *L. acidophilus* can display antimicrobial effect by many processes such as the making of antibacterial materials or substance (hydrogen peroxide, lactic acid, Benzoic acid, Hydroxy fatty acids, bacteriocin), competition to nutrients, inhibition of microbial, and improvement of the immune response (13). Certain in vitro research have too exposed that *Lactobacillus* strains have ability display antibacterial act in contradiction of *K. pneumonia, E. coli, Shigella spp., S. mutans, P. aeruginosa, and S. aureus* (14-17).

Figure (2): Effect of Different Concentrations of *L. acidophilus* in *K. pneumonia* growth

The mixture effect of silver nanoparticles and *L. acidophilus* with most resistance antibiotics:

The results proved that the antibacterial activities of most resistance antibiotics were include Amoxicillin (AMC) Ceftriaxone(CRO) Ceftazidime (CAZ) Tetracycline (TE) increased in the presence of silver nanoparticles as well as *L.acidophilus* to causes the inhibition of multi-resistance isolates *K. pneumonia* growth.
Furthermore, *L. acidophilus* is amongst a several *lactobacilli* this must been research to the antimicrobial properties in previous studies (18). as of the therapeutic effect of probiotic lactobacilli to MDR bacterial infection, they are one such microbes of special for use as the remedial agents in mixture with antibiotics (14). and has been recounted through (19) the *L. acidophilus*-ciprofloxacin combined therapy against several gram negative pathogenic bacteria of the intestine and stomach. Silver nanoparticles (AgNPs) are the most promising nano antibiotics now adays , lately, an development in antibacterial action–synergistic effect- it studies however AgNPs are synergism with many antibiotics, example ampicillin, amoxicillin, and chloramphenicol (20).

AgNPs with antibiotics shared actions have been studied previously but never mechanism of effect has been established since varied phenotypes have been observed among studies (21). Furthermore, the action of AgNPs-antibiotics activity may be alteration in diverse organisms, these discrepancies create on interaction AgNPs-antibiotics may be effect with diverse features: this stabilizing factor used also its comparative concentration, it can effect the capability of contact between AgNPs and antibiotics (22).

The mixture influence of *L. acidophilus* and silver nanoparticles together with most resistance antibiotics

The results displayed that the presence of *L. acidophilus* with silver nanoparticles together with the resistance antibiotic resulting in decrease in the ability of the antibiotics to inhibit the *K. pneumonia* resulting in the occurrence of inhibition zone of *K. pneumonia* and insignificant compared with the presence of silver nanoparticles alone as well as less than the case of the presence of *L. acidophilus* alone with these antibiotic.

The decrease in the size of the inhibition zones in the case of the interaction of Ag-NPs *L. acidophilus* with resistance antibiotics means the antagonists effect between them, the cause may be the effect of the silver nanoparticles on the inhibition of *L. acidophilus*, so the sizes of the inhibition zones were less than the case of the presence of *L. acidophilus* with resistance antibiotics alone, lately, an development in antibacterial activity–synergistic effect- may be reported after AgNPs are joint with many antibiotics, such as ampicillin, amoxicillin, and chloramphenicol ,enoxacin, kanamycin, neomycin, and tetracycline (20;22). The interaction between AgNPs with antibiotics has been also credited previously for chemical binding between the sulphur cluster of antibiotics with AgNPs (23;24). Therefore, *L. acidophilus* can be fermented the sugars resulting in lactic acid, hydrogen peroxide, enzymes and vitamin (B) complex, as well as antibacterial materials that inhibit or kill many pathogenic bacteria (25). its effect on pathogenic bacteria isolates by adhesion agents and their secondary metabolic products such as bacteriocins, it’s have the inhibitory activity through association with special receptors found on membranes, the plasmatic of pathogenic bacteria and this association leads to an uncontrollable flow of charged ions Cation and a flow of amino acids causing in the explosion of cellular membranes and to kill bacteria and decrease bacterial infections (26;27).

Detection of genes that responsible for β-lactamase-resistance:

The results showed that the bla *oxa* and *ctxm* was detected in *K. pneumonia* isolates, from the 30 (100%) isolates of *K. pneumonia* 17 (56.66%) were have bla *ctx-m* gene, and 22 (73.33 %) were have bla *oxa* gene Figure (3 and 4). Beta-lactam antibiotics are it one of the greatest usually prescribed treatment classes with many therapeutic indications, these advent initial from the 30s of the twentieth century drastically different the scenario of the fight in contradiction of bacterial infectious diseases, the mechanism of action for this antibiotics comprise, the peptidoglycan or murein is a vital basic of the bacterial cell wall this gives mechanical constancy for it, that is an very conserved constituent of within the gram-positive and gram-negative covers, the beta-lactam antibiotics prevent the latter stage in peptidoglycan creation via acylating the transpeptidase involved in cross-linking peptides to make peptidoglycan (28)(29). The goals for activities of beta-lactam antibiotics it called as penicillin-binding proteins (PBPs), the binding, in turn, interrupts the terminal transpeptidation method and gives failure of viability and lysis, and by
autolytic methods with the bacterial cell, β-Lactamases are by far the greatest significant resistant process in Gram-negative bacilli, with the popularization of genetic techniques, an increasing number of this enzymes have been categorized different in amino acid series and hydrolytic activity for β-lactam antibiotics (30).

Gram-negative bacteria, inducible appearance of β-lactamases is ordinarily originate in chromosomal β-lactamases whereas plasmid-mediated enzymes are usually constitutively expressed, improvement appearance for this hydrolytic action is frequently controlled within promoters appear in upstream genes (31). This findings of it current study revealed that the rate of bla oxa gene, and bla ctx-m gene are excessive in K. pneumonia isolates, and it is accordance with previous studies (32-34), when they found the bla ctx–m gene and bla oxa gene are the most frequently detected gene encoding in clinical isolates of K. pneumoniae and Pseudomonas spp at different rates.

**Figure (3) Agarose gel with ethidium bromide stained of mono-plex amplified product from extract DNA of K. pneumoniae isolates with bla bla ctx-m gene primers, Lane (L) DNA molecular size marker (100-bp ladder), Lane (4,6,7,8, 11,12,13,14,18,19,20,22,24,25,27,28,30) show positive results bla ctx-m gene**

**Figure (4) Agarose gel with ethidium bromide stained of mono-plex PCR amplified product from extract DNA of K. pneumoniae isolates with bla oxa gene primers, Lane (L) DNA molecular size marker (100-bpladder), Lane (1, 4, 5, 6,7,8, 9,11, 12,13, 14, 15,17, 18,19,20,22, 24, 25, 27, 28, 30) show positive results with bla oxa gene**

Accuracy of Different Apex Locaters. (A Comparative in Vitro Study)

Mohammad Munthir Abdulrazzaq¹, Emad Farhan Alkhalidi²

¹Lecturer Dr. PhD, Conservative Dentistry/Al-Iraqia University College of Dentistry/Department of Conservative Dentistry, ²Assistant Professor, Dr. PhD Conservative Dentistry/University of Mosul/College of Dentistry/Department of conservative Dentistry/Iraq

Abstract

Aims: The objective of this in vitro study was to compare the accuracy of the Root-ZX II, Root ZX Mini, i Pex II, Kerr apex ID, Root PI and YD2 electronic apex locators (EALs) in locating the apical foramen.

Materials and Methods: Fifty extracted human teeth with mature apices were used. Access cavities were prepared. In order to make sure that we have an accurate working length of 21 mm the crown was sectioned with diamond disc (control). The teeth were then embedded in an alginate model to simulate the periodontium after that the Canals were irrigated with 2.5% sodium hypochlorite. The actual length and electronic length measurements were made on each specimen separately by apex locator devices with an aid of a K-type file.

Results: Statistical results showed no significant difference between the 6 devices although concerning locating the apical foramen, Root-ZX II, Root ZX Mini, were accurate 96% of the time to ±0.5 mm, where as I pex II and Kerr apex ID were accurate 94% of the time to 0.5 mm from the apical foramen, 44% ±0.5 mm for the Root PI and 44% ±0.5 mm for the YD2. Conclusions: All the apex locators were able to determined the position of the apical foramen but consequently the Root-ZX II, Root ZX Mini, i Pex II, Kerr apex ID were more accurate than Root PI and YD2 apex locators.

Key word: Apex Locator, Root-ZX II, Root ZX Mini, i Pex II, Kerr apex ID , Root PI apex locator and YD2 apex locator.

Introduction

The determination of an accurate working length is one of the most critical steps of endodontic therapy. The cleaning, shaping, and obturation of the root canal system cannot be accomplished accurately unless the working length is determined precisely. Most operators attempt to terminate instrumentation 0.5-1 mm short of the radiographic apex. Although radiography is the most commonly used diagnostic aid in endodontics, clinically root morphology and radiographic distortion may cause the location of the radiographic apex to vary from the anatomic apex which could lead to over or under filling (1). Furthermore, radiographic interpretation of the apices of some teeth (e.g. maxillary molars) may be so difficult that radiographic working length determination is not accurate (2).

Recently, electronic methods for tooth length determination have gained popularity. The latest generation of apex locators has many advantages when compared to earlier devices. Unfortunately, many devices are inaccurate in root canals that contain moisture, vital pulp tissue, blood, and other exudates (3).

On the other hand many studies report on the accuracy achieved by the new generation of electronic apex locators as well as their extended measurement capabilities, which include accurate measurements in the presence of electrolytes (4).

Many types of EALs were manufactured but most studies on electronic apex locators using two frequencies (the third generation) report accuracy rates of 85–95% (5).
The objectives of the present study were to test the accuracy of six types of apex locators in an in vitro model and to compare its accuracy to the actual working length.

Materials and Methods

This study was approved by Research Ethics Committee at College of dentistry, University of Mosul (Approval number UoM.Den/H.L.34/21).

The research involved 50, extracted, single-rooted, human lower premolar teeth with mature apices, preserved in Thymol solution and kept refrigerated.

In order to make sure that we have an accurate working length of 21 mm the crown was sectioned with diamond disc to a level so that all the teeth have a constant working length of about 21 mm (control) and establish a level surface to serve as a stable reference for all measurements and also for statistical purposes.

The access cavities were prepared (Diamond burs, 10541M, Technical & General Ltd). The actual root canal length is the distance from the coronal reference point to the apical foramen. It was measured by inserting a #20 file into the root canal until the file tip was just visible at the level of the apical foramen and this procedure was done under a stereo microscope (Heerbrugg, Switzerland) at this point the stopper adjusted to the coronal reference point. This procedure was done to make sure that all the teeth have constant working length of about 21 mm.

Each measurement was repeated three times and if there was a difference in the measurements from the 21 mm the working length of the tooth was adjusted to be 21 mm.

Teeth were then embedded in an alginate model to simulate the periodontium specially developed to test apex locators (6). The alginate (Kromopan Lascod, Italy) was poured into the mold then each tooth was embedded into the alginate and kept in position until the alginate had set completely. The model was used immediately so that to keep it humid and when not in use; it was wrapped with a wet paper and refrigerated to keep it in a moist environment throughout the experiment. Previous studies have shown that keeping the model in such an environment was satisfactory (Kaufman & Katz 1993) (6).

Measurements were taken after irrigation with normal saline into the root canals. Cotton tips were used to dry the tooth surface and eliminate the excess irrigating solution.

The file was placed in to the canal while attached to the appropriate electrode of the apex locator and the other electrode (lip clip) was attached to the alginate (figure 1).

Figure 1 show tooth inside alginate with apex locator.
The file size was 20 Flexo file (Dentsply,Maillefer), it was inserted slowly inside the canal till the signal of the apex locator reached the '0' mark (apical foramen), at this point the stopper of the file was moved to the coronal reference point, then the file was removed from the canal and working length was measured with an endodontic ruler and its length registered as the electronic length (EL). On each tooth this procedure was repeated for each one of the six types of apex locators, in this study the apex locators used are

1. Root ZX II (Morita, Japan).
2. Root ZX Mini (Morita, Japan)
3. ipex II (NSK, Japan)
4. Kerr apex ID (Kerr, USA)
5. Root PI apex locator (Osakadental, China)
6. YD2 apex locator (Shanghai S&D Dental International Co., China).

The results obtained (in millimeters) for each electronic apex locator was recorded in independent tables. In each case, we subtracted the corresponding reference measurement (i.e. actual length) from the electronically determined distance, recording the result in tabular form as positive form (measurements exceeding the apical foramen), negative (measurements short of the apical foramen), or correct (measurement coinciding with the actual length) with a ±0.5 mm acceptable range.

Percentage was used to statistically analyze the significance of the mean differences between electronic length and actual length.

**Results**

Each tooth served as its own control. Statistical results showed Root-ZX II, Root ZX Mini were accurate 96% of the time to ±0.5mm, where as I pex II and Kerr apex ID were accurate 94% of the time to 0.5 mm from the apical foramen, 44% ±0.5mm for the Root PI apex locator and 44% ±0.5mm for the YD2 apex locator Table(1).

**Discussion**

The main purpose of this study was to evaluate the accuracy of electronic apex locators most widely used in clinical practice that are available in the local markets. An in vitro study was developed in comparing electronic measurements with a control.

No individual technique is truly satisfactory in determining endodontic working length. Modern electronic apex locators can determine this position with accuracies of greater than 90% but still have some
Two operators measured the actual working length (control) with the use of a stereo microscope to be sure that all the samples having a working length of 21mm in order to get a precise measurement and the same operators measured the electronic measurements. All the teeth used were single rooted teeth with mature apices; several studies have demonstrated that EALs can accurately determine the working length in between 75 to 96.5% of the root canals with mature apices \( (8-11) \), therefore any tooth with wide or opened apex was neglected because it gave inaccurate readings.

Study carried out by Lucena-Martin et al. \( (12) \) showed that the Root ZX gave a precise measure in 85% of the cases. Shabahang et al. \( (13) \) produced values to a precision of 96.2% for the Root ZXII which is in general agreement with our study. It was not possible to compare the results of the other five apex locators with other existent studies because of the lack of research on these devices however there was no significant difference in the accuracy between the root ZX II, Root Zx Mini and i pex II and the kerr but all of them significantly differ from the Root PI and YD2 in which there was no significant difference between them.

The accuracy of the Root-ZXII , Root ZX Mini, were accurate 96%, where as i pex II and Kerr apex ID were accurate 94% , 44% for the Root PI and 44% for the YD2. these variations showed a difference in the accuracy of the measurements between the devices.

It is important to mention that these measurements were made in vitro and in ideal situations but clinically there are more problems related in working length measurement like the presence of blood and the use of different irrigate solutions so more studies are needed to evaluate the accuracy of EAL under different situations and also in vitro studies are needed to evaluate the real accuracy of the EAL clinically.

**Conclusions**

Within the limitations of this in vitro study the following conclusions could be drawn:

All the apex locators were able to determine the position of the apical foramen but consequently the (Root-ZX II, Root ZX Mini, i Pex II, Kerr apex ID) were more accurate for the determination of the root canal length than (Root PI apex locator and YD2 apex locator).

Assessment of Enzymatic Bioremediation for Catechol in Water by the Role of Immobilized Catechol 1,2-dioxygenase on Biosilica of Diatoms Frustule and other Polymers

Khalid Dheyaa Abdulwahid¹, Najm Abdulla Al-Zubaidy²

¹Post Graduate/ Department of Biology, College of Science, University of Diyala, Iraq.
²Prof., Department of Biology, College of Education for Pure Science, University of Diyala, Iraq

Abstract

The highest specific activity for (C12O) enzyme purification was within the second stage of the purification steps represented by precipitation with ammonium sulfate AS 2% (weight/ volume), reaching about 14.56 U. mg⁻¹ after achieving the purification by 6.6 folds with a recovery rate of 78.3%. The optimum catalytic activity of the enzyme (C12O) was within the pH of 6.5-8.5 and the temperature of 25 °C. Immobilization of (C12O) enzyme by biosilica of diatom frustules DFS/G GA gave a double shifting of 20 °C from the optimum temperature for enzyme activity, within all the purification stages, as the percentage of catechol degradation through it at the temperature of 45 °C reached about 93% and 87.2% and 85% were in the precipitation stage with ammonium sulfate AS and the precipitation with streptomycin sulfate SS and the enzymatic crude extract CEE respectively. While the shifting was only 10 °C in the case of immobilization on polymeric supports types: PAN / G and PAA / G. In contrast, the soluble (C12O) enzyme which did not show any shifting by its optimum temperature , and its highest activity values were within the optimum temperature of 25 °C. While the method of immobilization for (C12O) enzyme by biosilica of diatom frustules DFS/G gave a 1.5-degree shifting for the optimum pH of the enzyme activity, within all the purification stages, the highest rates of catechol degradation were reached through it at the base pH 9-10 about 91.8% and 86.5. % And 85.0% in the AS, CEE and SS stages, respectively. Whereas, the enzyme immobilization methods of (C12O) by PAN / G and PAA / G did not show such displacement during the enzymatic purification stage with streptomycin sulfate SS but were limited to the primarily stages of enzymatic purification. , As it was able to shift the optimal pH of the (C12O) enzyme by 1.5 degrees also within the purification stages of AS and CEE. The rates of catechol biodegradation through it at the base pH 9-10 were about 79.0% and 71.8%, respectively, in the case of immobilization by PAN /G and PAA / G with percentages of 71.8% and 62.0%, respectively. In contrast, soluble (C12O) enzyme did not show any shifting by its optimum pH, and its highest activity values were within the optimum pH of 6.5-8.5. The reason for these results may be attributed to the role of the large surface area ready for covalent immobilization of (C12O) enzyme by biosilica of diatom frustules compared with the surface area of pores of the two types of polymeric membranes used in current study.

Introduction

Many extensive studies have been conducted during the last decades on both types of aromatic ring-degrading enzymes, external and internal effects, due to their important role in the field of biological treatment (¹). The aerobic biodegradation of phenolic compounds takes place through Certain pathways, with catechol or its derivatives playing a major role. These intermediates are then metabolized by the intradiol or extradiol cleavage of the aromatic core ring by enzymes dioxygenases (²). In the case of phenol, the first step of biodegradation involves converting phenol in to catechol via specific enzymes including the enzyme phenol hydroxylases, whose action involves binding of a hydroxyl group at the
ortho-position of the aromatic ring \(^{(3,4)}\). Immobilization of enzymes to different carriers or stents is an important challenge in the field of biotechnology. To date, a large variety of systems designed in this area have been examined and discussed. The main goal of enzyme immobilization is to obtain stable and reusable enzymes with resistance to various environmental factors \(^{(5,6,7)}\). The immobilization improves the control of a reaction through the possibility of using different forms of interaction. Moreover, the immobilization enzymes exhibit a high degree of selectivity and specificity \(^{(8,7)}\). The immobilization of dioxygenases, which has a low stability of action, has been shown to allow an increase in its value in terms of biotechnology \(^{(9,10,7)}\). In contrast, polyphenol oxidases and peroxidases are enzymes that most often require electron carriers to effectively complete their activity. Therefore, fixing these enzymes on insoluble carriers facilitates the construction of stable electron transport chain systems \(^{(11)}\). The activity of dioxygenases has been found in *Candida tropicalis* \(^{(12)}\), and *Candida albicans* \(^{(13)}\). In another study conducted by Tsai and Li, the enzyme catechol 1,2-dioxygenase was purified from the yeast strain TL3 *Candida albicans*, and they found that the homodimer has a molecular weight of 32,000 Dalton and each subunit was mono iron. And the optimum temperature and pH were 25 °C and 8.0, respectively \(^{(14)}\).

Diatoms are widely distributed unicellular algae capable of carrying out photosynthesis and which can deposit a silicon cell wall in a highly precise and unique arrangement called the Frustule cap, which is characterized by its porous structure that includes the presence of micro- to nano porous structure, which has an important role. In increasing the surface area of the wall with the potential to be easily modified \(^{(15,16)}\). The use of diatom biosilica as a support for restriction of enzymes came due to its various advantages such as natural origin, low cost and presence of hydroxyl groups as well as being non-toxic, these things are very important because the use of polymers of petroleum origin as restriction supports is not desirable because they are mostly toxic, which makes them a major cause of pollution \(^{(17)}\). Listed as a priority pollutant by the US Environmental Protection Agency \(^{(18)}\), phenol is the most hazardous industrial liquid waste with minimal toxicity at 1 mg. L\(^{-1}\) was developed by the World Health Organization (WHO) relatively to control the concentration of phenol in drinking water \(^{(19)}\). Thus, treatment of wastewater containing phenolic liquid wastes is essential \(^{(20)}\). Therefore current study aims to assessment of enzymatic bioremediation for catechol in water as phenolic compound by the role of immobilize catechol 1,2-dioxygenase on diatoms frustule and other some polymers.

### Materials and Methods

#### Extraction and purification of catechol 1,2-dioxygenase enzyme

Biodegradation potential of *Candida albicans* for phenolic compounds were identified, a qualitative examination was performed to determine the presence of the activities of Catechol 1,2-dioxygenase and Catechol 2,3-dioxygenase according to the approach followed by \(^{(4)}\), yeast strains were selected from the genus *Candida ssp*. Yeast cultures, with the biodegradation capacity for catechol, were grown in yeast cultures, in 8 Erlenmeyer flasks 2 liter at 30 °C, each flask containing 800 ml of MSM or YNB 0.67% (w / v) and 10 mM of phenol \(^{(13)}\), and inoculated with an initial cell density (ICD) of *Candida albicans* which isolated and purified in previous other study, had about 0.02 absorbance-induced OD optical density using a spectrophotometer at the wavelength of 600 nm. Harvesting of the yeast cells was started when the growth of the strain reached the stationary phase, that is, when the optical density due to the absorption reached approximately 1.4 on the wavelength of 600 nm \(^{(14)}\). The harvested yeast cells were transferred to freezing at a low temperature of below zero degrees Celsius. Freeze was used for this purpose in preparation for the enzymatic purification steps. The enzyme catechol 1,2-dioxygenase was extracted and purified from *Candida albicans* and the enzyme activity was assessed according to the method described by \(^{(14)}\). All the following enzyme purifications steps were carried out at low temperatures (0 to 6) degrees Celsius.
**Determination of the total enzymatic protein**

Protein concentration of the enzymatic extracts was determined by the Bradford method \(^{(21)}\), so that one unit of the enzymatic activity or activity of the enzymes under study was defined as the amount of enzyme that formed 1 µmol of the product per minute at 40 °C. The specific activity was expressed as one unit (U) per mg protein \(^{(1)}\). Although some researchers argue and adhere to the fact that the enzymes present in the crude extract are more stable and useful in building biosensors \(^{(22)}\), a dissolving and cleaning step of enzymes has been suggested according to the approach followed by \(^{(23)}\) with the aim of eliminating potential interactions, such as salts, sugars, and phenol.

**Preparation of biosilica from diatomaceous frustule**

Standard method was used to remove the organic and carbon materials from the diatoms samples obtained from the river according to modified method followed by \(^{(24,25)}\), briefly it was done through the following steps: 2 grams of the diatom samples collected in the previous study were passed in a baker with a Teflon beaker and heated to 60 °C in a 30% \(\text{H}_2\text{O}_2\) solution (w/w) for 2 hours, diatomaceous sample was washed three times using distilled water and centrifuge at 2000 rpm for 5 minutes, then the precipitate formed was transferred to a baker with a Teflon film and 20 ml of \(\text{H}_2\text{SO}_4\) solution 30% (v/v) was added and placed in an incubator at a temperature of 105 °C for 12 hours. After the incubation period had elapsed, the diatom biosilica particles were washed with pure water and dried at 40 °C.

**Preparation of immobilization membranes**

Current study included enzymatic immobilization on three types of immobilized materials: Diatom Frustule Silicon (DFS) membrane as Nano filtration with pore size (micro - nano), and polyacrylamide membrane (PAA) as microfiltration with an average pore size of 0.2 micron , and a polyacrylonitrile (PAN) ultrafiltration (PAN) with an ultrafiltration of 0.01 micron pore size .Phase inversion technique was used to prepare the immobilize film membranes that included a diatom frustule silicon (DFS), polyacrylamide (PAA), and a polyacrylonitrile (PAN) membrane, by following the modified method according to \(^{(26)}\), which is briefly as following: 2g of the immobilized materials (DFS, PAN, or PAN) was immersed in a solution containing 8g of DMF( N, N-dimethylformamid) and under continuous stirring at a temperature of 60 °C for 4 hours to form a solution of a homogeneous gel. Then the homogeneous gel solution was placed in a vacuum pump at 37 °C for a period of 12 hours to ensure complete exit of air bubbles.

**Fixing of immobilized material films on glass support**

Diatom Frustule Silicon / Glass (DFS / G) films, Polyacrylamide / Glass (PAA / G) and Polyacrylonitrile / Glass (PAN / G) films have been fixed by following the modified method according to \(^{(27, 26)}\), which is briefly as following: Mercaptol ester (NOA 61) was deposited as a heat-malleable polymer on a thin layer of 1.5 cm² from a glass slide and this was done with the help of centrifugation by a spin-coater device with a thermo adaptive procedure \(^{(27)}\). Then 10-20 µL of the homogeneous gel solution of the immobilized membrane material (DMF- DFS) or (DMF-PAA) or (DMF-PAN) was applied in a thin layer over the glass slide that was pre-coated with mercaptol ester with a weight of not more than 250 mg. Distributing it over the entire slide with the help of centrifugation by means of a spin-coater device with a thermoplastic process, and this treatment process was repeated again to obtain optimal adhesion. After fixing the immobilized membranes, the glass slides were placed in a petri dish containing deionized water with gentle stirring to ensure complete conversion of the homogeneous gel material to a solid state according to the phase inversion technique \(^{(26)}\). Slides which have regular immobilized films were picked up and discarded irregular ones, then washed with distilled water for 3-4 times, then the obtained slides were transferred to a beaker to storage for further use.

**Amine modification and chemical activation of immobilized films**

Chemical amine modification for films of the immobilized membranes was carried out by modified
procedure according to (28,26,27) as follows: Immobilized films on the glass slides, which included: (DFS / G), (PAA / G), and (PAN / G) were treated with 10% aqueous solution of NaOH at 50 °C for 60 minutes. After complete washing of the Immobilized films with distilled water, they were treated with 10% of aqueous solution 1,2-diaminohexane for 60 minutes at 40 °C and allowed to interact with continuous stirring in a magnetic stirrer at about (200) rpm. Then, they were cooling at room temperature. After that washed with acetone and ethanol to remove residual reagents. Then they were dried at 40 °C for 12 hours to a constant weight of approximately 250 mg. Finally, the glass slides with DFS, PAA, and PAN which are amino-modified immobilized films were transferred to a 5% aqueous solution of glutaraldehyde prepared in a phosphate buffer 0.1 M; pH: 7.0 to complete glutaraldehyde bonding reaction at 35 °C for a period of 3 hours. After the reaction period, the activated immobilized films by glutaraldehyde were sequentially washed with 0.1 M of acetic acid solution and 0.1 M phosphate buffer.

**Immobilization of (C12O) enzyme on activated immobilized films**

After completing the amine modification and chemical activation procedure with glutaraldehyde for immobilized films that fixed on the glass slides, the immobilization of catechol 1,2-dioxygenase enzyme (C12O) on these films were carried out through the following procedure according to (28,26). Slides of DFS/G, PAA/G and PAN/G immobilized films which were previously modified and activated were immediately treated with C12O enzyme solution, prepared in 4 mL of phosphate buffer 0.1 M; pH: 7.0 containing enzymatic protein as concentration (20.8, 16.7,20.2) mg. ml⁻¹ in cases of purification steps (CEE, AS 30%, SS 2%) as respectively, which are equivalent to activity as (71.6, 256.3,126.2) U.ml⁻¹ in cases of purification steps( CEE, AS 30%, SS 2%) as respectively. And then slides were placed in an incubator at 22 °C for 8 hours to complete the reaction. After reaction period, the membranes were washed with phosphate buffer 0.1 M and pH: 7.0. the same buffer was used to store glass slides which are containing immobilized catechol 1,2-dioxygenase enzyme for further use. Immobilized enzymatic protein on DFS, PAA and PAN membranes was quantified by Bradford method (21).

**Efficacy of enzymatic immobilization**

Enzyme activity for immobilized Catechol-1,2-dioxygenase (EC1.14.13.1) was determined by estimating the residual catechol by the Fujita et al colorimetric method (29) with a modification procedure consistent with the current study by using specimen cup plastic tube for each test equipped with a screw cap (QT) type with a capacity of 60 ml, provided that the total volume of additives in test tube is only 60 ml. Modification procedure and additives for each test tube could be illustrated as following: For the purpose of testing the effect of the pH difference on enzyme activity of catechol 1,2-dioxygenase, 32 ml of certain different buffers at a concentration of 50 mM were added to provide a medium (acidic, neutral, and basic), so that a sodium acetate buffer (pH: 5.0--6.0) was used when performing an activity test in a medium with acid characteristics and use a buffer of potassium phosphate (pH: 6.5--8.5) when performing an activity test in a medium with neutral specifications, while Tris–acetate buffer (pH: 9.0-10) was used when performing an activity test in a medium with basic specifications. 4 ml of free (soluble) C12O enzyme or immobilized C12O enzyme on immobilized films as weight of 250 mg, provided that the concentration added in both cases was about 17.6 mg. ml⁻¹ or equivalent to the specific activity of 256.3 U.ml⁻¹. The enzymatic addition was carried out depended on testing the different enzyme status, which included: soluble enzyme, and immobilized enzyme. Three types of enzymatic immobilization were tested as follows: immobilized on (Diatom Frustule / Glass) encoded DFS / G, immobilized on (Polyacrylamide / Glass) encoded PAA / G, and immobilized on (Polyacrylonitrile / Glass) encoded PAN / G. As well as testing activity of soluble and immobilized C12O enzyme were performed on different purification stages, including: crude extract enzyme and CEE encoded, precipitation with streptomycin sulphate encoded SS, and precipitation with ammonium sulphate encoded as AS. 24 ml of catechol substrate at 40 mM was added to the reaction mixture, and as soon as the
substrate was added the enzymatic reaction began. The reaction solutions were well mixed in each test tube and left under different incubation conditions in a Shaking water-bath at different temperature conditions: 15, 25, 35, 45 and 55 °C for 3 days. After the incubation period had elapsed, 1.6 ml of H₂O₂ hydrogen peroxide was added at a concentration of 5% (v/v), in order to inhibit the activity of the enzyme catechol 1,2-dioxygenase. Portions of the reaction solution (aliquots) were withdrawn and the same procedure of colorimetric method described by (29) were performed by ELIZA microplate reader for determination of residual catechol.

**Statistical Analysis**

The statistical analysis was done according to Completely Randomized Blok Design (CRBD) and Completely Randomized Design (CRD) with significance level 0.05 and 0.01, using SPSS version 22 of 2019.

**Results and Discussion**

**Characterization of (C12O) enzyme**

Catechol 1,2-dioxygenase (C12O) was extracted purified from *Candida albicans* strain which gave a positive result of qualitative primarily test (4) towards intradiol or ortho-cleavage of aromatic ring in catechol. Purification data for (C12O) enzyme were calculated under its optimal conditions, which are pH: 8 and a temperature of 25 °C, as indicated earlier (14,30) and as shown in Table1.

*:One unit of catechol 1,2-dioxygenase (C12O) enzyme activity represents 1 µmol of substrate per mg of protein per minute.

It is evident from the data of Table1. that the highest specific efficacy of the enzyme purification (C12O) was within the second stage of the purification steps represented by precipitation with AS 30% (w/v) ammonium sulfate, reaching about 14.56 U.ml⁻¹ after completion the purification was 6.6 times, with a recovery rate of 78.3%, in order to reach the amount of enzyme protein close to 20 mg.ml⁻¹. Indeed, the enzymatic protein was purified by 17.6 mg. mg.ml⁻¹, which is equivalent to an enzymatic activity of 256.3 U.ml⁻¹. Whereas, (C12O) enzyme was purified by 15.3 times during the third stage of the purification steps by precipitation with streptomycin sulfate SS 2% (w/v) with an activity recovery rate of 70.3%, and enzyme protein was purified by 20.2 mg.ml⁻¹, which is equivalent to an enzymatic activity of 126.2 U.ml⁻¹ and specific enzyme activity of 6.25 U.mg⁻¹. The optimal catalytic activity of the enzyme (C12O) was within a pH of 6.5-8.5 and a temperature of 25 °C. This result is consistent with (14,30) in their studies on characterization of this enzyme, as they indicated its optimum catalytic conditions are pH 8 and a temperature of 25 °C.

**Biodegradation of catechol by (C12O) enzyme**

The percentages of biodegradation of catechol were calculated based on the concentrations of the catechol...
residues that were extracted with the concentration mM according to the conversion of the OD optical density readings from micro plate reader and on the basis of the tendency equation inferred from the standard curve of catechol shown in Annex (2-4), which was made.

**Optimum thermal limit of (C12O) enzyme**

As shown in Table 2. It was found that there are high significant differences in biodegradation ratio of catechol according to the variation in the temperature of the reactant mixture on the one hand and the degree of purity of (C12O) enzyme on the other hand, and that highest rates of biodegradation for catechol in moderate acid conditions were within the stage of precipitation with ammonium sulfate AS30% (w/v), specifically at temperatures 35, 25 and 45 Celsius degrees, as its rates were about 73.6 ± 15.0%, 72.6 ± 13.2%, and 70.0 ± 17.7%, respectively, which indicates that the peak activity of the enzyme (C12O) is in the neutral condition pH level was at 35 °C, meaning that there is a shift in the optimum temperature of the enzyme activity, perhaps due to the role of enzymatic immobilization. This result may not agree with the study conducted by (30), to assess the environmental conditions for the activity of the two enzymes (C12O) and (C23O) produced by the Gordonia polyisoprenivorans strain of actinomycetes, as they tested cell free enzymes in their soluble and immobilization states. As previously, the optimum conditions for pH, temperature, time path and the effect of ions on enzyme activity were determined, and they found that the peak of the enzyme activity for (C12O) was at a pH of 8.0.

Mean ± S.D. | 82.2±7.8 | 44.7±16.2 | 57.3±13.7 | 30.2±18.3 | 53.6±23.9 |
While the lowest biodegradation ratio of catechol were within the crude enzyme extract stage of CEE, specifically at temperatures 55, 45 and 15 Celsius degrees, as their rates were about 28.6 ± 27.3%, 39.2 ± 33.5% and 41.6 ± 24.9%, respectively, as it seems clear the role of temperature extremes in enzymatic inhibition, especially in degrees above 25 Celsius degrees, and that the best ratios of catechol degradation within the crude enzyme extract stage as moderate acid conditions were at temperatures 35°C and 25°C, reaching about 49.7 ± 25.9% and 47.9 ± 23.2. It also shows in Table 2, the displacement amount of 10 degrees from the optimum temperature limit, which may also be due to the role of enzyme immobilization in increasing the stability of the enzyme and the permanence of its activity towards high temperatures.

As for the precipitation stage of streptomycin sulfate SS 2%, it was observed that the highest rates of biodegradation for catechol as moderate acid conditions were at temperatures 35, 25 and 15°C, reaching 56.2 ± 23.0%, 54.8 ± 20.7% and 49.9 ± 23.2% as respectively, through which the effect of the different kinds of enzyme immobilization under current study was also shown on the displacement of the optimum thermal limit of (C12O) enzyme action to include the temperature of 35 °C, while the low values of the rates of biodegradation ratios of catechol during the precipitation stage of streptomycin sulfate in moderate acid conditions were about 39.8 ± 24.0% and 49.1 ± 28.3% at high temperatures (55 °C) and 45 °C, respectively, and this may be due to the role of high temperatures in inhibition of (C12O) enzyme activity (31). And as shown in Figure 1. The increase in the optimum temperature may be due to the improvement in the stiffness and stability of the enzyme action due to immobilization method by covalent bonding method using the glutaraldehyde. These results may be in agreement with the study conducted by (25), in which they found that immobilization of tyrosinase to diatoms’ modified biosilica had a role in its activity within a wider temperature range compared to the free enzyme. A similar displacement to the optimum temperature of the immobilized enzymes has been observed in many studies, but the extent of the displacement varied with the different immobilization methods, the type of binding stent, as well as the type of binding or interaction between the immobilized enzyme and the immobilized support (32,31). It was found that the thermostability in the organic solvents of HabB enzyme was much higher in the case of the enzyme being included genetically within the biosilica of the diatom compared with the enzyme in its free state. Also, the stability of this enzyme was equal or even better if it was used within silica envelopes in laboratory experiments (in vitro). Examination by electron microscopy proved that genetic manipulation did not affect the silica architecture in Thalassiosira pseudonana (33).
Figure 1. biodegradation ratio of catechol (%) as an initial concentration of 40 mM by catechol 1,2-dioxygenase in incubation conditions: constant pH:(6.5-8.5) and different temperatures, for a period of 3 days

On the other hand, the statistical analysis showed high significant differences in biodegradation ratio for catechol according to the variation in the temperature of the reactant mixture on the one hand and the state of the enzyme on the other hand, and that the highest rates of biodegradation for catechol under moderate acid conditions were within the enzyme immobilization method by covalent glutaraldehyde on the modified biosilica support as DFS / G diatoms, with a rate of about 82.2 ± 7.8%, followed by polymeric support of the type of PAN / G at 57.3 ± 13.7%, while the lowest rates of biodegradation of catechol in the moderate acid conditions were in the case of the free enzyme (soluble) as about 30.2 ± 18.3%, followed by immobilization on the polymeric support of the type of PAA / G at 44.7 ± 16.2%, as is Shown in Figure 1. Which indicates that the used enzymatic immobilization method has given good results in all types of the immobilization supports used under this study in maintaining the thermal stability of the enzyme (C12O) and making it stable under different temperature conditions under the current study compared to the use of the enzyme in its free or soluble form.

The method of immobilization of the enzyme (C12O) on the biosilica supports of the diatom plate gave a double displacement of 20 °C from the optimum thermal limit for the enzyme activity, within all the purification stages. 87.2% and 85% were in the precipitation stages of ammonium sulfate AS and the precipitation with streptomycin sulfate SS and the enzymatic crude extract CEE respectively. While also the methods of immobilization of the enzyme (C12O) on the polymeric supports of the type of PAN / G and PAA / G gave a displacement of 10 Celsius degrees from the optimum thermal limit of the enzyme activity, within all the purification stages, the rates of breakdown rates reached Catechol with it at 35 °C is about 78.0%, 62.2% and 56.5% in the case of PAN / G immobilization, followed by the PAA / G immobilization condition with ratio of 69.5%, 49.0% and 41.5%, respectively, in the enzymatic purification stages AS SS. And CEE. On the other hand, the free enzyme (C12O) did not show
a displacement from its optimum thermal limit, and the highest values of its activity were within the temperature of 25 °C in all the purification steps under current study. This may be due to the fact that the pores in the polymeric immobilization supports are of microscopic sizes and are relatively few in terms of quality and quantity compared to the large number of micro and nanoscale pores and nano silicon in the biosilica of the diatomatum (16). The sizes of the polyacrylamide microfiltration (PAA) had a microfiltration rate of 0.2 m while the sizes of the polyacrylonitrile (PAN) were ultrafiltration with the average pore size of 0.01 m. This means that the surface area ready for covalent immobilization of the enzyme (C12O) using the glutaraldehyde method was higher in the organic silica of the diatom frustule compared with the two types of polymeric films used under current study, followed by the surface area ready for enzymatic binding in the polymeric membrane PAN and then the polymeric membrane of PAA. This, in turn, leads to a variation in the number of units of the bound (C12O) enzyme. It appears that the amine modification using 10% diaminohexane solution 1,2 in order to increase the amount of amine groups on the surface of the carriers had a role in making the surface carboxyl groups on the surface of the polymeric restraint supports on the one hand and the carboxylic end of the silaffin groups, which represent one of the most important organic components of diatom frustule, on the other hand (33), binds to one of the amine groups, leaving the other free and predisposed to binding with glutaraldehyde, which in turn binds to the enzyme units. This indicates the possibility that the biosilicate of the diatom layer was modified to a greater degree compared to the PAN films which were also to a greater degree than the PAA films. This result may be consistent with what was indicated by (28).

Optimum pH of the (C12O) enzyme

Table 3. shows biodegradation ratio for catechol with an initial concentration of 40 mM, resulting from the activity of the enzyme catechol 1,2-dioxygenase (C12O), whose efficacy was tested under reaction conditions that included different acidic conditions, as solutions were used during enzymatic purification. PH (various pH) such as sodium acetate buffer pH: 5.0-6.0; Potassium phosphate buffer pH 6.5--8.5; Tris-acetate pH 9.0--10 buffer, for the purpose of assessing the optimum pH of the enzyme activity (C12O) under conditions of its free and immobilization state on the biosilica of the DFS / G diatomaceous frustule on the one hand and on the polymeric films PAA / G and PAN / G, which is in turn fixed on glass struts on the other side.

After conducting a statistical analysis of the values shown in Table 3., it was found that there are high significant differences in the percentages ratios of biodegradation for catechol. According to the variation in the pH conditions of the reaction mixture on the one hand and the purity of the enzyme on the other hand, and the highest percentages of biodegradation ratios of catechol under constant temperature conditions, it was within the precipitating stage of ammonium sulfate AS 30% (w / v), specifically at the acidic functions 6.5-8.5 and 9. - 10, as the biodegradation rates of catechol reached 72.6 ± 13.2% and 63.0 ± 36.6%, respectively, while the lowest rates in all the purification stage were at the acidic function 5-6 and were about 28.5 ± 29.4. The reason for this may be due to the role of acidity in inhibiting the denaturation of the enzyme protein (34), especially the free unconstrained enzyme and thus its catalytic activity decreases in breaking down the catechol substrate. The enzyme is within the acid and base levels.

On the other hand, the statistical analysis showed high significant differences in the percentages of biodegradation for catechol according to the variation in the acidic function of the reactive mixture on the one hand and the state of the enzyme on the other hand, and that the highest rates of percentages of biodegradation of catechol under constant temperature conditions of 25 °C were within the method immobilization of the covalent enzyme with glutaraldehyde on the modified biosilica support of the DFS / G diatoms, reaching a rate of about 80.3 ± 9.3%, followed by the method of immobilization of the covalent enzyme with glutaraldehyde on the modified biosilica support of the DFS / G diatoms, reaching a rate of about 80.3 ± 9.3%, followed by the method of immobilization of the covalent enzyme with glutaraldehyde on the modified biosilica support of the DFS / G diatoms, reaching a rate of about 80.3 ± 9.3%, followed by the method of immobilization of the covalent enzyme with glutaraldehyde on the modified biosilica support of the DFS / G diatoms, reaching a rate of about 80.3 ± 9.3%, followed by the method of immobilization of the covalent enzyme with glutaraldehyde on the modified biosilica support of the DFS / G diatoms, reaching a rate of about 80.3 ± 9.3%, followed by the method of immobilization of the covalent enzyme with glutaraldehyde on the modified biosilica support of the DFS / G diatoms, reaching a rate of about 80.3 ± 9.3%, followed by the method of immobilization of the covalent enzyme with glutaraldehyde on the modified biosilica support of the DFS / G diatoms, reaching a rate of about 80.3 ± 9.3%, followed by the method of immobilization of the covalent enzyme with glutaraldehyde on the modified biosilica support of the DFS / G diatoms, reaching a rate of about 80.3 ± 9.3%.
method of immobilization of the covalent enzyme with glutaraldehyde on the polymeric support of the type of PAA / G with a rate of $42.7 \pm 20.7\%$, and as shown in Figure 2., which indicates that the used enzymatic immobilization method gave good results in all types of immobilization supports used for current study in maintaining the stability of the enzyme (C12O), the extreme values of the acidic function and making it stable, especially under the basic pH conditions, compared with the instability of the enzyme in its free or soluble form under such basic conditions.

The method of immobilization of (C12O) enzyme on the biosilica supports of the diatom frustule gave a displacement of 1.5 degrees to the optimal pH of the enzyme activity, within all the purification stages, the highest rates of catechol degradation were reached through it at the basal pH 9-10, about 91.8% and 86.5%. And 85.0% in the precipitation stages with ammonium sulfate AS and the crude enzyme extract CEE and precipitation with streptomycin sulfate SS respectively, and the reason for this may be attributed to the water absorption, if it exceeds the retention capacity (i.e. saturation) of the ionic liquids at room temperature, to facilitate denaturation. The enzyme was found at the interface between the solvent and the water, thus reducing the enzyme activity (31), whereas the C12O immobilization methods did not appear such as those displacements on the PAN / G and PAN / G as polymeric supports. The optimal pH of the enzyme activity during the enzymatic purification stage with streptomycin sulfate SS, but it was limited to the initial stages of enzymatic purification, as it was able to deflect the optimal pH of the enzyme (C12O) by 1.5 A score also within the AS and CEE purification stages, the rates of catechol degradation through it at a base pH 9-10 were about 79.0% and 71.8%, respectively, in the case of PAN / G immobilization, followed by the case of PAA / G immobilization with percentages of 71.8% and 62.0%, respectively. On the other hand, the free (C12O) enzyme did not show a displacement from the optimum pH, and the highest values of its activity were within the neutral pH 6.5-8.5 in all the purification steps under current study, with the highest rates of biodegradation of catechol about 58.8%, 34.3% and 25.3 in enzymatic purification stages AS, SS and CEE, respectively. Although the results obtained may not agree with the opinion of (35) and (36) who have demonstrated that immobilization of enzymes does not fundamentally change the properties of the pH response, they noted in their studies of tyrosinase immobilization, that the limit maximum stimulatory response to the immobilization enzyme was in the pH range of 5.6 (35) and at pH 7 (36), so now this may not apply to the features that the biosilica
possesses in the diatom frustule that he found \(^{(25)}\), in enhancing the properties of the immobilized tyrosinase compared to the free form of the same enzyme. It has been found that the optimum pH of polyphenol oxidase extracted from mushrooms is about 6.2 \(^{(37)}\) and according to many scientific studies including \(^{(38,39)}\), the optimal pH of this enzyme may differ when it is immobilized and dependent on the type of immobilization prop and the method used for immobilization. There are many studies that are consistent with the results of our current study related to determining the optimum temperature and pH of the enzyme (C12O) from \textit{C. albicans} which is of 25 °C and pH 8.0, respectively, including isolation and characterization of the enzyme (C12O) among the \textit{Pseudomonas} bacteria. By \(^{(40,41)}\), but less if compared to those isolated from different species such as \textit{Rhizobium leguminosarum} \(^{(42)}\) and \textit{Rhizobium trifolii} before \(^{(43)}\), as they found that it was optimally active at the pH was 9.0-9.5 and the enzyme purified from it was stable and maintained its activity at a rate of >85% for at least 30 minutes in the pH range of 7.0-9.0, while the stability of the enzyme was significantly reduced at pH outside this range.

**Conclusions**

It was observed that the surface area ready for covalent immobilization of the (C12O) enzyme was higher in the basilica of the diatom frustule compared with the two types of polymeric films used under study, followed by the surface area ready for enzymatic binding in the polymeric membrane (PAN) and then the polymeric membrane membrane (PAA). This, in turn, leads to a variation in the number of units of the bound (C12O) enzyme. As the method of immobilization of the (C12O) enzyme on the biosilica supports of the diatom frustule gave a double displacement of 20 °C from the optimum thermal limit for the enzyme activity, within all the purification stages. Whereas, the enzyme immobilization (C12O) methods on the polymeric supports of the type PAN / G and polyacryl amide PAA / G gave a displacement of 10 Celsius degrees from the optimum thermal limit of the enzyme activity, within all the purification stages. In contrast, the free, unbound (C12O) enzyme did not show a displacement from its optimum thermal limit, and the highest values of its activity were within the temperature of 25 °C in all the purification steps under study.

Comparison Between 3 Different Types of Mouthwash on the Healing Process of Periodontal Diseases

Ammar Alwan Ali1, Zainab Kasim Mohammad1, Abeer Isam Abdulhameed1
1 B.D.S., H.D.D. Researcher, High Diploma in Periodontics / Dental Health Specialist Center in Sheikh Omar / Baghdad, Iraq

Abstract
Dental plaque is the principal etiological agent for the development and progression of gingival and periodontal diseases. Three different mouthwash types were compared in this study for the periodontal healing process based on the results. For all bacterial strains, the culture type collection is used. The serial dilution process is used for preparing every mouthwash and adding it to the tubes with a specific dilution. In certain microorganisms of the respective mouthwash, the last tube dilution that does not show any turbidity will be considered MIC. The three types of mouthwashes were compared in terms of the ability to inhibit microbial growth. Twenty-four hours after the agar was solidified and the colony forms (CFU) units counted, the plates were incubated. This study showed that bacterial growth inhibition might occur in the three types of mouthwash. Boht, Behsa and Kin-gingival mouthwashes had a significant difference in their antimicrobial effect. This study showed that they were unable to perform s after 24 hours of in vitro incubation while the bacterial count was lowered after two weeks of in vivo use in the boht washings. Continuous exposure to bacteria may be necessary to wash the mouth, especially for Behsa and Boht. It is difficult to remove all bacteria from the mechanical plaque controls; antibacterial mouthwash can cause additive. In the current study, three types of mouthwash have compared antimicrobial effects. The results showed only that bacterial counts are affected by mouthwash. Based on this study’s results, Boht mouthwash is more effective than Kin Gingival and Behsa mouthwash for oral microorganisms, but further clinical studies are necessary to confirm our findings.

Keywords: Dental plaque, Periodontal diseases, Mouthwash, Bacterial, Boht, Behsa, Kin-gingival

Introduction
A variety of microorganisms, mainly bacteria, can be colonised and developed through the mouth; one influence factor in teeth and periodontal tissue destruction is bacterial plaque. The primary etiological factor for tooth decay, gingivitis, and periodontal disease is dental plaque. Dental and periodontal conditions are diseases associated with the prevention of biofilm. Dental plaque is the primary etiological agent in gingival and periodontal disease development and progression. Dental and periodontal susceptibility varies according to risk factors, including genetics, systemic factors and oral hygiene.

The primarily mechanical removal of plastic plaque through regular tooth brushing is used to prevent different periodontal diseases’ development and progression. The use of mouthwash to control plaque bacteria is about 5000 years long when the Chinese suggested that urine for children be used to prevent gingivitis. Various bacterial and fungal communities integrated into a highly specialised extracellular matrix are present in oral biofilms. The decrease in oral biofilm accumulation (dental plates) and the control/reduction of dental disease risks are essential for good oral care practices.

The primary effect of Mouth rinses on the supragingival and marginal plaque is limited due to tight gingival contact with the tooth in healthy persons. It must always be used in conjunction with mechanical plaque control measures but should never be used
solely as a means of oral hygiene \(^8\). Mouth washing can help prevent oral infections, reduce inflammation, decrease halitosis and local fluoride prevent caries. Mouth washing has several preventative and therapeutic purposes. Usually, mouthwash is based on anecdotal evidence instead of on-the-counter (OTC) scientific evidence \(^9\).

The use of mouth washing and chemical cleansing of teeth is typically to reduce dental accumulation \(^10\). It can even be used as oral care only for patients who cannot brush their teeth either after surgery or due to the motor or cognitive constraints \(^11\). Chlorhexidine (CHX) is long considered a short-term gold standard of action for bacteria, spores and fungi, including many antiseptic components of oral mouth washing. Mouthwash is a safe and effective anti-plaque and antimicrobial agent, which prevents adhesion, colonisation, metabolic activity and bacterial proliferation \(^12\). Due to the variety of antibacterial efficacy, cytotoxicity and kinetics of different solutions, it’s not easy to decide whether to use a particular mouthwash. In decreasing oral microbial counts, CHX is regarded as the gold standard \(^13\).

In preventing periodontal illnesses, mechanical plaque control measures (tooth brushing and flossing) are essential. Benzylamine chloride can also help avoid periodontal diseases by chemical plaque control measures, such as utilising only 0.12 or 0.2 per cent mouthwashes preparations with chlorhexidine \(^14\). If there is unevenness between the host defence and the bacterial niche, periodontitis may occur. The primary aetiology of the gingival tissues and the paradental attachment is the bacterial plaque \(^7\). Mechanic removals of the plaque or calculus and topical antimicrobial agents that can inhibit periodontal pathogens are commonly used in periodontal therapy. Moreover, in current periodontal and other applications, extracts from plants have been offered as anti-plaque agents \(^15\).

Body rinse can produce a therapeutic effect on the tooth’s entire surface, including interproximal areas where toothpaste is very effective \(^16\). Although it is effective in plaque control, chlorhexidine cannot be used for a long time because of some of its unpleasant side effects after a long time. The use of mouthwash in oral hygiene is ancient, in contrast to the popular notion. The use of mouthwash originates from religious codes of behaviour such as the outdated Manu laws of India that must rinse their mouths after a meal \(^11\). This study aimed to compare three different mouthwash types for the periodontal healing process based on the findings.

**Methodology**

This study aimed to determine the effect of three types of mouthwash on the treatment of periodontal disease. The impact on Kin Gingival, Behsa and Boht are assessed on the selected bacterial. Thus, minimum inhibiting concentrations (MIC) were used. The collection of culture type is used for all bacterial strains. The serial dilution method has been used to prepare every mouthwash with specified dilution and added to the tubes \(^3\).

The last tube or the last mouthwash dilution not showing turbidity is considered the MIC in certain microorganisms of the respective mouthwash. In terms of the ability to inhibit microbial growth, the three mouthwash types’ MIC was compared \(^17\). The tubes without turbidity (transparent) were then transferred to a solid media after 24 hours of incubation, which showed bacterial growth inhibition with the respective mouthwash and evaluated for the microbial growth to determine the MBC of mouthwash. In terms of the solid medium culture, the last tube, which was negative, indicated the minimum concentration (MBC) of bactericidal fluid \(^17\).

For all bacterial strains, this procedure was done. 0.5 ml diluted samples have been transferred in empty plates for counting bacterial colonies. The agar was cooled to 50°C and poured into each plate. The pouring of the agar was done into each plate. The plates were incubated 24 hours after the agar had solidified and the colony forms (CFU) units counted. On dilute samples collected before the patients’ used mouthwashes or water, the zone of growth inhibition test was done in vitro \(^8\). On the agar surface with the swab, bacteria were streaked. The filter paper impregnated disks were then placed at the centre of each section and slightly pressed to the agar with the
water and mouthwash. The plates were then incubated for 24 hours at 37°C inverted positions. The inhibition zone was measured after 24 hours \(^{(10)}\).

**Results**

![MIC and MBC of the Mouthwashes](image1)

Discussion

This study showed that the three types of mouthwash could cause bacterial growth inhibition. The antimicrobial effect of Boht, Behsa and Kin, gingival washes of the gum, were significantly different (Figure 1). The SM growth inhibition areas in the three study groups are shown in Figure 2. Two-week use of Boht, Behsa and Kin gingival mouthwash, before and after periodontal patients, is summarised in Figure 3. In patients with periodontal disease, the summary of bacterial counts is also presented in Figure 3 before and after two weeks.

Mueller Hinton Agar was the artistic medium of this study, used as a growth speciality for those bacteria in procedures commonly conducted for aerobic and optional anaerobic bacteria (neogen.com). Therefore, it would appear logical to assume that both aerobic and optional bacteria cultivated on agar plates were actual. The results of this study demonstrated a difference in the antibacterial effects shown by Behsa and Boht, as they were unable to make s after 24 hours of in-vitro incubation, while boht washings showed a reduced bacterial count after two weeks of in-vivo use. The culture medium was treated only once and then after 24 hours in inhibition tests with mouth washing. At the same time, bacteria were repeatedly exposed to the effect of mouth washing for the in vivo testing for two weeks. The results were obtained after 24 hours only. It may require continuous exposure to mouth washing, especially for the Behsa and Boht, to reduce bacterial counts. Mechanical plaque controls are difficult to remove all bacteria; antibacterial mouthwashes may help additives to this effect. Antimicrobial effects were compared in three types of mouthwash in the current study.

The role of bacterial plaques was demonstrated by dental caries aetiology and by periodontal diseases.
The mechanical methods of plaque inhibition are limited; this problem is proposed to chemical methods for plaque inhibition (6). Therefore, the utilisation of mouth washing as disinfectants can help mechanically reduce plaques. Mouth washing takes place in few ways, including apoptosis, bacterial growth inhibition, metabolic inhibition of cells, and bactericidal inhibitions based on their concentration (11).

A great deal of study has shown that washing chlorhexidine’s mouth is the best way to wash the mouth. The supremacy of most studies comparing mouthwashes, with only a few studied products competing in antibacterial characteristics with chlorhexidine, has been demonstrated. Streptococci are the primary etiologic agent for tooth decay (18).

Removal of streptococci prevents plaque formation and disease spreading. In the study of S. mutans susceptibility to mouthwashes, Jarvinen et al. showed that S. mutans is resistant to antimicrobial agents. S. mutans have the highest mouthwash strength and even greater varnish resistances (19).

We also have confirmed that S. mutans are somewhat resistant to chlorhexidine. The most significant anti-caries effect of fluoride chlorhexidine was achieved using a study comparing Behsa polyphenol extracts with fluoride washes, showing its synergistic effect on microorganisms (20).

A study comparing oral-B with other mouthwashes has demonstrated greater efficacy in reducing the S. mutans by washing Boht in plaques around orthodontic brackets, indicating high antimicrobial activity mouth (14). Kin Chlorhexidine Gingspace effectively eliminates Streptococci causing decay and beneficial antimicrobial and anti-gingival effects, as they support initial plaques in these microorganisms. Studies have shown that a higher concentration of the antimicrobial effect. The main impact on the microorganism concentration is Kin gingival mouthwash (20).

The first microorganisms to develop dental caries are lactobacilli and chemical or mechanical removal. The differences between the chlorhexidine compound may lead to previous studies since different combinations have other products (21).

Streptococcus mutans are the primary etiologic agent for dental caries. It may adhere to the acquired film as the first step in plaque formation. By eliminating this bacterial species, I prevent plaque formation and caries development (7). Mechanical methods of plaque inhibition have several limitations; dental plaque inhibition techniques have therefore been suggested. The use of disinfectants to wash the mouth can help to reduce plaque. The effect of Behsa mouthwash on SM inhibition has been evaluated and compared with Boht and Kin Gingival mouthwash’s effectiveness (22).

The results showed that all three washers could inhibit SM’s spread with the highest Boht-inhibiting effect. Many oral studies in microorganisms have shown that Boht is the most appropriate gold standard for chemical treatment with SM and dental cavities. The study showed the inhibition by Boht containing mouthwash and Total Care Kin gingival of the formation of the plaques by various Streptococci species (23). They also say Boht’s mouthwash is more efficient than Total Care Kin’s gingiva mouthwash. Dental caries and pathology decreased, damaging the innocent bacterial species that competed with SM effectively inhibited by washed-in (1).

Boht’s positive effect on reducing the SM and Lactobacillus colonies has been described in the literature. Boht is a large anode and adsorbs the tooth, plaque and mucus surface and increases adsorption to the above characters by its cationic nature. The extracellular polysaccharides cause the absorption of this antibacterial mouth washing (24).

However, previous authors, contrary to this study, have shown a better effect on the Kin gingival mouthwash plankton and biofilm bacteria than Boht (diluted). Boht also decreased the number of plaques and gingivitis, but no antibacterial activity existed when Boht was diluted. In its antimicrobial activity, Boht concentration appears to play a vital role (2).
Another discovery of this study was Behsa mouthwash’s best, higher, antibacterial effect than Kin Gingival mouthwash. The essential oils available are kin gingival. The antimicrobial activity of Kin gingival against oral microorganisms has already been evaluated and has been confirmed (2).

The main flavonoids in tea are epigallocatechin-3-Gallate and epicatechin. The catechin’s anti-cancer activity may be attributed to a direct anti-bactericidal effect on SM inhibition adherence to tooth surfaces. Behsa purifies the oral cavity, and reduced dental caries affects people who drink large quantities of Behsa (8). The combination of several antibacterial agents in a single product is one way of increasing anti-plaque efficiency. In Behsa mouthwashes, the higher antibacterial effect is higher than that of Kin gingival, given confirmations from various studies on the impact of Behsa extract and Kin Gingival mouthwashes in SM (25).

The positive effect of Behsa extract on the decrease in SM and Lactobacillus colony figures has previously been demonstrated in line with this study. Contrary to current research, the use of Behsa extract mouthwash has been shown to reduce the number of oral Kin Gingival-like micronutrients and have similar implications for both mouthwash types (17). The differences in the concentration of active agents in the formulation of mouth washing can be due to the study results. Unfortunately, the manufacturer’s Behsa concentrations in the Kin gingiva mouthwash have not been reported, and studies’ attention is not similar (26).

Therefore, Boht may be used every day as the natural component is present in Behsa and the tooth’s lack of dental colour potentials (5).

**Conclusion**

The results showed just that mouthwash affects bacterial counts. Since the oral cavity for commensal species has nevertheless played a positive part, there is still discussion of the need to maintain a constantly low number of bacteria within the mouth. This study demonstrated that three types of mouthwash could reduce the number of bacteria in the oral cavity. The S. mutans proliferation was more efficient than Kin gingival due to the Behsa containing a mouthwash. But Boht was less potent than both types of mouthwash. This study helps doctors to select the best antimicrobial agent on the market. Based on this study’s findings, boht mouthwash is more effective for oral microorganisms than Kin Gingival and Behsa mouthwashes, but further clinical studies are required to confirm our findings.

Induced Hyperlipidemia in Adult Male Rats and Treated by using *Rosmarinus officinalis* Aqueous Extract

Marwa Karim Taha¹, Mohammed Salman Dalas², Ahmed Hamad Saleh³

¹Assist Lec. M.S.C. in Physiology/ Radiology Department/University of Al-Qalam College, Iraq, ²Assist. Lect M.S.C. in Cell Biology/ Dental Industry Department/University of Al-Qalam College, Iraq, ³Lect. Ph.D. in Histology/Medical Laboratory Department/University of Al-Qalam College, Iraq

Abstract

The current work was goaled to revealed anti-hyperlipidemia activity of *R. officinalis* extract. This work utilized 20 male rats that divided to negative group; positive group was given drinking water containing 0.5% H₂O₂ and (1%) cholesterol for 60 days. Third group: hyperlipidemia rats were treated with (50mg/kg/daily) extract. Fourth group: hyperlipidemia rats were treated with (100mg/kg/daily) extract. The outcomes revealed significant (P < 0.05) rise in cholesterol and triglyceride and reduce the HDL in positive group compare with negative group. Malonedialdehyied (MDA) was increased with reduce in glutathione (GSH) compare with negative group. Otherwise, diameters of aorta artery show significant (P < 0.05) rise compare with negative group. *R. officinalis* aqueous extract when used in treatment, the outcomes exhibited improvement in lipid profile, MDA, GSH and diameters of aorta artery compare with negative group. It was concluded that *R. officinalis* extract possess anti-hyperlipidemia activity.

Keywords: *Rosmarinus officinalis*; hyperlipidemia; lipid profile; malonedialdehyied; glutathione.

Introduction

*R. officinalis*, arising from the Mediterranean region is describe as aromatic plant (family: Lamiaceae)¹¹, and is called rosemary [²]. As well as to utilize in culinary side due to the feature aroma, *R. officinalis* is widely used by indigenous people [³]. The products of *R. officinalis* are utilized in testing resulting in their low toxicity and major medicinal properties [⁴]. *R. officinalis* extract composed of various types of polyphenols inclusive phenolic acids and flavonoids. These molecules show strong antioxidant properties which decrease lipid peroxidation, prevent reactive oxygen species production and suppress inflammation, and comprise from terpenoids with flavonoids, phenols and volatile oil [⁵]. *R. officinalis* is important for its therapeutic in folk medicine utilized for example like antidepressant activity, hepatoprotector activity, antidiabetic activity, antiangiogenic activity, anti-inflammatory activity and antitumor activity [⁶-⁹]. Hyperlipidemia is defined as a heterogeneous cluster of troubles characterized by an increase of lipids profile in the blood, hyperlipidemia also refers to elevate in concentrations triglycerides, and cholesterol in the serum [¹⁰]. Hypercholesterolemia may be occurring through high-fat diet or in persons with physiological defects like decreased of receptors number functioning LDL-cholesterol [¹¹].

Materials and Methods

Animal model

In this work 20 rats, (wt 140-180 gm with age 2-4 month) were used and kept on a standard diet and normal saline until beginning the experiment.

Aqueous extraction

The solution of 20% extract was prepared by utilizing boiling water (100 ml) with leaf powder (10 gm), then the mixture was centrifuged at 10000 rpm for 10 min, then supernatant of mixture was put in oven at 45ºC to dry, after that dried powder was collected and stored until use [¹²].
Experimental design

20 rats were utilized in this work and divided in four groups (each group consist five rats):

- Negative group: received normal saline only.
- Positive group: drinking water containing 0.5% \( \text{H}_2\text{O}_2 \) and (1%) cholesterol for 60 days
- Third group: hyperlipidemia rats were treated with (50mg/kg/daily) extract for 30 days.
- Fourth group: hyperlipidemia rats were treated with (100mg/kg/daily) extract for 30 days.

Biochemical measurements

Total cholesterol, triglycerides and high density lipoprotein (HDL) levels were determined using standard kits of biomereiux kit, France. Malondialdehyde (MDA) is determination based on formation of colored complex upon reaction with thiobarbutyric acid. The detection was recorded at (500 nm). Glutathione was measured according to method of [13].

Histological study

Aorta artery from all studied groups were fixed by using formalin 10% , then embedded by using paraffin. After the routine processing, paraffin sections of aorta tissue were cut into 7 μm and stained by using haematoxylin and eosin [14].

Statistical analysis

All data of present work were collected and analyzed by utilizing the SPSS version 12. Descriptive data was summarized using mean, standard error (SE). P values < 0.05 were considered statistically significant.

Results

Lipid profile

The levels of TC (283.1 ± 11.15), TG (243.83 ± 9.35) and HDL (25.92 ± 3.6) in second group show high significant changes (P < 0.05) compare with control group (94.1 ± 5.72; 78.03 ± 4.1 and 32.9 ± 2.62 respectively). The levels of TC (98.2 ± 8.63; 91.61 ± 6.51 respectively), TG (81.4 ± 4.8; 74.3 ± 5.17 respectively) and HDL (30.1 ± 4.2; 34.6 ± 5.39 respectively) in third and fourth groups show non-significant changes (P < 0.05) compared with control group as shown in figure (1).

![Figure (1): levels of lipid profile in studied groups.](image-url)
MDA and GSH

The levels of MDA (2.38 ± 0.32) and GSH (0.235 ± 0.028) in positive group show high significant changes (P < 0.05) compare with control group (1.48 ± 0.24 and 0.362 ± 0.038 respectively). The levels of MDA (1.61 ± 0.38; 1.52 ± 0.19 respectively) and GSH (0.378 ± 0.028; 0.366 ± 0.026 respectively) in third and fourth groups show non-significant changes (P < 0.05) compared with control group as shown in figure (2).

![Figure (2): levels of MDA and GSH in studied groups.](image)

Aorta diameters

Aorta diameter (72.2 ± 6.1) in positive group show high significant changes (P < 0.05) compare with control group (34.3 ± 3.5). Aorta diameter (38.17 ± 5.63; 33.28 ± 4.82 respectively) in third and fourth groups show non-significant changes (P < 0.05) compared with control group as shown in figure (3).

![Figure (3): Aorta diameter in studied groups.](image)
Discussion

The current work exhibit the role of *R. officinalis* extract to reduce the levels of cholestrel and triglyceride, aorta diameters and oxidative/antioxidant factors. In study carried out by [15] referred that *R. officinalis* extract lead to reduce the elevated cholesterol in rats that feeding on the high-fat diet (HFD) that is in agreement with outcomes of present work. Al-Sheyab et al. [16] demonstrated clearly the hypolipidemic activity of *R. officinalis* species. The lipid profile (TC, HDL, LDL and TG) showed reduction in rosemary-fed mice as compared to the HC mice. Otherwise, significant elevation of the HDL was observed in rosemary-fed mice as compared to the HC mice. Otherwise, *R. officinalis* extracts have the ability to decompose free radicals by quenching active singlet oxygen and by trapping and quenching radicals before they reach a cellular target [17] that explains the role of *R. officinalis* extract to regulate the oxidative/antioxidant factors. Also, Rosemary is also capable preventing of lipid peroxidation process that is caused by oxidative stress [18]. In addition to reducing the amount of reactive species in the body, rosemary has been found to increase the activity of antioxidant enzymes [19-20]. About the thickness of aorta and the role of *R. officinalis* extract, rosemary extract prevented weight gain by limiting lipid absorption process in the intestine. This was made possible through the prevent of pancreatic lipase activity [21]. Finally, the third study found rosemary extract to inhibit and prevent lipid synthesis via the suppression of diacylglycerol acyltransferase (DGAT) [22] that may explain the ability of rosemary extract to prevent the accumulation of lipid in tissues.

Combined Effect of Physical and Psychological Stress Exposure during Pregnancy on the Expression of Caspase-3 Cerebrum and Cerebellum of Newborn Mus musculus

Binta Dwi Novitasari¹, Hermanto Tri Joewono², Widjiati³

¹Postgraduate Student of Reproductive Health Science, Airlangga University, Surabaya, Indonesia, ²Lecturer at Department of Obstetrics and Gynecology, Faculty of Medicine, Airlangga University, Surabaya, Indonesia, ³Professor at Department of Embryology, Faculty of Veterinary Medicine, Airlangga University, Surabaya, Indonesia

Abstract

Background: Prenatal stress affects fetal development including brain development. When a stressor is felt, the brain as the main target for stress will release a hormone that stimulates the release of pro-apoptotic proteins and activate caspase-3 which acts as an executioner caspase in the cell death process. The aim of the study was to analyze the effect of combined stress during pregnancy on the expression of caspase-3 cerebrum and cerebellum of newborn Mus musculus. Methods: An experimental study using 24 pregnant mice (Mus musculus). Subjects were randomized into four groups, consisting of physical stress exposure group (forced swimming) (G1), psychological stress exposure group (noise) (G2), combination stress exposure group (forced swimming + noise) (G3), and control group (G4). Stress exposure was given on 6th-15th days of pregnancy. From each mother, three Newborn of Mus musculus were taken to make preparations from brain tissue. Immunohistochemical examination was performed to assess caspase-3 expression. Results: The study shows that the mean and standard deviation of the expression of caspase-3 cerebrum and cerebellum in the physical stress exposure group is 5.70 ± 0.99 and 5.80 ± 1.35, the psychological stress exposure group is 7.23 ± 1.39 and 7.40 ± 1.24, the combined stress exposure group is 8.67 ± 1.09 and 9.30 ± 1.12, and the control group 4.17 ± 1.18 and 3.90 ± 1.06. ANOVAs statistical test results show significant differences among groups with a value of p = 0.000 in the cerebrum and p = 0.000 in the cerebellum. Conclusion: Exposure to physical and psychological stress during pregnancy increases the expression of caspase-3 in the cerebrum and cerebellum of newborn mice.

Keywords: Caspase-3, stress, pregnancy, cerebrum and cerebellum

Introduction

Pregnancy stress not only has a negative impact on the survival of the pregnancy, it can also affect fetal development and maternal well-being. Prenatal stress affects the fetus resulting in low birth weight, prematurity, and impaired brain development (5, 21). Studies report that the prevalence of stress during pregnancy in the world ranges from 5.5 to 78%, while in developing countries it ranges from 6% to 52.9% (4, 15).

The brain is the main organ that interprets, responds to, and becomes the target of stress marker hormones (14). When a stressor is felt, the hormone (CRH) which acts on the anterior pituitary to promote the secretion of adrenocortico-tropic hormone (ACTH). This hormone then stimulates the adrenal cortex to release glucocorticoids (GCs) into the bloodstream (8). High glucocorticoids will reduce BDNF expression and stimulate cell apoptosis (18).

Caspase-3 acts as the executioner caspase in the cell apoptosis process (12). Caspase-3 when activated has the function of controlling cell death (20), causing cleavage of protein kinases, cytoskeletal proteins, DNA repair proteins, endonuclease inhibitory subunits and ultimately to deterioration of cellular function (9).
Increased apoptotic activity of brain cells will reduce the number of cells making up the central nervous system in the fetal brain where there are two main types of cells that make up the central nervous system, namely neurons and glial cells (9). The cerebellum is a part of the brain that contains more neurons than other parts of the brain (7), the cerebrum and cerebellum are interconnected by means of polysynaptics, forming a system related to cognitive function and neuropsychiatric disorders (1). There is little literature and researches on the impact of stress and neurobehavioral studies on the impact of stress on the cerebrum or cerebellum.

This study identifies differences in caspase-3 expression in the cerebrum and cerebellum of newborn mice (Mus musculus) whose mothers are exposed to physical and psychological stress during pregnancy.

Materials and Methods

This research is an experimental study on mice (Mus musculus) which was conducted from January to March 2021 at the Laboratory of the Faculty of Veterinary Medicine, UNAIR, Surabaya. This study used 24 adult female mice (Mus musculus) aged 2-2.5 months of pregnancy which were exposed to stress during pregnancy on the 6th until 15th days of pregnancy. The research subjects were divided into 4 groups which were randomly selected (G1, G2, G3, and G4) with 6 mice in each group.

First group: Exposure to physical stress in the form of forced swimming for 5 minutes once a day in a special box measuring 50x30x25 cm filled with water with a height of 18 cm with a water temperature of 24 °-28°C and put in a dark box cage, exposure time is 09.00 am.

Second group: The group of exposure to psychological stress by giving noise with an intensity of 90 dB once a day for 1 hour successively in a dark and soundproof enclosure measuring 1x1x2 m, TrueRTA software (real time audio analyzer) was used to produce noise. Noise intensity was measured with a real time sound analyzer (TES 1358) each day prior to exposure to experimental animals, by placing the analyzer in animal cages at several locations, and taking the average of the different readings.

The third group: The stress exposure group, a combination of physical and psychological, was given a noise of 90 dB for 1 hour, then given a break of 5 minutes and then be swam for 5 minutes per day, exposure time starts at 09.00 am.

Fourth group: Control group with standard treatment without stress exposure.

Sampling Inspection

Mus musculus mothers were anesthetized then the pups were born by sectio caesarea (SC) on the 16th day of pregnancy. The pups of Mus musculus which were to be sacrificed were anesthetized first, and then the cranium was cut in the sagittal direction from caudal (occipital) to rostral (frontal), right between the two hamisters of their brain. Furthermore, the brain was released. The separated brain was weighed, and then put in a 10% formalin solution for organ preservation; the cerebrum and cerebellum were taken. Furthermore, immunohistochemical preparations and Hematoxylin-Eosin (HE) staining were made.

Data Analysis

To see the normality of the data, the Shapiro-Wilk test was used. If the data obtained are normally distributed, then the ANOVA test is used followed by LSD (Least Significant Difference) to see the differences in all groups. If the data obtained are not normally distributed, the Kruskall Wallis test and the Mann Whitney test are used. This study uses a significance level of P<0.05. To simplify statistical calculations, researchers used the SPPS tool version 21.

Results and Discussion

Results

The results show the highest expression of caspase-3 in the cerebrum and cerebellum in the combination of physical and psychological stress exposure group compared to the physical stress exposure group, psychological stress exposure group, and the control group (Table 1). The results of the normality test using
the Shapiro-Wilk test on the treatment group obtained a significance value (p-value)> 0.05, which means that the data distribution is normally distributed, so the Analysis of Variance (ANOVA) test was used to test whether there were differences in the treatment groups on the expression of caspase-3 in the cerebrum and cerebellum.

Based on the ANOVAs test results in table (2), it is known that there are significant differences among the groups in the expression of caspase-3 in cerebrum and cerebellum of newborn *Mus musculus*.

The combination of physical and psychological stress exposure group (G3) is the strongest among the physical stress group (G1), psychological stress group (G2), and the control group (G4). The expression of caspase-3 in the control group is the weakest. IHC is with a magnification of 400 times.

Discussion

The developing brain is the most sensitive organ to the effects of stress during the prenatal period, due to
substantial changes in structural growth and connectivity during fetal life (2). During the gestational period, there are processes of proliferation, differentiation, migration, and aggregation of fetal neurons which are strongly influenced by environmental factors (2). Prenatal stress exposure shows a long-term effect that includes both behavioral and molecular changes (6, 13).

When a stressor is felt, the hypothalamus will release the hormone cortisol. During pregnancy, fetal exposure to maternal cortisol is limited by the placental enzyme 11β-HSD-2 which functions to convert cortisol to cortisone, an inactive glucocorticoid (17). High glucocorticoids under stress reduce placental expression of 11βHSD2 which is associated with intrauterine growth restriction (19).

In acute stress, the binding of glucocorticoids and glucocorticoid receptors increases the tissue-plasminogen activator (tPA) which helps in the process of converting proBDNF to mature BDNF (mBDNF) and increases proteolytic processing of proBDNF in mBDNF which can increase BDNF levels during stress, but in chronic stress due to decreased tPA hence the process of proBDNF to mBDNF is inhibited and BDNF expression is reduced. If proBDNF is not processed into mBDNF then proBDNF will bind more highly to the p75NTR receptor which induces a pro-apoptotic signaling pathway (3). The proBDNF binding to the p75NTR receptor will activate the apoptotic pathway through the co-receptor bond, namely sortilin. Sortilin will activate jun-N terminal kinase (JNK) which will then phosphorylate C-Jun which will activate pro-apoptotic proteins such as p53, Bad, BIM, BAX so that it will stimulate mitochondria to release cytochrome-C which then activates caspase (12).

It is known that there are two types of caspases that have been identified, namely the initiator caspase and the effector / executioner caspase. Caspase 8 and 9 are the initiator caspases, while caspase-3 is the effector / executioner caspase (22). Caspase executioner mediates cell death during apoptosis, caspase-3 has the ability to partially cleave caspase substrates and its activity is required to induce cell death (10).

The results of our study indicate that there are significant differences in the expression of caspase-3 in cerebrum and cerebellum of newborn mice among treatment groups. Combined stress exposure show the strongest expression of caspase-3 compared to the physical, psychological, and control stress exposure groups. This finding is supported by a study by Qiao Y et al in 2020, where the combination of stress exposure caused significantly more hyper-activity of the HPA system as indicated by increased serum cortisol, CRH and ACTH levels (16).

High caspase-3 expression can cause an increase in apoptotic activity of brain cells and will decrease the number of cells making up the central nervous system in the fetal brain (9). A study conducted by Kinsella et al in 2009 shows that chronic stress during the prenatal period interferes with fetal neurodevelopment. Sandman et al found that prenatal stress impaired cognitive performance during infancy and decreased brain volume (11).

**Conclusion**

Stress exposure during pregnancy increases the expression of caspase-3 in cerebrum and cerebellum of newborn *Mus musculus*.

Correlation between *Cryptosporidium parvum* and *Helicobacter Pylori* Infections in Gastrointestinal Patients at Wasit Province

Abdulsada A. Rahi¹, Safa A. Fadhil²

¹Prof, Post Doctorate, ²Research Scholar, Department of Biology, College of Science, Wasit University, Kut, Iraq

Abstract

The present study aimed to identify the relationship between *Cryptosporidium parvum* parasite and *Helicobacter pylori* in patients at Wasit province and its environs. One hundred stool samples were collected (male and female) from suspected diarrheal patients of parasitic and bacterial infection during the period October 2020 to April 2021 who attended to Al-Karamah Teaching Hospital at Wasit province and General Hospital of Martyr Fairuz at Hay district.

The investigation of the oocysts of the *Cryptosporidium parvum* parasite was carried out by staining with Modified Ziehl Neelson method and also detecting of *Helicobacter pylori* by using dipstick. The results of our study revealed that 55(55%) was positive for *C. parvum* and 48 (48%) was positive for *Helicobacter pylori* and the co- infections between the parasite and bacteria reached to 32(32%). The age group(1-20 years) showed the highest11 (11%) prevalence rate while the lowest prevalence was in patient with age group (21-40 years) reached to 6(6%) interplay infections between the parasite and bacteria.

Keywords: Direct smear, Modified Ziehl Neelson, Cryptosporidium parvum, Helicobacter pylori, dipstick.

Introduction

*Cryptosporidium* is a small protozoan parasite that infects microvillus region of epithelial cells in the digestive tract of vertebrates. It is an obligate intracellular parasite of man and other mammals. Environmentally robust oocysts are shed by infected hosts into the environment, these oocysts can survive the adverse conditions on the environment for months until it is using resources of the host [1]. Cryptosporidiosis is considered as emerging pathogen by CDC, the disease is mostly asymptomatic and not noticed but might be presented with fever and mild to severe diarrhea which is self-limiting in immunocompetent individuals [2].

*Helicobacter pylori* is a Gram-negative bacterium that can infect the human stomach. Its significance for human disease was first recognized in 1983. The bacterium lives in the lining of the stomach, and the chemicals it produces causes inflammation of the stomach lining. Infection appears to be lifelong unless treated with medications[3]. Among the commonest prevalent diseases worldwide were intestinal parasitosis [4]. These infections included intestinal protozoa; *Giardia lamblia* and *Cryptosporidium spp*. that proved to have a serious impact on children [5]. In addition, *H. pylori* may support *Cryptosporidium spp*. and *G. intestinalis* colonization in human gastro-intestinal tract by producing urease enzyme to overcome gastric acidity [6]. On the other hand, gastrointestinal parasitic infection may affect inflammatory response to *H. pylori*. This significant co-existence may suggest that *H. pylori* could be a risk factor for intestinal parasitic infection or vice versa[7]. This study aimed to evaluate co-infection prevalence of *Helioabacter pylori* in symptomatic patients with intestinal protozoa causing diarrhea *C. parvum* of Al-karamah Teaching Hospital at Wasit province and General Hospital of Martyr Fairuz at Hay district.

Materials and Methods

A total of 100 stool samples collected from suspected patients suffering from Cryptosporidiosis (strong to moderate diarrhea) and *H. pylori* symptoms like burping feeling of bloating nausea heartburn loss of appetite fever unexplained weight loss difficulty swallowing. The samples were collected from suspected patients attended to Al-karamah Teaching Hospital at Wasit province and General Hospital of Martyr Fairuz at Hay district during the period October 2020 to April 2021. The stool samples were collected in clean and label plastic containers and examined by Modified Ziehl-Neelsen stain for staining fecal smear has been the gold standard for detecting *Cryptosporidium* oocysts. This method is commonly used in clinical microbiology laboratories to easily identify *Cryptosporidium* oocysts. Although the concentration and staining procedures are time-consuming [8], Fecal antigen test (FAT) (SAT - stool antigen test) detects *H. pylori* antigen in feces using an immunoassay sensitivity: ~95% [9].

Statistical analysis

Statistical analysis: The statistical analysis was performed using SAS (Statistical Analysis System-version 9.1) [10].

Results:

A total of 100 stool samples collected from suspected patients suffering from Cryptosporidiosis (strong to moderate diarrhea) and *Helicobacter pylori* symptoms which collected from patients attended to Al-karamah Teaching Hospital at Wasit province and General Hospital of Martyr Fairuz at Hay district. Samples of feces were stained using Modified Ziehl-Neelsen and examined under microscope for detection of *C. parvum*. Also, the stool was examined by dipstick to detect the presence of *Helicobacter pylori* antigen. In (table-1) show out of 100 samples were detected 55% (55/100) of stool samples which considered as a positive result for *C. parvum*, while 45 (45/100) were negative also 48% (48/100) which considered as a positive result for *H. pylori* while 52(52/100) was negative. While the rate of co-infections between the *C. parvum* parasite and the *H. pylori* bacterium was 32(32/100).

Discussion

*Cryptosporidium parvum* is a zoonotic protozoan parasite that mainly affects the ileum of humans and livestock, with the potential to cause severe enteric disease [11]. And when staining with modified Ziehl–Neelsen stain digested *Cryptosporidium* spp. oocysts appear as bright red sphere (4 to 6 mm) containing four crescent-shaped sporozoites (which may or may not be seen) in all oocysts [12]. Cryptosporidiosis remains a debilitating disease in third world countries, particularly in infants and young children, in whom it is associated with chronic diarrhea and malnutrition [13]. There was a strong correlation between age distribution of diarrhea and the occurrence of *C. parvum*, between the ages of 3 and 36 months [14]. This agreement with our study that documented prevalence of *C. parvum* infections among people living in Wasit province, Iraq which was the rate of infections higher among patients with age group (1-20). And disagreement with study of *C. parvum* dispersal in children in Ramadi province which showed more infection were at age (1-12) months [15]. Worldwide more than 50% population is infected by *H. Pylori* gram-negative bacterium, the infection rate is much higher in developing countries due to the lack of hygiene and sanitation [16]. The prevalence of the bacterium is higher among middle-aged adults [17]. This study agreement with our study which indicated that the largest infection rate was recorded in the age group (1-20) years old. The prevalence of *H. pylori* shows more than 80% of the population is *H. pylori* positive, generally it is consider ably lower in children and adolescents than in adults and elderly people [13]. This is not in line with our study, as the results showed that the age group most affected by is the *H. pylori* category of adults and children, and this is due to the lack of hygiene and health awareness among many of them. The current study also revealed the existence of a relationship between the presence of *C. parvum* and *H. pylori* in patients suffering from diarrhea, and their percentage was about 32 out of a total of 100 samples, this agreed with study which revealed that more than half of cryptosporidiosis (60%) and giardiasis (58%) cases coexisted and showed a duplicated risk for *H. pylori* [18], which was among its statistical results found a rate of 5.3% with a significant statistical association between *H. pylori* infection and *Cryptosporidium* [19]. This is also consistent with our current study. While there are studies that do not agree with our current study, in Modifaid Ziehl-Neelsen staining, acid-fast parasites were never observed in patients infected with *H. pylori* [20]. There are some studies suggest that interaction between resident bacteria and invading *C. parvum* is not pathogenic, but rather synergistic [21]. And it was among the studies that did not correspond to our study is diagnosis of intestinal protozoan infections in patients in Cuba where confirmed the absence of information about co-infections between protozoa and bacterial, viral pathogens [22]. As for the relationship between gender and the rate of infection with the *C. parvum*, the current study showed that males are the most infected, as the percentage is 35(35%), while females were 26(26%), and our study corresponds to the study of Zhang which showed *Cryptosporidium* infection in males more than females [21]. While Salman mentioned in his study marked by prevalence of *Cryptosporidium parvum* among Iraqi displaced people in Kirkuk that there are no significant differences in infection for both genders as the infection rate higher frequency of males and females, respectively, is 22.66%, 21.2 by using MZN method [24], this is inconsistent with the current study. A study was also conducted in Nigeria on *Cryptosporidium* infection, which showed the rate of infection was higher among females (27%) than males (17%) among adults [25]. And this does not correspond with our current study, which showed that the rate of infection in males is higher than that of females. As for *H. pylori*, the results do not differ much in this study from the results of infection with *C. parvum*, as it has also shown that the rate of infection of males with *H. pylori* infection is higher 26(26%) than that of females 22(22%), this agreed with Rodrigues study about *H. pylori* infection which showed the frequency of infection was higher among men (33.4%) rather than women (30.7%) [26]. Whereas, other studies showed that the infection rate for females is higher than males, like the study Şeyda, which was among its results *H. pylori* positivity was 67.7% in males and 68.2% in females [27] and Almadi studies that showed the prevalence rate between male and female students (34 % and 38% respectively) [28]. While other studies showed that no differences were found between
males and females\textsuperscript{29}. These studies are not compatible with this study currently in force.

### Conclusion

Our study revealed that the prevalence rate of infection with \textit{C. parvum}, \textit{H. pylori} and co-infections with bacteria and parasite was respectively 55 (55\%), 48 (48\%) and 32 (32\%) and higher infection found in age group (1-20) years in patients at Wasit Province.

Relationship between *Cryptosporidium parvum* in Water And Diarrheal Infections at Wasit Province

Abdulsada A. Rahi¹, Safa K. Alwan²

¹Prof, Post Doctorate, ²Research Scholar; Department of Biology, College of Science, Wasit University, Kut, Iraq

Abstract

The present study aimed to identify the relationship between *Cryptosporidium parvum* in water and diarrheal infections at Wasit province. One hundred stool samples were collected (male and female) from suspected diarrheal patients of parasitic infection who attended to Al-kut hospital and Al-karamah teaching hospital at Wasit province and fifty water samples were collected from different points at Dijlah river; Household water supply and Kut Liquid water during the period from October 2020 to April 2021. The investigation of oocysts of the *Cryptosporidium parvum* parasite carried out by staining with modified Ziel Neelson method. The results of our study revealed that 60(60%) was positive for *C.paravum*. The age group (1-5) months showed the highest 12(12%) prevalence rate while the lowest prevalence was in patient with age group (>20) months reached to 1(1%).

Keywords: Water ,Stool, Modified Ziehl Neelson ,Cryptosporidium parvum, Human

Introduction

*Cryptosporidium* is a coccidial protozoan parasite Which can infect a widely variety of vertebrates and not seem to be host specific [¹]. *Cryptosporidium parvum* is a common enteric protozoan parasite of humans and other species that contract young farm animals (calves, lambs, goats) and pets (kittens, puppies). It is can be found worldwide in virtually every human Society. The prevalence of infection varies widely but seems to be highest in young children and immunocompromised persons [²]. In the other hand the infection in immunocompetent persons is self-limited[³]. *Cryptosporidium* oocysts are spherical (in *C. parvum* about 3 to 5 lm in diameter) and are subtract in numbers of up to 105 to 107 oocysts per g in hurry feces. It particularly oversensitive to cryptosporidiosis. In children younger than 5 year [⁴] developing countries, *Cryptosporidium* is cause of diarrheal disease in humans, and several groups of humans are infections occur frequently Cryptosporidiosis is an opportunistic parasitosis. It is characterized by self-limiting gastroenteritis in otherwise healthy humans, but it is more severe in immunocompromised in HIV-infected patients and constitutes a serious life threatening leading to chronic or fulminant disease, wasting and death [⁵]. The present study aimed to identify the relationship between *Cryptosporidium parvum* in water and diarrheal infections at Wasit province.

Materials and Methods

A total of 100 stool samples were collected from suspected patients suffering from Cryptosporidiosis (strong to moderate diarrhea). The samples were collected from suspected patients attended to Al-kut and Al-karama teaching hospital and fifty water samples were collected from different points at Dijlah river; Household water supply and kut Liquid water at Wasit province during the period from October 2020 to April 2021.

The stool and water samples were collected in clean and label plastic containers and examined by Modified Ziel Neelson stain for staining fecal and water smear has been the gold standard for detecting *Cryptosporidium* oocysts. This method is commonly used in clinical microbiology laboratories to easily identify *Cryptosporidium* oocyst.
Result

A total of 100 stool samples were collected from suspected patients suffering from Cryptosporidiosis (strong to moderate diarrhea). The samples were collected from suspected patients attending Al-kut and Al-karama teaching hospital and fifty water samples were collected from different points at Dijlah river; Household water supply and Kut Liquid water at Wasit province were stained using Modified Ziel Neelson stain and examined under microscope for detection of *C. parvum*. The result shows that 60 samples were positive for *C. parvum* which means 60% while the rest of the samples (40) were negative which means 40% as shown in table 1.

Table 3. Distribution of positive water samples with *C. parvum* infection
Discussion

The results of the present study recorded the prevalence rate of Cryptosporidium parvum collected from suspected diarrheal patients of parasitic infection who attended to Al-kut hospital and Al-karamah teaching hospital at Wasit province.

Table -2 showed that males are more likely to be affected than females by the rate 32% while females were 28%. This may be due to that males at this age possibly are more exposed to C. parvum oocysts because of their more activities than the females. Our results were disagreed with Fatimah, (2013) in Sulaimani which were 15.5%, 14.8% respectively[6]. Abdulsadah, (2013) showed the rate of male that infected with C.parvum was 33.74% which is somehow agreed with our data 32% [7]. Also, the results of the current study were disagreed with Tumwine, (2003) in Uganda [8], Abdel-Messih, (2005) in Egypt [9], and Ali, (2014) in Iraq [10].

The results of present study revealed that the hight rate of C. parvum infection 26(26%) was recorded in the age group ( more than 20 months) This result agreed with the results of Mumtaz et al., (2010) [11] which was(27.8%) and El-Helaly et al., (2012) in Egypt[12], but it disagreed with the results of the studies that were carried out in Iran by Khalili and Mardani (2009) [13] which was (43.3%) and Abdulsadah et al., (2013) (30.83%) [7]. There was a strong correlation between age distribution of diarrhea and the occurrence of C. parvum, between the ages (6 month to 3 years) at a rate of (15.6%) by Ali et al., (2013) [14] with our study 16% age group (1-5 months). Also In the age group (1-5months) agreed with Saneian et al., (2010) [15] Cryptosporidium oocysts were detected in 12.5%. Mismatch of readings could be due to the number of samples or geographical location.

In the other hand water samples were collected from various areas of Kut city and C. parvum infection was recorded (28%) in tap water which quite agreed with ul Akbar,(2015) in Pakistan which was 25% [16]. Rivers samples were recorded 4% which disagreed with Franco, (2001)which reported 30% [17] and Yang,(2008) [18]. There are some many factors affecting the prevalence competing Interests: location of sampling, the diversity of animals in the areas, season, climatic condition, volume of sample, the population of the animals in the areas and rainy seasons etc. So the transmission of C. parvum is different in emerging countries than that of developed countries [19].

Conclusion

Our study revealed that the prevalence rate of infection with C.parvum was 60 (60%), and higher infection found in age group (months <20) in patients at Wasit Province. While the prevalence rate of C.parvum infection in water sources was 26 (52%).

Detection of *Cyclospora cayetanensis* by PCR in Wasit Province, Iraq

Abdulsada A. Rahi¹, Israa N. Abed Al-Saadi², Yoosra N. Abed Al-Saadi²

¹Prof, Post Doctorate, ²Research scholar; Department of Biology, College of Science, Wasit University, Kut, Iraq

Abstract

The present study aimed to detect the *Cyclospora cayetanensis* among patients that attended in Al-karama Teaching Hospital and General Hospital of Martyr Fairuz in Wasit City. The sample were collected from October 2015 to April 2016. Thirty stool samples were collected from patients that suffering from diarrhea, their aged between 1 year to 50 years old from both genders who attended the hospitals at Wasit province. Data was collected using a questionnaire form including information about gender, age, location. Stool samples were examined by PCR technique to detect the presence of *Cyclospora cayetanensis*. The result showed that 8 of 30 (26.7%) samples were positive while 22 of 30 (73.3%) were negative. Our study is considered as a first study that detect the *Cyclospora cayetanensis* in Wasit province, Iraq. This study was aimed to determine the prevalence of *C. cayetanensis* in Wasit Province, Iraq.

Key words: *Cyclospora cayetanensis*, Stool, PCR, Human.

Introduction

The risk of exposure to exotic and uncommon tropical diseases has increased in parallel with the globalization of the food supply, increased consumption of fresh foods, and increased travel. The rapid transport of fresh fruits and produce from developing countries has increased the chance that endemic parasites from other regions may come into contact with consumers from industrialized nations. Changes in nutritional habits have resulted in increased consumption of undercooked or raw foods, thus potentially exposing consumers to parasites that proper food processing would otherwise reduce or eliminate (¹). *Cyclospora* is obligate intracellular apicomplexan protozoan parasites that infect the mucosal epithelium of the small intestine or bile duct of a variety of hosts, mostly vertebrates (²). *Cyclospora* was first identified as a human pathogen in three patients from Papua, New Guinea and concluded that they could be a coccidian of the genus *Isospora* (³). In recent years, *Cyclospora cayetanensis* has consider as an important human pathogen that causes diarrhea in both immuno-compromised and immunocompetent hosts. In the later, diarrhea is usually prolonged, but self-limited, while in immuno-compromised, it may be prolonged and severe (⁴). It differs significantly from all other *Cyclospora* species not only in its host but also in its oocyst stage, which is much smaller and spherical rather than oblong (⁵,⁶). The route of transmission is by ingestion of contaminated water and food products with sporulated oocysts, especially vegetables that are the most implicated source for the spread of cyclosporiasis (²). It is unlikely transmitted directly between individuals. The infection dose is presumed to be low (⁷). In view of this, the present study was designed for the detection of *Cyclospora cayetanensis* by PCR in Wasit province, Iraq.

Materials and Methods

**Stool Collection.**

A total of 30 stool samples were collected from
patients that suffering from diarrhea in Al-karama Teaching Hospital and General Hospital of Martyr Fairuz in Wasit city. The sample were collected from October 2015 to April 2016. The fecal sample was placed to a clean, dry plastic container and transported to the laboratory for analysis.

**Stool DNA Exteraction**

Genomic DNA was extracted from stool samples by using (Stool DNA extraction Kit, Bioneer. Korea). The extraction was done according to company instructions by using stool lysis protocol method with Proteinase K (8). After that, the extracted gDNA was checked by Nanodrop spectrophotometer, and then stored at -20°C until used in PCR amplification.

**Convention PCR**

PCR technique was performed for specific detection *Cyclospora cayetanensis* based on subunit ribosomal RNA gene (ITS1 region) from human stool samples. This method was carried out according to (9). The primers were provided by (Bioneer company.Korea) (Table-1). PCR reaction solution was prepared by using (AccuPower PCR PreMix Kit) according to company instructions with the volumes (Table -2).

Discussion

The first record of *Cyclospora* in Arabic countries was in Basra/Iraq where three diarrheic cases have been observed by (11). The laboratory diagnosis of recently recognized infectious agents, such as *Cyclospora cayetanensis*, is frequently problematic because of lacking of required detection techniques (12). Microscopy is mostly a monotonous procedure and take long time that may lead to extreme tiredness for the analyst and incorrect negative results, but PCR assay is more valuable for identification of *Cyclospora oocysts* (5). Therefore, the PCR assay for 18S rRNA gene is highly sensitive and specific, it was also capable of overcoming many errors of microscopic diagnosis (13). Infection rate of *Cyclospora cayetanensis* obtained in this study was agreed with other previous studies reported in Egypt (14) and (15) that were (24.5%) and (25%) respectively using PCR test. The results of this study were approximate to (16) who recorded (38%) positive results in the PCR *Cyclospora* test in India. The prevalence of Cyclosporiasis were reported in India (13) who found the prevalence rate of *Cyclospora cayetanensis* was (89%), while Mundaca’s study (17) recoded 57.1%in Lima and Peru this results observing that the prevalence was highest in India because *Cyclospora cayetanensis* endemic in India , and it appears to be the more common disease in tropical and sub-tropical countries whereas this protozoan is endemic in Haiti, Guatemala, Peru, and Nepal. The prevalence of *Cyclospora cayetanensis* is higher in developing countries than in Europe and North America, this parasite cause diarrhea infection in voyagers who provide the more extensive facts about *Cyclospora* infection (18,13). Typically, the Cyclosporiasis infection has been related to international consumption of imported fruit and vegetable, which may be the reason that led to existence of 26.7% Cyclosporiasis infection in our current study. The investigations of Cyclosporiasis prevalence in developing countries, which the studied area is one of them, have listed some reasons of infection including numerous variables such as region of study, sanitary conditions, season, and individual properties (age, term of stay in the territory, socioeconomic status, probability of prior *Cyclospora* infection, and immunocompetence) (19).

Conclusion

PCR is considered as an alternative tool in epidemiological studies and the diagnosis of *C. cayetanensis*. The results showed that the PCR is sensitive
test to obtained *C. cayetanensis* in stool samples.

Epidemiological Study of Cutaneous Leishmaniasis in Wasit Province

Abdulsada A. Rahi 1, Zainab K. Hashim 2, Ali Mohsin Al-Jamea 3
1 Prof, Post Doctorate, Department of Biology, College of Science, Wasit University, Iraq
2 Research scholar, Department of Biology, College of Science, Wasit University, Iraq
3 Research Scholar, Dermatologist, Al- Karamah Teaching Hospital, Directorate of Wasit Health, Iraq

Abstract

The present study was conducted to detect the cutaneous Leishmaniasis from a total of suspected cases that were collected from dermatology center of AL-Karamah Teaching Hospital in Al-Kut city from 1st October 2019 to the end of February 2020. Totally 60 patients were included 36 males and 24 females. The collected skin specimens were smeared and stained with Giemsa stain, then examined by microscope under oil immersion lenses. The results of current study appeared that 56(93.3%) were positive amastigotes, The prevalence of CL were 36 (60%) in males and 24(40%) in females, while the highest infection 36(60%) in rural area and lowest 24(40%) in urban area. The percent of infection with Cutaneous leishmaniasis according to type of lesions recorded were equal in dry and wet ulcers type (50 %) for each one.

Keywords: cutaneous leishmania, Giemsa, Leishmania major, Leishmania tropica

Introduction

Leishmaniasis is an old protozoan parasitic disease that is caused by Leishmania species. The infection is widespread in approximately 100 countries, and more than 10 million people are infected with the parasite. Additionally, 350 million people are at risk of acquiring the infection (1,2). Leishmaniasis can present itself in three forms: cutaneous leishmaniasis (CL), mucocutaneous leishmaniasis (MCL), and visceral leishmaniasis (VL) (3). The spread of Cutaneous leishmaniasis is linked to multiple economic and environmental factors such as population growth, population migration, population expansion, and agricultural activity. Population movement and rapid urbanization projects and the invasion of disease-endemic areas are the most important factors in the emergence and survival of the disease (4).

The disease is endemic in 88 countries of 5 continents with a total of 350 -million people at risk and 12 million cases. Among the 88 endemic countries, 22 are in the New World and 66 in the Old World with an estimated incidence of 1- 1.5 million cases of cutaneous leishmaniasis (CL) and 500, 000 cases of visceral leishmaniasis (VL) (5).

Cutaneous leishmaniosis in Iraq has 2 forms, zoonotic cutaneous leishmaniasis (ZCL), which is mainly caused by Leishmania major, and anthroponotic cutaneous leishmaniasis (ACL), which is mainly caused by Leishmania tropica (6).

In recent decades conventional identification and taxonomic procedures for Leishmania microscopic examination slides, geographic distribution, clinical manifestations, pathogenic features, and culturing patterns were identified and categorized. These lack the necessary precision because there is a high similarity among species that makes the morphologic identification difficult, and also there are epidemiologic distributions for multiple Leishmania species coexisting in both nonendemic and endemic areas (7).
The study aimed to identify some epidemiological factors accompanying the spread of Cutaneous leishmaniasis in Wasit province which includes gender, types of skin lesion and residence of patients.

**Material and Methods**

**Population study**

This study was carried out during the period from 1st October 2019 to February 2020 in Al-Karamah teaching hospital of Kut city, Iraq. A total of 60 skin samples were taken from suspected patients with CL. Samples were taken from the skin leishmanial lesion, smear samples are taken from the active edge of the leishmanial lesion, presumably due to the maximum number of parasites in the active edge (8). After the smears dried completely, they were fixed with 100% methanol, allowed to dry again, and stained with Geimsa stain for microscopic examination under oil immersion lenses for presence of amastigotes (9).

**Results and Discussion**

**Table (1): Microscopic examination of Leishmania parasite in skin lesions by Giemsa stain**

<table>
<thead>

<tr>
<td>Microscope examination</td>
<td>60</td>
<td>56</td>
<td>93.3</td>
</tr>
</tbody>
</table>

Microscopy was positive in 56 (93.3) samples for amastigotes of *Leishmania* presence. Our result was in agreement with what was reported by (16) that found (80.7%) was positive, also agreed with another study that found (83.3%) was positive in the direct microscopic examination (17).

**Table (2): Gender characteristics of patients enrolled in the present study**

<table>
<thead>
<tr>
<th>Gender</th>
<th>No. (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Male</td>
<td>36 (60%)</td>
</tr>
<tr>
<td>Female</td>
<td>24 (40%)</td>
</tr>
</tbody>
</table>

Male: Female ratio 1.5

The results of this study showed the percent of infection in males were about (60%), while female was (40%), the percent of infection in males were higher than females as shown in table (2). The reason of higher infection take out in males more than females, possibly, due to the high incidence of working or sleeping males in open areas (surfaces of houses) with less coverage of body as well as more exposure to infected vectors compared with the females (10). Some studies have hypothesized that the gender difference observed in some parasitic disease can be attributed to hormonal effects (11). However, controversy still exists regarding the role of sex hormones in the cellular immune response (12,13). On the contrary of other studies that found the higher incidence of infection among females than males (14-16).
Table (3) : Residency of patients enrolled in the present study

<table>
<thead>
<tr>
<th>Residency</th>
<th>No. (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rural</td>
<td>36 (60%)</td>
</tr>
<tr>
<td>Urban</td>
<td>24 (40%)</td>
</tr>
<tr>
<td>Total</td>
<td>60 (100%)</td>
</tr>
</tbody>
</table>

This study showed that 60% of CL infection were appeared in rural region while in urban region 40%, this study reported the significant prevalence of CL in urban region more than in rural region. This study agreed with Wisam and Yisnnh, (2007) who finding the rate of infection in urban region was lower than rural region (17). Also, our results disagreed with Abdulsada, (2014) who finding that the higher infection in urban areas than rural areas (18).

Table (4) : The distribution of patients according to the type of CL lesions

<table>
<thead>
<tr>
<th>Type of CL Lesion</th>
<th>No.</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dry</td>
<td>30</td>
<td>50%</td>
</tr>
<tr>
<td>Wet</td>
<td>30</td>
<td>50%</td>
</tr>
</tbody>
</table>

Nodule dry type lesions (ACL) were present in (50%), while the ulcerative wet type lesions (ZCL) were present in (50%). The results of study showed that percentage of dry type are equal to wet type. This result was disagreement with the results of (19-23) who mentioned that wet type more finding than the dry type.

Conclusions

Cutaneous leishmaniasis lesions affecting both sexes, but male is more prone to infection than female, patients from rural areas appeared high infection of cutaneous leishmaniasis.

Co-infection between *Entamoeba histolytica* and *Helicobacter Pylori* in Patients at Wasit Province

Abdulsada A. Rahi¹, Sima’a H. Mohammed², Magda A. Ali³
¹Prof, Post Doctorate, ²Research Scholar, ³Research Scholar, PhD, Department of Biology, College of Science, Wasit University, Iraq

Abstract

The current study was conducted at Wasit province, Iraq during the period from 28 October 2020 to 28 December 2020. The study included one hundred stool samples taken from questionable patients of *Entamoeba histolytica* and *Helicobacter pylori*. Samples were collected from patient attended to General Hospital of Martyr Fairuz at Hay district, Saeed Health center and Hospital of Al-Kut. All samples have been checked using direct smear lugol’s iodine stain for *Entamoeba histolytica* and dipstick for *Helicobacter pylori*. The result showed that 40 samples (40%) out of 100 patients were gave positive by rapid test cassette; females 23 (23%) positive samples and males 17(17%). While 14 samples (14%) out of 100 samples were positive for *Entamoeba histolytica*. The highest infection in females 8(8%) and the lowest in males 6(6%). The result showed 10 samples (10%) out of 100 patients positive for both *E. histolytica* and *H. pylori*. The highest infection was recorded in females 6(6%) and the lowest in males 4(4%).

The highest infection of *H. pylori* in age group (39 and more) years ; females recorded 6(6%) and males recorded 6(6%), while the lowest infection in group (>1) years old ; females recorded 1(1%) and males recorded 1(1%). The infection rate of *Entamoeba histolytica* was highest in age group (1-13) years old ; females was recorded 1(1%) and males was recorded 4(4%) , while the lowest in age group (26-39) years old ; females recorded 1(1%) while males without infection. Infection with both *E.histolytica* and *H.pylori* was recorded the highest in group (39 and more) years old ; females was recorded 3(3%) and males was recorded 2(2%) while the group (>1) years old do not recorded infections.

Keywords: *Entamoeba histolytica*, *H. pylori*, Dipstick, Lugol’s iodine stain, Human, Stool

Introduction

A parasite is an organism that cause harm in its host. *E.histolytica* was first described by Fedor Losch in 1875 in St. Peters burg, Russia. cause anemia in pregnant and children. The spread of intestinal parasites differ from one region to another and its spread related to many factors such as geographical factors, climate, poorness, malnutrition, personal clean less and other factors. One trophozoites of *Entamoeba histolytica* reach the host intestine can damage the mucosa epithelial layer and prevalence through the sub-mucosa and the lamina propia and other tissues. Infection of the gastrointestinal tract include two distinct clinical entities: *Helicobacter pylori* the causative of gastric infection this bacteria was first isolated by Warren and Marshal in 1983. And *Entamoeba histolytica* the causative agent of inflammation of the gastric and intestinal mucosa. *Entamoeba histolytica* cause the human amoebiasis is endemic in most tropical and sub-tropical countries and it the causative agent of the dysentery. *Helicobacter pylori* (*H.pylori*) are gram-negative bacilli responsible for chronic gastritis. It has been known for more than a century are present in human’s stomach. The epidemiology of the *Helicobacter pylori* changing with...
parallel decline in peptic ulcer and gastric cancer (10). Poor socioeconomic circumstances is a risk for H. pylori infection and parasite infection.

**Materials and Methods**

**Materials:** glass slides, cover slides, microscope, normal saline, lugol’s iodine stain, pipette, stick, eppendorf tube, dipstick for H. pylori.

**Samples collection:** A total of one hundred stool specimens collected from suspected persons with Entamoeba histolytica and H. pylori in general Hospital of Martyr Fairuz at Hay district, Saeed health center and Al-Kut Hospital. Stool samples were collected during the period from 28 October 2020 to 28 December 2020. These specimens were collected in sterile plastic containers in morning (11) and from different ages and both sexes.

**Methods**

For examination with microscope used two slides for each specimen, one drop of Iodine and added small amount of stool on one slide and mix well and cover slip, then one drop of normal saline (0.9%) on another slide with added small amount of stool, mix well and cover slip, then examination with microscope at 40 magnification 40X (12). Each sample checked H. pylori by dipstick (13).

**Results**

A total of 100 samples of stool collected from patients with solid, semisolid and diarrhea.

Table 1 shows the rate of Helicobacter pylori infection 40 positive samples out of 100 patients. The highest infection in females 23 (23%) positive samples and the lowest infection in males 17 (17%). The rate of Entamoeba histolytica infection 14 (14%) positive samples out of 100 patients. The highest infection in females 8 (8%) and the lowest in males 6 (6%). The rate of infection association between E. histolytica and H. pylori 10 (10%) positive samples out of 100 patients. The highest infection was recorded in females 6 (6%) and the lowest in males 4 (4%).

### Discussion and Conclusion

Intestinal parasites are common in developing countries, poor socioeconomic conditions is major risk factors for acquiring *Entamoeba histolytica* and *Helicobacter pylori*. *Helicobacter pylori* colonizes gastric mucosa and cause gastric ulcer. The spread of intestinal parasitic infection and *H.pylori* associated with contaminated food and water and the extent of personal hygiene. *Entamoeba histolytica* causes amoebic dysentery, infection with *H.pylori* is strongly associated with an increased risk of gastric ulcer. Most persons infected with *H.pylori* will never have gastric ulcer. Other factors that increase the risk of gastric ulcer among persons infected with *H.pylori* need to be detected. Several methods are available for identification of *E.histolytica* oocyst and trophozoites and *H.pylori* including direct smear and lugol’s iodine stain for *E. histolytica* and dipstick for *H.pylori* in stool.

The present study for *Entamoeba histolytica* and *Helicobacter pylori* infection at Wasit province for different ages and gender. A total of 100 samples collected from patients were suffered abdominal pain with solid, semi-solid, or diarrhea in general Hospital of Martyr Fairuz and Saeed Health center at Hay district and Al-Kut Hospital. Stool samples were detected by direct and Lugol’s iodine stain to diagnose *Entamoeba histolytica*, the result showed 14 (14%) positive samples out of 100 samples ; 8(8%) females and 6(6%) males. The highest infection appeared in age group (1-13) years old ; females recorded 1(1%) and males 4(4%), this result agreed with (15). Ten positive samples for both *Entamoeba histolytica* and *Helicobacter pylori*, the highest infection in group age group (39 and more) years old ; females recorded 3(3%) while males recorded 2 (2%). This result disagreed with (16) that showed (0.528) for *E.histolytica* and (0.02) for *H.pylori* out of one hundred and sixty – one patients. *H.pylori* examined by dipstick for each sample, 40 (40%) positive samples of *H.pylori* was detected (17). The highest infection appeared in females 23 (23%) and the lowest infection in males 17 (17%). Our results appeared that age group (39 and more ) years old recorded the highest for *H.pylori* where the females registered 6(6%) and the males recorded 6 (6%), while the age group (>1) years old revealed 1(1%) for females and 1(1%) for males, this results disagreed with (18).The higher infection in males and the lowest infection in females, this result agreed with (19) and disagreed with (20). *Helicobacter pylori* is known to be pathogen in many gastrointestinal disorders, such as...
gastric cancer (21). The infections caused by H. pylori depending on the age, the highest infected patients was in over 30 years old (22,23). The present study showed association between Entamoeba histolytica and H. pylori infections at Wasit province. Females recorded the higher infections with E.histolytica, also the higher infection with both E.histolytica and H.pylori in patients. The highest infection with H.pylori recorded in females 23(23%) while in males 17(17%) out of 100 samples. Microscopic identification of trophozoites and cyst in the stool is the common method for diagnosing Entamoeba histolytica in fresh stool (24).

Identification of Cryptosporidium parvum in Stool Specimen Using Different Diagnostic Methods in Wasit Province/Iraq

Abdulsada A. Rahi¹, Salam M. Khlaif²
¹Prof, Post Doctorate, ²Research Scholar, Department of Biology, College of Science, Wasit University, Iraq

Abstract

The present study aimed to investigate the presence and prevalence of Cryptosporidium among immunocompromised patients in Wasit Hospitals and health centers to determine the best method for its diagnosis. The study started from the 1st of August to the end of November 2020. One hundred forty stool samples were collected from immunocompromised patients from both genders who attended the hospital and health centers at Wasit province. Stool samples were inspected by modified acid-fast stain as a standard method, enzyme linked immunosorbent assay (ELISA) and Molecular Nested PCR method. Modified Ziehl-Neelsen technique revealed 46 (33%) positive cases for Cryptosporidium oocysts, of 85 males and 55 females, highly significant relationship was found between the genders and between different age groups of infection with a highly significant difference between rural and urban area. The prevalence of Cryptosporidium was 57.14% using nested PCR and 38.46% for ELISA in comparison with MZN method. It is concluded that cryptosporidiosis found to be endemic in Wasit Province for the first time and the nested PCR was the most reliable technique for its diagnosis.

Keywords: Modified Ziehl Neelson, Nested PCR, Cryptosporidium parvum, Stool, Immunocompromised, ELISA

Introduction

Cryptosporidiosis is an emerging zoonotic disease in humans and animals that contributes to intestinal and extra-intestinal diseases. The major factor controlling the susceptibility and severity of cryptosporidiosis appears to be the immune status of the host [¹]. Those with great risk of infection including the immunocompromised patients [²,³]. They are including AIDS and T.B patients and those with various malignant, cytotoxic drugs receivers, prolonged corticosteroid therapy, the drugs used to prevent organ transplant rejection [⁴]. Those with chronic diseases and persons who have congenital immunodeficiency’s [⁴,⁵]. In such patients, cryptosporidiosis is characterized by painful, persistent, frequently cholera-like diarrhea along with extreme abdominal colic, body weight loss of more than 10%, and dehydration [⁶]. The infection is transmitted through the fecal-oral route and results from the ingestion of Cryptosporidium oocysts through the intake of food, water or direct contact with individuals or animals. It has been documented that infected individuals shed 10⁸-10⁹ oocysts in a single bowel movement and excrete oocysts for up to 50 days after diarrhea cessation [⁷]. The aims of this study were:

1. Detection the infectious rate of cryptosporidiosis in immunocompromised patients at Wasit province.
2. Study of some related variables with cryptosporidiosis infection.
3. Discover the relationship of some immunological factor in cryptosporidiosis infection.
4. Comparison of different technical diagnostic
**Materials and Methods**

**Sample collection**

Samples were collected from patients who attended the Al-kut and Al-zahraa Teaching Hospital in Wasit Province from 1st of August 2020 till the end of November 2020. The samples were classified according to the rural and urban area, gender, age of patients, immune status. All patient samples were freshly collected and placed in a dry, clean, sterile and screw-capped plastic container and each container was labelled with the patient’s number and name. Stool samples were divided into two parts: one section was fixed for the Modified ZN stain, and the other part of the stool sample was retained for the ELISA test and Nested Multiplex PCR as frozen form under (-22°C). The following techniques analyzed each stool sample:

1. **Direct Stool Examination**: A total of 140 stool samples were examined with a microscope as direct identification of *C. parvum* infections by staining using the Modified Ziehl-Neelsen stain technique [8].

2. **Immunoassay Method**: A total of 91 samples of stool were examined by ELISA assay. The ELISA kits were used on the frozen stool specimens. The *Cryptosporidium parvum*-ELISA based fecal antigen detection kit made by (Epitope Diagnostics, Inc. USA) was used according to manufacturer’s instructions to screen 91 randomly selected stool samples for *Cryptosporidium* inclusive of the ones positive by microscopy.

3. **Molecular Diagnosis**: DNA was extracted by using Presto™ Stool DNA Extraction Kit stool (Geneaid, Taiwan) was used according to manufacturer’s instructions to screen 91 randomly selected stool specimens for *Cryptosporidium* inclusive of the ones positive by microscopy then DNA purified and a Nested Multiplex PCR approach was used to amplify a heat shock protein 70 (hsp70) gene were designed in this study using NCBI-Genbank (MT303115.1) and primer 3 plus design fragment of *C. parvum*. The Nested PCR product was analyzed by Agarose gel electrophoresis.

**Statistical Analysis**

For each returned questionnaire, statistical analysis was performed using the SPSS (Statistical Package for Social Sciences version 16.0) software package program for statistical analysis. For both variables, descriptive statistics (numbers and percentages) were measured, as well as empirical statistics were carried out to find the relationships between the variables. The relationship between variables was determined by Chi-square using the necessary statistical tests [9].

**Results**

A total of 140 stool samples were tested, 46 (33 %) of which were positive for *Cryptosporidium* oocysts using MZN stain (Figure 1).

![Figure 1: The rate of Cryptosporidium infection with MZN.](image-url)
Over all, the prevalence of Cryptosporidium infection in male and female was (37.64%) and (25.45%) respectively, with no significant difference in the total rate of infection with Cryptosporidium between males and females (p>0.05), there was a highly significant difference found between the rate of infection among the patient of urban areas (65.51%) and children of rural areas (24.32%) (Table 1).

Patients of age group (48-63) years showed the highest (50%) rate followed by the age group of (32-47) years at a rate of (36.36%), and (1-15 year) with (64-80 year) at rate of (33.33%) then lowest rate of infection (28.94%) was among those of (16-31) years of age, with no significant difference between the rate of infection and the age groups (Table 2).

### Discussion

*Cryptosporidium parvum* accompanied by diarrhea is more frequently seen in bad hygiene, malnutrition cases, among the old and child category, and in immunocompromised patients [10]. Waterborne *Cryptosporidium* outbreak are seen commonly in recent years, and revealed a serious public health problem [11]. The identification of *Cryptosporidium parvum* is important to reveal the epidemiology of *Cryptosporidium* infections in humans [12].

In the present study the percent of Modified acid fast stain technique in patients suffering from diarrhea who attended to Al-kut and Al-zahraa Teaching Hospital in Wasit province was (33%). This finding is disagree with the results obtained in Al-Dewanyia [13] who reported (14.7%), while a previous surveys studies carried out in numerous parts of the world revealed that the prevalence rate of cryptosporidiosis was anywhere from 3-50% [14,15].

In the present study, cryptosporidiosis rate showed a statistically differences between the rural and urban center. *Cryptosporidium parvum* infection was seen in rural population higher than urban area (65.51%). Thus, returns of living in the rural could have been related by such factors as problems of drainage, lack of enough clean water sources, fecal droppings from both animals and humans are found in most places and unselective defecation. The rural population’s also shows that person-to-person transfer through food or water was high and this confirms that there is a high level of contamination with human feces. this result were nearly similar to previous study that carries out the percent rate of Cryptosporidiosis in rural area (55%) [16].

In relation to gender, the present study showed the males were higher percent than females in cryptosporidiosis rate, this is may be due to the male in Iraqi population were more frequenter to coffee shop and restaurant and thus make them more deal with the contaminated instrument , water, vegetable and, this result were nearly similar to previous study in Iraq revealed that 33.74% of samples were positive for *Cryptosporidium*, with higher frequency of cases in male patients [17].

Cryptosporidiosis is accompanying with age and immunity, in this study, the common of the positive cases was frequently seen in older patients (48-63) years. The occurrence of high infection rates in this category may be patients older than 30 years had a higher risk of this infection. Similar age related increases in *Cryptosporidium* infection have previously been reported [18].

Recently, PCR and immunodiagnostic methods have become more popular in diagnosis of cryptosporidiosis to overcome the limitations of microscopy. Compared with microscopy, DNA-based detection methods display several advantages such as an increased sensitivity and specificity, the possibility for molecular typing and an optimized turnaround time [19,20,21]. Given these
trends in diagnosis, PCR was chosen the gold standard in this study. Indeed, it yielded the highest detection rates (57.14%), compared to ELISA (38.46%) and examination of MZN stained slides (32.85%) and this was found to be statistically significant. This result agreed with the results recorded in Beni-Suef, Egypt [22].

Comparison between Microscopic Identification and Nested PCR for Detection of Cutaneous Leishmaniasis at Wasit Province

Abdulsada A. Rahi¹, Zainab K. Hashim², Ali Mohsin Al-Jamea³
¹Prof, Post Doctorate, ²Research Scholar, Department of Biology, College of Science, Wasit University, Iraq, ³Research Scholar, Dermatologist, Al- Karamah Teaching Hospital, Directorate of Wasit Health, Iraq

Abstract

Cutaneous leishmaniosis in Iraq has 2 forms, zoonotic cutaneous leishmaniasis (ZCL), which is mainly caused by Leishmania major, and anthroponotic cutaneous leishmaniasis (ACL), which is mainly caused by Leishmania tropica. Twenty skin samples were taken from suspected patients with CL and checked for Leishmania amastigote, during the period from October 2019 to February 2020 in Al-Karamah teaching hospital of Kut city, Iraq. The highest infection 100% using Giemsa- smeared and 75% using Nested PCR methods. Totally 20 patients aged from (1- <40) years old were included in current study. The prevalence of CL were in males 9(45) and 11(55) in females and high prevalence in age groups (>20) years old. The current study 12(60%) were brought on Leishmania major and 4(20%) Leishmania tropica using Nested PCR method. In present study the direct smear could be considered a good test for testing the cutaneous Leishmaniasis but Nested PCR assay was more touchy than parasitological technique in diagnosis of Leishmania species in skin lesions. L.major is the main species responsible of cutaneous leishmaniasis in areas of Wasit Province.

Keywords: Cutaneous Leishmaniasis, Nested PCR, Giemsa, Human

Introduction

Leishmaniasis is a disease spread through the bites of a female sandfly and triggered through different varieties of leishmaniasis, which is expressed in three main clinical types: cutaneous, mucous and visceral leishmaniasis (¹–⁴). Cutaneous leishmaniasis exists in at least two shapes; Amastigote elliptical and non-flagellated, 3-5 μm long and promastigote was a cutaneous type contained in the host sand fly (⁵). Cutaneous Leishmaniasis cases were more abundant in winter, with a peak in February, the rate of infection then started to decline from April and reaches its lowest in July and August (⁶).

Cutaneous Leishmaniasis, commonly known as called Baghdad boil, is a very old disease in Iraq, it is a less severe of disease which manifests self-healing ulcers. Leishmania major and Leishmania tropica are causative agents of Cutaneous Leishmaniasis in Iraq (⁷). According to species of parasite and immune response of the patients, the symptoms differ in regions, that beginning as erythematous papule, increase in size producing a nodule, ulcerate and crusts (⁸,⁹). The zoonotic type is caused by Leishmania major and anthroponotic type is caused by Leishmania tropica (¹⁰,¹¹). Other modes of transmission such as parenteral, congenital, sexual, occupational exposures, and person to-person transmission could also theoretically occur(¹²).

Nested PCR approach was applied for the detection and identification of the Leishmania species according to the Noyes et al., (1998) method (¹²). Nested PCR is a one of the best parts of the parasite genome for sequencing.
to identify different *Leishmania* species \(^{(13,14)}\). The current study aimed to compare between microscopic identification and Nested PCR methods for detection of cutaneous leishmaniasis at Wasit province.

### Materials and Methods

#### Population study

This study was carried out during the period from October 2019 to February 2020 in Al-Karamah teaching hospital of Kut city, Iraq. A total of 20 skin samples were taken from suspected patients with CL. All patients were divided into four age groups. Samples were taken from the skin lesion, and kept into two tubes; one stored in freeze at -20°C for Nested-PCR and the second tube for direct smear. After the smears dried completely, they were fixed with 100% methanol, allowed to dry again, and stained with Giemsa stain for microscopic examination for presence of amastigotes \(^{(15)}\).

#### DNA Extraction

Genomic DNA was extracted from skin lesions and aspirates using AccuPrep®Genomic DNA extraction kit (Bioneer, Korea) and done according to company instruction. The extracted genomic DNA was checked using Nanodrop spectrophotometer (Thermo, USA), and measured the purity of DNA through reading the absorbance at (260/280 nm) \(^{(16)}\).

#### Nested-PCR

Nested – PCR was performed as follows: in the first stage two external primers CSB1XR (CGAGTAGCAGAAACTCCCGTTCA) and CSB2XF (ATTTTTCGCGATTTTCGCAGAA CG) and in the second step, two internal specific primers 13Z (ACTGGGGGTT GGTGTAAA ATAG) and LiR (TCGCAGAAGCCCT) was used for amplification of variable minicircles of *Leishmania* kDNA. All primers provided from (Bioneer, Korea) company. Two *Leishmania* species produced the amplified fragments of about 750 bp for *L. tropica* and 560 bp for *L. major*.

Amplification reactions visualized in 1.5 % Agarose Gel Electrophoresis, using a 100 bp DNA ladder \(^{(17)}\).

### Results and Discussion

**Table (1): Prevalence of CL According to the Age Groups and Gender**

</tbody>
</table>

Twenty skin samples of suspected patients were enrolled in our study: 9 (45%) males and 11(55%) females. The high prevalence (55%) in age group (>20) years old and the lowest prevalence (20%) in age group (<40) years old. Which may be due to several factors, such as children’s outdoor activities and sleeping outdoors, which increases exposure to sand fly bites during their active hours. The same result has been reported by some other researchers \(^{(24,25-28)}\). AL-Janabi, (2001) in Najaf province, who found that the age group
10-15 years old was the most affected age group \(^{(31)}\). While the most rate of disease reported by Azizi et al.,(2013) was in age group (10-19) years old assemble for Esfahan region in Iran \(^{(32)}\). The rate of the disease although not significant is more seen in females 11(55%) than males 9(45%) which is do not agreed to previous studies and most likely because of the more exposure to sand fly bites in males than females \(^{(29,30)}\).

| Table (2): Comparison between Giemsa-smeared and Nested-PCR in Diagnosis of CL |
|---------------------------------------------|-----------------|-----------------|
| Test                                        | Positive (%)    | Negative (%)    |
| Giemsa-smeared                             | 20(100)         | 0               |
| Nested-PCR                                 | 15(75)          | 5 (25)          |

In this study, the results showed that the rate of positive cases of CL using Giemsa-smeared were 20 cases which constitute (100%), while Nested PCR recorded 15 positive cases constitute (75%) from total samples. The highest infection (100%) appeared using Giemsa-smeared method while the lowest infection (75%) appeared by Nested-PCR method.

There are many diagnostic tests used to detect the *Leishmania* parasite, microscope examination is the most reliable and conventional method, the parasite is demonstrated in direct smear stained with Giemsa stain or leishman stain to detect the presence of amastigotes \(^{(17)}\).

The diagnosis of CL classically relies on microscopic examination and in vitro cultivation. These classical methods require the presence of a relatively high number of viable or morphologically intact parasites. This may pose a problem particularly in the chronic phase of CL where parasite levels in skin lesions are very low. In contrast, the molecular approach is both sensitive and specific \(^{(18)}\). Several reports have shown the high rates of infection with *Leishmania* species and that agreed with our results, our finding is steady with the discoveries of the study conducted by others \(^{(19)}\). Al Samarai and Al Obaidi, (2009) reported that 73% of the cases were certain to Giemsa stain and 43% were sure in societies for Al Hawija locale of Kirkuk region in Iraq \(^{(9)}\). Rahi, (2015) was recording that the rate of infection was 97.8% by utilizing Giemsa technique for Wasit province in Iraq. Rahi reporting the pervasiveness of positive instances of CL was 94% by utilizing smear strategy for Wasit region in Iraq and microscope examination of smears is quick and simple to use for conclusion of CL \(^{(20)}\). In Tuz- Kirkuk province, suggested the diagnosis of CL by staining the aspirated material with Giemsa stain and culturing on semi-solid media, found that 73% of samples were positive for Giemsa stain, while 27% were negative \(^{(35)}\).

Most regularly utilized strategies for the immediate identification of the parasite (e.g., minute examination of Giemsa-recolored smears and in vitro development) need affectability as a result of the shortage of *Leishmania* parasites in a few examples or the parasites might be inadequate and are generally extracellular in the slide arrangements, or are hampered by the issue of defilement \(^{(21)}\). These techniques have restricted sensitivities since they require coordinate perception of the parasites and the scarcity of parasites inside the injury is a sign of sores with old age. Our result were about like the outcome reported in Iraq \(^{(19)}\). Among these, currently, the most ordinarily utilized strategy is DNA-based systems, utilizing PCR and particular ground works for species and even strains portrayal \(^{(22,23)}\).
Table (3): Distribution of CL cases in relation of Residence

In Iraq, cutaneous leishmaniasis (Baghdad boil) caused by two species *L. major* zoonotic disease and *L. tropica* anthroponotic disease (20). The present study revealed that prevalence of *L. major* (60%) were higher than *L. tropica* (20%) in the studied areas. Agreement to the findings were recorded of some other studies (18,33). The present study also agreed with Rahi et al., (2019) revealed that prevalence of *L. major* (63.3%) were higher than *L. tropica* (6.7%) (34).

**Conclusions**

In present study the direct smear could be considered a good test for diagnosis the cutaneous leishmaniasis, the high rate of infection with *Leishmania* species at Wasit province, but Nested PCR assay was more touchy than parasitological technique in recognition of *Leishmania* parasite in skin lesions. *L. major* is the main species responsible of cutaneous leishmaniasis in areas of Wasit Province.

A Comparison of use of Microscopic Examination and PCR for Detection of Entamoeba Histolytica at Wasit Province

Magda A. Ali
Research Scholar, PhD, Department of Biology, College of Science, Wasit University, Iraq

Abstract

A microscopic examination of multiple feces samples of 100 suspected patients with Entamoeba histolytica infection who suffered from diarrhea was attended to Al-Karamah Teaching hospital at Wasit Province from January 2020 to March 2020. The feces samples were collected into two

Parts; first of direct wet film preparation were done for each sample using normal saline 0.9 % for detecting the motility of trophozoites and Lugol’s iodine 5% for demonstrating structures and cyst. The 2nd part was kept in freeze (-20C) until used in PCR method .

The current study recorded that the overall prevalence rate of Entamoeba histolytica 80(80%) by microscopic examination and 88(88%) by PCR methods. The prevalence of E. histolytica was higher among families who live in rural areas 44(55%) than those in urban areas 36(45%) and in males 49(61.3%) more than females 31(38.7%). The highest infection rate 37(46.3) was recorded in age group (21-40) years old. The present study was aimed to compare between the microscopic examination and PCR methods in the diagnosis of E. histolytica in human clinical samples.

We concluded our results that using PCR technique was more accurate and sensitive (88%) than microscopic examination method (80%).

Keywords: Entamoeba histolytica, Lugol’s iodine stain, PCR, Human, Stool

Introduction

The spread of intestinal parasites differ from one region to another and its spread related to many factors such as geographical factors, climate, poorness , malnutrition, personal clean less and other factors (1). One trophozoites of Entamoeba histolytica reach the host intestine can damage the mucosa epithelial layer and prevalence through the sub-mucosa and the lamina propia and other tissues (2).

Entamoeba histolytica infections occur mostly in adults, although they see in children. Since the parasite infects the large intestine, severe infection result in serious loss of blood and also may cause systemic problem such as liver abscesses due to infection of the liver by the parasites, amoebiasis can cause nutrient loss and can lower the levels of circulating proteins, this sometimes leads to under nutrition (3).

The diagnosis of amoebiasis is often difficult and time consuming. Microscopic identification of trophozoites and cysts in the stool is the common method for diagnosing E. histolytica either in fresh stool or stool concentrates (4). The conventional method of diagnosing E. histolytica utilizes microscopy, but its sensitivity is less than 60% (5). To improve the rate and sensitivity of the diagnosis, PCR-based approaches have been used since the early 1990s, and many studies have been conducted to detect target E. histolytica DNA in the human stool (6-9).

The present study aimed to compare between the microscopic examination and PCR methods in the diagnosis of E. histolytica in human clinical samples.
Materials and Methods

Stool Collection

A total of 100 fecal samples were collected from suspected patients who suffering from diarrhea in Alkarama Teaching Hospital at Wasit Province. The fecal sample were collected from January 2020 to March 2020 and it was divided into 2 parts; 1st part it placed in dry plastic container and transported to the laboratory for microscopically examination and the 2nd part kept in freeze (-20 C) until used in PCR method.

Stool DNA Exteraction

Genomic DNA was extracted from stool samples by using (Stool DNA extraction Kit, Bioneer. Korea). The extraction was done according to company instructions by using stool lysis protocol method with Proteinase K (10). After that, the extracted gDNA was checked by Nanodrop spectrophotometer, and then stored at -20C until used in PCR amplification.

Convetion PCR

PCR technique was performed for specific detection *E. histolytica* from human stool samples. This method was carried out according to (10). The primers were provided by (Bioneer company. Korea). PCR reaction solution was prepared by using (AccuPower PCR PreMix Kit) according to company instructions.

Statistical Analysis

Statistical analysis: The statistical analysis was performed using SAS (Statistical Analysis System - version 9.1) (11).

Discussion

In developing countries, poor hygiene and the use of untreated human feces (i.e. fecal sludge) are important factors that contribute to the contamination of food and water. In such countries, prevention of infection with *E. histolytica* can be attained by improved community health education, sanitation, hygiene, and water treatment. To reduce enteric pathogens, including intestinal protozoa that may be present on fresh vegetables and fruits, the produce can be washed by clean tap water and soaked in a solution of acetic acid or vinegar for 10 to 15 minutes before consumption (12).

According to the results of the present study *E. histolytica* had an overall prevalence of 80/100(80%) (table 1). These results in agreement with Rahi and Majeed, (2019) at Wasit Province, Iraq (13) and disagreed with other studies like Ali et al., (2003) that reported 15.6% prevalence of *E. histolytica* from preschool children in Bangladesh (14), Aza et al., (2003) who reported 21% prevalence of intestinal parasites in seven villages of Malaysia (15) and Zahida et al., (2010) who recorded 11% prevalence of *E. histolytica* in children of Delhi, India (16).

The results of current study showed the prevalence of *E. histolytica* in the rural areas 44(55%) was higher than urban areas 36(45%) (table 2). Thus, returns of living in the rural could have been related by such factors as problems of drainage, lack of enough clean water sources, fecal droppings from both animals and humans are found in most places and unselective defecation. The rural population’s also shows that person-to-person transfer through food or water was high and this confirms that there is a high level of contamination with human feces. this result were nearly similar to previous study that carries out of *E. histolytica* infection (17). The present study was appeared the predominance of male 49(61.3%) to female 31(38.7%) as showed in table 3, this result agreed with (18) and it was disagreed with (19).

Correlation between Interleukin(IL-6) and Procalcitonin (PCT) Level among Diarrheal Children

Nihad Khalawe Tektook¹, Ahmed Salim Hadi Al-Khafaji²

¹Assist Prof Middle Technical University / College of Medical & Health Technology, Medical Laboratory Techniques Dep., ²Pediatrics Specialist, Iraqi Board In Pediatrics, Karbala Pediatric Teaching Hospital/Karbala Health Directorate/Iraq

Abstract

This study was conducted in Baghdad for the period from December 1, 2019 to June 3, 2020 for determination of the level of elevation of interleukin-6 and procalcitonin in children with acute diarrhea. I was included 50 children suffering from diarrhea and 50 children without any other disease, where the ages of children in both groups ranged from one month to five years. The study included collecting information from children in both groups, including gender, age, living situation, number of family members, standard of living and social as well as the number of family members, number of rooms in the house. Amount of 5 ml of blood samples were collected from all the children included in this study, where the blood samples were separated by the centrifuge device and the serum samples were separated from them and kept in the refrigerator until the tests for detecting the level of Interleukin 6 and procalcitonin using ELISA technique. In this study, 76% of diarrheal children were suffered from abdominal pain, 68% with dehydration, 58% of fever, 46% had vomiting. The presented study found that, 78% of families with diarrheal children were lived in crowed houses, 73% didn’t wash vegetables before eat, 69% haven’t wash hands, 66 used tap water for drinking. In this study, IL-16 was observed in elevated mean in diarrheal children (19.66±2.19 ng/ml), when it compared with the control healthy children (4.27±1.46 ng/ml) (P<0.001). In this study, procalcitonin was also observed in elevated mean in diarrheal children (42.17±9.28 ng/ml), when it compared with the control healthy children (28.19±8.27 ng/ml) (P<0.001). The study showed that the maximum means of PCT and IL-6 in diarrheal children were observed in those with fever, followed by abdominal pain. The study revealed a significant positive correlation between IL-6 and PCT level among diarrheal children.

Conclusions:
The study showed a significant relation of PCT and IL-6 with diarrhea.

Keywords: Procalcitonin; diarrhea; IL-6; Abdominal pain

Introduction

Diarrhea is one of the most common diseases among children in various parts of the world, although it is considered one of the common diseases that its severity is almost limited, and this risk is that children are afflicted with what is called the term dehydration, which leads to the loss of salts and water from the body through the digestive system and abroad. The risk of developing dehydration in children increases in children under five years of age (¹).

Corresponding author:
Nihad Khalawe Tektook
Gmail: drnihadkhalawe@gmail.com

Diarrhea is of two types, and they are acute diarrhea, the period of which increases to more than 14 days from the date of injury and chronic diarrhea, and it is not when the patient suffers from diarrhea for a period longer than that (²). It is also classified according to the persistence of stool in children into two types of watery diarrhea, which results from injuries in microorganisms like bacteria, viruses, and parasites, the infection is often in the upper part of the intestine, and the stool is liquid, which may cause dehydration.

Bacteria such as Escherichia coli, salmonella, shigella, and V.cholera, predominantly cause acute diarrhea, in addition to viral infection also could be on of causes of watery diarrhea plus vomiting and
fever in children with gastroenteritis\textsuperscript{(3,4)}. Interleukin-6 is considered one of the most important inflammatory factors among the types of cytokines in the body, which are raised due to infection with bacteria, viruses or parasites in the body.\textsuperscript{(3)} Where the scientific evidence indicates that the high level of interleukin 6 in children with diarrhea may be caused by an acute bacterial or viral infection.

The level of interleukin 6 rises directly with the severity of infection in these children \textsuperscript{(5)}. In addition, the protein factor procalcitonin was found in recent studies to be high in bacterial infections, especially due to gram negative bacteria in diarrhea, urinary tract infection and bacteremia in people with this condition, as its height is directly proportional to the severity of the disease and is also directly proportional to the high level of interleukin.\textsuperscript{(6,7)} This study was conducted for the purpose of determining the level of elevation of interleukin-6 and procalcitonin in children with acute diarrhea who are less than five years old and related to ages, their level of hygiene.

### Patients and Methods

This study was conducted in Baghdad for the period from December 1, 2019 to June 3, 2020, and included 50 children suffering from diarrhea and 50 children without any other disease, where the ages of children in both groups ranged from one month to five years. The study included collecting information from children in both groups, including gender, age, living situation, number of family members, standard of living and social as well as the number of family members, number of rooms in the house. Amount of 5 ml of blood samples were collected from all the children included in this study, where the blood samples were separated by the centrifuge device and the serum samples were separated from them and kept in the refrigerator until the tests for detecting the level of Interleukin 6 and procalcitonin using ELISA technique.

### Results

In this study, 44% of studied children were within the age group \(<1\) year followed by 36% in the age group 1-2 year, 27 of 50 were females and 55% rurals, (Table 1).

The study revealed a significant positive correlation between IL-6 and PCT level among diarrheal children, Figure 3.
Discussion

In this study, 44% of studied children were within the age group <1 year followed by 36% in the age group 1-2 year, 27 of 50 were females and 55% rurals,(Table 1).In line with this study that there are many studies that have proven that diarrhea in children often occurs at young ages of less than five years, especially in those who are less than two years of age. A study conducted in previous decades or previous years stated that children who are less than two years old are More vulnerable to acute diarrhea due to bacteria or viruses (6-8).In this study, 76 % of diarrheal children were suffered from abdominal pain, 68% with dehydration, 58% of fever, 46% had vomiting, Figure 1.Dehydration and colic are among the most important symptoms of all ages, especially children, as past studies have shown that most children, and most of those children who are less than five years old and who suffer from severe diarrhea, were implicitly suffering from colic and dehydration, as well as high temperatures, which often accompany anorexia and thinness(9,10).The presented study found that, 78% of families with diarrheal children were lived in crowed houses, 73% didn’t wash vegetables before eat, 69% haven’t wah hands, 66 used tap water for drinking (Figure 2).Past studies show that people or children suffering from diarrhea, the majority of whom are families suffering from limited income and suffer from a disruption of the health system, and a high percentage of children with diarrhea do not wash their hands before eating and use running water for drinking (11-14).In this study, IL-16 was observed in elevated mean in diarrheal children (19.66±2.19 ng/ml), when it compared with the control healthy children (4.27±1.46 ng/ml) (P<0.001), Table 2.In line with this study, the study previously conducted in different countries of the world has shown that Interleukin-6 significantly increases blood serum in people with many diseases, including urinary tract infection, diarrhea, blood market store, and fever of unknown cause(15).In this study, procalcitonin was also observed in elevated mean in diarrheal children (42.17±9.28  ng/ml), when it compared with the control healthy children (28.19±8.27  ng/ml) (P<0.001), Table 3.The study showed that the maximum means of PCT and IL-6 in diarrheal children were observed in those with fever, followed by abdominal pain, Table 4.The study revealed a significant positive correlation between IL-6 and PCT level among diarrheal children, Figure 3.Where the level of interleukin-6 and the level of procalcitonin rises in people with acute diarrhea due to causes that lead to diarrhea such as the bacteria that cause diarrhea (16).Where the researcher(16)mentioned in his study that
the increase in the level of interleukin-6 came with an increase in the level of calcitonin, and the increase was proportional, meaning the higher the first, the higher the level of the second variable was very high, especially in children with diarrhea and those suffering from high temperatures\(^{17}\). The high temperatures in children with diarrhea are often due to the fact that the bacteria that cause diarrhea are of the type gram-negative bacteria, which contain endotoxins that in turn lead to elevated levels of interleukin-6, and the CRP and procalcitonin, which are automatically preserved as a result of infection in infected patients or any diseases, bacteremia, cough and urinary inflammation\(^{18&19}\). Conclusions: The was a significant relation of PCT and IL-6 with diarrhea.

Abstract

This case control study was carried out in Baghdad city from 1st of April 2018 to 1 March 2019 included 40 studied cases (children with inguinal hernia) and 40 healthy children to evaluate the prevalence of UTIs in children with inguinal hernia repairs. It was known that the children are infected or not with urinary tract infection through clinical examination of the signs that indicate urinary tract infection, as well as a laboratory examination of the urine to detect the presence of bacteria that cause urinary tract infection in the laboratory. All children under 15 years of age were included in the study who attended pediatric surgery clinics. Ages over the age of 15 years old, children with complex inguinal hernia such as blocked, irreducible, strangulated hernia and children with recurrent hernia were excluded. All children included in our study included in the study were examined through routine and microscopic examination of urine, urine culture and sensitivity. Children with urinary tract infections were treated according to sensitivity culture reports. This case control study included children with inguinal hernia (90% males and 10% females), their age range was <1 year to 15 year (mean: 9.52±1.3 year), the study also included 40 healthy children (as control group) with the same characteristics of patient. The study revealed that urinary tract infection was observed in 25% of (10 of 40) of children with inguinal hernia compared with 5% of (2 of 40) of the control group (P<0.001). This study showed that most of children with inguinal hernia were suffered from abdominal pain, urge to urinate, polyurea, cloudy urine, fever and pyelonephritis. The study found that, 50% of children with inguinal hernia who suffered from UTI were due E. coli, S. aureus with rate 40% and Klebsiella spp with rate 10%. The study showed that 80% of E. coli isolates were sensitive to ampicillin, 60% to amikacin and 40% to Amoxiclave, while 100% of S. aureus were sensitive to Ceftriaxone and cand 75% to Cefotaxime. It was concluded that, there significant positive correlation between UTIs and inguinal hernia repairs in children.

Keywords: Children; inguinal hernia; UTI; Prevalence

Introduction

Herniorrhaphy operations have become the most important and successful options for treating inguinal hernia in children, as the percentages in these operations reached twenty million successful operations per year(1). The availability of databases for cases who suffer from hernia repair in general, especially in children, may be almost rare. Studies indicate that approximately 26% of men and a small minority of women experience inguinal hernia repair operations worldwide once in their lifetime (2). Some disorders and bacterial infection are associated with the operations of repairing inguinal hernia in children, and among those problems and diseases is urinary tract infection, where urinary tract hernia in children, as the percentages in these operations reached twenty million successful operations per year(1).
infection is one of the most important causes suffered by children under the age of 12 years and the distance between the operations of repairing inguinal hernia and the urinary tract is close\(^{(3-5)}\). Like the bladder and the ureter between, it is expected that they will have urinary tract infections, especially those children who suffer from high temperatures, colic and decreased urination. The infection caused by multidrug resistance (MDR) organisms is more likely to prolong the hospital stay, increase the risk of death, and require treatment with more expensive antibiotics \(^{(6-8)}\). The aim of this study was to evaluate the prevalence of UTIs in children with inguinal hernia repairs.

**Materials and Methods**

This case control study was carried out in Baghdad city from 1\(^{st}\) of April 2018 to 1 March 2019 included 40 studied cases (children with inguinal hernia) and 40 healthy children. It was known that the children are infected or not with urinary tract infection through clinical examination of the signs that indicate urinary tract infection, as well as a laboratory examination of the urine to detect the presence of bacteria that cause urinary tract infection in the laboratory. All children under 15 years of age were included in the study who attended pediatric surgery clinics. Ages over the age of 15 years old, children with complex inguinal hernia such as blocked, irreducible, strangulated hernia and children with recurrent hernia were excluded. All children included in our study included in the study were examined through routine and microscopic examination of urine, urine culture and sensitivity. Children with urinary tract infections were treated according to sensitivity culture reports.

**Results**

This case control study included children with inguinal hernia (90% males and 10% females), their age range was <1 year to 15 year (mean: 9.52±1.3 year), the study also included 40 healthy children (as control group) with the same characteristics of patient. **Discussion**

Numerous studies have shown that the results that we have reached in our study are limited by the fact that the most vulnerable children to me hernia are males, especially those over the age of five years (5,7). This is due to the fact that males are more susceptible to movement and activity than females and that ages more than five years are among the factors (8).

The task and influencing the movement of the child, where he has knowledge and love in movement. Going outside the house, which leads to exposure to a hernia in the lower abdomen (9). In view of the prevalence of UTIs in children with inguinal hernia repairs. Different studies also showed that there is a strong relationship between urinary tract infection and people at risk of inguinal hernia (11-13). Several studied also found similar finding as *S. aureus* and *E. coli* were the predominate bacterial isolates of UTI in children (14,15). Other studies indicated that most of *E. faecalis* were resistant to Amikacin (16,17), as another study found that most of *E. faecalis* isolates were resistant to vancomycin and Ceftriaxone with rate reach to 80% (18). The reasons for the high resistance of these bacteria to many antibiotics are due to the fact that they are present and in abundance the medical body as well as the community hospital environment (19). And that the excessive and wrong use of antibiotics in the community has a negative impact on these bacteria and made them resistant to antibiotics, which are used frequently and in excess in all pathological conditions such as urinary tract infection, diarrhea and coughing. To the other by many means, which makes it more harmful than other types that are resistant to antibiotics (20,21). On the related level, there are many studies that prove that most people, especially children who suffer from urinary tract infection, actually suffer from a high temperature, the desire to urinate, in which women who suffer from diabetes do not suffer from frequent urination and fatigue (22,23).

**Conclusions:** It was concluded that, there significant positive correlation between UTIs and inguinal hernia repairs in children.

Abstract

Background: Prostate enlargement is defined as an increase in size of the prostate gland. The disease may be presented clinically as lower urinary tract symptoms (LUTS). The disease is increasing with age. There are many risk factors as age, genetic, geographical, obesity, physical activity, diabetes mellitus, hypertension.

Subjects and Method: A descriptive study was conducted on patients with lower urinary tract symptoms who were attending Tikrit teaching hospital outpatient’s clinic during the period from 1st July - 1st October 2018. The demographic characteristics of patients were obtained according to a questionnaire and the patients were examined clinically to determine if there was enlargement of prostate or not. The diagnoses was confirmed by PR and ultrasound examination.

Results: The frequency of among sample study was (83%). The cases were more prevalent among the followings: age group 60 years and more (94.3%), positive family history (89.7%), low physical activity (93.4%), hypertensives (87.4%) and with those with erectile dysfunction (94.9%).

Keywords: Prostate enlargement; Risk factors; lower urinary tract symptoms (LUTS)

Introduction

Prostate enlargement means there is an increase in size of the prostate gland. The clinical features include frequent urination, weak stream, loss of bladder control, inability to urinate and difficulty in starting urination (1). This disease may lead to many complications such as bladder stone, infection and chronic renal diseases (2).

The causes are unclear (1). About 105 million men are affected in the world (3). The disease begins after age 40 (1) and half of males age 50 and over are affected (2). and the age after 80 years about 90% of males are affected (1) and reach in 2010 (6%) of population (4, 5, 6).

Prostate enlargement rises markedly with increased age (5-7) and may reach in male freely asymptomatic with age 46 years, the risk of developing the disease in the next 30 years, may reach 45% (8). The older age will be at risk to be affected with clinical features of the disease (9-11).

There are other risk factors other than aging which are positive family history (12-14), obesity (15, 16), diabetes mellitus type 2, hypertension (17), not enough exercise (18, 19) erectile dysfunction (1). Eating red meat, fat, dairy product and starch increase risk while eating vegetables, fruits decrease the risk (19, 20).

Some drugs like calcium channel blockers, anticholinergics and pseudoephedrine may worsen symptoms (2).

Diagnosis is depend on clinical bases which based on lower urinary tract symptoms, digital rectal examination then Ultrasound (2).

Patients and Methods

A descriptive study was conducted on adults attending urology outpatient clinic in Tikrit general hospital. The study started from 1st July - 1st October 2018. The patients were diagnosed clinically by the specialist and sent for
further investigation as ultrasound. The sample study individuals demographic information was obtained according to structured-designed questionnaire and by direct interview. Body weight, height, were measured in addition to obtain from patients other investigation which help in relation with common risk factors.

**Statistical Analysis:** Frequencies, per cent and Chi-square test was used to assess association. Statistical analysis at p-value < 0.05 was considered significant.

**Results**

It has been revealed that the frequency of prostate enlargement among study sample was about (83%) (Fig. 1).

![Fig. 1: Distribution of sample study according to presence of prostate enlargement](image)

The frequency of prostate enlargement was progressively increased with age group, the highest frequency was among age group 60 years and more (94.3%) followed by age group 50-60 years (87.1%) and the less frequency among age group less than 50 years (44.4%) with significant difference.

Regarding the residence factor, there was no statically difference between urban and rural area patients even there was slightly high frequency among rural area (84.7%). There frequency of prostate enlargement cases was more frequent among the patient with a positive family history (89.7%) with a significant difference. Table (1)

The frequency of cases with prostate enlargement was higher among patients with low physical activity (93.4%) than those with high physical activity (62.5%), the difference was highly significant.

Regarding the presence of obesity, prostate enlargement cases were higher among obese than nonobese patient (83.3%, 82.4% respectively), but there was no significant difference.

Hypertensive patients had more frequent cases than normotensive (87.4%, 60% respectively) and there was a significant difference.

Hypertensive patients had more frequent cases than normotensive (87.4%, 60% respectively) and there was a significant difference.

Regarding presence of diabetes mellitus, prostate enlargement was more frequent among diabetics (83.3%, 82.4% respectively) with no significant difference.

It has been reported that prostate enlargement cases were more frequent among smokers than nonsmokers’ cases (85.2%, 79.6% respectively) but there was no significant difference.

There was a significant relation between erectile dysfunction and presence of prostate enlargement. The frequency of prostate enlargement cases was higher among patients with erectile dysfunction than those without erectile dysfunction (94.9%, 69.6% respectively). Table (2).

Discussion

The frequency of prostate enlargement in the current study was about (83%). This frequency is higher to that reported in general population , the prevalence of 8%, 50%, and 80% in the 4th, 6th, and 9th decades of life, respectively(9-11). This result may be attributed to that our study result was obtained from the patients with lower urinary tract symptoms which is considered as a risk factor of prostate enlargements(21-24).

The prostate enlargement cases in this study was increasing with increasing age and it was with high frequency among age group (60 years and more) (94.3%) followed by age (50-59) years (87.1%) with significant difference. This results were similar to studies report that prostate enlargement increasing positively with increased age(25). Many researchers revealed that older age is a risk factor of prostate enlargement(9-11,26-29).

According to residence there were slightly high frequency among rural (84.7%) than urban (80.4%) residence but without significant difference.

There was highly significant difference in the current study between those with positive family history of prostate enlargement and those without for occurrence of the disease. The disease was high frequent among those with positive family history (89.7%) than those without(60.7% ). This result was similar to that documented by others.4,12,14,30,31

Prostate enlargement cases in our study were more frequent among patients with low physical activity (93.4%) than those with high physical activity (62.5%) with significant difference. This results were similar to that reported by other in which they revealed that moderate to vigorous physical activity was a protective factors from the disease19,18

It has been found in the current study that there were no significant difference between obese and non-obese and between diabetics and non-diabetics even that obesity and diabetes mellites are considered as a risk factors of prostate enlargements15,16.

Regarding hypertension disease it was documented that prostate enlargement cases were more prevalent among hypertensive patients (87.4%) than non-hypertensive(60%) with significant difference. This result is going to results which consider hypertension is a risk factor of the disease17.

Regarding smoking habit ,the disease was more frequent among smoker than nonsmoker with no significant difference. This result is with agreement of other studies32-Zheeno found that most of patients with benign prostatic enlargement were nonsmokers.

Regarding erectile dysfunction , it has been reported in the current study that prostate enlargement cases were more frequent among patients with erectile dysfunction (94.9%) than those with normal erectile function (69.6%) with significant difference. This evidence support the relation between erectile dysfunction and prostate enlargements21-24.

Conclusions The current study revealed that there are a significant association between hyperchloremia and hypertension, cardiac diseases and diabetes mellites.

Prevalence of Neonatal Septicemia in Karbala Pediatric Teaching Hospital and Al-alwiyah Pediatric Teaching Hospital, Iraq

Ahmed Salim Hadi Al-Khafaji1; Mohammed Ahmed Jassim Alogaidi2; Anfal Akram Hasan3; Yasir Ayad Khallawi4

Abstract

Background: Neonatal sepsis is a major cause of morbidity and mortality worldwide and especially in developing countries. The incidence of neonatal septicemia varies widely between the developed world and developing countries. Methods: The data was collected from the records of the Department during period (February 2019- December 2020), incubated blood culture at 37°C for 7 days. Subcultures were done onto blood agar and MacConkey agar plates. Results: Clinical feature of neonatal septicemia as Fever 31(67%); Feeding difficulty 22 (48%); both Jaundice and Lethargy as 9(19.5%); also, Diarrhea 7(15%); Skin rash 6(13%) and Meningitis 3(6.5%).so current results showed male with positive bacterial culture (69.5%) when compare with Female (30.5%), Among a total of 46 bacterial isolates recovered, 34 (74%) were Gram-negative isolates more than Gram-positive isolates 12 (26%) , so among a total of 46 bacterial isolates recovered, E.coli were recovered from the cases as (24%) followed by both Klebsiella pneumoniae and Pseudomonas as (13.5%), So Citrobacter species and Proteus mirabilis as (8.5%) , and Strep pneumonia and Staphylococcus aureus were recovered from a single case , Staphylococcus epidermedis (7 cases - 15%). Conclusions: Most clinical feature of neonatal septicemia as Fever; Feeding difficulty; and Jaundice and Lethargy, so the male with positive bacterial culture more than Female as well as gram negative bacteria is more common septicemia children with predominant of E.coli .

Keywords: neonatal septicemia; Karbala Pediatric Teaching Hospital; Karbala.

Introduction

Neonatal sepsicaemia (NNS) may be defined as systemic bacterial infection in a neonate documented by positive blood culture within the first twenty eight days after birth1, or define as the clinical syndrome of bacteraemia with signs and symptoms of infection in the first twenty eight days after birth2.

Neonatal sepsis accounted for 1.4 million neonatal deaths or around 40% of total lives lost, annually 3. About 99% of neonatal deaths occur in low and middle-income countries (LMIC) and approximately 62% occurred during the first 3 days of life 4.

There are two types of neonatal sepsis, early- and late-onset. There is little consensus about applicable age limits in literature5. Usually, the age limit defined for early-onset sepsis varies from 3 to 7 days6. Some clinicians and researchers use 7 days as the limit7. Late-onset sepsis is usually caused by organisms acquired after delivery and considered as nosocomial community-acquired infection8.

Breast feeding is another effective strategy in term and preterm infants that improves cognitive and behavior skills, and decreases rates of infection9. An increase in sepsis caused by Gram-negative organisms has been
reported in recent years\(^{(10)}\). Neonatal sepsis caused by Gram-negative microorganisms is responsible for 18%–78% of all neonatal sepsis\(^{(11)}\). Early-onset neonatal sepsis is caused by microorganisms acquired from the mother before or during birth (vertically transmitted and perinatally acquired); thus, microorganisms from the maternal genital tract may play an important role in early infection\(^{(12)}\).

In the developing world, \textit{Escherichia coli} (\textit{E. coli}), \textit{Klebsiella} species, and \textit{Staphylococcus aureus} (\textit{S. aureus}) are the most common pathogens of EOS, whereas \textit{S. aureus}, \textit{Streptococcus pneumoniae}, and \textit{Streptococcus pyogenes} are the most commonly reported organisms in LOS\(^{(13)}\).

**Patients and methods:**

This retrospective observational study was conducted in the Department of Microbiology in Karbala Pediatric Teaching Hospital and Al-alwiyah Pediatric Teaching Hospital. The data was collected from the records of the Department during period (February 2019- December 2020). 2ml blood drawn under aseptic precautions and inoculated into 20 ml blood culture bottles, these blood culture bottles were incubated at 37°C under aerobic conditions in the incubator for 7 days. The first subculture was done after 24 hours of incubation, the second on the third day and a final on the seventh day. Subcultures were done onto blood agar and MacConkey agar plates. The inoculated plates were incubated aerobically at 37°C for 24 hours, and the plates were observed for growth. The growth was identified by colonial characteristics, gram’s stain and standard biochemical tests as well as used Vitek system for identified bacterial isolates.

Among a total of 46 bacterial isolates recovered, *E. coli* were recovered from the cases as (24%) followed by both *Klebsiella pneumoniae* and *Pseudomonas* as (13.5%), So *Citrobacter species* and *Proteus mirabilis* as (8.5%), and *Strep. pneumonia* and *Staphylococcus aureus* were recovered from a single case, *Staphylococcus epidermedis* (7 cases - 15%) (Table-4).

**Discussion**

Data from developing countries shows variable prevalence of Gram negative and gram-positive organisms in neonatal septicemia. Some have predominant gram-negative isolates (14), others show Gram positive isolate predominance (15&16). During lysis, Gram-positive bacteria release peptidoglycans whilst the Gram-negatives release lipopolysaccharides-A (LPS-A) or endotoxins. These substances initiate a cascade of events that lead to the sepsis syndrome, septic shock, multiple organ failure and death. Bacterial fragments, endotoxins and/or exotoxins stimulate monocytes and neutrophils to produce inflammatory mediators (17).

The reason for male preponderance is unknown, but this could be due to sex-dependent factors (18). The synthesis of gamma globulins is probably regulated by X–linked immuno regulatory genes and as males are having one X chromosome, they are more prone for neonatal septicemia than females (19). Previous study as Aletayeb et al., Celicia et al., Rabia et al., and Ahmad et al., have reported higher number of male neonatal septicaemia than female neonatal septicaemia (20 ;21;22).

A study by Ojukwu reported Gram-positive organisms as the predominant with Staphylococcus aureus accounting for 45% while for Gram-negative, *E.coli* accounted for 18.2% (23). Although Gram-positive organisms are the most common causes of nosocomial blood stream infections, Gram-negative bacteremia carries higher risks of severe sepsis, septic shock, and death. Of these, one-third were caused by gram negative bacilli and 70 (18.6%) were multidrug resistant (24). Some of the most frequently isolated bacteria in sepsis are *Staphylococcus aureus* (*S. aureus*), *Streptococcus pyogenes* (*S. pyogenes*), *Klebsiella spp.*, *Escherichia coli* (*E. coli*), and *Pseudomonas aeruginosa* (*P. aureginosa*) (25). Also Hornik et al., showed most commonly bacterial isolate as GBS, Escherichia coli, CONS, *Haemophilus influenzae* and Listeria monocytogenes (26).

Sundaram et al., (27) records *S. aureus* was (22%), *Klebsiella spp.* (18%) and NFGO were (17%). Other organisms in decreasing frequencies were Enterobacter spp. (11%), *E. coli* (9%), *Acinetobacter spp.* (7%), CONS (6%), and *Pseudomonas spp.* (3%). So Kaith et al., 2010 (28) found that CONS were 41%, NFGO were 27% and Klebsiella were 18% of the total isolates, So Al-Shamahy et al., from Yemen had 97% Gram negative isolates. Klebsiella spp. (36%) and *Pseudomonas spp.* (30%) were the two commonest isolates (29).

**Conclusions**

1) Most clinical feature of neonatal septicemia as Fever; Feeding difficulty; and Jaundice and Lethargy.

2) Male with positive bacterial culture more than Female.

3) Gram negative bacteria is more common septicemia children with predominant of *E. coli*.

Seroprevalence of BKV-Antibodies among Cancer Patients and Healthy Individuals

Vian Ibraheem Husain¹, Salah Mahdi Hassen², Amal Aziz Kareem²
¹Msc Student, Health and Medical Technical College, Kirkuk. Northern Technical University, ²Assistance Professor, College of Health and Medical Technology
Baghdad. Middle Technical University

Abstract

BKPyV, a small DNA virus classified into the polyomaviridae family, is holoendemic with global distribution among human population. The objective of this study is to determine the prevalence of anti-BK polyomavirus IgG antibodies among cancer patients and healthy controls. In the present study, A total of 85 serum samples were collected (65 cancer patients and 20 healthy controls) with age range between 15-75 years, the female-to-male ratio was 3:1. All obtained sera samples were tested using ELISA method for the detection of anti-BK polyomavirus IgG antibodies. BKV-IgG seroprevalence show high rate of exposure to the virus 48.23% (41 of 85 samples) revealed positive result (50.77% in cancer patient and 40% in healthy control). Seroprevalence was not different between female and male. The frequency of IgG antibodies decreased from 66.67% in the age group <40 years to 46.94% among age group 40-60 years, and drop again to 38.1% in >60 years old.

Key words: BK polyomavirus, seroprevalence, cancer, ELISA, Kirkuk.

Introduction

Human polyomaviruses (HPyVs) are recognized as a source of benign initial infection during early age. These viruses are highly prevalent in the population with frequent incidences of reactivation and pathologic consequences in elderly and immunosuppressed patients [1]. HPyVs are a growing challenge in those patients in view of the increasing number of currently 12 HPyV species and their various diseases potential [2].

BKPyV represent one of the first two HPyVs that have been identified. It was isolated from the urine and ureteral epithelial cells of a Sudanese renal transplant patient with renal failure and ureteral stenosis [3]. BKV is a small, non-enveloped DNA tumor virus with icosahedral capsid and small, circular and double-stranded DNA [4, 5, 6]. Primary infection with BKPyV usually occurs during early childhood, after waning of the maternal antibodies. In children under the age of 10 years, the seroprevalence rises to 91% and the overall frequency of seropositivity for the virus is 81% [7].

After BKPyV primary infection, the virus establishes a lifelong infection in the renourinary tract [8, 9, 10]. The infection is completely asymptomatic in most immunocompetent individuals, but frequent episodes of viral reactivation can occur and the virus shed into the urine [11, 12]. In seropositive individuals with altered immunity and immunocompromised patients, viral reactivation is followed by high-level of replication and this can result in severe diseases such as polyomavirus-associated nephropathy and hemorrhagic cystitis [12, 13].

Several early studies on the seroprevalence of BKPyV were done using indirect immunofluorescence (IFA), complement fixation assay (CFA), or immunolectroosmophoresis (IEOP). Though, the hemagglutination inhibition assay (HIA), has been used for most of the seroprevalence studies with human polyomaviruses [14]. HIA have been now mostly replaced by ELISA techniques for the detection of antibodies against BKPyV capsid protein using recombinant proteins as antigens. Virus-like particles are produced by expressing the VP1 protein in eukaryotic expression
systems or expressed in *E. coli* as a glutathione-S-transferase (GST) fusion protein \[^{[15]}\].

**Methodology**

**Specimen Collection:** This study was carried out in Kirkuk Specialist Center for Oncology and Hematology, during the period February 2020 to September 2020 and included 85 individuals (65 cancer patients and 20 controls). Single serum specimen were collected and stored at – 20 °C until processed.

**Methods:** To detect the presence of BKV-IgG in the serum, Human BK Virus IgG (BK-IgG) ELISA Kit (Abbkine\China, **item no.** KTE63708) was used according to manufactures instructions with a cutoff concentration 3.43 pg/ml.

**Results**

Table (1) shows the result of IgG ELISA test among the two groups and demonstrates that 33 (50.77%) of cancer patient and 8 (40%) of healthy control revealed positive results while 32(49.23%), 12 (60%) of cancer patients and healthy control, respectively showed negative results. The results show no significant difference at (P>0.05).

### Discussion

BK polyomavirus (BKPyV), a member of the family Polyomaviridae, comprises dsDNA viruses [16]. The virus infect about 90% of human populations at early life and remains latent in the epithelium cells of the proximal tubule of the kidney and the urothelial cells of the bladder, ureters, renal pelvis and other tissue types [17]. The viral reactivation and replication occur when individuals become immunosuppressed or immunocompromised due to cancer, diabetes, pregnancy, HIV-infection, organ or bone marrow transplantion[18].

BKPyV seroprevalence is the lowest at the age of 6 months after losing maternal antibodies. Serological studies reported 50% seropositive rate in children aged 3–4 years old, suggesting that 50% of children had been infected with BKPyV. The seropositive rate rises from 50% to about 90% in adult population. In healthy population, 5% individuals show low-level BKPyV replication with asymptomatic viruria. During adulthood, a gradual drop in antibody prevalence was reported in some studies. This was possibly due to the decrease in antibody titer which was undetectable using hemagglutination inhibition assay or enzyme link immunosorbent assay. This phenomenon revealed a lack of BKPyV antigenic stimulation in older immunocompetent individuals [19].

Reports show that positive serology for BKPyV infections in adults ranged between 60% and 100% [18, 20, 21].

Antibody seroprevalence has been reported by Stolt et al, 2003 in 290 Swedish children aged (1-13 years), grouped by age in 2 year intervals, revealed that seropositivity increased with increasing children’s age, reaching 98 % at (7-9 years) of age, followed by a minor decline in seropositivity [22].

In a study by Knowles et al, 2003 from individuals aged 1–69 years. 81% of sera tested for antibody to BKV revealed positive result and the prevalence varied significantly with age (P < 0.001). 64% of children in the age group of (1–4 years) showed positive results, with rise in the figure to 91% at (5–9 years). This seroprevalence was sustained until around 40 years of age with subsequent decline in the frequency of detectable antibody to 68% in the age group (60–69 years)[7].

In a study by Egli, et al., 2009 included the analysis of serum samples from 400 healthy blood doners. IgG
seroprevalence was 82% for BKV. The seroprevalence decreased from 87% in the youngest group (aged 20 –29 years) to 71% in the oldest group (aged 50 –59 years) (P <0 .006). No significant difference was present between female and male (83% vs. 82%; P > 0.795) [13]. Another study by Kean et al, 2009, found that 82% of 1501 healthy blood donors over the age of 21 revealed antibodies to BKV and 73% of 721 study subjects under the age of 21 was positive [23].

Evaluation the Role of Malondialdehyde in Myocardial Infarction Patients

Dina A. Ibrahim¹, Sami A. Zbbar², Muhib A. Salih³

¹MSC Student, Kirkuk Health Directorate, Kirkuk City, Iraq; ²Assist Prof. Department of Biochemistry, College of Medicine, Tikrit University, Iraq; ³Prof. Department of Internal, College of Medicine, Tikrit University, Iraq

Abstract

Case control study was carried out in Kirkuk city in the intensive care unit in Kirkuk general hospital from Feb 2020 to May 2020. The study included 90 individuals including sixty myocardial infraction patients and thirty healthy individuals to evaluate the level of Malondialdehyde (MDA) in myocardial infraction patients and healthy controls. All patients were aged between (40-80) years, with a negative family history of heart attack. Blood samples were collected from each patients and controls to evaluate the levels of malondialdehyde by using immunofluorescence technique. The study showed no significant differences between myocardial infraction patients and control groups regarding their age, although 33.33% of MI patients belonged to the age group 60-69 year flowed by 28.33% in the age group 50-59 year. The study displayed that the highest mean of MDA was recorded in MI (104.7±13.0 ng/ml) as compared with the control group (66.7± 22.7 ng/ml), The result was significant (P: < 0.05). The study concluded that, the MDA levels were elevated significantly in patients group as compared with the control group and MDA is may be an important cardiovascular parameter, which may be followed before and during the disease.

Keywords: Malondialdehyde; Myocardial infraction; Oxidative stress.

Introduction

Myocardial infarction (MI) is heart muscle damage that results from interruption of tissue blood flow caused by occlusion of coronary arteries due to thrombus. It potentially causes permanent damage (myocardial tissue death) unless there is prompt intervention to open up the coronary artery either by percutaneous or surgical methods¹. According to the World Health Organization (WHO), 17.9 million people die each year from cardiovascular diseases (CVDs), an estimated 31% of all deaths worldwide. This implies that CVDs are the first cause of death globally with heart attacks and strokes producing 85% of all CVD deaths². The most popular form of coronary heart disease is myocardial infarction and is responsible for over 15% of mortality each year³. Unlike the other type of acute coronary syndrome, unstable angina, a myocardial infarction occurs when there is cell death, diagnosis of MI is dependent on the sensitivity and specificity of the clinical criteria, electrocardiographic findings, imaging studies and biomarkers (such as cardiac troponins)⁴. Oxidative stress plays a crucial role in the development of endothelial dysfunction and is a potent modulator of the inflammatory response, cell growth and differentiation, apoptosis and changes in vascular tone⁵. Studies have demonstrated that the excessive activation of lipid peroxidation has a key role in the development of many diseases such as angina and MI. This is because the lipid peroxidation is a chain of reactions providing a continuous supply of free radicals that increase further peroxidation⁶,⁷. Malondialdehyde (MDA) is currently considered to the most widely used representative of oxidative lipid damage⁸. The best evidence of lipid peroxidation is the increased formation of malondialdehyde (MDA) which is one of the principal breakdown products by the action of endoperoxidase, and hence the determination of MDA has been widely used in human studies to prove the involvement of lipid
peroxidation in various diseases. A number of studies reported the elevated level of serum MDA in heart diseases, indicating a link between oxidative stress and AMI\(^9,10\). The study aim of this work was to evaluate the level of Malondialdehyde (MDA) in Myocardial infarction patients and healthy controls.

**Patients and methods**

Case control study was carried out in Kirkuk city, in the intensive care unit in Kirkuk general hospital from Feb 2020 to May 2020. The study included 90 individuals including sixty myocardial infarction patients and thirty healthy individuals to evaluate the level of Malondialdehyde (MDA) in myocardial infarction patients and healthy controls. The information about patients in this study was retrieved from patient’s itself. The myocardial infarction patients were diagnosed by Clinical features, Electrocardiographic (ECG) findings, Elevated values of biochemical markers such as (Cardiac troponin). All patients were aged between (40-80) years. The criteria of exclusion include negative family history of heart attack. The results of the patients groups were compared with healthy individuals nearly comparable age and. About five milliliters of blood were collected from the antecubital vein of patients and controls in plain tubes without any anticoagulant at room temperature for 10-15 minutes and allowed to clot. The tube then were centrifuged (3000 rpm) for 15min. The clear serum was pipetted into clear dry Eppendorf’s and stored at (-20°C) until used for the various investigations. The level of malondialdehyde, was measured by using immunofluorescence technique.

**Results**

The study showed no significant differences between AMI patients and control groups regarding their age, although 33.33% of AMI patients belonged to the age group 60-69 year flowed by 28.33% in the age group 50-59 year, Table 1.

**Figure 1.** : Serum Malondialdehyde Level Comparison Between Patients Group and Control Group in (ng/ml).

**Discussion**

The study showed no significant differences between AMI patients and control groups regarding their age, although 33.33% of AMI patients belonged to the age group 60-69 year flowed by 28.33% in the age group 50-59 year. In agreement with these finding, previous research has found that older age is associated with a higher prevalence of AMI presentation\(^\text{11}\). The elderly with acute myocardial infarction (AMI) have been reported to present with more atypical symptoms\(^\text{12,13}\). AMI is associated with significantly higher mortality in the elderly compared with the young, yet the elderly are treated less aggressively than the young\(^\text{14}\). Another study found that, elderly patients, those 65 years of age and older, represent 13% of them yet account for half of hospital admissions for acute myocardial infarction (AMI) and 80% of AMI deaths\(^\text{15}\). Despite the greater risk of AMI among older patients and the increasing size of this population, the relationship between age, clinical presentation and outcome of AMI in elderly patients is incompletely understood. Many prior observational studies and clinical trials have classified elderly patients as a single population, not specifically evaluating differences in older subgroups, particularly those 75 years of age and older\(^\text{16-17}\). In the elderly, numerous disorders often coexist. Ischemic heart disease, hypertension, diabetes mellitus, chronic obstructive pulmonary disease, chronic renal failure, digestive system disorders, as well as, joint and bone disorders occur more often in this group of patients. The coexistence of several diseases may cause the clinical picture of acute coronary syndrome to be uncharacteristic\(^\text{18,19}\). The study displayed that the highest mean of MDA was recorded in MI (104.7±13.0 ng/ml).
ng/ml) as compared with the control group (66.7 ± 22.7 ng/ml). The result was significant (P: < 0.05), as shown in the Table (2.) and Figure (1.). In agreement with this finding, Yin et al. (11) found that, circulation MDA was significantly increased in patients with acute myocardial infarction as compared with healthy individuals. Majid (12) showed that, patients with acute myocardial infarction have a significant increase in serum MDA comparing with healthy persons. Additionally, Lopes-Virella et al. (13) stated that, levels of circulated MDA showed a significant increase in MI patients when compared with normal persons. Several studies also indicated significant increase in MDA levels in AMI patients as compared to controls (14-16). Another study on 22 AMI patients and 15 controls has found serum MDA levels significantly elevated (20). While in AMI patients a significant increase in serum MDA was observed in the days following the acute event, reaching a maximum 6-8 days later, when 90% of the patients had values higher than the upper normal limit of the control group (17). Another study showed that, the levels of thiobarbituric acid reactive substances (TBARS, predictor of MDA) were significantly increased and total antioxidant status was significantly decreased in AMI (18). Moreover, Bagatini et al. (19) have demonstrated a significant increase in MDA levels and a decrease in nonenzymatic antioxidants such as vitamin C and vitamin E levels in 40 AMI patients when compared with the same number of normal subjects. The significantly higher level of MDA in patients with unstable angina and myocardial infarction than in the control group were attributed to significantly higher level of serum cholesterol, high blood pressure, smoking and increased BMI in patients (21). Oxidative stress has been regarded as one of the most important contributors to the progression of atherosclerosis (13). MDA levels increased following by oxygen free radicals accumulation, which lead to lipid peroxidation in cell membranes, acute cardiac injury, mitochondrial function impairment and reduced myocardial systolic function, and eventually induced AMI (12,19).

Conclusions

The study displayed that the MDA levels were elevated significantly in patients group as compared with the control group and MDA is may be an important cardiovascular parameter, which may be followed before and during the disease.

Assessment of the Coverage Rate of Expanded Program of Immunization among Five Years Children in Tikrit City – Iraq

Hala Mohammad Yosif1, Nisreen Mohammed Ibraheem2
1Physician, 2Prof. Community Medicine Department, Medical of College, Tikrit University, Salahaddin, Iraq

Abstract

Background: Childhood immunization is the initiation of immunity through the application of vaccines. It is considered important for improving child survival. Immunization is a primary health care preventive measure and remain the most cost-effective public health intervention to reduce child morbidity and mortality attributed to infectious diseases. Subjects and Method: Cross sectional study was conducted on five year children who attended (8) kindergarten in Tikrit city and their information from PHCC sector. Children were selected by cluster sample then simple random from each cluster. The study was conducted in the period from November 2019 to August 2020. Results: The study revealed a significant inverse relation was observed between household crowding and socioeconomic status children’s parents. The percentage of full immunized children (40.90%) these children were considered as having had complete immunization, but more than half of the children had one or more than one missed doses and were considered as is having had partial immunization (56.25%). The number of unvaccinated children were five children (2.84%). Complete immunization of children were found among male (54.77%), while complete immunization among children female were (28.26%) and there strong association statistically. The partial immunization among male children were (39.28%) and female were (71.74%) the coverage rate of vaccination among immunized children the coverage rate was (97.2%). The highest for immunized children was for the vaccines Bacillus Calmette Guerin (BCG*)+OP90+first dose of Hepatitis B Virus vaccine (HBV1) (92.04%) while the lowest rate (6.0%) was for the vaccines OPV2booster+MMR+TETRA (DTaP +IVP ). Conclusion: this study concluded that the highly percentage of partially immunized children in kindergarten (56.25%).

Key Word. Bacillus Calmette Guerin (BCG), Oral polio vaccine (OPV), Hepatitis B Virus vaccine (HBV1), Measles Mumps Rubella (MMR), Expanded Programm Of Immunization (EPI).

Introduction

Vaccination is that the administration of agent-specific, however comparatively harmless, substance elements that in immunized people will induce protecting immunity against the corresponding infective agent. Clinically, the terms “vaccination” and “immunization” area unit usually used interchangeably(1). Vaccination could be a extremely effective technique of preventing bound infectious diseases. Vaccines area unit usually safe, and heavy adverse reactions area unit uncommon(2,3). Routine protection programs shield most of the world’s children from variety of infectious diseases that antecedently caused millions deaths annually(4). Several years after wars have ended, children living in war and conflict settings are at risk of developing immunogenic preventable and infectious diseases. Except in times of war, immunogenic campaigns are common(5), but the environment remains conducive to the spread of communicable disease epidemics. Vaccine shortages, problems with the cold chain for immunogenic fidelity, and the inability to locate and inoculate children all result from the war (especially those not in their original families or who are wounded)(6).

Subject and Methods

Study sampling.

Cross sectional study was conducted on five year children who attended (8) kindergarten in Tikrit city and...
their information from PHCC sector. The study included 176 children at five years old who attended kindergarten and their parent and caretaker agreed to take part in the study. Children selected by cluster sample then simple random from each cluster.

**Data Collection and Analysis.**

A suitable questionnaire designed to collect the related information to immunization coverage particularly EPI. Questions included opened and closed questions, demographic information for the child as (age, weight, residence, birth order, place of delivery number of living children in a household, medical history of the child) and Demographic data of the parents like (educational level of the father/mother, occupation of father/mother, socioeconomic status for the family, source of the information about immunization).

**Result**

Regarding to the coverage rate of vaccination among immunized children the coverage rate were 171 (97.2%) while non-immunized children were 5 (8.3%) (figure 1). The highest for immunized children was for the vaccines Bacillus Calmette Guerin (BCG)+OP0+first dose of Hepatitis B Virus vaccine (HBV1) 162 (92%) while the lowest rate (6.0%) was for the vaccines OPV2booster+MMR+TETRA (DTaP +IVP)

![Figure (1) coverage rate of vaccination among children](image)

However the coverage rate decrease for the vaccine OPV2 + Hexa2+ Rota2+ Pneumococcal2 139 (79%), OPV3 + Hexa3+ Pneumococcal3 116 (66%), then increase for the Measles vaccine and MMR (154 (87.5%), 22 (83%) respectively, coverage rate decrease for the vaccine OPV2booster+MMR+TETRA (DTaP +IVP) 72 (41%). Table (1)

Figure (2) show the immunization status for the children. Seventy two of the children were immunized with all vaccination doses; 23 (41%) these children were considered as having had complete immunization, but more than half of the children had one or more than one missed doses and were considered as is having had partial immunization 44 (56%). The number of unvaccinated children were 5 (3%).

**Discussion**

The highest coverage rate for children in this study was for vaccines BCG+OPV0+HBV1. This is may be attributed to the fact that more than three fourth of the children were born in hospitals where these vaccine doses were given soon after birth. This is in agreement with Maheshwari et al in India\(^7\), study in 2014 which had the highest coverage rate for the same vaccine doses, also agree with study by Al-Kazrajy and et al, which conducted on the displaced Iraqi children\(^8\).

Coverage rate for poliovirus vaccine was ≥65% for ≥3 doses of vaccine, this percentage are lower than the National Vaccination Coverage in the America which reach to (92.7%) for more than three doses\(^9\), but similar to this finding with other study was conducted in Africa\(^10\).

Measles and rubella elimination remain a top WHO priority\(^94\). The coverage rate for measles vaccine in current study reach to 87.5%. This finding are agree with Al-Kazrajy and et al study\(^8\) and many study conducted in the many countries\(^11\). The explanation for this finding return to some studies which proved that one-dose vaccines have high coverage of vaccination compared to more than one dose vaccines, which may be due to shortages and delays in completing immunizations on time.

This finding are similar to many studies in the world like the study by Rahman M, Obaid from Bangladesh which revealed the male children were more likely to be fully immunized than female\(^12\). But disagree with the another studies from Iraq by Omer Qutaiba B Al- lemon and et al\(^13\), which mention that many studies in different countries, such as Nigeria and Bangladesh, have found no significant connection between gender and immunization completeness\(^13,14\).

When children are not vaccinated according to the prescribed schedule, they not only miss out on timely protection from preventable diseases at a time when they are most vulnerable, but they also increase their chances...
of never finishing the course. Any of these results jeopardize the effectiveness of a childhood vaccination program\textsuperscript{(15)}.

It’s likely that partial immunization is attributable to a lack of vaccination awareness among parents or providers. Inadequate vaccination information can result in inconvenient timing or missing immunizations, resulting in less disease safety, more side effects, and higher costs\textsuperscript{(16)}.

Furthermore, partial immunization may have occurred as a result of the immunization card or health reports failing to provide a consistent and accurate record of immunization. The immunization card is essential for the immunization provider to know which vaccines are due at the time of the child’s visit. Furthermore, the immunization card is mandatory for both father and mother to be capable to assess or verify their child’s immunization status\textsuperscript{(16)}.

Forty percent of children with high socioeconomic status were fully immunized. This finding was agree with study by Noh J-W, and et al from Pakistan\textsuperscript{(17)} Level of Socioeconomic status for the families in this study were determined by the level of education , occupation of parents and household crowding index. Previous research has found a link between living in wealthier households and having complete full immunization coverage\textsuperscript{(18,19,20)}, which is consistent with a Bangladeshi study that found a positive impact of high socioeconomic status on full immunization coverage\textsuperscript{(12)}. Perhaps one explanation for this result is that income no longer has as much of an impact on full immunization coverage as it once did since immunization offered by the EPI program is free, and public efforts to reach poor mothers and infants are still ongoing.

So the effort made by Iraqi Ministry of Health through vaccination campaign have contributed to the delivery of vaccines to as many children as possible. Incomplete immunization for children with high socioeconomic status may be return to the lack of time due to employed parents and education.

Factors Affecting the Severity of RH Incompatibility Newborn

Nfal Akram Hasan1, Mohammed Ahmed Jassim Alogaidi2, Areej Ali Abbood3

1Pediatrics Specialist, CABP Pediatrics Al-alwiyah Pediatric Teaching Hospital, Baghdad-Alrusafa Health Directorate, 2Pediatrics Specialist F.I.B.M.S pediatrics, Al-alwiyah Pediatric Teaching Hospital, Baghdad-Alrusafa Health Directorate/ Ministry of Health and Environment; 3Gynecologist Specialist FICOG CABOG, Al-elwiyah Maternity Hospital, Baghdad- Alrusafa Health Directorate/ Ministry of Health and Environment / Baghdad / Iraq

Abstract

Rh incompatibility is a not common pediatric problem, that cause morbidity and mortality in children, and it is an important cause of hemolysis, anemia and jaundice in newborn. To study Rhesus hemolytic disease, its severity, its complications; to evaluate if ABO incompatibility is protective or not, so to find out the efficacy of anti-D globulin; to evaluate the efficacy of phototherapy and exchange transfusion as a treatment.

This study was done on neonates with jaundice, seventy five patients (1-10 days old) who had Rh incompatibility were studied during period from the first of January 2008 to the 30th of June 2008.

History was taken about age, gender and gestational age of the patients, determination of gestational age and hepatosplenomegally as a cause of extramedullary hematopoiesis. Investigations done for patients were hemoglobin, total serum bilirubin, reticulocyte count, blood group and Rh, and direct coombs test. From 75 patients studied, 55 patients (73%) required treatment for jaundice; 25 of them (46%) required only phototherapy due to mild degree of hemolysis, and 30 of them (54%) required exchange transfusion with phototherapy due to severe degree of hemolytic. The remaining 20 patients (27%) required observation alone.

Family history of previous hemolysis was positive in 44 patients and it was a risk factor for having hemolysis in present pregnancy. Early evaluation of patients for jaundice was useful in early recovery. ABO incompatibility in association with Rh incompatibility was not necessarily protective against hemolysis. The administration of anti-D globulin to the mother within first 72 hours after delivery was protective against sensitization.

Early and proper management of Rh incompatibility may reduce need for exchange transfusion. ABO incompatibility was not necessarily protective against hemolysis. Anti-D globulin administered to mothers within 3 days after delivery was protective against sensitization, History of hemolytic in previous siblings is considered as a risk factor for present hemolytic in neonates with Rh incompatibility.

Keywords: RH Incompatibility; newborn; hemolytic disease

Introduction

Hemolytic disease of newborn due to Rh-incompatibility is an isoimmune hemolytic disease results from transplacental passage of RH(-ve) maternal blood containing antibodies active against RH(+ve) red blood cells antigens of the infant and is characterized by an increased rate of RBC destruction1, When Rh-positive blood is infused into an Rh-negatives woman through error or when small quantities(usually more than 1ml) of Rh-positive fetal blood containing D antigen inherited from an RH-positive father enter the maternal circulation during pregnancy, with spontaneous or induced abortion or at delivery, antibody formation against D antigen may be induced in the unsensitized RH-negative recipient mother.1
Hemolytic disease rarely occurs during first pregnancy because transfusion of RH-positive fetal blood into an RH-negative mother occurs near the time of delivery, too late for the mother to become sensitized and transmit antibodies to her infant before delivery.\(^1\)

When the mother and fetus are also incompatible with respect to group A or B, the mother is partially protected against sensitization by the rapid removal of RH-positive cells from her circulation by her preexisting anti-A and anti-B, which are IgM antibodies and not cross the placenta.\(^2\) In the fetus, anemia and heart failure are associated with hyperdynamic Circulation in both arterial and venous vessels.\(^3\) Fetal anemia in RH isoimmunization is the reduced life span of erythrocytes coated with antibodies, presumably from phagocytosis by reticuloendothelial cells.\(^4\) In severe cases of RH isoimmunization (erythroblastosis fetalis), hydrops and heart failure related to severe anemia in the fetus occur.\(^5\) Hydrops is often resulting in fetal or neonatal death without appropriate antenatal intervention.\(^5\)

Laboratory evaluation include blood typing, coombs test, complete blood picture with blood film.\(^5\) Reduced hemoglobin levels, reticulocytosis and blood film characterized by polychromasia and anisocytosis are expected with isoimmune hemolysis.\(^7\)

In Rh-negative women, a history of previous transfusion, abortion or pregnancy should suggest the possibility of sensitization.\(^1\)

Parents blood types should be tested, and maternal titer of IgG antibodies to D antigen should be assayed at 12-16, 28-32, and 36wk; the presence of elevated antibody titers at beginning of pregnancy, or rapid rise in titer, or titer of 1:64 or greater suggests significant hemolytic disease\(^1\). Immediately after birth of any infant to Rh negative woman, blood from the umbilical cord or from infant should be examined for blood group, Rh type, hematocrit and hemoglobin, and reaction of the direct coombs test; if the coombs test is positive, baseline serum bilirubin should be measured being done not only to establish the diagnosis but also to ensure the selection of the most compatible blood for exchange transfusion.\(^1\)

**Aim of current study:** To determine the severity of Rh hemolytic disease and its subsequent complications, and determine the protective effect of ABO incompatibility, so to find out the efficacy of anti-D globulin and effect of treatment of Rh incompatibility with phototherapy and exchange transfusion.

**Patients and methods:**

About 75 neonates with jaundice and Rh incompatibility admitted to Central Child Teaching Hospital and Al-Yarmook Teaching Hospital were studied during the period from the first of January 2008 to the 30th of June 2008. Forty six patients were males and twenty nine were females and their age range from 1-10 days.

**Clinical information collected** include: gestational age, gender, parity of the mothers, the presence of previous hemolysis or previous abortions, administration of anti-D antibody to the mothers, previous blood transfusion to the mother, presence of jaundice and its time of onset, and presence of pallor. So all the neonates were examined thoroughly for the presence of jaundice determination of gestational age, hepatosplenomegaly and ascitis. the pallor, in addition to investigations were done: for neonates = hemoglobin, reticulocyte count, blood group and Rh, total serum bilirubin, and direct coombs test (the method of direct coombs test in hospitals mentioned above is by putting on drop of whole blood and wash it 4 times with normal saline then remove supernatant and add 2 drops of antihuman globulin then test for agglutination by naked eye); *for mothers* = blood group and Rh. With regards to treatment, we found that -20 patients need no specific treatment. -25 patients need treatment with phototherapy alone (Group A). 30 patients need treatment with phototherapy and exchange transfusion (Group B).

**Results**

The frequency of severe Rhesus hemolytic disease and the need for exchange transfusion were more in those with multiparous mothers, as shown in table (1):
Table (1): Relationship between hemolysis in neonates and parity of their mothers.

### Discussion

In this study we found that when the parity increases, the severity of hemolysis will be more and the need for exchange transfusion will also increase as shown that exchange transfusion was needed more in those with multiparous mothers, this result was also proved by Swinhoe & Gilmore which found that Rh hemolytic disease increased with subsequent pregnancies\(^{(29)}\) and also Joseph & Kramer who found the same results\(^{(28)}\); and this is because fetomaternal transfusion occur with each pregnancy and the illness will be more worse with successive pregnancies\(^{(1)}\).

We found that the majority of those who required exchange transfusion had a history of previous hemolysis in their siblings (27 from 30 neonates) (90%) and 17 neonates of 25 neonates (68%) who required phototherapy had history of previous hemolysis siblings and this means that the history of previous hemolysis increases the the possibility that subsequent pregnancies and babies need active treatment; while no one in the untreated group had history of previous hemolysis; and this goes with the fact that consider previous kernicterus or severe erythro-blastosis fetalis in a sibling as a further factor to decide treatment and not only to base the decision for treatment on the degree of anemia and/or hyperbilirubinemia\(^{(1)}\).

Fifteen of 20 neonates (75%) who did not require treatment, their mothers received dose of anti-D immunoglobulin and it was effective in preventing hemolysis in the successive pregnancies and that is why their neonates did not need treatment. Only 5 of 55 mothers (9%) whom their babies required treatment, received dose of anti-D. This result is similar to what was found by Swinhoe & Gilmore \(^{(29)}\), and also by LAD & Jane \(^{(30)}\); while Hundric found that prevention of Rh immunization by anti-D immunoglobulin does not comprise all the Rh negative mothers especially inadequate after abortions and multiple pregnancies\(^{(34)}\).

So, we found that the presence of ABO incompatibility between neonates and their mothers was not effective in protection against hemolysis; this result is similar to that found in Vox who found that ABO incompatibility has no effect on ameliorating the severity of erythroblastosis after Rh-incompatibility has developed \(^{(32)}\), while VOS in his study found that Rh immunization in pregnancy is significantly less in ABO incompatible matings than in ABO compatible matings\(^{(31)}\). The fact that ABO incompatibility is protective against Rhesus hemolysis by the rapid removal of the fetal red blood cells by the mother’s natural IgM anti-A and anti-B antibodies which do not cross the placenta\(^{(1)}\).

Clinical features of hemolysis like jaundice and pallor were evident in 89% and 40% of the neonates respectively, this is because that Rhesus incompatibility is a cause of hemolysis; and this evidence of hemolysis was more clear in the group who required exchange transfusion than those patients treated with phototherapy alone.
We found in this study regarding the hematological findings that the difference in the hemoglobin and reticulocyte count between neonates who required exchange transfusion and those treated with phototherapy alone was highly significant (p-value less than 0.001), which means that there is lower hemoglobin level and higher reticulocyte count in the exchange transfusion group than in phototherapy group, also the TSB levels were significantly higher in the group who required exchange transfusion than those treated with phototherapy alone.

All the above findings indicate that hemolysis was more severe in the exchange group than in the phototherapy group, and this was approved by Hayde & Widness in their study when they found that among infants with severe Rh isoimmunization, high total serum bilirubin levels and low hemoglobin levels indicate continuing severe hemolysis. Direct coombs test was positive in 27 from 30 neonates (90%) who required exchange transfusion due to the presence of high titer of maternal anti-bodies against the babies Rhesus positive red blood cells and it was positive in 15 from 25 neonates(60%) treated with phototherapy alone.

**Conclusion**

1) Early and proper management of the Rh-incompatibility may reduce the need for exchange transfusion. So, ABO incompatibility if occur with Rh incompatibility is not necessarily protective. also Anti-D immunoglobulin was protective against Rhesus hemolytic disease.

2) History of previous hemolysis in previous siblings is considered as risk factor for present hemolysis in neonate with Rh-incompatibility.

A Comparative Study of Efficacy of Esmolol and Fentanyl For Blood Pressure and Heart Rate Attenuation During Laryngoscopy and Endotracheal Intubation

Bashar Naser Hussein1; Mohammad Kheiri Mahmod1, Ammar Hamid Hanoosh1
1Anesthetist, MBchB; DA Diploma of Anesthesia, AL-Yarmook Teaching Hospital, Ministry of Health and Environment, Baghdad, Iraq

Abstract

Background: Blood pressure and heart rate elevation during laryngoscopy and tracheal intubation may cause serious medical problems ex: patients with cardiovascular disease as well as patients with increased intracranial pressure. Aim of study: Comparism between Fentanyl and Esmolol in attenuating blood pressure and heart rate during laryngoscope and tracheal intubation. Patients and Method: 60 adult patients of both sex, ages between (20-33), labeled as ASA I and ASA II will undergo elective surgery, divided into two groups, each group contain 30 patients: Esmolol Group (E) takes 0.5 mg/kg esmolol IV. And Fentanyl Group (F) takes 1 mic/kg fentanyl IV. Blood pressure and heart rate was recorded before drugs administration as baseline reading and another reading was taken after drug administration as well as after tracheal intubation. Result: blood pressure and heart rate readings of both groups, when compared to baseline reading shows that Regarding heart rate, there are significance differences between the two groups, in that, esmolol reduce heart rate in all stages when compared to fentanyl. Regarding systolic blood pressure, both drugs reduce systolic blood pressure and there are significances in all stages, favored esmolol except in T3 due to rise in sbp when using fentanyl. Regarding diastolic blood pressure, both drugs also reduce diastolic blood pressure but there are no significances in these reading except in T3 due to esmolol reduce dpb much more than fentanyl does. Conclusions: esmolol in a dose of 0.5mg/kg is more effective than fentanyl in a dose of 1mic/kg in attenuation of hemodynamic response after endotracheal intubation.

Key words: Esmolol, fentanyl, hemodynamic changes, endotracheal intubation

Introduction

Due to sympathoadrenal discharge resulting from direct stimulation of epipharyngeal, laryngopharyngeal and par-pharyngeal area, together with increase plasma level of nor epinephrine [2]. The afferent sensory pathway is comprised of the glosopharyngeal nerve, which innervates the pharyngeal, structures superior to the anterior surface of the epiglottis, and the vagus, which innervates the posterior epiglottis distally into the trachea. The efferent responses to laryngoscopy and endotracheal intubation are mediated by both the parasympathetic and sympathetic nervous systems. The parasympathetic response, which is mediated by the vagus, can produce sinus bradycardia or arrest (occur mainly in children), but the main response in adult is sympathetic stimulation[3].

These response start with the first 5 second from laryngoscopic manipulation and intubation, and reach a plateau level after 45-60 seconds from intubation and return to normal level in 5 minutes[4].

Esmolol is cardioselective beta1 receptor blocker with rapid onset, a very short duration of action, and no significant intrinsic sympathomimetic or membrane stabilizing activity at therapeutic dosage. Esmolol reduce heart rate and, to a lesser extent, blood pressure. It has been successfully used to prevent tachycardia and hypertension in response to perioperative stimuli, such as intubation, surgical stimulation and emergence[13].
Although fentanyl has no significant effect on the cardiovascular system, it depends on the central Vigus stimulation \[14\]. Opioids neutralize the hemodynamic responses to intubation and surgical stresses, but are associated with nausea, vomiting, and hypoventilation, there are many studies into the reduction of hemodynamic responses to laryngoscopy and intubation, and many medications have been used, but there is still no specific medication for it \[14&15\].

**Patients and method:**

After approval obtaining from Arabic board council committees, and attaining a written consents from patients a double blind study was done to 60 patients.

**Inclusion criteria :**

* classified as ASA I , ASA II .
* scheduled for elective surgery ( lower abdominal surgery ) under general anesthesia and muscle relaxation with endotracheal intubation

the study was done in Al-yarmouk teaching hospital , in November the 1\textsuperscript{st} 2014 to December 1\textsuperscript{st} 2015 .

Exclusion criteria include:

* Pregnant patients .
* Patients refusing .
* Patients with ENT surgery .
* baseline pulse rate <60 bpm .
* Patient with suspected difficult intubation.
* patient on drug effecting autonomic nervous system .
* patients on antihypertensive drugs.
* Patient’s allergy to the corresponding drugs of the study.

Demographic data including:

1. Age (20-33) years.
2. Sex , male (36 ) , female (24 ).

3. Body weight (70 -90 kg ).

All patients were fasting for at least 6-8 hours. Basic monitoring which includes (Bp - HR - PR - SpO2) was attained by using non-invasive devices.

Patients divided into two groups as Group F take 1 mic / Kg fentanyl IV and Group E take 0.5 mg / Kg esmolol IV

**DATA collection:**

* At 0 time To (time just before the drug of the study was injected), blood pressure and pulse rate were taken as baseline measure , and the drug of the study were injected slowly over one minute .

* T1 after 3 minutes from drug administration the reading of blood pressure and heart rate were taken.

* T2 after general anesthesia was given; a reading was taken just before performing endotracheal intubation. (two minutes after T1 )

* T3 another reading was was taken just after performing endotracheal intubation.

* T4 final reading was recorded after 5 minutes from performing endotracheal intubation. Intubation was fascillating with a sleeping dose of propofol (1.5 - 2.5) was injected slowly and 0.1 mg / kg of vecuronium bromide.

At the end of the operation, Halothane was stopped and muscles reversal was done with neostigmine (0.01 mg / kg) together with Atropine (0.01 mg / kg) were given.

All patients were awake extubated in left lateral position and safely discharged from operating room.

**Statistical Analysis**

Analysis of data was carried out using the available statistical package of SPSS-20 (Statistical Packages for Social Sciences- version 20).
Data were presented in simple measures of frequency, percentage, mean, standard deviation, and range (minimum-maximum values).

The significance of difference of different means (quantitative data) was tested using analysis of variance (ANOVA) for more than two groups, using independent student-t-test for difference between two independent means, and paired t-test for difference between two dependent means (paired observations). Statistical significance was considered whenever the P value was equal or less than 0.05.

Results

First of all there are no difference between the two groups according to body weight, gender and age.

T1: Systolic blood pressure was decrease in both groups, from the baseline reading, the reduction in sbp was so obvious with esmolol and it was a significant change when compared with fentanyl. P value <0.05.
Diastolic blood pressure was decreased in both groups, from baseline reading, although dbp was reduced, when using esmolol, more than when using fentanyl but it was not significant. P value > 0.05

Mean blood pressure was decreased in both groups, although esmolol reduce mbp more than fentanyl, but the changes were not significant. P value > 0.05

Heart rates were decreased in esmolol group only and fentanyl group show slight increase in heart rate, but the overall changes was a significant value which favored esmolol. P < 0.05.

Discussion

In the present study we compare between esmolol in a dose of 0.5/kg and fentanyl in a dose of 1mic/kg in order to attenuate the hemodynamic response that occur during endotracheal intubation. and we found that esmolol is more effective than fentanyl in that respect [16]. Esmolol provide a smothe and gradual control of the blood pressure .and prevent the rise of blood pressure during intubation.

Esmolol also prevent the rise of the heart rate during intubation [17]. Increasing the dose of the study drugs may cause unplanned hypotension and bradycardia [18], especially fentanyl which may augment the hypotensive effect of the propofol.

We need to increase the dose of fentanyl in order to control the heart rate [19], as it shows in our study fentanyl failed in attenuating the rise of heart rate during intubation.

The following two studies below were performed by using same dose [or even less] of esmolol that has been used in our study and proved that esmolol in a dose of 0.5 mg/kg and 0.4 mg/kg was effective in attenuating the rise of blood pressure and heart rate during endotracheal intubation as Jazaer state that esmolol in a dose of 0.5mg/kg is enough for attenuating hemodynamic response during intubation [20], whilst Kasey found that esmolol in a dose of 0.4mg/kg is enough for attenuating hemodynamic response that occur during intubation [21].
Many previous studies favored esmolol in attenuation the rise of blood pressure and heart rate during endotracheal intubation, when compared to fentanyl, although the doses of the study drugs were higher from the doses in current study: Shobhana and Purvi found that both fentanyl in a dose of 2mic/kg and esmolol in a dose of 2 mg/kg, can attenuate the hemodynamic response. But only esmolol provided consistent and reliable protection against increases in both heart rate and systolic blood pressure accompanying laryngoscopy and endotracheal intubation [22], so Feng et al., found that esmolol in a dose of 2 mg/kg could reliably offer protection against increase heart rate and blood pressure, while fentanyl in a dose of 3mic/kg only protect against hypertension not tachycardia [23] as well as Gogus et al., found esmolol in a dose of 2 mg/kg is better than fentanyl in a dose of 2 mic/kg in attenuation of hemodynamic response [24], whilst Sampangiramaiah and Jodumut found that esmolol in a dose of 1.5 mg/kg is better than fentanyl in a dose of 2 mic/kg, in attenuating hemodynamic response, and fentanyl in such dose may cause severe hypotension [25]. So Habib Bostan, Ahmet Eroglu found that both esmolol in a dose of 1 mg/kg and fentanyl in a dose of 1 mic/kg, can attenuate the hemodynamic response, but esmolol is more effective [26].

Study of Possible Predisposing Factors that May Result in Congenital Abnormalities among Newborn Infants a Hospital-based Study

Munaf Authman Hreeth¹, Ahmed Nadher Kareem², Sabah Noori Rashid²

Abstract

The term congenital abnormalities signifies that there has been disruption in the normal process of organogenesis occurring before birth. The earlier the insult, the more gross the abnormality.

This study aimed to study some predisposing factors that may result in congenital abnormalities among newborn infants in neonatal care unit (NCU) of Al-Kadhymia teaching hospital-Baghdad/Iraq. This prospective study was carried out during the period from 1st February to 1st August 2011. A total of 2700 neonates were admitted to NCU, and (100) newborn infants were proven to have congenital abnormalities by physical examination alone in the nursery care unit.

The results showed that of the total (100) affected neonates, 63 (63%) were full term as compared to only 37 (37%) preterm baby (<37 weeks gestation) with a significant difference (P <0.05). Of the total 2700 neonates, 1440 (53%) were females and the remaining 1260 (47%) were males.

Out of the (100) neonates who were proven to have congenital anomalies, 55 (55%) were males and 45 (45%) females. The percentage of newborns with congenital abnormalities was 3.7% with respect to total number of newborns (2700); 2.1% were males and 1.6% were females.

Our results showed that (55%) had neurological abnormalities followed by (12%) cleft lip and palate then (11%) chromosomal abnormalities (most of them Down syndrome and only 3 cases had Edward syndrome and 1 case had Patau syndrome). In this study, it was shown that the highest incidence of congenital abnormalities (55) occurred between (20-30) years.

It can be concluded that most the affected newborns were full terms, with a slight male predominance. Incidence of neurological abnormalities was higher than other types of congenital abnormalities, the highest incidence of congenital abnormalities occurred between 20-30 years, and in multigravida mothers, and most of parents were reported to be consanguineous or relatives.

Key words: Congenital abnormalities, newborn infants, predisposing factors.

Introduction

There are two types of congenital abnormalities, the major congenital anomaly, which is a structural abnormality present at birth, and has a significant effect on function or social acceptability, e.g. cleft lip, while the minor congenital anomaly is a structural abnormality present at birth, which has minimal effect on clinical functions, but may have a cosmetic impact, e.g. pre auricular pit [1].
Congenital malformations or birth defects are common among all races, cultures and socioeconomic strata. Birth defects can be isolated abnormalities or part of a syndrome and continue to be an important cause of neonatal and infant morbidity. Based on a World Health organization (WHO) report, about 3 million fetuses and infants are born each year with major congenital malformations; congenital malformations accounted for an estimated 495,000 deaths worldwide in 2005 [2].

Regarding etiology, congenital abnormalities can be the result of monogenic, chromosomal, maternal infections, maternal illness, twinning, environmental agents, medications, nutritional and unknown etiologies [3].

Congenital anomalies can be classified either based on timing of insult, underlying histological changes, or based on its medical and social consequences.

Congenital anomalies based on insult can be placed into following three categories: malformation, disruption and deformation. Classification based on underlying histological changes includes: aplasia, hypoplasia, hyperplasia and dysplasia [4].

Regarding management of congenital abnormalities, newborns with one or more malformations should receive ongoing care and may require multidisciplinary care and case management. Some clinical problems or physical findings may evolve over time and become more apparent with age [5,6].

Patients and Methods

This prospective study was carried out in Al-Kadhymia teaching hospital (Neonatal care unit) during the period from 1st February to 1st August 2011.

A total of 2700 neonates were admitted to NCU. One hundred newborn infants were proven to have congenital abnormalities by physical examination alone in the nursery care unit. The questionnaire for neonatal evaluation included: gestational age, sex, body weight and type of congenital anomaly. A detailed maternal history including age, parity, antenatal care, any history of abortion, previous baby with congenital abnormality, still births, medical illness, or drug intake during pregnancy were also obtained.

Moreover, the residency of the family and consanguinity between father and mother were recorded.

Statistical Analysis

The Statistics Package for Social Science (SPSS) version 17 was used for data analysis. The results are expressed in form of numbers, percentages and Chi-square Pearson correlation which was statistically significant at P.value less than 0.05 and statistically not significant at P.value more than 0.05.

Results

Of the total (100) affected neonates, 63 (63%) were full term when compared with 37 (37%) preterm babies (<37 weeks gestation), as shown in table (1), with significant difference (P<0.05).

Results in table (4) showed the highest incidence (55%) of congenital abnormalities occurred within the age group (20-30) years, and (38%) within the age group (30-40) years, while (5%) occurred within (> 40) years and only (2%) within <20 years. The table demonstrated that the occurrence of congenital abnormalities in multigravida mothers was the highest (81%) when compared with primigravida mothers (19%). Out of 100 cases, (34%) had regular antenatal care and folic acid supplement during pregnancy, while (20%) were with maternal illness during pregnancy, which included (11% D.M), (8%) with hypertension and (1%) with epilepsy. Table (4) also showed that (13%) had a history of congenital abnormalities in their families, which was mainly neurological (10%), cleft lip and palate (2%) and (1%) chromosomal disorder (Down syndrome). Out of
100 cases, (56%) were living in urban areas and (44%) in rural areas. In regard to consanguinity between father and mother, (70%) were reported to be consanguineous, and only (30%) were negative (strange). Finally, (6%) of mothers were reported to be giving birth to a baby with congenital abnormalities and (2%) with stillbirth.

Discussion

Our results indicate the prevalence of congenital malformation disorders at Al-Kadhymia teaching hospital in NCU was 3.7% (100/2700), where males were higher than females, and male to female ratio was 1.3/1. This finding is in agreement with the Iranian study [7].

In a recent study done in Iran in June 2008, there was 2.9% of live births have major congenital abnormalities [7], while another study in Kuwait documented 1.25% of children with congenital abnormalities [8]. Considerable variation in frequency in different populations has been reported, from as low as 1.07% in Japan [9] to as high as 4.3% in Taiwan [10]. This wide variability could be due to the difference in population’s genetics.

Also, in this study, out of 100 newborn infants with congenital abnormalities, (63%) were full term with body weight (2.5-3.5 Kg), and only (37%) preterm babies with body weight (1–2.5 Kg), whereas a slight increment in incidence had been found in preterm and small for gestational age infants in a studies done in U.K [11] and India [12]. Such results could be attributed to the absence of facilities regarding antenatal diagnosis of such anomalies in our country leading to delivery of a full term babies with such anomalies.

Moreover, this study showed that the commonest anomalies were neurological (55%), followed by cleft lip and/or palate (12%), then chromosomal abnormalities (11%); among the neurological anomalies, the neural tube defects was the commonest one.

Different observations were recorded in other studies. A study in India [13,14] revealed an increase in frequency of musculoskeletal anomalies (30%), neurological (20.5%), then cleft lip and palate (18.5%); Other studies in Iran and Tunis [15,16] showed higher incidence of cleft lip and palate, while a study in Saudi Arabia [17] reported that the major anomalies are genitourinary (25%), cardiovascular (15%) then neurological (10%).

This partly implies a poor compliance of pregnant women regarding the intake of folic acid, in addition to poor antenatal care in regard to screening for such anomalies.

The neurological anomalies in this study were 55%, while in Wales (1%) [18], and in Germany (2%) [19]; this could be related to inadequate education of our people in regard to supplementation of folic acid during pregnancy and poor antenatal care, while in Wales and Germany, there are facilities for prenatal diagnosis and interruption of affected pregnancy.

The chromosomal abnormalities in this study was 11% which is similar to the study of United Kingdom, but higher than a study in in Norway 0.1% [20].

The chromosomal abnormalities in this study was 11% which is similar to the study of United Kingdom [11], whereas 0.1% in Norway [20].

On the other hand, this study showed that the percentage of occurrence of congenital abnormalities was (70%) among newborns delivered to consanguineous parents, which is similar to the figure in India and Iran and Saudi Arabia studies [15,17,21]. Despite the high prevalence of consanguineous marriages, the overall incidence of congenital abnormalities was not higher than developed countries [22].

The percentage of congenital abnormalities was very high among mothers aged (20-30) years (55%). A study done in England concluded that the increasing age of the mother may increase the risk of congenital abnormalities especially chromosomal defects [23], which may be attributed to the fact that this age is a common age of child bearing and higher fertility rate that is why most congenital abnormalities can be diagnosed in this age group.

Also, this study revealed that the residency of the families was from urban areas (56%) and this could be related to physical and environmental exposures (hot climate, air pollution, chemicals like lead exposure [24] and ionizing radiation [25,26]. In addition to the proximity of Al-Kadhymia teaching hospital to these areas, more anomalies can be diagnosed and documented. This result was in disagreement with a study done in India by Datta V Chaturvedi [14] who revealed higher incidence
of congenital malformations (57%) among people living in rural areas.

With respect to parity of mothers, this study revealed that most anomalies occur in multigravida mother (81%). Similar observations were recorded in other studies \[27,28\], which could be related to presence of a history of previous abortion, still births or delivery of affected baby with major anomaly, making such mothers attend hospital for their delivery of subsequent babies, whereas the least occurrence of anomalies in primigravida mother (19%). Chaturvedi et al \[21\] recorded increase in frequency of congenital anomalies in primi mothers.

Our study showed that there is significant family history of congenital abnormalities, as there were thirteen (13%) cases reported to have such a history which could be explained by the fact that most anomalies would be the result of genetic inheritance or mutation of certain gene in the family. This had been approved by a study done in Tokyo by Otake et al., \[27\] who revealed high frequency of congenital anomalies (10%) out of 1000 families with history of congenital anomalies).

Finally, this study showed that the diseases during pregnancy with drugs taken during such period were relatively insignificant regarding the occurrence of congenital abnormalities in newborns, as only (20%) mothers who had taken drugs during pregnancy. This could be due to that either most pregnant ladies in our society have no regular antenatal care follow up so most diseases passed undiagnosed, or the pregnant women who had medical disease during their pregnancy are well controlled by medication that had no impact on the growing fetus. Other studies done in Pakistan by Mishra and Baweja \[29\] and Garner \[30\] revealed increased incidence of congenital abnormalities with maternal illness.

Risk Factors of Rebound Hyperbilirubinemia in Post Phototherapy Hyperbilirubinemia Infants

Alexander Leonard Caesar Josediputra¹, Martono Tri Utomo², Risa Etika³

¹Researcher, Pediatric Resident, ²Associate Professor, ³Scientist, Head of Neonatology Division, Faculty of Medicine, Airlangga University, Dr. Soetomo General Hospital, Surabaya, Indonesia

Abstract

Background: Post phototherapy rebound hyperbilirubinemia is a cause for readmission in some infants. However, this phenomenon data of rebound hyperbilirubinemia is lacking from Indonesia. Our study aims to describe the risk factor of post phototherapy rebound hyperbilirubinemia in the infant.

Method: Cross-sectional study of all infants with indirect hyperbilirubinemia who were treated phototherapy according to standard guidelines in neonate intermediate unit Dr. Soetomo hospital for 6 months from June 2017 until December 2017. Bilirubin was measured 24 hours after phototherapy. Bilirubin rebound is considered as increasing total serum bilirubin that needs reinstitution of phototherapy.

Result: A total of 53 (44.9%) infants developed rebound hyperbilirubinemia. We revealed the following risk factor for rebound hyperbilirubinemia was the onset of jaundice on < 3 days, (10 babies, p <0.05). Other results are 30 (56.6%) female infants, 39 (73%) birth weight < 2500 g, 36 (67%) infants with a history of cesarean section, and 38 (71%) preterm infants but there are not statistically significant.

Conclusion: Post phototherapy rebound hyperbilirubinemia should be considered in the onset of jaundice < 3 days.

Keywords: Phototherapy, Neonatal hyperbilirubinemia, Rebound hyperbilirubinemia

Introduction

Hyperbilirubinemia in neonates is a common condition. Approximately 60-70% of term neonates and 80% of preterm neonates develop jaundice in the first week of life. Most of the hyperbilirubinemia is physiological and does not require special therapy, but there are some conditions where after phototherapy the hyperbilirubinemia recurs. Rebound hyperbilirubinemia after stopping phototherapy is a rare phenomenon.¹,² Some authors define it as a post-phototherapy bilirubin level that requires reinstitution of phototherapy according to AAP guidelines.³ The detection of rebound hyperbilirubinemia after stopping phototherapy is a common practice that prolongs hospital stay and increases laboratory costs.

In the previous study, recurrent hyperbilirubinemia occurred in 24.9% of the neonates who were the study subjects, the majority causes are hemolytic disease (71%) (ABO incompatibility 54.8%, Rhesus 4.8%, other etiologies unknown 16.9%). From previous studies, it was found that low birth weight increased...
the risk of recurrent hyperbilirubinemia by 3.5x and the male gender increased the risk by 1.6x. Other risk factors include gestational age, mode of delivery, birth weight based on gestational age, pregnancy more than once, and the onset of jaundice. Phototherapy is widely recognized as a relatively safe and effective method for the treatment of neonatal hyperbilirubinemia.

Bilirubin levels often increase after discontinuation of phototherapy. The factors causing the elevated bilirubin levels after stopping phototherapy have been investigated in several previous studies with different risk factors. This research has not been carried out in Dr. Soetomo hospital so that this study is the beginning to find risk factors for recurrent hyperbilirubinemia babies so that it can find prevention and prognosis for babies with the disease.

Material and Methods

Study Population

A case-control study was conducted on hyperbilirubinemia infants (age 0-28 days) in Dr. Soetomo General Hospital, Surabaya. Subjects were chosen using the total sampling technique and were included in the study if they met the following inclusion criteria: hyperbilirubinemia which had phototherapy. Exclusion criteria in this study include multiple congenital anomalies, sepsis, and direct hyperbilirubinemia. The control of this study is an infant with hyperbilirubinemia but does not have rebound hyperbilirubinemia.

Phototherapy is using blue light (minimum intensity of phototherapy light 10-12mW/cm²/nm) with an effective surface area of 60x30 cm and a distance of the light from the baby of 40 cm for 1-2 x 24 hours.

Hyperbilirubinemia is defined as a condition in which bilirubin levels increase with normal values depending on gestational age or birth weight and postnatal age (in hours) and clinically requires phototherapy or exchange transfusion.

Rebound hyperbilirubinemia is defined as post-phototherapy bilirubin level requiring reinstitution of phototherapy according to AAP (American Academy of Pediatrics) guidelines (Bansal et al., 2010). Data of sex, the onset of jaundice, birth weight, gestational age, and mode of delivery from all infants that met the criteria of rebound hyperbilirubinemia were recorded from the medical records. Birth weight is grouped by ³ 2500 gram < 2500 gram; onset of jaundice is grouped by and ³ 3 days and < 3 days old; mode of delivery is grouped by vaginal delivery and caesarean section; gestational age is grouped by term and preterm infant.

Statistical Analysis

The data were analyzed using Microsoft Excel 2019 and using IBM SPSS Statistic Version 21.0. A descriptive analysis was used to present the correlation. A Chi-square test was used to seek the bivariate correlation of rebound hyperbilirubinemia and risk factors.

Variables that have correlations were analyzed further by analysis of variance to define any influences between variables. A value of $p < 0.05$ was considered to be significant.

Ethics

This study was conducted after obtaining ethical approval from the Health Research Ethics Committee of Dr. Soetomo General Hospital, Surabaya. Before conducting the research, the procedure was fully explained to the parents. The study was conducted only after informed consent was signed by the parents/guardians. The confidentiality of the research subjects was maintained in this study.

Result and Discussion

A total of 118 infants in neonatal inpatient installation of Dr. Soetomo hospital with hyperbilirubinemia requiring phototherapy were involved in this study. The base characteristics of this study are described in table 1. Correlation of sex, onset of jaundice, mode of delivery, birth weight, and gestational age with rebound hyperbilirubinemia described in table 2

*p-value statistically significant

In this study, 53 infants (44.9%) were found with rebound hyperbilirubinemia. Female babies are more than male babies. Hyperbilirubinemia was more found in cases of infants with birth weight <2500g. The onset of hyperbilirubinemia occurs mostly at <3 days of life. Most cases of hyperbilirubinemia occurred in infants caesarean section delivery. In addition, the most cases of hyperbilirubinemia were also found in infants with pre-term infant.
Female infants with rebound hyperbilirubinemia are more than male infants. The results of this study are different from previous studies with 9% of female babies compared to 12.9% of male infants who experience recurrent hyperbilirubinemia. The cause of the differences in this study is that it does not exclude the possibility of hemolytic diseases such as ABO incompatibility, Rhesus, Coomb test, G6PD, sepsis, type of nutrition, and other risk factors so that there is a possibility that female patients are included in the study sample that will affect the study results.

Onset of jaundice in infants with rebound hyperbilirubinemia was found to be significantly different in infants with yellow onset <3 days with a risk of 2.5 times compared to ³ 3 days. The highest incidence of jaundice was observed on the second to fourth day after birth. Among all infants with the onset of jaundice within 72 hours after birth, 13.8% showed hyperbilirubinemia after cessation of phototherapy. Contributing factors to the development of physiological hyperbilirubinemia in the neonate include increased bilirubin load due to relative polycythemia, shortened erythrocyte life span (80 days compared to 120 days of adults), immature hepatic absorption and conjugation processes, and increased enterohepatic circulation. This study does not record the nutrition of the baby so that the result can be biased.

Mode of delivery by caesarean section also showed more results in infants with rebound hyperbilirubinemia (30.50%) compared to normal delivery (14.40%), but in this study, it was not statistically significant. In another study after discontinuation of phototherapy, rebound hyperbilirubinemia was found in 13.3% of neonates born via cesarean section, but no statistically significant association was found (p = 0.520). In this study, the data on infants with cesarean delivery were not recorded with the indication.

Low birth weight babies and preterm infants are not statistically significant in this study. In another previous study, birth weight <2000gram was found to be a significant risk for recurrent hyperbilirubinemia (p <0.001). Similar results were also found by Kaplan M et al. The difference in this result can be caused by the other risk factor like ABO, Rhesus, G6PD were not excluded in this study. Premature babies have immature hormonal and enzyme responses, and hyperbilirubinemia is caused by the liver maturity factor, where the baby’s liver function is not fully mature to process erythrocytes so that indirect bilirubin conjugation is not perfect either.

Jaundice can be aggravated by polycythemia, hemolysis, and infection because hyperbilirubinemia can cause a jaundiced kern, so the baby’s skin color must be monitored frequently. The three best predictors for recurrent hyperbilirubinemia were gestational age of the infant, age at initiation of phototherapy, and total serum bilirubin.

**Conclusion**

Jaundice in infants with rebound hyperbilirubinemia was higher in subjects with onset of jaundice < 3 days. There was no correlation of sex, mode of delivery, birth weight, and gestational age with rebound hyperbilirubinemia in infants in this study. Factors affecting rebound hyperbilirubinemia such as ABO, Rhesus, G6PD, and Coomb’s test should be investigated at the time of sample selection.

Abuse of Topical Glucocorticoids among Patients Visiting Community Pharmacy in Basrah-Iraq

Alhassan Shaker Abed¹, Jubran K. Hassan²
¹Researcher, ²Assistant Professor, Department of Clinical Pharmacy, College of Pharmacy, University of Basrah, Basrah-Iraq

Abstract

Introduction: Topical glucocorticoids have been the mainstay for the treatment of many skin conditions since their introduction due to their anti-inflammatory, anti-proliferative, vasoconstrictive, and immunosuppressive properties. Availability of topical glucocorticoids in different potencies as over the counter medication in Iraq encourages their use for non-labeled indications, thus increasing the side effect of such drugs.

Objectives: The aim of this study was to evaluate the use, knowledge of the patients and patient education of topical glucocorticoids.

Methodology: A cross sectional community pharmacy based survey was conducted throughout Basrah city. Inclusion criteria were customers visiting the community pharmacies asking for topical corticosteroids without prescription, aging 15 years and older and willing to participate in the study. 600 questionnaire forms for topical corticosteroids were distributed in the center and the districts of Basrah city. 254 forms out of 600 were returned out of which 212 were completed. Incomplete forms were excluded.

Result: 106 (50%) participants out of 212 misused topical glucocorticoids. As a single product, Betamethasone valerate and Clobetasol propionate was majorly used by the participants which are potent and ultra-high potent topical steroid respectively. The major source of topical steroid prescription was relatives. 49.8% participants didn’t recognize any side effect of topical glucocorticoids while hypopigmentation was the most side effect identified by the participants (21.8%). Only 35% of the participants, whose topical steroid prescription source by physicians and pharmacists, was educated about the use of topical glucocorticoids.

Conclusion: Topical glucocorticoids are commonly abused in Basrah city and probably other cities of Iraq. Looking fair and improving face appearance is a common cultural believe in Iraq that push people to seek topical glucocorticoids from community pharmacies for skin lightening in addition to other unapproved indications without prescription.

Key words: topical corticosteroids, abuse of topical corticoids, misuse of topical corticoids.

Introduction

Topical glucocorticoids possess various properties which make them very effective to be used for different non-infectious dermatological conditions¹. These properties are anti-inflammatory, anti-proliferative, vasoconstrictive, and immunosuppressive properties². Hydrocortisone was the first introduced then with various structural modifications others, such as betamethasone, mometasone, clobetasol, dexamethasone and triamcinolone, was produced³. Due to their usefulness and effectiveness, they have been used widely for treating inflammatory dermatologic diseases which
led to their abuse and emergence of their side effects such as hypopigmentation, telangiectasia, acne, hypertrichosis, suppression of hypothalamic–pituitary–adrenal (HPA) and rosacea(4)(5). Topical glucocorticoids are classified according to their potency into 7 classes by WHO, Class 1 (most potent) to Class 7 (least potent). The individual topical glucocorticoids may exist in different classes depending on formulation (cream or ointment) and concentration.

For example, betamethasone valerate ointment 0.05% is in Class II (potent), while betamethasone valerate cream 0.05% is in Class III (upper mid-strength(6).

Abuse of the drug is using drug for non-medical purposes while misuse is the wrong use of the drug for medical purposes(7). In Iraq and other developing countries topical glucocorticoids are purchased as over the counter drug without medical supervision, from some community pharmacies, for different medical purposes which is not accepted legally. That may be due to different reasons such as low patient income and insufficient regulatory enforcement level(7). Usually Iraqi patient keeps the prescription after being dispensed to refill it again with or without medical supervision which may encourage drug abuse or misuse(8). Low level of patients counseling and education or insufficient knowledge of healthcare providers decrease patients adherence and awareness about the side effect of glucocorticoids(9)(10).

Topical glucocorticoids misuse occurs at different levels starting from pharmaceutical companies, prescription, sales ending with the patients and layperson. Pharmaceutical companies make irrational combinations such adding moderate potent steroid with other combination for treatment of melasma(3). Prescription misuse of Topical glucocorticoids occurs when prescription requirements are not taken into consideration that ranges from incomplete prescription (not writing the strength and vehicle of TC, dosing, site of application and length of treatment on the prescription) to erratic prescription of topical glucocorticoids for the treatment of skin disorders with undetermined diagnoses(2).

Sales misuse can occur from over-the-counter (OTC) availability of all strengths and formulations of Topical glucocorticoids. This does not allow for proper supervision of patients’ using topical steroid resulting in indiscriminate purchase for self, family and friends. Salespersons play a critical role, as they often dispense these agents(2).

Topical glucocorticoids are used for incorrect indications tinea, nonspecific pruritus and acne, etc. by general practitioners, homemade doctors (parents, siblings, neighbors) and chemists. Use of combination of antibacterial or antifungal with topical glucocorticoids for the treatment of bacterial or fungal infection randomly has led to emergence of resistant organism(11).

Brown and dark races with no skin disease abuse topical glucocorticoids, to look fair and hide their blemishes, due to their vasoconstrictive and hypopigmentation effect. Some of the, reasons indicates why topical glucocorticoids are abused as cosmetic cream, are shown below(11):

- inexpensive.
- Easily available.
- careless about adverse effects.
- incomplete counseling by prescribers when prescribing topical glucocorticoids for appropriate indication.
- Social attitudes to skin color

Topical glucocorticoids have been used for the treatment of melasma either alone or in combination with tretinoin and hydroquinone, this triple combination is known as Kligman’s formula. Majority of cases treated with this combination subjected to relapse once stopped the treatment forcing them to use the treatment again for months without medical advice leading to adverse effects on their face such as telangiectasia, hypertrichosis, acne, skin atrophy(12).
Topical steroids are being misused by parents for diaper rash in their children where excess use of which lead to Cushing’s syndrome\(^{(13)}\).

**Methodology**

This study was a community pharmacy-based survey. It was carried out in Basrah city only as other cities of Iraq where inaccessible because of COVID19 Lock down.

This forma was allocated for costumers visiting the community pharmacies asking for topical or oral corticosteroids without prescription, aging 15 years and older and willing to participate in the study.

The questionnaires form comprised of six parts where the first part was about the sociodemographic information such as age, sex, place of residence and chronic diseases. The second question was to investigate the most topical corticoid asked by the patients while the third part identified the source of topical corticosteroids prescription. The fourth part was to investigate if the patients was educated properly about the use of corticosteroids and the fifth part was to identify the reason for using topical steroids. The last part to evaluate the awareness of the patients about the side effect of both topical corticosteroids.

Community pharmacists was, after providing the topical corticosteroids, asking the patients for their agreement verbally about participation in the study. After their agreement, the community pharmacist introduces the questionnaire paper (who was previously trained on) of the topical corticosteroids and report the answers of the patients. The survey was completely voluntary and required about 10 minutes to complete.

In this study we define abuse of the drug is using drug for non-medical purposes without prescription\(^{(7)}\)

**Sample size**

600 forma of questionnaire for topical corticosteroids were distributed in the center and the districts of Basrah city. 254 forma out of 600 were returned out of which 212 were completed. Incomplete questionnaires were excluded from the study.

**Statistical Analysis**

Data has been tested using specialized software for data analysis and Microsoft Excel 2019. The data of this study were analyzed using descriptive statistic and chi-square test. The level of significant was considered for p less than 0.05.

**Result**

Table 1 shows characteristics of participants answered the questionnaire related to topical glucocorticoids where the total number of participants where 212. 52% of them are female and 48% are male, p=0.4922.

There was non-significant (p<0.05) difference among the ages of the patients that participated in the study where 33.1% had an age of (15-20), 31.1 had an age of (25-35) and 35.8 had an age of (>40), p=0.6)

There was significant (p<0.05) difference in the residency of participants where 37% in the center of the city versus 63% outskirt, p=0.0001.

Discussion

Table 2 demonstrates the frequency of prescriptions sources for common types of topical glucocorticoids used by the participants in the questionnaire. This study found that relative personnel are considered the main source of topical glucocorticoid prescription (p value < 0.0001) followed by pharmacists and physicians respectively. Meena S et al. found that pharmacists were the main source of prescription(17).

That is may be due to most participants where from outskirt (63% versus 78%) or due low level of education (about 30% graduated versus 70% non-graduated). Other reasons are patients may have trust in their relative personnel that tried same product for same indication without getting advice from healthcare provider, this due to low economic conditions made the patients seek free of charge advice from the pharmacists rather than visiting the physicians.

A firm regulations about dispensing topical glucocorticoids by prescriptions from qualified healthcare advisers should be made.

In contrast to this study, Hon et al 2006 in china found that physicians are the main source of topical glucocorticoids prescriptions followed by newspaper(18). Also a different results were found by Lee et al 2015 in Korea where internet was the main source of prescriptions followed by media or TV(19).

As a single product betamethasone was the most prescribed topical glucocorticoids followed by clobetasol. Deena et al. 2014 in Mosul-Iraq found the same result while different results was found by Al-Dhalim et al 2006 in Najaf-Iraq where clobetasol was the most prescribed followed bybetamethasone(20)(21) In Meena S et al. Clobetasol was the most prescribed topical glucocorticoids(17).

These are highly potent topical glucocorticoids and only physicians have the right to prescribe them while other sources are considered unofficial sources which includes pharmacists also as these products are non-OTC products. In this study relatives of the patients are more
familiar with betamethasone and clobetasol than other single products, therefore, they are the most prescribed and misused because relatives are unofficial source of prescription.

Majority of mometasone prescriptions has been prescribed by its official source (physicians) because relatives of the patients, main source of prescription in this study, are not familiar with mometasone or due to its high cost. Hydrocortisone is the other topical products prescribed by its official sources as relatives may not be familiar with it.

In Charman et al 2000 in UK; hydrocortisone was the most prescribed topical glucocorticoids followed by betamethasone which is not matched with this study(22). Also different results were found in.

Table 3 expresses what topical glucocorticoids was used for by the patients. 50% of the participants used topical glucocorticoids for unapproved indications where skin lightening and melasma were the most reason of use. Also same result were found by Deena et al. 2014 in Mosul-Iraq(20). In Al-Dhalim et al 2006 in ALNAJAF-IRAQ skin lightening and acne were the most reason of use(21). Fungal infection and acne were the most reasons of use while skin lightening was the third most reason of use in Meena S et al.(17).

Table 4 expresses the knowledge of the patients about the side effect of topical glucocorticoids. About 50% of the patients didn’t know any side effects of topical glucocorticoids. Hypopigmentation is the most side effect known by the patients and this clarifies the use topical steroids for skin fairness.

Table 5 demonstrate the level of education for patients whose source of prescription was physicians and pharmacists only as its their duty to ensure safety and a suitable use of the medication(23). A significantly higher percent (p value 0.0027) of patients was not educated by either physicians and pharmacists indicating inadequate level of patient’s education practiced by them.

A similar result were found by Wing Man Lau et al. where pharmacists were less likely to advice the patients about topical glucocorticoids(24). Ammar Abdulrahman Jairoun et al. found that deficiency in curriculum of pharmacy courses also affects the practice and advising process regarding topical glucocorticoids(25).

Low level of patients counseling may be due to lack of information or time, the patients feel negatively about topical glucocorticoids or/and the physicians feel negatively about the counseling for topical glucocorticoids by the pharmacists. Min Jung Kang et al. found that bad feeling and physicians attitude was the most barrier for counseling(9).

This study finds that topical glucocorticoids are abused commonly in Basra city and probably in other cities of Iraq also where Al-Dhalim et al 2006 in Najaf (another city in Iraq) and Deena et al. 2014 in Mosul(another city in Iraq) found the same results. In this study the major responsibility of misuse was put on the relatives of the patients. Pharmacists also bear a part of the responsibility as they were dispensing a potent topical glucocorticoids as OTC, or with prescription but with inadequate level of education. On other hand potent topical glucocorticoids relieve the symptoms of the patients and after stopping the medication the symptoms recur leading the patients to reuse the potent topical glucocorticoids again without seeking medical advice.

Physicians and pharmacists should develop an intense relationship, reduce the inter-professional practice gap and improve communication lead to delivering a unified clear massage about drug use and safety for the patients(26)(9).

Conclusion

In Basrah-Iraq, topical glucocorticoids are used without prescription for unapproved indication such as skin lightening and melasma addition to other unapproved indication. Having culturally accepted skin color represents the dominant incentive that urges people to abuse topical glucocorticoids. Betamethasone valerate is the predominant abused or misused topical glucocorticoids as a single product. Half of the participants who abuse topical glucocorticoids are
unaware of their adverse effect.

Community pharmacists can enhance people knowledge about the adverse effects of topical glucocorticoids through counseling before dispensing. Finally, Iraqi health officials need to promote people awareness about the risks of misusing topical glucocorticoids without medical supervision through education programs and advertisements in public health settings, media, and social networks.

4Ph.D. Candidate of Nursing, Faculty of Nursing and Midwifery, Golestan University of Medical Sciences, Gorgan, Iran

Abstract

Background: Integrity is one of the professional values mentioned in the ethical codes of the Professional Nursing Association. It is defined as a commitment to the five fundamental values of integrity, trust, equality, respect, and accountability. This study aims to explore factors affecting professional integrity in nurses.

Methods: A descriptive content analysis was carried out by 17 interviews with Iranian nurses who were chosen through purposive sampling. The data collection instruments were semi-structured interviews and observation. The interviews were recorded and transcribed word by word; then, they were coded and analyzed by Graneheim and Lundman qualitative content analysis method. For the trustworthiness of the study, Guba and Lincoln’s criteria were used.

Result: After analysis, the latent meanings formulated into one theme,” keeping up confident beliefs,” which consists of “religious beliefs,” “inner call,” “philanthropic sense,” “empathetic care” and “divine rewards” categories.

Conclusion: Many factors are heading to internalizing professional integrity in nurses in Iran. Authorities, managers, and faculty members should pay special attention to the internalization of professional integrity and ethical values, such as altruism, conscience, empathy, and the presence of God in life to decrease the mistakes and promote quality of care.

Keywords: Nurse, Integrity, Spirituality, Qualitative research

Introduction

Professional values are standards for action accepted by the professional groups and experts, which provide a framework for evaluating values and beliefs that affect behavior. These values are the basis of nursing practice and guides nurses’ interactions with patients, colleagues, other professionals, and the public. Values provide a framework for commitment to patient well-being and guide them to ethical behaviors in the provision of humanitarian and safety care.

The American Nursing Association has identified a set of ethical values and behaviors specific to the nurses. Nurses are needed to internalize these values in order to maintain and develop their profession. These values include respect for human dignity, accountability, compassion, trust, and professional integrity.
Professional integrity, as a profound individual phenomenon and as a part of professionalization, provides a connection between actions on the one hand, and beliefs and principles, on the other hand. It is defined as a commitment to the five fundamental values of integrity, trust, equality, respect, and accountability, besides referring to the acceptance of principles plus ethical standards and practices based on ethical codes. The value systems of a person form the basis of professional integrity.

A struggle for maintaining professional integrity in a care challenging environment can lead to moral distress and consequently leaving the profession. Moral distress with deleterious effects on mental health is followed by anxiety and failure in nursing care. In the case of vulnerable, the negative effects are expressed as anger, worthlessness, depression, and discomfort. Determine factors affecting professional integrity in nurses are very important. However, the factors affecting professional integrity in nurses are unknown and no study has been conducted in this field to reveal these factors. Few studies in this field have been mostly quantitative and have considered only one aspect of professional integrity. For example in a study in Iran, which has been done in a cross-sectional descriptive method, has only examined the level of professional honesty in nurses and in the recommendations section of this study, it has been suggested a study should done for identifying factors can reduce or increase the rate of professional integrity. On the other hand, quantitative study cannot answer complex and less known issues, with a qualitative study can be discovered, deep description and explanation of unknown or less known phenomena. Qualitative studies in the field of professional integrity have also focused on other aspects of this phenomenon that are different from the purpose of the present study besides these research were done in other countries which are different in the context and culture. Such as a study in USA aimed to explore local experiences of professional integrity in pre-registration nurse education by grounded theory that objective of this study, research method and also participants of this study are different with our study. Therefore, this study aims to investigate factors affecting professional integrity in Iranian nurses.

**Materials and Methods**

This study is a qualitative content analysis driven from a Ph.D. thesis carried out from April to October in 2019. The research environment was the educational hospitals affiliated to Golestan University of Medical Science (North of Iran). By a purposive sampling approach, 17 participants were enrolled. Participants were nurse practitioners, head nurses and faculty members. Data collection instruments were semi-structured interviews and observation. The interview lasted from 25 to 90 minutes, depending on the participants. Interviews were held in a calm room according to the nurse’s suggestion. Two interviews were held in the faculty of nursing and midwifery and the rest in their wards. All interviews were conducted face-to-face by one researcher (first author) and audio-taped. The interview began with tow general questions: “Can you please describe professional integrity in nursing?” and based on your opinion, what factors are affecting to professional integrity in nurses. Participants were also asked to expand on their responses. Then, more questions were asked depending on the answers of the participants. Each interview transcript verbatim in the first 24 hours, coded within 48 hours by one researcher (Ph.D. candidate), and checked by the rest of the authors. In addition to interviews, the researcher wrote 14 field notes from his observations in teaching hospitals. Observations were purposive and based on interviews data analysis. All observations which were in 19 shifts (eight in the morning, seven in the afternoon and four in the night shift) were written. MAXQDA10 software was used for managing the data.

**Data Analysis**

Data analysis was performed by the Graneheim and Lundman qualitative content analysis method. The researcher transcribed the interviews and observations
verbatim and read them all several times to obtain an immerging sense of the data. Paragraphs, sentences, or words were taken as a meaning unit; they were coded according to their underlying concepts. In the second step, these codes were compared based on their similarities and differences; then, they were assigned specific labels and came to specific subcategory. After deep reflection on subcategories content, subcategories were merged into a category based on their similarity. Finally, similar categories with the same meaning merged the main theme. In addition of interviews several observations has done in various shifts to enrich the data analysis. Observation notes were coded and these codes merged with interview code index. In analyzing observations, the researcher was reviewing what was witnessed and recorded. Then researcher arranged them by converting all the data into a text format. The next step was organizing observations by going back to research objectives and then organizing the data based on the questions of research. After organizing they coded by the first author. In coding stage categorizing and assigning properties and patterns to the collected data was done. Ultimately, codes were used in data analysis process.

Trustworthiness

For the validity and reliability of the study, Guba and Lincoln’s criteria were used. It has four criteria including credibility, dependability, conformability, and transferability. The researchers tried to fulfill the credibility by engaging with the participants and the data collection process for a long period and checking the transcripts with the participants. Dependability was established by performing the process of step-wise, as well as auditing reviews by supervisors (second and third authors), consultants (third and fourth authors), and other experts. Conformability was improved over reviewing the study by checking the analyses process by supervisors. To achieve the transferability of this study, the researchers tried to provide an accurate report of the participants’ statements for the feasibility of findings in other contexts.

Ethical Consideration

The study was approved by the Research Deputy and Research Ethics Committee of Golestan University of Medical Sciences (Project number: 970405058, Ethics Code: ir.goums.rec.1397.032). Information included aim of the study, the voluntary nature of the participation, their right of confidentiality as well as right to withdraw from the study at any time were explained to the participants. Additionally, permission for voice recording was taken from the participants. The participants then signed an informed consent form.

Results

17 participants were interviewed, 17 interviews were overall held, seven of whom were male and the rest female. From the job position, three participants were head nurses (HN), two of them were a faculty member (FM) and the rest were clinical nurses (NP). Age ranges of participants were 23 to 53 years with a work experience of 6 months to 30 years.

Theme and categories

After deep reflection on the data transcripts (interviews, observation notes), 1583 initial codes were extracted; by the merging of similar codes, 686 primaries were extracted, these codes were categorized in 19 subcategories and consequently merged to the five categories according to their similarities and differences. After analysis, the latent meanings were formulated into one main theme,” keeping up confident beliefs,” which consists of “religious beliefs,” “inner call,” “philanthropic sense,” “empathetic care,” and “divine rewards” categories (Table 1).

1 (Religious Beliefs)

These categories were labeled on “God’s observation on acts,” “considering God in care affairs,” “acquiring Halal income,” “trust in God,” and “acquiring God’s satisfaction” subcategories. Almost all participants disclosed the role of God in internalization of professional integrity. One of the most important factors which influenced their care quality was their beliefs about God. They were believed that God is always observing their acts, record them and return the result of their acts to them.

1.1. God’s observation on acts: participant 2 said: “What I see, God is watching everything; we do our care, may nobody see what I am doing, but I’m sure that God is always watching our activities” [P2].

1.2. Acquiring God’s satisfaction: one of the participants said: “we have to acquire God satisfaction by doing our best for patient’s wellness [P12].

1.3. Considering God in care affairs: Another one emphasized that” we do what asked by the doctor; besides these, God asks us to do the right thing for patients. Situations in which nobody is present, you are yourself and God. May patient does not know what you are doing exactly. It is integrity based on which, for example, a medication that should be injected is injected properly “[P5].

1.4. Trust in God: The third participant said: “Every day, I start my work keeping trust in God. Before going to work and after prays, I say to God: please help me to have a chance helping patients and not being shameful in front of them.”[P3].

1.5. Acquiring Halal income: Two participants said that our income has to be earned in a Halal way (the right way); so, we must consider integrity in our professional affairs [P1, P5].

2) Inner call

The inner call is assumed as an appropriate title for “inner persuasion to do the best for patients,” “job conscience,” and “inner call for having integrity in care” subcategories. Some participants had a sense of hearing a voice that pushes them to do their care accurately. Most of them call this inner voice as “conscience,” and some call it “inner force feeling.” They know it as a strong force, which is not ignorable. They revealed that if they ignore it or make a mistake in care affairs due to clinical challenges, they get disturbed; in some cases,
they also involved with bad feelings, such as “a doom of conscience” or “sorrow” after work at home.

2.1 Inner persuasion to do the best for patients: Another one said: “I’m a responsible person. If someone asks something to do, I have to do my best; if I do not, a doom of conscience comes to me. I have to complete my responsibility. I try not to harm anybody; if a bad event is going to happen, I prefer it to happen to me, not to others”[P7].

2.2 Job Conscience; Participants 6 said I always remind myself that as a head nurse I have some responsibilities which is important for improving the quality of care delivering by nurses who work in the ward [P6].

2.3 Inner call for having integrity in care: One of the participants disclosed: “Conscience is with me everywhere. Whatever I do, my conscience is with me. Yesterday evening it happened, I said to myself that I do not check the temperature of patients today. It was in the morning; I checked their symptoms in the morning. I checked the temperature. Patients were not febrile; I decided to only check the blood pressure in the afternoon. I feel I can’t do it”[P8].

3) Philanthropic Sense

The philanthropic sense was labeled on “being interested in serving the people,” “cherishing the existence of humans,” “feeling the need to help people,” and “loving the profession” subcategories. All study participants except the last one (contrary case) adored their profession and helping others. It gave them a great energy for overcoming many challenges that exist in clinical setting.

3.1 Being interested in serving the people: participant 5 said: “Interest is very important. I terribly love my job. If I go backward, I will choose this job again. I love working with sick persons. When I do something for a patient, and he/she says God bless you or God forgives/bless your parents, it’s very valuable for me”. [P5].

3.2 cherishing the existence of humans: Participants I said: “All humans are valuable in my opinion. We are gathered to help each other and I think helping others is the philosophy of human existence” [P1].

3.3 feeling the need to help people: participant 10 stated that: “I chose to work as a nurse here to meet the patient’s needs I feel happy when the patients’ condition improves. as a matter of fact, I have a need to help others to feel more happiness in my life.”[P8]

3.4 Loving the profession: Another participant disclosed: “I love nursing. I like to continue my education. If I have a choice for a job again, I will choose to be a nurse practitioner. Even if I continue studying for the Master or Doctoral level, I will never leave the clinical practice” [P14].

4) Empathetic care

Empathy was one of the prominent characteristics of all study participants. The item subcategories consist of “consider myself as a patient,” “consider relatives as a patient,” and “empathy with patients.” All participants emphasized that when they are taking care of patients, they consider patients as themselves or relatives, such as their parents or children. They disclosed that as they won’t anybody take inappropriate care from their relatives, they are careful about patients to prevent mistakes.

4.1. Consider myself as a patient: Participant 3 said: “I’ve tried to think from first that my family or I am lying on this bed. Right or wrong, I do not know, maybe it’s a bit too hard to imagine. I always consider that, for example, a young one who is patient lying on the bed is my brother. I won’t anything bad happen for my brother, so I do my best to care appropriately and prevent mistakes” [P3].

4.2. Consider relatives as a patient: Another one said: since I do not want any nurse to harm my family when they are sick by their carelessness or irresponsibility, I try to do my job with responsibility and integrity [P15].

In the observation period, sometimes we encountered with dishonesty in taking care. For example; patient’s
participant referred to the nurse station and asked her to visit his patient, she said I will come but did not do that. When the researcher asked the reason of her neglecting, she replied “we have many works to do in the shift especially patient’s file recording. If we go several times on patient’s bed, we have no time for recording files and other jobs. Based on participants declarations there are many challenges a heading of clinical nurses, which decline their motivation for taking care, based on integrity such as organizational and managerial affairs, high workload, lack of facilities, low income and etc. For example, one of them complained of challenges and said:” you also know our burdens, we have any support from the nursing organization in this system even a patient’s companion is more valuable than me as a nurse. It happened that a one of them insulted me but the supper visors did not support me. There are many examples like this. Why I scarified myself for this system (nursing)?”[P17]

4.3. Empathy with patients:

One of the participants stated that:” Sometimes patients may complain of pain or problems. I try hard to understand her and take immediate action to reduce or alleviate her pain” [P2].

5) Divine rewards

Study participants strongly believe that the financial aspect of their job did not affect their integrity. They believe that God returns the result of their honest care in their life in another way. This category was the outcome for the empathetic care for main participants and raises from “God returns the result of honest care,” “having God’s blessings,” “low worthiness of profession financial aspect” and “tranquility in life” subcategories.

5.1 Low worthiness of profession financial aspect: One of them said: I cannot say that the financial aspect is not important for me at all. It’s far from reality, but from the bottom of my heart, I do not care much about it. I believe that if I do my job with integrity, God will help me more than money in life. Money is a small part of life [P11].

5.2 God returns the result of honest care: Another one says: you may hear from some nurses that “they don’t pay enough money based on our work hardship, so why we should devote ourselves for patients, “ but I am totally disagree with this thought because the patient should not pay a fine for it. God will give us more than money.”[P10].

5.3 Tranquility in life: The same participant stated that: “I have tranquility in my life; it’s more valuable than money for me “[P10].

5.4 Having God’s blessings: Participant 5 says:” I worked nearly twelve years as a nurse in this ward and nine year as a head nurse. In both position I did my best for patients. I passed several hard situation in my life that I understand its just for God’s blessing in result of my professional integrity. [P5].

Discussion

The aim of present study was explaining the factors affecting professional integrity in nurses. Based on the result of this study, many factors included religious beliefs, inner call, philanthropic sense, empathetic care, divine rewards, were effective to internalizing professional integrity in nurses in Iran.

The religious beliefs is the first category in this study. Religious values and beliefs are the most widely documented personal influencers of ethical beliefs among health professionals. Participants discussed religious beliefs about God and his influence in their actions. Religious beliefs are recognized as a tangible expression of spirituality and the affirmation of higher power 18. These beliefs affect one’s ethical decision-making. Religious beliefs affect the performance of nurses. This is confirmed in a British study based on which, nurses’ spiritual beliefs contribute to their attitude towards patients’ suicide 19. The experiences of participants reveal that their beliefs influence their actions, similar to the previous study. Study participants mention beliefs about God’s presence in their life, Halal income, and attempt to acquire God’s satisfaction. These thoughts strongly affect their actions and prevent
them from ignoring integrity in their professional roles. Professional integrity involves one’s conscience, and when his/her belief systems differ with a situation, it can cause conflict with the decision-making 20.

The second category is inner call. Participants mentioned inner call as a main reason for internalizing professional integrity. The current study participants show feelings, such as “a doom of conscience” or “sorrow” after incompatibility due to deviating from integrity in care affairs. They were believed that working according to the integrity help them feel tranquility in their occupation. Nurses confront situations that require ethical consideration and judgment on routine affairs. When they can meet their expectations under certain care conditions and their moral decisions are in accordance with their conscience, they are at a lower risk of suffering from the feel of sin or mind disturbance21. Another study confirm the influence of conscious and inner feelings of moral obsession on their care roles. When nurses are unable to balance their moral integrity with ethical issues, the result can be moral distress22.

Philanthropic sense is the third category. Caritas’s idea, love, and affection are the core of all nursing care. According to Ericsson, the ability to love is the true humanity that is nurtured in the form of caring. Loving care indicates unselfishness and altruism; “altruism is selfless concern for the welfare of others” 23. Loving the profession is one of the prominent factors in all study participants. They emphasize that they really love helping others. They devote themselves in spite of difficulties in nursing profession in the country, such as issues mentioned by Farsi Z et al. as low levels of respect, low income, heavy workloads, high patients’ expectations, managerial issues, lack of staffs’ resources in the healthcare system 18. In our study, some declare even they spend a part of their wage to help patients, and some do nursing for some poor patients at home free.

Another category is empathetic care. In this study main participants who were nurses qualified by professional integrity revealed empathetic care in clinical setting in spite of many challenges. Based on experiences, empathy with patients has a very effective and accelerating role, in other words, nurses’ empathy with patients provides a shortcut to communication with patients. Based on another study in Iran, nurses’ empathy with patients is the core of the interaction between nurses and patients and causes nurses to understand the conditions, needs and feelings of patients in performing nursing intensive care and take steps to meet their needs24. In confirmation of the results of our research, empathy is defined as, “the ability to understand and share the feelings of another.” It is the capacity to put one’s self in another’s shoes and feel what that person is going through and share their emotions and feelings. It is the recognition and validation of a patient’s fear, anxiety, pain, and worry25. Besides of finding our study, result of a review study demonstrated empathetic also care lead to enhancing quality of care, eliminating of errors, and an increasing satisfaction of patient and nurse 26.

Divine rewards is the last category. Based on experiences of our study, God returns the result of honest care, having God’s blessing, low worthiness of profession financial aspect and tranquility in life are main sub- categories of this category. Based on a study nurses emphasized that many of the prayers of the patients’ companions lead to inner rewards for them, which include keep our nurses healthy and strong in all areas of their lives. Protect their families, their marriages, their children, bless them with so much compassion that it spills effortlessly into their patients’ lives, which are consistent with our research findings 27. However, in a qualitative study which is done in Netherlands nurses placed more emphasis on external rewards, which in that research three main reward categories were derived: financial, non-financial and psychological rewards. These differences may be due to the role of different religions in care as well as different cultures and contexts28.

Conclusion

This study shows that many factors are effective to internalization of professional integrity in nurses. Keeping up confident beliefs is as a main theme that
contain all of them. It a great role in acting in nursing according to the principles and in many cases it is beyond their responsibilities (we can call it self-devotion). This study is carried out in Iran; however, professional integrity has no boundary and it may be different in other countries and other cultures, thus, it can be investigated in all nurses and other allied health care professions in the all of world. Authorities, managers, and faculty members should pay special attention to the internalization of ethical values, such as altruism, conscience, empathy, and the presence of God in life to decrease the mistakes and promote quality of care.

Acknowledgments: We thank all participants who shared their experiences with the research team. This study was approved by the Research and Technology Deputy of Golestan University of Medical Sciences, Golestan, Iran

Conflict of Interest: The authors declare no conflict of interest in this study.

Post-mortem Gross Detection of Early Myocardial Infarction using Triphenyl Tetrazolium Chloride Test

Ali Ayad Abdulridha¹, Saad Kadhim Kareem²

¹Scholar Researcher, Medico-Legal Directorate, Ministry of Health, Iraq, ²Professor of Forensic Medicine, College of Medicine, Al-Nahrain University, Iraq

Abstract

Background: Ischemic heart disease is the leading cause of mortality in the world. More than 17 million people die each year as a result of myocardial infarctions. Post-mortem histochemical detection of early myocardial infarction using 2,3,5-Triphenyl Tetrazolium Chloride (TTC) technique is based on the fact that ischemic myocardial cells lose their membrane integrity and release dehydrogenase enzyme into the blood stream, resulting in decrease or total depletion of these enzymes within the necrotic areas of the myocardium, and so, after immersion in TTC solution, enzyme depleted necrotic myocardium will not retain TTC dye and therefore appears as pale/yellow areas.

Materials and Methods: This prospective postmortem study was conducted at Medicolegal Directorate in Baghdad city during the period from March 2020 to December 2020. Myocardial specimens were isolated from 75 cases of sudden natural death and were subjected to 1% TTC solution staining for gross assessment, and subsequently, tissue samples were taken from suspected areas, processed and stained with H&E for histopathological evaluation and detection of a possible acute myocardial infarction.

Results: The mean age of studied cases was 50.3 ±12.57 years, ranging from 18 to 78 years, median age was 53 years. Males constituted the majority of cases (80%). Cases were predominantly within 40-59 years age group (58%). The postmortem interval was ranging from 2 to 17 hours (mean= 8.6 ±3.6 hours). After immersion in 1% TTC solution, 45 myocardial specimens showed macroscopic pale/yellow areas which were indicative of acute myocardial infarcts within the ventricular wall, while histopathological examination of specimens revealed features of acute myocardial infarction (AMI) in 62 specimens. TTC stain was found to have a diagnostic sensitivity of 69.4% and specificity of 76.9% in postmortem detection of AMI.

Conclusion: The TTC technique allows identification of early myocardial necrosis. It’s practical, reliable and valid method that promises to be of considerable value. It can be used together with histopathology for postmortem detection of visually unapparent acute myocardial infarcts.

Keywords: TTC, myocardial infarction, sudden death, postmortem diagnosis

Introduction

Ischemic heart disease (IHD) is considered as the main cause of natural deaths in both men and women. (1) Sudden natural deaths involve important challenges in forensic pathology, especially when death takes place shortly after coronary occlusion. Following myocardial ischemic damage, it usually requires 24 to 48 hours for the damaged area to be visually apparent, area of hyperemic borders with central tan softening maybe observed after 3-7 days. Wavy fibers, in association with interstitial edema are often described as the earliest light microscopic changes of necrosis as it can be detected in the infarcted region within 3 hours after coronary occlusion. (2) Triphenyl tetrazolium chloride (TTC) is commonly used in histochemical staining for detection of necrotic myocardial tissue, it’s based on the fact that ischemic myocardial cells lose their membrane integrity and release their enzyme contents into the blood stream, resulting in a marked decrease or total depletion of these enzymes in the ischemic areas of the myocardium. The postmortem histochemical detection of myocardial
infarction is relied on immersion of myocardial specimens in TTC solution, intact myocardial tissue will be visualized as brick red while dehydrogenase deficient infarcted zones will not retain TTC stain and therefore appear grossly as pale/yellow areas\(^{(3)}\). The current study aim to explore the reliability of Triphenyl Tetrazolium Chloride staining in gross delineation of necrotic myocardium. Furthermore, to facilitate postmortem macroscopic recognition of early myocardial necrosis for subsequent histopathological evaluation.

**Materials and Methods**

This prospective postmortem study was conducted at Medicolegal Directorate in Baghdad city during the period from March 2020 to December 2020. Seventy five cases of sudden natural death were investigated for a possible underlying acute myocardial infarction (AMI) as a cause of death. On a hard dissecting platform, serial 10mm-thick sections of the heart was obtained using a dissection knife, each section was thoroughly examined in order to identify the ischemic risk zones, the territories of coronaries perfusion were examined, with careful appreciation to zones at risk. Slices were photographed using digital camera with magnification. Specimens with no visually apparent infarcted zones were taken from each heart, washed with distilled water, the slices were placed in a sealed container with 1% TTC solution and incubated in 38°C degrees; slices were turned upside down after 15 minutes to obtain a uniform staining. After incubation for 30 minutes, heart slices were photographed and examined for unstained zones within myocardium, normal myocardium stained brick red whereas infarct zones appear pale/yellow or show very much reduced staining. Pale unstained zones were regarded as indicative for AMI, whereas slices completely stained brick red regarded as negative for AMI. After macrostaining with TTC solution, both TTC positive and negative specimens were incubated in 10% formalin. Sections were mounted on labelled microscope slides for routine histopathological examination. Microscopic observations of ischemic changes including myofibrillar waviness, hyper eosinophilia, coagulative necrosis, neutrophilic infiltration were considered as a diagnostic feature of AMI.

**Results**

This prospective study included 75 cases of sudden death autopsies conducted at Baghdad Medicolegal Directorate; their mean age was 50.3 ±12.5 years, ranging from 18 to 78 years, the median age was 50 years. Males constitute the majority of cases (n=60). Table 1 illustrates the frequency of cases according to age groups, 44 subjects were within 40-59 years age group and within this group, 35 subjects were males. Considering past history prior to death, 70.7% (n=53) of cases had at least a single pre-existing risk factor for developing IHD.

Approximate time of death was obtained from information provided by police autopsy inquest, in addition to the observed postmortem changes. The postmortem interval (PMI) was ranging from 2 to 17 hours (mean= 8.67 ±3.69).

Following immersion in 1% TTC solution, slices from 4 cases failed to retain the dye, and within the remaining 71 cases, 45 showed macroscopic pale/yellow areas which were indicative of acute myocardial infarcts within the ventricular wall (Figure 1). Microscopical histopathological examination of specimens revealed features of AMI in 62 specimens (Figure 2).

Figure 1: Triphenyl tetrazolium chloride (TTC) staining of transverse heart slices. Photographs on the left are myocardial sections before TTC staining. Same slices on the right after immersion in TTC solution showing areas of staining defect which are indicative of acute myocardial infarcts (arrows).
Figure 2: Photomicrograph showing acute myocardial infarction by H&E  A. Interstitial edema with myofibrillar waviness (10x).  B. Subendocardial MI showing vacuolated myocytes with coagulative myocytolysis (40x).

Table 2 summarizes the statistical values considering TTC and H&E staining of specimens. There was significant statistical differences (p value= 0.001). TTC stain was found to have a diagnostic sensitivity of 69.4% and specificity of 76.9%.

Considering the four specimens which fail to retain TTC stain, no significant correlations were evident when the stainability of TTC was compared with age of deceased’s or the PMI. The final postmortem diagnosis was ruled as AMI in 62 cases (82%), other cardiac diseases in 6 cases and respiratory infections in 4 cases. AMI was more prevalent in male and more profound within 40-59 years age group.

† Negative predictive value ‡ Positive predictive value * Sensitivity § Specificity
Discussion

Triphenyl tetrazolium chloride (TTC) staining is a convenient procedure for detection and demarcation of myocardial infarct zones. It’s dependent on loss of dehydrogenases from the irreversibly damaged myocytes. In this study, MI was the leading post-mortem diagnosis of natural death autopsies and was more prevalent in 40-59 age group which is consistent with recent studies conducted in Iraq by Al-Qazzaz et al. (2012)(4) and Abdulrahman (2016). (5)

More than 70% of the examined individuals in this postmortem study had at least single risk factor for developing IHD. A review study by Aljefree and Ahmed (2015) showed high prevalence of risk factors for developing cardiovascular diseases in the countries of The Gulf Cooperation Council, which was attributed to urbanization, cultural, lifestyle, and environmental factors in these countries.(6) In Iraq, however, bad social and dietary habits, lack of awareness, poor preventive measures might be crucial contributing factors.

The main concept of this study is the visual macroscopic detection of AMI using TTC regardless the size and extent of necrotic area, a study by Kakimoto et al. (2013) relied on computerized software planimetry to detect minute foci of infarction as well as to quantify the size and ratio of infarct zones in comparison to the remaining viable ventricular mass. (7)

As summarized in Table 2, the comparative analysis of histopathological examination with TTC staining technique in the present study showed that out of the total 75 cases, AMI was evident in 62 specimens by H&E, and out of these cases, it was observed that specimens of 43 cases showed macroscopic demonstration of AMI by TTC staining technique and 16 specimens were TTC-stained negative for AMI. The overall TTC sensitivity and specificity were 69.4% and 76.9% respectively.

Adegboyega et al. (1997) reported that histochemical staining using TTC solution for gross detection of early infarction has diagnostic sensitivity of 77%. (8) A review article by Kundal et al. (2012) showed that the overall efficacy of TTC test in postmortem diagnosis of AMI is 88%. (9)

Another study by Shrigiriwar et al. (2019) had noticed that TTC staining technique is more superior to the conventional H&E staining in detection of AMI, the study included known cases of MI and IHD. TTC staining technique was positive for MI in 80% of cases while H&E method was positive in 33.3% of cases, the study further recommended the TTC staining technique to be included in natural deaths autopsies as it was considered more sensitive and efficient method than the H&E microscopic examination. (10) These results support the previous findings by Gupta et al. (2013) who suggested that TTC stain has a higher efficacy than microscopical evaluation by H&E in detection of AMI. (11)

Unfortunately till date, there is no local published data considering the use of TTC technique in postmortem practice, and it’s well known that postmortem diagnosis of AMI is essentially relied on histopathological examination by H&E to define necrotic zones, but unapparent infarcted zones are often missed during random sectioning.

There were 26 cases that showed no evidence of AMI by TTC staining even though H&E examination identified AMI in 16 cases in this group. Some studies have questioned whether staining of viable cells can mask necrotic ones in the highly irregular border zone. It is known that the formazan compound of TTC is lipid soluble and readily diffuses to adjoining cells/tissues, especially those rich in lipids, therefore necrotic tissue in the TTC stained slices might be estimated as being smaller than their actual size. (12)

Some observations suggest that TTC staining may be subjected to artefacts, it appears that superoxide dismutase has the potential to enable necrotic myocardium to retain its ability to stain as viable tissue for at least 24 h after the onset of the ischemic insult followed by reperfusion. (13-15) It’s possible that myocardial cells, which have become irreversibly injured but have not yet lost a sufficient amount of NADH will be stained,
Therefore, infarct size will be underestimated.

Following immersion in TTC solution, only 4 specimens fail to retain the TTC dye, this could be attributed to PH of the solution, a precise PH range of 7.4 is required for proper tissue staining. Photosensitivity of the Tetrazolium dye, prolonged exposure of TTC salts or TTC solution to light leads to inactivation of the tetrazolium salt. Another factor that may compromise the efficacy of the test is the prolonged storage of TTC salts. Kakimoto et al. (2013) found that TTC stainability decrease logarithmically when PMI is more than 1.5 days. Another limitation was the decrease in TTC staining quality for aged patients (more than 80 years). In the current study, however, no correlations were evident between TTC staining results and age or PMI in this study.

Conclusions

The overall Triphenyl Tetrazolium Chloride (TTC) sensitivity and specificity in this study were 69.4% and 76.9% respectively. TTC technique allows identification of early myocardial necrosis. It’s practical, reliable valid method that promises to be of considerable value. Random sectioning of heart for histopathological examination often miss the necrotic zones if the section does not include the unapparent infarct area, in these instances, TTC can be used together with histopathology for detection of early and unapparent myocardial infarctions.

Fetal and Maternal Plasma Thyroid Hormone’s Levels in the Guinea Pigs

ALwan Ali Fadil¹, AL-Souz Mohammed Abdul Hadi Khalil², TareqHafdhiAbdtawfeeq Al-Khayat¹
¹Prof., ²Asist.Prof., AL-Farahidi University.Medical Technology College.Department of Medical Laboratory Technology, Baghdad, Iraq

Abstract

Background: All available data indicate that the thyroid of the guinea pig fetus is capable of functioning independently of that of the mother. Therefore fetal thyroid function is necessary for normal growth in utero. Intrauterine adaptation to the outside environment is important mechanism via which fetus increases the chance to thrive after birth. Aim and Objective of this work to assess the plasma level of thyroxin (T4) and Triiodothyronine (T3) through most period of pregnancy in fetal and maternal guinea pigs. Materials and Methods: Blood samples collected from 51 pregnant guinea pigs and their fetuses (93), by the Cobase 411 device produced by, Roche com. and it works with technology Electro, Plasma T4 and T3 were measured by ChemiLuminescence immune-assay. Results: Fetal plasma Thyroxin (T4) concentration was greater than that of the mother between Results 50 and 62 days of gestation while fetal plasma T3 concentration was less than that of the mother throughout gestation. In fetal guinea pig the reciprocal relationship between pituitary and thyroid is established at approximately day 34-35 of gestation. Conclusion: The results indicated that the fetal pituitary–thyroid system (PTS) is functioning at a relatively high level than that of the maternal, starting few days before the second half of pregnancy. Thyroid hormones are important for fetal growth and maturation event.

Keywords: Fetal, Maternal, thyroxin, Tri-iodiothyronine, Guinea pig.

Introduction

The follicle is the smallest functional unit of the thyroid. The iodine containing thyroid hormones (TH) are synthesized from a large glycolprotein thyroglobulin. The anterior pituitary gland secretes a thyroid stimulating hormone (TSH) which is under the control of hypothalamic neurohormone¹.

Human as well as animal studies have suggested that very high or very low maternal TH level during development may induce a shift in Hypothalamus-Pituitary-Thyroid (HPT) system². AL-Zubaidy³ showed that the fetal pituitary gland of guinea pig has the same morphology as in adult after 40 days of gestation.

In most species total plasma T4 concentrations are usually approximately 100 times as great as the total plasma T3 concentrations¹. The total plasma THs concentrations are about 80 ng/ml and 1.5 ng/ml, respectively⁴&⁵. Thyroid hormones are necessary for body growth, especially, brain growth and differentiation⁶. THs are also required for full maintenance of the function of the nervous system and the lack of these hormones lead to an impairment of

brain function \(^{7,8}\). As well as their effects on energy metabolism, the calorigenic actions important for small animals to tolerate prolonged exposure to cold\(^9\). THs are involved in the maturation of various tissue and organs including lung maturation \(^{10}\).

Intrauterine adaptation to outside environment is important mechanism via which a fetus increases its chance to thrive after birth\(^9\).

The previous studies concerning the thyroid hormone level in guinea pigs in pregnancy and in fetal stage lack specificity. Therefore, this work aims to assess the plasma concentration of thyroid hormones throughout different periods of gestation.

**Methods**

Dunkin Hartley guinea pigs of both sexes were used throughout this experiment. Animals were obtained from the closed colony maintained in the Animal House and were housed (2 to 3 animals per cage), under temperature controlled conditions and fed pelleted diet. The experiment was carried out on a female guinea pigs were caged with a male and the day on which sperm was found in the vagina was taken as day one of pregnancy.

Blood samples were collected from pregnant guinea pigs and their fetuses at 45, 50, 55, 60 and 65-67 days of pregnancy. All animals were either killed quickly by a blow at the back of the neck or anaesthetized by an Intra Prenatally (I.P.) injection of sodium pentobarbitone (45 mg/Kg body weight). After 10 minutes, five milliliters of blood were collected from the mother by cardiac puncture. The fetuses were located by palpation and the abdomen and peritoneum were opened by a midline incision and the uterus was exposed. Blood was collected from the umbilical vessels of each fetus. All experiments were performed between 11.00 and 12.00 a.m. Blood samples were transferred to EDTA tubes and centrifuged immediately. The plasma was aliquoted and stored at \(-20\) C until assay.

Thyroid hormones levels were determined using electrochemiluminescence immunoassay technique performed by Cobas e411 Analyzer, Roche company, The intra assay coefficient of variation was determined and found to be 11.7%. The extraction efficiency was found to be 81.87\(\pm\) 0.54% (mean\(\pm\) SEM; \(n=10\)).

Statistics: Treated groups have been compared with normal as control. All result have been presented as the mean \(\pm\) the standard error of the mean, where \(n=\) the number of samples in each group. Significance limits have been determined using Student's t-test with \(p<0.05\) were considered significant.

**Results and Discussion**

**Fetal and Maternal T4**:

The T4 concentrations in fetal plasma are low at 45 days (18.5\(\pm\)2.4 ng/ml) and increased significantly (\(p<0.05\)) by 50 days (27.6\(\pm\)2 ng/ml). Concentrations then again rose significantly (\(p<0.0001\)) to reach the highest level at 55 days (36.7\(\pm\)1 ng/ml). At this time, the T4 concentration in the fetus was significantly greater (\(p<0.0001\)) than the corresponding maternal value (25.4\(\pm\)1 ng/ml). Measurements of fetal T4 concentrations from 50 days of gestation until term, the difference was only significant between days 50 and 62.

After 55 days of gestation fetal plasma T4 concentration declined to 34.9\(\pm\)2 ng/ml at 60 days, 30.0\(\pm\)2.3 ng/ml at 62 days and 25.0\(\pm\)2.5 ng/ml at 64 days by which time there was no significant difference from that of maternal values (Table-1). These results indicated that the fetal PTS is functioning at a relatively high level.

**Fetal and Maternal T3**:

Plasma T3 concentrations changed in similar manner to fetal plasma T4 concentrations. Fetal T3 concentrations were significantly less maternal T3 concentrations at all stages of gestation except at 60 days (Table -1). Fetal T3 levels increased from 0.6 \(\pm\)0.1 ng/ml at day 40 to 1.5\(\pm\)0.1 ng/ml at day 50 of gestation. Peak concentrations of T3 (1.7\(\pm\)0.1 ng/ml) occurred on days 55 and 60 of gestation after which fetal T3 concentrations fell significantly (\(p<0.05\)) to day 62 and fell significantly (\(p<0.001\)) again by day 64 (1.1\(\pm\)0.1 ng/ml). The lowest levels, (0.96\(\pm\)0.1 ng/ml) were found on days 65 and
There were no significant changes in maternal plasma T3 concentrations throughout last third part of gestation (Table-1).

**Table 1 :- Plasma T4 & T3 concentration (ng/ml) in the mothers and their Fetuses during gestation.**

The figure between brackets indicate the sample size.

The period between 32/33 and 34/35 days of gestation can be considered as the earliest time in gestation when fetal thyroid of the guinea pig might begin to synthesis hormone. Mitskevich concluded that the onset of the fetal guinea pig functional activity was at about 35 days of gestation. In human Fisher reported the concentration of iodide in fetal thyroid is about 10-12 weeks of gestation. Iodine is required for the production of TH control by fetal pituitary TSH. In the present study the concentration of T4 was much higher than that of T3 in the plasma of the fetal guinea pigs. The results of the present study agree closely with those reported by and less well, with those of in the fetal guinea pigs. Low serum T4 concentrations have also been measured in 11-16 week human fetuses. Obregon reported fetal thyroid gland reaches maturity by week 11-12, and begin to secrete hormone by about week 16. THs are controlled by fetal pituitary TSH at approximately 20 weeks of gestation these authors commented that the low T4 values are primarily due to low T4 binding protein (TBP) concentration. In humans the increases in fetal plasma T4 concentration could be due to increased fetal thyroid gland secretions and probably TSH dependent. These results indicate that the fetal...
pituitary–thyroid system is functioning at a relatively high level than the maternal at this time, resulting in a high fetal T4 secretion rate. Mean fetal plasma T4 concentration exceeds that of the motherat 50-62 days of gestation. During this period, an adequate supply of maternal thyroid hormones must be sustained to ensure normal neurological development.

In present study plasma, T3 had was found to be lower in the fetus than in the mother throughout gestation (Table 1). The low fetal T3 concentrations are in agreement with those reported by but higher than those reported by. Low fetal T3 concentrations have been seen in human. Plasma T3 was measured at 64, 65 and 67 Days of gestation showed a significant decrease compared to that at 55 or 60 days, this results is in agreement with the results reported by. These results indicate that the T3 change in fetal guinea pigs is quite different from that of the human fetus. The low level of T3 could be due to decreased T3 secretion, decreased availability of T4 for de iodination, or a decreased rate of extra thyroid conversion of T4 to T3. In human, Castro have measured a high level of rT3 in the plasma of fetal guinea pigs at 62 days. It appears that conversion of T4 to T3 is reduced in the fetus whereas conversion of T4 to rT3 is well preserved. During pregnancy thyroxin binding globulin (TBG) concentrations increase because of estrogen stimulated TBG production and thyroid gland secrete hormones under the control of the HPS. In human fetal TSH, T4 and TBG gradually rise to adult level by 36 week.

Effect of hypothyroidism in pregnancy are anemia, low birth weight and mental retardation in neonatal. Increase T4 production and T3 is critical for fetal brain development. Fetal development adaptively refers to the process by which the fetus is prepared for the environment it is about to enter, this is important for optimal chance of survival and reproductive success for offspring. Present results indicated that pituitary and thyroid hormones secretions are important for fetal guinea pig differentiation and development of various organs and neonatal outcome.

Effect of Different Drugs on Diuretic Resistance Indices in Patients with Renal Impairment Using Intravenous Furosemide

Alyaa Abdalrazaq Abass¹, Ali Mohammed Hadi², Jubran K. Hassan³

¹Pharmacist, College of Pharmacy, University of Thi Qar, Iraq, ²Assist.Prof, Clinical Pharmacy, Department of Clinical Pharmacy, College of Pharmacy, University of Basra, Iraq, ³Assist.prof, Clinical Pharmacy, Department of Clinical Pharmacy, College of Pharmacy, University of Basra, Iraq

Abstract

Chronic kidney disease is a medical condition defined as a reduction in kidney function, made known by glomerular filtration rate of a less than 60 mL/min per 1·73 m², or signs of kidney impairment (albuminuria), or both for at least three months period, nevertheless of the original cause.

Diuretic resistance in the edematous patient is defined as a clinical state in which diuretic response is diminished or lost before the therapeutic goal of relief from edema has been reached.

This study aims to find the effect of different drugs on kidney functionindices and the relationship of using these drugs with the development or improvement of diuretic resistance.

The study is a cross-sectional observational study. It was carried out at Al-Hussein-Teaching Hospital in Thi-Qar. Nasiriya. Data from 104 patients were collected and analyzed using different statistical methods.

The results showed that there was a different odd of effects of the drugs commonly used to patients with CKD due to other comorbidities on diuretic resistance indices. There was a significant increase in the body weight and decline in serum urea in patients already with edema when they used calcium ampoule. Serum urea was not affected by any of the other studied drugs. There were two drugs affected positively on serum creatinine, which are clopidogrel and heparin. Albuminuria was highly improved in patients receiving aspirin and atorvastatin. Clopidogrel significantly increased GFR in these patients.

Key words: Aspirin, Atorvastatin, Calcium ampule, Clopidogrel, CKD, Heparin, Hydrocortisone, serum urea.

Introduction

Chronic kidney disease is a medical condition characterized by a reduction in kidney function, made known by rate of glomerular filtration of a lesser amount of than 60 mL/min per 1·73 m², or signs of kidney impairment (albuminuria), or both, for at least three months period, nevertheless of the original cause (¹).

The main causes of CKD globally are Diabetes (DM) and hypertension in all high, middle-income nations and in many low-income countries (²) Rate, occurrence, and advance of CKD also differ within countries by ethnicity and social causes of health, possibly through epigenetic influence (³).
Diuretic resistance is a clinical condition when diuretic effect is lessened or disappeared before the helpful objective of edema has been overtaken (4). The most demanding problems that the cardio nephrologist must mark in daily clinical practice is diuretic resistance, because of considerable burden on health care costs and hospital admissions (5).

Loop diuretics are agents used in CKD to decrease blood pressure and treat edema (6, 7), such as Furosemide, bumetanide, and torsemide, they bind to the extracellular surface of sodium-potassium-chloride symporters (NKCCs) of thick ascending limb cells along the loop of Henle by translocation pocket at the blocking ion transport directly. Hence, they increase the excretion of sodium, potassium, magnesium, and hydrogen (8-9).

Loop diuretics are used for medical conditions like in Oedematose disorders include (congestive heart failure (CHF), hepatic cirrhosis, nephrotic syndrome), renal insufficiency, hypertension in kidney disease, hypercalcemia, hypernatremia, syndrome of inappropriate antidiuretic hormone (SIADH) and renal tubular acidosis (10, 11).

The comorbid diseases which associated with CKD should be treated, like hyperlipidemia, diabetes mellitus and hypertension, in order to decrease the cardiovascular events and improve the kidney function so that the quality of life. These drugs like aspirin that is used for its antiplatelet action. It is well known to use in secondary prevention of stroke and myocardial infarction (12). Clopidogrel, which is a thienopyridine drug that, by blocking the adenosine diphosphate P2Y12 receptor, inhibits platelet aggregation. Clopidogrel is used more commonly to avoid potentially lethal thrombosis of newly inserted coronary stents (13).

Meanwhile in CKD, both thrombotic events and bleeding are at greater risk. The initial stages of CKD are predominantly associated with prothrombotic risk, while platelets can become unstable due to uremic-related toxin toxicity in their advanced stages, besides the prothrombotic condition, leading to an increased predisposition to bleed. For the treatment or prevention of thromboembolic diseases, CKD patients typically need anticoagulation therapy like heparin (14).

In (CKD), hyperparathyroidism occurs in a reduced parathyroid hormone calcemic response (PTH). Ca ampule helps to establish hyperparathyroidism and is presumed to be due to decreased bone efflux of calcium, so prevent osteoporosis (15, 16).

Atorvastatin is used in patients at CKD due to risk of or with cardiovascular disease. It had renal protective effects and given for dyslipidemia atorvastatin improved kidney function over time in a dose dependent manner (17, 18, 19). The patients also take corticosteroid as hydrocortisone and dexamethasone which are used for breathing problems to asthmatic patients or for skin or drug allergy (20).

All these drugs may affect positively or negatively on diuretic resistance indices, which are body mass index (BMI), serum urea, serum creatinine, estimated glomerular filtration rate (eGFR) and albuminuria or they may have no any significant effect.

The goal of this study is to find the effect of different drugs on kidney function indices in patients with CKD treated acutely by furosemide, as a method of detecting diuretic resistance and factors affecting it.

**Patients and Methods**

This research was conducted at (Al-Hussein-teaching hospital) in Thi-Qar, Nasiriya. Data were collected from patients after getting approval from the Ethical and Scientific Committees of the Faculty of Pharmacy/ Basra University in addition to the Scientific Committee of Researches of Thi-Qar Health Directorate.

This study is a cross-sectional observational study, carried out from October 2019 to June 2020.

The Inclusion criteria were patients age of 18 years and older of either gender, patients or relative should be able to communicate and willing to participate in this study, patients that take loop diuretic (intravenous furosemide) only. Also, patients with chronic kidney
disease (GFR ≤ 60), diabetes mellitus, asthma, Chronic obstructive pulmonary disease (COPD), hypertension (HT), cancer and had no contraindication to diuretics or other standard medications for heart failure and kidney diseases. Excluded patients were those with acute infectious diseases like pneumonia, complicated urinary tract infection (UTI), human immunodeficiency virus (HIV), Children or Patients who were <18 years. Patients excluded if they refused to participate. Patients who had cognitive deficits (physical or mental state), females who were pregnant or breastfeeding, Patients taking oral diuretics or other diuretics than loop diuretic and patients with Acute Surgery. Patients with recent myocardial infection (MI) within 3 weeks also were excluded, in addition to patients who already on anticoagulant therapy for other indications. Patients with nephrotic syndrome, urinary tract malformation, urolithiasis, kidney transplant, Hemodialysis also were added to the exclusion list.

In the present study, (104) patients were recruited. They were all agreed with the data collection formats used. The data collected from patients by their specific file and the laboratory analysis.

Statistical analysis used in this study included the use of SPSS version 2017 and Excel Soft ware 2019, the p value of (<0.05) is considered as statistically significant. Statistical programs were Chi Square for analysis of frequency, T- test used for analysis for continuous variables defined as Mean ± Standard deviation (SD), Pearson correlation was performed to find correlation among different variables.

Estimation of GFR is done by modification of diet in renal disease (MDRD) equation\(^{(21)}\) and BMI (kg/m\(^2\)) calculated as BMI= \(\text{weight}/\text{height}^2\)\(^{(22)}\).

Albuminuria is known as an indicator for renal dysfunction, the method used to detect albuminuria is Albumin-to-creatinine ratio (ACR). This method detects albuminuria by a spot urine sample. By dividing concentration of albumin in (mg) to concentration of creatinine in (gm), we can calculate ACR \(^{(23)}\).

### Results

One hundred and four patients were included in this study, number of females was 54 (51.9%) and that of male was 50 (48.1%). Mean age of patients was (67±13.5). Other data regarding patients in the study considering BMI, laboratory data, age distribution are involved in table (1).

General characteristics of patients enrolled in the study and the drugs used are detailed in table (2).

4. Effect of Clopidogrel on diuretic resistance parameters (BMI, serum urea, serum creatinine, eGFR and albuminuria severity).

Clopidogrel administration showed non-significant (p<0.05) effects on BMI, serum urea, and Severity of albuminuria. However, patients using clopidogrel showed significantly (p<0.05) lowered serum creatinine as compared with those non using it, (2.8 ± 1.7 with clopidogrel vs. 3.3 ± 1.7 without clopidogrel, p=0.0356). In addition, eGFR was significantly (p<0.05) higher with clopidogrel as compared with clopidogrel free group (33.8 ± 29 with clopidogrel vs. 25.5 ± 22.7 without clopidogrel, p=0.0276). See table (4).

5. Effect of Heparin on diuretic resistance parameters (BMI, serum urea, serum creatinine, eGFR and albuminuria severity.)

Heparin administration showed non-significant (p<0.05) effects on BMI, serum urea, eGFR, and severity of albuminuria. Patients using Heparin showed significantly (p<0.05) lower serum creatinine levels as compared with those non using it, (2.8 ± 1.3 with Heparin vs. 3.2 ± 1.8 without Heparin, p=0.0146). See table (4).

6. Effect of Calcium ampoule on diuretic resistance parameters (BMI, serum urea, serum creatinine, eGFR and albuminuria severity.)

Calcium ampoule administration showed non-significant (p<0.05) effects on Serum creatinine, eGFR, and Severity of albuminuria. However, patients using Calcium ampoule showed significantly (p<0.05) lowered serum urea as compared with those not using it, (103.3 ± 47.9 with Calcium ampoule vs. 142.7 ± 62.1 without Calcium ampoule, p=0.0242). In addition, BMI was significantly (p<0.05) higher with Calcium ampoule as compared with non (25.8 ± 2.7 with calcium ampoule vs. 24.4 ± 2.9 without calcium ampoule, p=0.0243). See table (4).

P value < 0.05 considered significant
Discussion

1. Effects of Aspirin on diuretic resistance parameters (BMI, serum urea, serum creatinine, eGFR and albuminuria severity).

The results of this study were not consistent with a study of Okada et.al 2016 concerning albuminuria. He found that there is non-significant effect of low-dose aspirin on albuminuria severity in patients with DM2 who had renal dysfunction (24) but the study done on patients not using intravenous furosemide. However, this study was consistent with a study of Pastori. et.al, 2016 who found that the low dose of aspirin had no effect on the eGFR in patient with CKD and hypertension, who was taking intravenous furosemide (25).

Aspirin is an active inhibitor of cyclooxygenase enzyme, at low dose (75mg-160mg) it acts as an antiplatelet agent, which demonstrates its action by inhibiting irreversibly platelet COX-1 enzyme, thereby stopping the development of thromboxane A2 (TXA2). It has been used in the Prevention of vascular thromboembolic event (26-27).

Aspirin may positively interfere with the severity of albuminuria, through interference in thromboxane A2 synthesis that affects the albuminuria severity according to studies (28).

TXA2 is a potent vasoconstrictor and platelet aggregator, its production increases in renal dysfunction, HF and hypertension; when aspirin inhibits cyclooxygenase, it will inhibit the production of TXA2, which may reduce deteriorating the renal function, and reduce of albuminuria (29).

2. Effect of Hydrocortisone and dexamethasone on diuretic resistance parameters (BMI, serum urea, serum creatinine, eGFR and albuminuria severity).

Corticosteroids are potent anti-inflammatory drugs and immuno-suppressants used in many conditions like asthma (30). Patients that use hydrocortisone and dexamethasone in low doses through injection in the present study as a combination with furosemide, showed non-significant (p<0.05) effect on kidney function and their use were to avoid allergic reaction and not intended to treat any possible adrenal or endocrine problems or any autoimmune problem.

Since all corticosteroid-treated diseases have inflammatory components at least, so that exacerbation of this inflammation is treated with a systemic corticosteroid, the impact on renal function was attributed to diseases themselves (31).

3. Effects of Atorvastatin on diuretic resistance parameters (BMI, serum urea, serum creatinine, eGFR and albuminuria severity).

In this study, the results regarding atorvastatin effects were consistent with result of Stefano Bianchi et.al 2003 who found that using atorvastatin would decrease the albuminuria severity (32), however, his study was done on patients using diuretics but intravenous furosemide was not specified.

Atorvastatin is a class of HMG-CO reductase inhibitor drugs, which decreases the glomerular damage and preserves the renal function by decreasing the deposition of lipid in the kidney (33).

Therefore, Atorvastatin had a role in reducing the renal injury that comes from elevation in oxidative stress levels, procoagulant and inflammatory biochemical levels in renal insufficiency (32), resulted in improvement of intra renal endothelial functions (34).

4. Effects of Clopidogrel on diuretic resistance parameters (BMI, serum urea, serum creatinine, eGFR and albuminuria severity).

The study of Tonelli et.al. 2007 found that patients who had CKD and HF would benefit from the addition of clopidogrel, as antiplatelet with or without aspirin, and this was consistent with our study that clopidogrel will reserve the eGFR (35). However, the study was done on patients using diuretics, the intravenous furosemide was not specified.
It was also consistent with finding of study of Gremmel et.al., 2013 who found that using clopidogrel had significant effect on serum creatinine and eGFR but the study was done on patients not using intravenous furosemide(36).

Using ADP receptor antagonist like clopidogrel may have beneficial effects on eGFR and creatinine. This indicate implicated role of platelets in deterioration of kidney function (37) may be through interference with renin and kidney perfusion pressure and hence eGFR (38).

5. Effects of Heparin on diuretic resistance parameters (BMI, serum urea, serum creatinine, eGFR and albuminuria severity.)

The clearance of heparin occurred by renal excretion, the unfractionated heparin doesn’t accumulate in the kidney like LMW heparin (39)Nagge, et.al.,2002. Heparins have many physiological effects beyond their anticoagulant property; Nagge study was done on patients not using intravenous furosemide (40).

Heparin, in animal model, was associated with reduction levels of parameters that indicate renal problems like urea, creatinine, reduce renal damage induced by ischemia and albuminuria and it may improve eGFR (40).

In this study, these finding came in agreement to those mentioned by previous studies. Blood urea was lower for patients using heparin (91.8 ± 52.3 with heparin vs. 124.4 ± 55.9, p=0.0518) but was non-significant for eGFR; there was improvement but again it was nonsignificant (34.7 ± 37.4 with heparin Vs. 26.1 ± 20.1, p=0.0786). However, serum creatinine was significantly (p<0.05) lowered in patients with heparin as compared with those not using it.

Histones might be implicated in the damage of kidney infrastructures, through inducing inflammation and the apoptosis (41). Heparin may attenuate these effects by neutralizing these histones and may help in reserving kidney function (41). In addition to that, heparin injection may affect level of midkine, a heparin-binding growth factor. Recently it was found to be implicated in many inflammatory processes and its expression was elevated in renal tubules (42). In acute and chronic kidney diseases, Pulsated elevation of midkine, after injection of heparin may has a beneficial effect on renal tubules and other endothelial cells by reducing apoptosis, and it enhances tubular cells regeneration. The effect of heparin and midkine on kidney function may be more complicated and not fully elucidated (43).

6. Effects of Calcium ampoule on diuretic resistance parameters (BMI, serum urea, serum creatinine, eGFR and albuminuria severity.)

In this study, High percentage of Patients had CKD, where its complications are hyperparathyroidism and alteration in the absorption of calcium and phosphate. This causes osteoporosis. Therefore, calcium ampule has a tendency to decrease the release of calcium from bone to blood in order to prevent osteoporosis and to replace calcium lost in urine by using of furosemide, which may increases calcium resorption and degradation of bone by action of parathyroid hormone (44).

One of complications of renal failure is the uremic encephalopathy where serum urea level increased significantly. It was found that PTH, one of hormones that had a direct effect on serum urea by regulating the calcium in the cerebral area. Calcium will decrease the uremic encephalopathy caused by elevation of serum urea (45). It was found also that any increase in PTH hormone would increase renin release (46). Addition of calcium may reduce renin release and study of Davies, et. al 2000 found that calcium intake decreases BMI and that was not consistent with our findings (47) and the study was done on patients not using intravenous furosemide.

Conclusion

Concomitant use of drugs with furosemide injection that is used to overcome edema associated with CKD has had different odd of effects on the activity of the diuretic on renal function itself. It was found in this study that drugs frequently used to treat comorbidities associated
with CKD were most likely helpful in potentiating the
effect of furosemide on renal function and we may be
able to say that they decreased likelihood of diuretic
resistance that usually associated with the diuretic in
CKD patients due to different causes.

From this study, we can get issue that no drug
affected positively on BMI. In case of calcium ampule,
the effect was negatively by increasing the body weight
in patients already with edema. The only drug that
affected positively on Serum urea was calcium ampule;
however, all other drugs had no significant effect on
serum urea.

Clopidogrel and heparin reduced significantly
Serum creatinine levels, meanwhile, they did not reduce
albuminuria severity, the effect that was positive from
two drugs, Aspirin and Atorvastatin only. The only
drug that affects the eGFR was clopidogrel. It affected
positively by increasing eGFR in these patients.

Acknowledgments: I would like to express my
deepest gratitude to al Hussein teaching hospital for
helping me throughout my study.

Limitations:
The limited number of patients where only 104
patients were involved, it was only one group and
there was no control group to compare the effect on
kidney function. In addition, lack of follow up for these
patients; all data collected were in the time of patient’s
admission only. In addition, the study was a single
center study.

Recommendations: We recommend by increasing
the number of patients and using more lab tests that
indicate diuretic resistance like urinary Na – K ratio,
Fractional Na excretion (FeNa), Spot urinary Na and
more marker for kidney to see the effect of drugs on this
organ.

Conflicts of Interest: The author had no conflicts
of interest.

Source of Funding: Self.

Ethical Clearances: Approval from the Ethical and
Scientific Committee of the Faculty of Pharmacy/ Basra
University in addition to the Scientific Committee of
Researches of Thi-Qar Health Directorate.

Assessment of Relationship between Ectopic Pregnancy and Assisted Reproductive Technology in Baghdad City

Alyaa Khazaal Neamah1. Wisam Mashaan Muttaleb2
1Assistant Lecturer, 2Lecturer, Maternal and Neonate Nursing Department, College of Nursing/ University of Baghdad, Iraq

Abstract

Objectives: To find out the relationship between assisted reproductive technology, Some demographics characteristic and ectopic pregnancy among women with ectopic pregnancy Methodology: A descriptive study was applied to assess the relationship between ectopic pregnancy and Assisted Reproductive Technology among purposive sample of (60) women aged between (20-43) years old attended the hospitals in Baghdad city. Results: The study show that the most woman in the age group (32-37) years old, was primary school graduate, most of them have no gravidity, were treated with assisted reproductive technology previously for (5-12) month, Clomiphene citrate (clomid) is used in the rate (50%), suffering from lower abdominal pain and Darker or brown vaginal spotting. Conclusions: The study concluded that there is significant relationship between the use of Clomiphene citrate (clomid) and ectopic pregnancy and the most benefit treatment for ectopic pregnancy is methotrexate. Recommendations: The study recommended a furthers study on ovulation induction, training program about the effect of ovulation induction especially (clomid) on women health

Keywords: Assessment, ectopic pregnancy, assisted reproductive technology

Introduction

Ectopic pregnancy is a pregnancy in which the fertilize ovum not implanted in the endometrial of the uterine cavity, meaning outside the uterine cavity, most commonly in fallopian tube, the important of management as pharmacologic treatment with methotrexate, or surgery especially with tubal rupture (1).

The incidence rate of ectopic pregnancy is 1–2 percent in the general population, and ART lead to increase this rate in pregnancies than in spontaneous pregnancies about 2–5 %. Although the overall mortality has decreased over time and about 6% of cases suffer from ruptured EPs of all maternal deaths, the fallopian tube EP is the most common ectopic implantation site, others 10 % of it occur in the cervix, ovary, myometrium, interstitial portion of the fallopian tube, abdominal cavity or within a cesarean section scar (2).

Nowadays, by increase infertility rate in the world, the demand to use ART had increase which a common technique for infertility treatment. However, with the time the complications that come from this technology appear widely, such as ovarian hyperstimulation syndrome, Ectopic Pregnancy, and multiple pregnancy, have drawn more and more attention. Even though the incidence of EP is rare during IVF (approximately 2%–11%) (3).

Ovulation induction agents is one of the most drugs used for infertility treatment, in the United States there are more than 2 million women within age group (15–44 years) have taken fertility medications. On the other hand, Janee and David reported that the possible complications associated with ovulation induction become more than
before, like ovarian hyperstimulation syndrome, multi fatal gestations, preterm delivery, heterotopic/ectopic pregnancy, spontaneous abortion, and the theoretic risk of a possible increase in the incidence of ovarian cancer so we deal more with these complication of ART in this study (4).

Methodology

A descriptive study was applied to ass the relationship between ectopic pregnancy and Assisted Reproductive Technology among purposive sample of (60) women aged between (20-43) years old attended the hospitals in Baghdad city. Data is collected through using the questionnaire format which consisted of five parts, including demographic, reproductive history, Diagnosis of Ectopic Pregnancy, Assisted Reproductive Technology, Management Treatment, and complications of PCOS included short, the items of questionnaire are rated by (yes) scored as (2) and (no) scored as (1).

Data are collected through using study instrument and the interview technique in purpose of data collection after agreement of woman which suffering from ectopic pregnancy which implemented for the period of (20th October 2019 through 25th February 2020). The reliability and Content validity of the questionnaire are determined through a pilot study of (10) women with ectopic pregnancy which was excluded from the study sample, a panel of (6) experts reviewed the study tool for its validity, and internal consistency reliability ‘split-half technique’ is employed for the determination of the study instrument internal consistency. The correlation coefficient is ($r=0.89$) which indicates that the questionnaire is an adequately reliable measure. Descriptive and inferential statistical analyses were used to analyze the data by using frequency (F), percentage (%), mean of score (MS), assessment (ASS), and Bivariate Pearson correlation, through SPSS program the statistical procedures tested at $p \leq 0.05$.

Discussion

The study shows that the most woman in the age group (32-37) years old, was primary school graduate, most of them have no gravidity, were treated with assisted reproductive technology previously for (5-12) month, the most of them were used Clomiphene citrate (clomid) (50%), suffering from lower abdominal pain and Darker or brown vaginal spotting.

The most site of presence the ectopic pregnancy in
Ampullary of fallopian tube, more management used to treat EP is Methotrexate IM.

Also, there is no significant relationship between the studied variables in table (5) and ectopic pregnancy except use Clomiphene citrate (clomid) and used of artificial insemination had significant relationship.

The age is consider one factor that increase the incidence of ectopic pregnancy as the study done by Shayestehm et al 2014, reported highly improbable an increase in chromosomal abnormalities in the trophoblastic tissue be caused by advanced maternal age (19, 20yrs). In addition, the fallopian tube function decreased in effectively transport the ovum to the uterus during increase maternal age. However, these hypotheses remain to be tested (5).

In this study the educational level is important to women for knowing and following their health condition like the study that indicated the social and demographic factors determining the level of awareness of the signs and symptoms of ectopic pregnancy (6).

The study shows that more patient with ectopic pregnancy is treated with ART in the past and Use the ART put the woman at risk for development ectopic pregnancy as the study done by Cihan K. & Eray Ç. Mentioned that ART and ectopic pregnancy and associated risk factors have increased the incidence of an ectopic pregnancy, so the exact method that bind the ectopic pregnancy and ART still between ectopic pregnancy and ART still ambiguous. After the IVF the most common risk factors are ectopic pregnancy which include (Day of transfer, fresh or frozen-thawed cycle single or double transfer), also mentioned that ectopic pregnancy will happened at day 5 blastocyst transfer that the day 3 blastocyst transfer, and frozen-thawed cycle has lower risk of ectopic implantation than fresh cycle (7).

Table (2) shows that most women with ectopic pregnancy in Baghdad city had significance relationship with the use of Clomiphene citrate (clomid). In the summary of product characteristics of clomid (January 2020) mention that clomid increase the chance of ectopic pregnancy in women use it for treat fertility, Clomid uses lead to Ovarian Hyperstimulation Syndrome (OHSS) which is most common causes of EP. Clomiphene has direct effect on pituitary gland to release more amount of FSH and LH therefore the estrogen receptors are blocked this pose to increase the rate of EP in future confirm by (8).

In the study performed at Arash Women Hospital, Tehran, shows that long duration of treated with ovarian hyper stimulation (clomid) lead to increase the level of estrogen which consider as a direct cause of ectopic pregnancy (EP) (9).

In this study it was observed that there is a relationship between used of artificial insemination and ectopic pregnancy, as in the study conducted in Arak Taleghani Hospital, Iran. which showed that women’s who undergo artificial insemination, that used to treat some cases of infertility especially tubal factor infertility, after 30 days of this treatment suffer from ectopic pregnancy which was diagnosed by ultrasound (10).

The diagnosis of ectopic pregnancy associated with some signs and symptoms like miss one or two menstrual period and Darker or brown vaginal spotting which appear high in this study while the study in Nigeria showed that 80 % of study sample have abdominal pain when come to hospital, Also the study show that the most types of ectopic pregnancy was in the ampullary and isthmus site of fallopian tube (66.7%,18.3%) respectively, this result corresponding with result of the study of done in south-east Nigeria that showed (n:52/82) of women have ampullary ectopic pregnancy (11).

The study shows that 50% of women are treated by methotrexate IM and 35% of them treated by mixed of surgical and use of methotrexate drug methotrexate drug is a folic acid antagonist that inactivates dihydrofolate reductase and de novo synthesis of purines and pyrimidines, and therefore, cellular DNA. The most common action of methotrexate is increasing the trophoblastic cell division and not allow these cells to
become multiplying (12).

American society for Reproductive Medicine 2013, mention that the dose of MTX depended on the level of hCG in blood, so the dose may be single or double. This mentioned that 84.5% of women with ectopic pregnancy are receiving treatment by MTX and it was benefit to remove ectopic pregnancy (13). The most management of EP is Methotrexate IM. This result is disagreement with another study done by Togas Tulandi which fine that the surgical treatment is the best solution to EP (14).

Ectopic pregnancy is a potentially life-threatening condition. While surgical method is better way to treat the ectopic pregnancy. In the 1980’s discover that the early diagnosis is eased the initiation of methotrexate as a medical therapy for EP. With the routine use of early ultrasound, diagnosis of ectopic pregnancy can be established early, and medical treatment can be administered in most cases (14).

Conclusions

The study concluded that there is significant relationship between the use of Clomiphene citrate (clomid) and ectopic pregnancy and the most benefit treatment for ectopic pregnancy is methotrexate.

Recommendation:

The study recommended a future study on ovulation induction, training program about the effect of ovulation induction especially (clomid) on women health

Conflict of Interest: Nil

Source of Funding: the source of funding is our self

Ethical Clearance: is obtained from the Ministry of Health / Al-Russafa Health Directorate (Baghdad Teaching Hospital), and All women participants in the research - have been approved before the questionnaire is started.

Evaluating the Safety of Non-Steroidal Anti-inflammatory Drugs use in Asthmatic Patients: A Systematic, Critical Review of Literature

Amanj Baker Kurdi

Lecturer in Clinical Pharmacy, Department of Pharmacology and Toxicology, College of Pharmacy, Hawler Medical University, Erbil, Iraq

Abstract

Background: Evidence suggest avoidance of Non-steroidal anti-inflammatory drugs (NSAID) in aspirin-intolerant asthmatics due to the risk of triggering exacerbation attack; however, evidence around avoiding NSAIDs in all other asthmatic patients are unclear. This study aimed to evaluate the evidence surrounding the safety of using NSAIDs, including selective COX-2 inhibitors, among asthmatic patients.

Methods: A systematic review used Medline (OVID), Scopus and Embase from January-2008 to January-2019. Inclusion criteria included English, and human studies that evaluated the use of NSAID in asthmatics. Data was screened/extracted using a pre-designed data extraction form using Covidence®, then were critically appraised.

Conclusion: Of the 49 identified studies, eight were eligible. Prevalence of NSAID-induced asthma exacerbation was 9% (95%CI: 6.0–12.0%)-9.9% (95%CI: 9.4-10.5%). Asthmatics who were aspirin/NSAID intolerant had 37% higher risk of hospitalisation compared to tolerant patients (RR:1.37; 95%CI:1.12–1.67). Use of COX-2 inhibitors showed non-significant associations with worsening respiratory symptoms/exacerbation. Only low-quality evidence was found for the safety of topical NSAID. NSAIDs-induced respiratory reactions/symptoms is relatively uncommon with the majority of asthmatic patients could tolerate NSAIDs therapy. Asthmatic patients who suffer from aspirin-induced asthma or NSAIDs-exacerbated respiratory disease (NSAIDs intolerant) should be avoided NSAIDs prescribing but could be safely prescribed selective COX-2 inhibitors as an alternative.

Key words: Asthma; Non-steroidal anti-inflammatory drugs; safety; analgesics; exacerbation

Introduction

Asthma is a complex, heterogeneous airway disorder responsible for a variety of recurring symptoms, such as tightness of the chest, difficulty in breathing and wheezing, caused by bronchoconstriction, airway oedema, hyper-responsiveness and remodelling. Asthma is a prevalent chronic condition affecting over 300 million people, with its prevalence continues to increase with expectation that another 100 million people would be affected by 2025. In the UK, 5.4 million people currently suffer from asthma with one potentially life-threatening asthma attack every 10 seconds resulting in three asthma attack related deaths, on average, every day, giving the UK some of the highest asthmatic rates in Europe.
Multiple factors have been identified as potential risk factors for triggering acute attack of asthmatic exacerbations and these include poor medication compliance, allergies and exposure to some pharmacological agents such as non-steroidal anti-inflammatory drugs (NSAIDs). Non-steroidal anti-inflammatory drugs are one of the most commonly prescribed analgesics, accounting for approximately 5-10% of all annual prescribed medications. NSAIDs’ pharmacological effects are mediated via inhibition of prostaglandins via reversible inhibition of cyclooxygenase (COX) enzymes (both COX-1 responsible for the production of prostaglandins which maintain normal physiological functions and COX-2 involved only in production of pro-inflammatory prostaglandins). Based on their selectively toward COX enzyme, NSAIDs can be classified into standard NSAIDs (these are non-selective inhibiting both COX-1 and COX-2) such as ibuprofen, and indomethacin and Coxibs (these are selective COX-2 inhibitor) such as celecoxib and etoricoxib.

Use of NSAIDs in asthmatics might trigger an acute asthma exacerbation attack which is known as aspirin-induced asthma (AIA) or Non-steroidal anti-inflammatory exacerbated respiratory disease (NERD), which has an average prevalence of about 21% in adult asthmatics, even though it could vary between 4%-44%. AIA/NERD is a common cause of life-threatening asthmatic exacerbations, and although its exact pathophysiology has not yet been fully understood, current evidence suggest the involvement of leukotrienes. Although it has been suggested that the majority of asthmatics can tolerate NSAIDs, the current international guidelines, including the UK National Institute for Health Care and Excellence (NICE) recommend all asthmatics should be offered a NSAIDs provocation test before prescribing NSAIDs to assess patients’ tolerability to NSAIDs; and subsequently avoid NSAIDs in asthmatics who are intolerant to NSAIDs (i.e. AIA/NERD sufferers). However, due to issues with the availability and feasibility/practicability of undertaking provocation test for all asthmatics, these recommendations mean that NSAIDs should also be avoided in all asthmatics with unknown sensitivity status which constitutes the majority of asthmatic patients. Accordingly, avoiding NSAIDs in this large population of untested asthmatics for NSAIDs sensitivity leads to many untested asthmatics being unnecessarily denied the multiple advantages of NSAIDs and being prescribed alternative analgesics such as paracetamol, and opioids/opioid derivatives: this might be of particular concern since the latter could be associated with potentially problematic long-term adverse effects and harms such as dependence, risk of abuse and reduced quality of life.

Similarly, although evidence suggest the safety and efficacy of selective COX-2 inhibitors in many sufferers of AIA/NERD, due to their selective inhibition of COX-2, NICE continues to recommend their avoidance due to non-lethal intolerance in a small number of AIA/NERD patients. In order to avoid the unnecessary use of potentially harmful analgesics in asthmatic patients such as opioids, who could otherwise be prescribed NSAIDs, it is important to understand the current evidence around the safety of NSAIDs among asthmatic. Therefore, this study aimed to critically review and analyse the current scientific literature for the safety of NSAIDs in asthmatic patients including the safety and tolerability of selective COX-2.

Method

Data Source and Searches

This was a systematic review of the literature conducted and reported in accordance to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement checklist. The literature search was carried out in Medline (OVID), Scopus, and Embase from January 2008 to January 2019, using key terms related to asthma, NSAIDs, COX-2 inhibitors and aspirin induced asthma or NSAID exacerbated respiratory disease based on previously conducted systematic review in this area including the use of certain exclusion terms to limit the volume of irrelevant results. A population, intervention, comparison and outcome (PICO) approach was adopted to assist with the search and selection of the relevant articles (Table 1). Reference lists of the eligible articles were also manually searched to identify any further relevant articles.

</table>

(Note): COX-2: Cyclooxygenase enzyme 2; NSAIDs: Non-steroidal anti-inflammatory drugs

Study Selection

Studies were considered eligible if they were conducted in human, published in English, without restrictions to study designs and studies that matched our PICO criteria (Table 1). All the identified records from the search strategy were exported from the databases and imported into Covidence® whereby duplicate records were removed. The author (AK) independently undertook titles and abstract screening for relevance, followed by selecting records for full-text screening and data extraction; each of the above stages were validated by an independent reviewer (MM). Any discrepancy was resolved through discussion until consensus was achieved.

Data Extraction, quality Assessment, synthesis and analysis

After identification of the eligible studies, data from these studies were subsequently extracted into a spreadsheet including information on the study characterises (study design, setting, sample size, population) and outcome measures including prevalence of NERD/AIA, differences in the risk of asthmatic morbidity in relation to NSAIDs and COX-2 inhibitors, differences in FEV1 after exposure to NSAIDs and COX-2 inhibitors, average doses provoking asthmatic response in NSAIDs and COX-2 inhibitors and the presence of symptoms induced by NSAID and COX-2 inhibitor exposure. Studies’ quality and risk of bias was assessed using the National Heart, Lung and Blood Institute’s quality assessment tool for the various types of study design including observational studies, systematic reviews, meta-analyses and before-after studies except from case reports; whereby studies’ were classified based on their quality into good, fair or poor depending on the total scores from each tool. The evidence from all the eligible studies were then critically reviewed and appraised using the Critical Appraisals Skills Programme (CASP) checklists for the appropriate study design/type.

Literature Review Results

Overall, 316 articles were identified from the initial literature search, of which only eight studies were eligible for inclusion. A total of 50,086 patients were included in these eight records.

Study characteristics

The eligible eight studies comprised of two meta-analysis, one retrospective cohort study, one before and after study, one expert opinion, and
three case reports covering both adult and paediatric population, and short/acute and long-term complications.

In terms of outcomes, the eight included studies provided a wide range of information concerning the safety and use of NSAIDs in the general asthmatic population and those who suffer from AIA/NERD. Overall, the evidence indicated that the use of NSAIDs is associated with higher risk of asthmatic complications/exacerbations in those who suffer from AIA/NERD (intolerant patients) compared to those are tolerant to NSAIDs (Table 3). Furthermore, asthmatics who are suffering from NERD showed poorer asthma control when taking NSAIDs and the average NSAIDs dose that found to provoke asthmatic reaction is even below the therapeutic NSAIDs dose. Moreover, asthmatic children, compared to adults, using NSAIDs were at higher risk of asthma associated morbidity and mortality. In terms of the safety of COX-2 inhibitors, the evidence from the meta-analysis showed no harms or safety issues with the use of COX-2 inhibitors among asthmatic including those who suffer from AIA or NERD; this is despite some case report studies showed contradicted evidence as they reported an increase in the onset of asthmatic symptoms and a reduced FEV1 upon exposure to COX-2 inhibitors but only among AIA or NERD asthmatics. In terms of the quality and risk of bias, two studies were classified as good quality, one study as fair quality, and one as poor quality.

Critical appraisal and analysis

Use of NSAIDs

The highest quality evidence about the safety use of NSAIDs in asthmatics came from a meta-analysis of 46 clinical trials and observational/population-based studies conducted by Morales et al which included data from 20,162 patients with NERD and NSAIDs-tolerant asthma (NTA). This study determined the prevalence of NSAID hypersensitivity (intolerance) measured either by oral provocation challenge tests (OPCTs)(9%) or a self-reported questionnaire (9.9%); the observed difference between NSAID hypersensitivity (intolerance) prevalence was attributed to the vague respiratory reaction definitions used within the questionnaires which likely resulted in overestimation of NSAID hypersensitivity (intolerance) prevalence. These estimates were significantly lower than what initially estimated in a previous systematic review since this study, unlike the previous study minimised bias by including only studies that used blinded and controlled OPCTs. Data on aspirin dose that provoked asthma symptoms in both adults and children was also assessed; then observational studies reporting asthma morbidity in those with NERD and NTA were compared. In regard to the former, the mean aspirin dose that provoked respiratory reactions in NERD patients was 85.8 mg (95%CI:73.9-97.6) which is a clinically relevant doses of oral aspirin given the 75-100 mg aspirin dose recommended by the US guidelines for the CVD prevention; although the potential risk reduction of using 75 mg vs 100 mg aspirin was not possible to quantify due to lack of data, sub-group analysis results suggest a dose-response relationship between aspirin dose and the extent of fall in FEV1. Having said this, it should be noted that there were considerable variations in individual patients susceptibility to the low aspirin dose suggested other factors might play a role as well; accordingly, it could be concluded that using low-dose aspirin would not trigger clinically significant adverse respiratory symptoms in all asthmatics with NERD even though the risk would be higher when higher loading aspirin dose (≥300 mg) is used; however, these risks should be weighed against the net clinical benefits of using aspirin in the management and prevention of CVD. In terms of asthma morbidity in those with NERD and NTA, compared to NTA, use of NSAIDs was associated with higher risk of all asthmatic morbidity including 50% higher risk of severe asthma and double the risk of uncontrolled asthma as well as 80%, and 40% higher risk of emergency visits and asthma hospitalisation, respectively, emphasising the importance of considering NERD diagnosis to direct the safe use of NSAIDs and aspirin among asthmatic patients. Although this meta-analysis provided valuable findings about the safety of NSAIDs use among asthmatic and it was of a good quality, it has certain limitations including investigating
the safety of aspirin only without considering the other NSAIDs which do not exclude the possibility of selective hypersensitivity to aspirin and issues with generalisability to all the other NSAIDs.

The higher risk of asthmatic morbidity among NERD was further confirmed by another retrospective cohort study conducted by Lo et al.\textsuperscript{22} who investigated risk of asthma exacerbation hospitalisation with the use of NSAIDs among 29,484 paediatric asthmatic patients of which 9,862 (33.4\%) and 19,622 (66.6\%) were NSAIDs users and non-users, respectively. After adjusting for potential confounders, use of NSAIDs was associated with 41\% higher risk of hospitalisation compared to non-user (aRR: 1.41; 95\%CI:1.3-1.53) which equates to 9.2\% vs. 6.3\% in NSAIDs users and non-users, respectively. This study was of fair quality but still suffer from certain limitations such as failure to consider the over-the-counter use of NSAIDs as well as defining NSAIDs users as only those who were prescribed NSAIDs and anti-asthmatic therapy on the same day, both of which might have resulted in under-estimation of NSAIDs use and hence its risk. Overall, this study has clearly demonstrated the apparent safety risk of NSAIDs use among paediatric asthmatic patients.

Unlike the other identified studies, one of the studies\textsuperscript{23} investigated the safety of topical NSAIDs among 11 NERD asthmatics; this was a “before and after” study in which asthma control was evaluated 6-months before and after starting and ceasing topical NSAIDs, respectively. The study findings indicated improvement in all the asthma control measurements after ceasing topical NSAIDs. However, this study was of poor quality with many methodological flaws, that question the validity of the findings, including a very small sample size, failure to disclose anti-asthmatic medications being taken by patients as well as considering the adherence to the topical NSAIDs. Accordingly, despite suggesting topical NSAIDs are hazardous in asthmatics with NERD, this evidence is inconclusive and as such a recommendation on the safety of topical NSAID use in NERD patients cannot be made.

Furthermore, exacerbation of asthma symptoms upon exposure to NSAIDs was further reported by two case reports by King \textit{et al.}\textsuperscript{25} and Tang and Zhang\textsuperscript{24}; however, evidence from case reports are only considered as hypothesis generating which in turn has been confirmed in subsequent studies such as those described earlier\textsuperscript{20,22}.

### Use of selective COX-2 inhibitors

The safety of using COX-2 inhibitors (e.g., celecoxib, rofecoxib) and selective NSAIDs (e.g., meloxicam) among NERD asthmatic was investigated in a meta-analysis by Morales \textit{et al.}\textsuperscript{21}. The meta-analysis included a total of 426 NERD asthmatic patients from 14 clinical trials. Compared to placebo, the study found no significant differences in respiratory symptoms, FEV\textsubscript{1}, and nasal symptoms after exposure to COX-2 inhibitors but only a very small increase in respiratory symptoms (risk difference:0.08; 95\%CI:0.02-0.14) after exposure to selective NSAIDs, suggesting the safety of using COX-2 inhibitors in asthmatic patients with NERD.

This study was of high methodological quality in which bias was minimised by including only blinded clinical trials; however, only low-moderate dose in patients with stable, mild-to-moderate persistent asthma was evaluated in this study; hence this observed safety might not be applicable to high doses of COX-2 inhibitors or those with unstable asthma or those who have experienced severe life-threatening reactions requiring intubation after aspirin or NSAIDs exposure. This is despite two case reports\textsuperscript{26,27} who reported respiratory reaction to COX-2 inhibitors in a uncontrolled 33-year old asthmatic with NERD and a controlled 25-year old NERD asthmatics, respectively; however, these hypothesis generating evidence were subsequently contradicted and disapproved by several clinical trials as summarised in the meta-analysis by Morales \textit{et al.}\textsuperscript{21}.

### Discussion

The current evidence from the literature indicated that the prevalence of AIA/NERD among asthmatic was relatively uncommon with a reported prevalence...
of approximately of 9%, suggesting that the majority of asthmatic patients could tolerate NSAIDs; hence their safe prescribing among asthmatic with unknown history of hypersensitivity to NSAIDs. These findings might question the current guideline recommendations\(^1\), \(^1\) of avoiding NSAIDs in asthmatics unless they have proven to be NSAIDs tolerant through either NSAIDs provocation challenge test or self-reported questioning; however, both of the latter are problematic since, firstly, the NSAIDs provocation challenge test is not widely used in routine clinical practice due to issues with availability, practicality, feasibility\(^1\), \(^1\); and secondly, due to variability of self-awareness of NSAIDs-induced symptoms in patients with asthma\(^2\) which makes the self-reported intolerance to NSAIDs unreliable. Collectively, these guideline recommendations\(^1\), \(^1\) imply denying and withholding NSAIDs prescribing from the majority of asthmatics despite NSAIDs effective anti-inflammatory, analgesic, and antipyretic effects resulting in doctors prescribing alternatives analgesics to NSAIDs such as paracetamol, and opioids/opioid derivatives\(^1\); however, this is concerning since some of these alternatives such as opioids/opioid derivatives are associated with potentially problematic long-term adverse effects and harms such as dependence, risk of abuse and reduced quality of life\(^3\).

Furthermore, there are high quality evidence for increasing asthma morbidity among AIA/NERD patients upon exposure to NSAIDs suggesting that NSAIDs should be avoided in these group of asthmatic patients. However, unlike NSAIDs, selective COX-2 inhibitors are shown to be safe in AIA/NERD patients and could be prescribed safely as an alternative to NSAIDs in AIA/NERD patients. Moreover, selective COX-2 inhibitors could also be a safe option for the general asthmatic patients who are unwilling to accept receiving NSAIDs due to the potential risk of their asthma exacerbation in response to NSAIDs exposure. There is lack of robust and high-quality evidence about the safety of topical NSAIDs among AIA/NERD patients leaving this an area for further research.  

**Strengths and limitations**

To our knowledge, this is the first comprehensive systematic evaluation of the safety of using NSAIDs, including selective COX-2 inhibitors, among patients with asthma as well as asthmatics who suffer from AIA/NERD, without restrictions to study types across multiple databases over a 10-year period. Since the search was conducted up until January 2019 it is possible that we have missed potential studies that have been published after January 2019 which might have impacted our study findings.

**Conclusion**

In summary, it could be concluded that NSAIDs-induced respiratory reactions/symptoms is relatively uncommon with the majority of asthmatic patients could tolerate NSAIDs therapy. Asthmatic patients who suffer from AIA/NERD should be avoided NSAIDs but could be safely prescribed selective COX-2 inhibitors as an alternative.

**Acknowledgment:** I would like to acknowledge Mr M. McGarry for his help with the data screening, extraction and quality assessment.

**Conflicts of Interest:** Nothing to declare

Abstract

The purpose of this research is to study and find out the strategies implemented by KAI in dealing with the impact of the Covid-19 pandemic on KAI’s performance. The method of analysis in this study is a qualitative descriptive method by analyzing all the data related to the topic being studied, which is then presented with fairly comprehensive and comprehensive arguments. The results showed that the very fast growth in the last ten years is KAI’s performance that should be appreciated. However, the Covid-19 pandemic is a reminder that economic development (profit) must be accompanied by the principles of sustainability and environmental and social concerns. The current situation in the impact of the Covid-19 Pandemic is very unfavorable for achieving revenue targets for passenger and freight transport. KAI has carried out various strategies in dealing with the impact of the Covid-19 pandemic. Several things that have been done by KAI in dealing with the impact of the Covid-19 pandemic include: 1. Protecting passengers and employees of KAI by prioritizing health through the Covid-19 prevention protocol; 2. Maintain company liquidity by preparing several scenarios, if the pandemic ends in June, August or December; 3. Perform cost efficiency (operational expenditure) and reduced investment (capital expenditure) to balance the potential decline in income.

Keywords: Covid-19, Pandemics, Sustainability.

Introduction

PT Kereta Api Indonesia (Persero) is an Indonesian State-Owned Enterprise that provides railroad transportation services which are then called KAI. Various revolutionary efforts and steps in revitalizing business according to changing times and increasingly dynamic external conditions have been carried out. For a decade, KAI has continued to improve its performance in various aspects. In making continuous improvements and changes, companies are increasingly prioritizing commercial functions in addition to public service functions which are no less important. With the increasing company performance both in operational and financial management and consistency in management in implementing Good Corporate Governance (GCG), stakeholders’ trust in KAI will also increase.1

Starting from 2009, various important and significant efforts were made to improve overall company performance and financial performance in particular. KAI’s losses in 2008 amounting to 83 billion rupiah can be repaired directly in 2009 by recording a profit of 155 billion rupiah, until now in 2019 KAI has been able to achieve profits of up to 1.9 trillion rupiah. The 2008 revenue of 4.4 trillion rupiah was able to be improved in 2009 to 4.8 trillion rupiah, then KAI’s profit growth fluctuated from 2015 to 2018 and then in 2019, KAI’s

Corresponding Author:

Student, Masters in Management, Universitas Sebelas Maret. Street. Ir. Sutami No. 26, Surakarta, Indonesia
Email ID: mutiaraambar7010@gmail.com
total income could grow compared to 2018 reaching up to 26.2 trillion rupiah. For the development of company assets also grew significantly, from the position of assets in 2008 amounting to 5.8 trillion rupiah, growing to a value of 44.9 trillion rupiah until 2019.

During the 2009-2019 period, profit growth continued to increase, as did income and asset growth. The realization of an increase in financial performance is evidence that the management function is able to create value for the company, which is reflected in the ability to create profits. The success of marketing performance cannot be separated from the performance of human resources (HR) which is the main measure considering that KAI is a service provider and public transportation services where the HR factor is the most important variable in the delivery of services and services to customers. In 2019, the highest revenue contribution was obtained from passenger transportation and followed by freight transport.

Meanwhile, from the freight transportation segment, the largest contribution is obtained from coal transportation of the total freight revenue. The volume of goods transportation has started to increase since 2011, from 2015 to 2019 the revenue for goods transportation continues to grow, revenue for goods transportation comes from transportation of coal, containers, fuel, cement, bulk, plantation, general cargo, BHP and others. The success of commercial performance is inseparable from operational performance indicators, services, human resources and information technology as well as other supporting performance.

Human resources that are well managed will be part of the company’s strength and increase the company’s value. Human resources are the main capital for a company or it is called human capital. Human resource management in the railroad industry in Indonesia initially followed the production orientation that took place in the company. Many things have been done by KAI related to human resource management in supporting the company’s business, including implementing a new remuneration system, prioritizing performance over years of service, recruiting professionals, enforcing regulations and developing human resources including internal training, technical and management courses. The country, training abroad and almost all employees are given the opportunity to conduct comparative train studies abroad.

Various efforts in the train operation process have been made and achieved by KAI. From 2011 to 2019 KAI continued to increase its fleet of locomotives, trains and carriages in large numbers. One of the keys to the success of this process is the expertise in managing rail operations and traffic. The division of work areas begins with the relatively limited KAI rail network, most of KAI’s operational areas cover Java Island and partly on the island of Sumatra. The working area in Java Island is divided based on the Operational Area (Daop), while the working area in Sumatra is divided based on Regional Divisions (Divre). Train travel management stems from the existence of train travel schedules on certain routes and certain frequencies. Operational planning is defined from commercial targets, efforts to maximize the number of passengers carried out commercially are supported by operational reliability. The capacity of available operating facilities is used as the basis for production targets.

Behind the train operating system, it is inseparable from the main elements that regulate train travel to run efficiently and safely, namely the signal and telecommunication systems. Until now, the signaling and telecommunication systems have continued to experience improvement as evidenced by the investment in increasing signaling in the Jabodetabek area which has been implemented since 2018. Train travel management stems from the existence of train travel schedules on certain routes and certain frequencies. The scheduling process is an activity that connects various work units in the railroad industry.

All the successes that have been achieved by KAI have occurred due to the use of information systems and technology in each of its business processes. KAI continues to develop various applications in information
technology to facilitate services and information for railroad users. Every year there is always updating and reviewing of information technology plans so that the focus of KAI’s technology plans and strategies is always in line with the development of KAI’s business and corporate strategies. KAI is committed to carrying out good corporate governance (GCG) practices in all of its business activities. As a manifestation of this commitment, KAI has implemented various policies and guidelines such as GCG Guidelines, Code of Conduct, Guidelines for the Board of Commissioners and Directors, Information Technology Governance, Risk Management, Reporting of Alleged Violations, Internal Control Systems and Internal Control Systems, as well as various other policies made to support the consistent and sustainable implementation of Good Corporate Governance.

KAI’s revenue growth from year to year from 2009 to 2019 is a performance that will continue to be maintained. There are so many challenges that have been faced and all of them can be overcome by continuing to improve services accompanied by revenue growth that can always provide good performance for all stakeholders. Entering 2020 with high optimism, KAI plans revenue growth of around 20% in accordance with KAI’s long-term plan. In January and February, KAI’s performance started very well, but this got worse after the trend of KAI’s daily passengers began to decrease significantly since the announcement of the first Covid-19 patient in Indonesia as of March 2020.

This was followed by various Large-Scale Social Restriction policies that further limit the passenger speed of KAI and its subsidiaries. As of June 2020, KAI’s passenger volume per day has decreased by 45% and passenger transport revenue has decreased by 52% compared to normal conditions. KAI’s freight revenue until April 2020 still shows growth and supports KAI’s overall revenue to decrease in revenue. The pandemic resulted in company losses and reduced company performance, passenger revenue per day which had so far reached 23 billion fell to only 300 million per day, along with the number of passengers plunging from 1.2 million passengers per day to 200 thousand per day during the pandemic.6

Effisiensi skenario optimis (full year) Pencapaian efisiensi ke setahun penuh 34% 47%
The Covid-19 pandemic has made an important history in having a bad impact on company performance, the government’s appeal to all affected communities is to carry out social and physical distancing, even the government imposes large-scale social restrictions (PSBB) in areas experiencing red zones in Indonesia. So this is the main reason for the decline in KAI’s performance. For KAI itself, researchers are motivated to discuss what strategies KAI is doing and how KAI survives in the face of the current pandemic. It is important to research this in order to provide a reference for academics in future research as well as for practitioners when faced with the same conditions. This research will discuss the impacts and sustainability strategies that will be carried out by KAI during the Covid-19 pandemic.

Research Methods

This research was conducted using qualitative methods, where this research aims to explain the impact and strategies the company undertakes in dealing with force majeure (the Covid-19 pandemic). Qualitative design does not use hypotheses, does not contain variables and does not compare variable relationships but looks for information on a single concept - central phenomena and deep understanding (Ghozali, 2016). The data source in this article uses secondary data. As for the method of data collection through observation of literature studies, by reading and reviewing and analyzing various literatures, both in the form of documents, journals and KAI data that issue information relevant to the research.7

Discussion

KAI plays an important role as mass transportation that is energy efficient and environmentally friendly. The products offered by KAI are passenger train transportation, freight train transportation, property management services related to trains, train-based tourism services, restaurants and logistics distribution. To answer these challenges, it is necessary to make efforts that are better and structured in company operations. Adverse impacts related to company performance are reflected in a very significant decline in both passenger and freight transport. In passenger transportation the following occurs.8

1. Reduction and cancellation of train trips;
2. Limitation of railway transportation capacity (social distance government policy);
3. The number of passengers who cancel the train trip;
4. The decrease in the number of train users interested as a result of the decrease in the activity of the number of trips of people who use the train.

Meanwhile, the decline in freight transportation was caused by a decrease in coal market demand that occurred in several countries, this has resulted in coal transportation partners canceling train trips. KAI’s response to the impact of the Covid-19 pandemic was to take several strategic steps, including: First, what was carried out by KAI’s management was to protect KAI passengers and employees or what is known as “Protect Our People”, namely prioritizing the health of train transportation users. Api and the KAI employees. In December 2019, when news broke out for the first time about the Corona virus in Wuhan China, KAI management made instructions for the directors regarding the protocol to prevent the spread of the Novel Corona Virus (2019-NCOV) at stations and on trains. Then after on March 2, President Joko Widodo announced the first positive case of corona in Indonesia and was followed on March 16, the Minister of Administrative Reform and Bureaucratic Reform (Tjahjo Kumolo) wrote a circular with an appeal to all state civil servants to work at home. At the same time, the Management of KAI issued directors regulations regarding the following decisions:

1. Establishment of a Task Force for Handling Novel Corona Virus;
2. Work Arrangements for Workers in order to anticipate the spread of the corona virus (Covid-19);
3. The process of procuring goods and services
during the emergency period of the Corona virus disease outbreak (Covid-19);

4. Prohibition of traveling outside the region and / or homecoming activities in an effort to prevent the spread of the corona virus diseases (Covid-19);

5. Provide incentives for workers who are at risk of being infected with the corona virus diseases (Covid-19);

6. The protocol for preventing the spread of the corona virus diseases (Covid-19) on extraordinary train trips according to the criteria for limiting people’s travel in the context of accelerating the handling of the corona virus diseases (Covid-19)

The second step taken by KAI’s management in saving the company is to maintain the company’s liquidity by preparing several scenarios if the pandemic ends in June, ends in August and when it ends in December 2020. KAI continues to prepare payments, by preparing sufficient bank loans to maintain liquidity. The three scenarios are prepared as a projection for the end of the pandemic, including the optimistic, moderate and pessimistic scenario with the following explanations:

1. An optimistic scenario, if the pandemic ends in June with an estimated passenger transport revenue reaching 2.8 trillion or equal to 33% of the 2020 target and freight transport reaching 6.3 trillion or equal to 74% of the 2020 target.

2. Moderate scenario, if the pandemic ends in August with passenger transport revenues reaching 2.2 trillion or equal to 26% of the 2020 target and freight transport reaching 6.1 trillion or 71% of the 2020 target.

3. The pessimistic scenario, if the pandemic ends in December with passenger transport revenues reaching 1.7 trillion or equal to 20% of the 2020 target and freight transportation of 5.7 trillion or 67% of the 2020 target.

These three scenarios are scenarios when the pandemic ends at these times and also by predicting the losses incurred by the company from each scenario. This then makes management take the third step, namely by carrying out efficiency in costs (operational expenditure) and reducing investment (capital expenditure). With the decline in company revenue for the products offered due to the impact of the Covid-19 pandemic, the company has taken initiatives in terms of cost savings to balance the potential decline in revenue due to the Covid-19 pandemic. In addition to this, the company also supports government policies regarding social distancing in which people reduce their mobility by reducing the number of passenger train trips and limiting the number of occupancy passengers on passenger trains.

The company also undertakes optimization initiatives in managing capital expenditure with the aim of managing cash flow. Optimization initiatives are carried out with the aim of reviewing the feasibility study of the intended investment by readjusting the assumptions used including the expected rate of return on investment.

The new normal scenario applied to passengers is the first step in restoring public confidence in KAI transportation services. The company will also continue to increase its role in the Corporate Social Responsibility (CSR) program as a form of the company’s concern for the community during the Covid-19 pandemic. (Lloret, 2016) according to him there are three domains that can control sustainability, including stakeholders, sustainable leadership and corporate governance.

**Conclusion**

KAI has carried out various strategies in dealing with the impact of the Covid-19 pandemic. Several things that have been done by KAI in dealing with the impact of the Covid-19 pandemic include: 1. Protecting passengers and employees of KAI by prioritizing health through the Covid-19 prevention protocol; 2. Maintain company liquidity by preparing several scenarios, if the pandemic ends in June, August or December; 3. Perform cost efficiency (operational expenditure) and reduced investment (capital expenditure) to balance the potential decline in income.

Novelty Predictor ZnO Nano practical for Cancer Treatment

Anmar Hameed Bloh¹, Hassan Khuder Naji², Antesar Rheem Obead²

¹Lecture, Department of Radiology and Sonography Technique, AL-Rafidian University College, Babylon University, College of Education, Science Dept., Hilla, Iraq

Abstract

Zinc oxide nanoparticles (ZnO NPs) are used to increasing the number of industrial products such as rubber, paint, coating, and cosmetic and one of the most popular metal oxide nanoparticles in biological applications. The ZnO NPs have become exceptional biochemistry, trade and industry, and less poisonousness. In biomedicine the ZnO NPs have been appeared a encouraging possible, specially in the playing field of anticancer and antiseptic grounds, which are included by their effective capability to initiate additional of reactive oxygen species (ROS) creation, produce the zinc ions, and the cell apoptosis have been induce. Furthermore, to keep the structural integrity of insulin is well known zinc. Consequently, the ZnO NPs have been efficiently technologically advanced designed for antidiabetic drug. The ZnO NPs appearance exceptional luminescent material goods in addition have straight them into one of the chief applicants for bio imaging. Now, in the biomedical fields the synthesis of ZnO NPs for facilitating of future research progress and focusing in biomedical fields will be helpful.

Key words: ZnONPs, Nanoparticles, cancer, Cytotoxicity, Reactive Oxygen Species (ROS),

Introduction

The cancer, is a circumstance of uninhibited cell difference, it has typically been preserved by chemotherapy, radiation and surgery through the historical numerous periods (¹). The treatments are surely effective in the construction of cancer cells, but then, they derived through the charge of an increasing frequency of adversative significances because of indiscriminate special effects focused to standard cells also (²). The treatments have been currently become out-of-date in cancer management because of the progress of Nano medicine, targeted medicine delivery and multi-target inhibitors (³). The field of biomedical application of nanotechnology that is Nanomedicine (NPs) are using to treatment disorder. For early detection of cancer and cancer treatment, nanomedicine, have been advanced imaging then beneficial abilities, has been the possible (⁴). It has the properties of active/passive aiming, in elevation solubility and bio obtainability, biocompatibility then multi-functional in excess of outdated cancer treatments (⁵). The main feature of nanomedicine includes mineral NPs. Numerous mineral NPs conjugated using anticancerous medications or else bio-active fragments (peptides, proteins, DNA, etc.) have previously been appropriate via the U.S. Nutrition in addition Medication Management (FDA) and European marketplaces, such as Feridex, , etc. (⁴). Moreover, mineral NPs appearance discriminating cytotoxicity to cancer cells (⁶). iron oxide NPs, titanium dioxide NPs, cerium oxide NPs, zinc oxide NPs, copper oxide NPs, silica NPs, etc is like of mineral NPs., are being widely researched and used for anticancer therapy (⁷). The unique features of the nanoparticles has its own, which creates them a original then effective instrument for anticancer treatment. The Iron oxide NPs is conjugated through anticancer medications are being to create magneto-sensitive NPs for discriminating targeting via magnetic fields in cancer management (⁸).
Similarly, in photodynamic therapy, titanium dioxide NPs are used for cancer treatment. For photosensitizer are used as a replacement, that is excited by radiation to induce Reactive oxygen species (ROS) generation in addition of apoptosis (9, 10) in radiation treatment for cancer treatment that the Cerium oxide NPs are used, that in selectively kill irradiated cancer cells even though posing no properties on the adjacent usual cells (11) for selective cytotoxicity in cancer cells, the Zinc oxide NPs are also used, anywhere they appearance cytotoxicity by zinc-dependent protein activity disequilibrium then ROS induction (12). The plant extract such as Ficus religiosa is using for synthesized Copper oxide NPs (13) or Acalypha indica (14) and the methods of synthesis are simple, non-toxic and eco-friendly (15). A good carrier for drugs in anticancer treatment is making of controllable pores of silica NPs (16). Furthermore, gold, silver then platinum NPs, have been known as precious metallic or noble metal NPs, be present to used for cancer treatment by way of medication distribution and therapeutic agents (8). The advantageous of low reactive nature of these noble elements is drug delivery purposes.

2-Zinc-mediated protein activity disequilibrium

In the human body, the one of the major trace elements is found in Zinc and is preserved in a certain concentration secret a cell (17). Modification the concentration of zinc in the cell might reason severe difficulties in numerous cellular methods, such as zinc is the co-factor of additional than 300 mammalian enzyme (18). One of the application of ZnO NPs in the intracellular release of zinc ions, increases from normal level, subsequent in zinc facilitated protein activity disequilibrium. The disturbs a extensive variety of critical cellular methods, containing (DNA replication, DNA damage repair, apoptosis, oxidative stress, electron transport chain, cellular homeostasis, etc., rendering cytotoxicity towards the cell) (14).

![Figure 1. A schematic representation of the mechanism of cytotoxicity of a nanoparticle](image)

The synthesis of ZnO NPs and the biological activity of nanoparticles are determined by features of superficial chemistry, size circulation, morphology of the constituent component, and solution reactivity of the constituent part. Accordingly, nanoparticles advance through organized structures similar in Scale, morphology, and functionality are important for many biomedical applications.
The ZnONPs will be responsible for a wide range of assets taking place in an equal rich of proportions then shape. In recent years, stable ZnONP methods have been widely spread and developed, consisting mainly of the biochemical precipitation process, sol-gel process, solid-state pyrolytic process, solution-free mechanochemical process, and biosynthesis process.

2.1. Precipitation by biochemistry. The main general method for preparing ZnO NPs is biochemical precipitation, which also involves double reaction chemicals: a highly concentrated zinc precursor such as zinc acetate (Zn(CH3COO)2•2H2O), zinc nitrate (Zn(NO3)2), or zinc sulfate (ZnSO4) and a precipitator solution such as sodium hydroxide (NaOH) or ammonium hydroxide (NH3•H2O) \(^{(19)}\). The precipitator is normally additional droplet astute to the dissolved zinc precursor that awaits the pH level stretch to around 10. Fully mix together the solutions to become a white zinc hydroxide intermediary. Eventually, the example of zinc hydroxide (Zn(OH)2) was transformed into ZnO after sintering at elevation temperature. Organized factors in the process consist mostly of zinc meditation for runner then precipitator, molar ratio of double mixtures, calcination temperature reaction.

ZnO NPs have been synthesized using the Zn(CH3COO)2•2H2O and NaOH biochemical precipitation mechanism at a molar ratio of 1:5. In a muffle furnace, intermediate products were calcined at 200 °C for 2 hours to obtain clean, fine ZnO powder of 18.67±2.2nm \(^{(20)}\). ZnSO4 and NaOH solution provided a simplified methodology of precipitation in ZnO NPs with a molar ratio of 1:2. Available at chamber temperature under vigorous stirring for 12h. The white precipitate achieved has been washed away numerous periods and divided through centrifugation \(^{(21)}\). The precipitate (ZnO) stayed dried out in an oven for 6h at 100 °C as a last step. By a flake-like construction the structured ZnO NPs provided a supply of proportions of about 100 nm. Where ZnO NPs are located via In addition to being modest and simply organized, the biochemical precipitation process is informal industrial. On the other hand, owing to the superficial effect of nanoparticles, the nanooxide precursor organized via the process of biochemical precipitation could simply proceed with agglomerates.

ZnO Nanoparticles’ biomedical applications, such as a novel form of low-charge then low-toxicity nanomaterial, have been of great importance in various biomedical fields, containing anti-cancer, antibacterial, antioxidant, antidiabetic, and anti-inflammatory activities, as well as being used for drug delivery and bioimaging applications \(^{(22)}\). Here we have summed up the recent

2.2. Anticancer Activity: the cancer, a circumstance of restrained malignant cell proliferation, is classically preserved via chemotherapy, radiotherapy, and surgery in the historical numerous periods. Even though altogether the treatments appear to be identical effective for killing cancer cells in concept, the send on discriminating treatment approaches too present a lot of thoughtful cross effects \(^{(23)}\). In recent times, nanosubstantial-established nano medicine, by high biocompatibility, certainly superficial functional, cancer targeting, then medication delivery dimensions, has confirmed the possible to overwhelmed the adjacent effects. For adults The Zn2+ is an important nutrient, then ZnO nanomaterials remain deliberated to be not dangerous in vivo. The ZnO NPs can be designated as biocompanionable and biodegradable nano platforms then can also be discovered for cancer treatment \(^{(24)}\).

2.3. Anticancer activity by inducing apoptosis of cancer cells. It has been known to be associated with cellular ROS generation in the mitochondrial electron transport chain, so anticancer causes that arrive addicted to cancer cells may break the electron transport chain and then release huge amounts of ROS \(^{(25)}\). Extreme ROS, however, may result in mitochondrial injury in the damage.
**Conclusion**

In feature, Nanoparticles, have been presentation accumulative application in cancer investigation for treatment. ZnO NPs can be good alternatives used for outmoded cancer treatment such as a transporter agent. The assessment has mostly attentive on ZnONPs, with the relative among zinc and cancer, zinc’s character in the humanoid body then the ZnO NPs using the natural science of the human body, and cytotoxicity to cancer cells.

**Funding** : The authors received no financial support for the research, authorship, and/or publication of this article.

**Conflict of Interest** : There has been no conflict of interest of any kind with the authors of this work

Comparative Study Thymol Oil and Some Gel Face Washing on Resistance Propionibacterium Acnes

Mais E.Ahmed¹, Jenan A.Ghafil², Walaa Najim³
¹Assistant Professor, ²Lecturer, College of Science, Department of Biology, University of Baghdad, Baghdad, Iraq, ³Instructor Institute of Laser Graduate Studies, Baghdad, Iraq

Abstract

Acne is elevated of skin secretion with hyperkeratosis causing Propionibacterium acnes. The goal of study was to assess the anti-inflammatory, and antibacterial potential of Thymol oil compare Gel face ,and is the main bacterium involved in the acne. The unpredictable use of antibiotics for the treatment of acne may end up within the advancement of bacterial resistance.

Key words: Thymol oil, P. acnes, oil, Gel face, Hyperkeratosis

Introduction

A Gram-positive P. acnes is, anaerobic bacteria which colonizing the lipid-rich sebaceous surface of the human skin [¹]. It has a place to the clinical gather of skin commensals, but can every so often cause genuine contaminations deciding the nearness of P. acnes contamination can be troublesome. Due to its less harmfulness, contaminations are less dolente [²].

Skin break out could be an incessant incendiary illness of the pilosebaceous joins together, fundamentally of the confront, nose, shoulders and upper arms. It is one of the most common dermatoses affecting high school populace [³]. Acne vulgaris is one of the most common skin disarranges, and dermatologists are still have long struggled to treat acne completely. It primarily influences young people, in spite of the fact that it may display at any age. It is nearly all inclusive malady happening in all races. The rate of seriousness of skin break out, top at (40%) in 14-17 year ancient young ladies and (35%) in boys matured 16-19 year (4). It influences the skin of the confront, neck and upper trunk. These specific sebaceous follicles have capacious follicular channels and voluminous, multi acinar sebaceous organs. Skin break out creates when these specialized follicles experience pathologic change that comes about within the arrangement of non-inflammatory injuries (comedons) and fiery injuries (papules, pustules and knobs [⁵]. The intemperate utilize of anti-microbial for long periods has led to expanded resistance in skin break out causing microbes i.e. P.acne and S. epidermidis against a number of anti-microbial utilized to treat skin break out [⁶].

The antibacterial properties of (EO) has long been recognized and broadly tried in vitro against a broad run of pathogenic microscopic organisms, counting both (G⁺ve) and (G⁻ve) bacteria [⁷]. One of the foremost copious bunches of normal compounds is spoken to by the fundamental oils, Fundamental oils (EOs) are fragrant sleek fluids gotten from plant fabric.

They can amplify the rack lifeof natural or prepared nourishments by decreasing microbial development rate or reasonability. A few of these substances are moreover known in its contributions to self-defense of plants against irresistible life forms [⁸].

Thymol a phenolic compound show in undamental oils, may be a common monoterpen and carvacrol isomer that extricated from thyme and the other sorts of plants, Thymol is less water dissolvable at unbiased pH, but it is as well dissolvable in some natural solvents.
and liquor \cite{9}.

The carvacrol and thymol antioxidant impacts of have been affirmed in a few considers, recommending their organization as nutritious components within the enhancement of novel useful nourishments. Thymol defensive nature against charms the field of drugs in dental caries \cite{10,11,13}.

**Material and Methods**

Isolates strain were identified by microscopy and microscopy tests for identification of \emph{P. acnes} \cite{16,18}. Directly transport from the pus and sterile disposable cotton swabs, transport media and carry to the laboratory.

Final identification by Viteck System 2 : All the presumptive isolates (on blood agar (BA) medium and Brain heart infusion (BHI) agar were tested by Viteck 2 system (Biomerix, France). This system used for diagnosis of \emph{Propionibacterium acnes}.

**Antibiotic sensitivity test \emph{P. acnes}**

**Formulation of Face wash Gel**:

**Antibacterial test was determined using -well diffusing method according to the CLSI Clinical Laboratory Standards Institute** \cite{26}.

**Extraction of essential oils**:

About 20g of herb soaked in distilled water. The volatile vapour that condensed at water temperature of 80°C was called essential oils. The distilled oils were labeled and placed in a fridge until ready for use.

**Result**

The cases Most were obtain patients between the ages \cite{16-21} years old in both sexes, and the distribution of acne among female was higher than that of male (14% and 4%) respectively.

Discussion

The current results were coincides with previous results studied in Iraq of \( P. \) acne in different age (15). that acne prevalence was more in female than male, agree with most cases were in ages group between (15-20). Also agree with study in Iraq isolated \( P. \) acne \[17\]. These results for identification \( P. \) acne were in agreement with \[18, 19\]. Viteck 2 System was a rapid, sensitive, to distinguish clinical isolates (20). The result agree with \[21\] The most using treatment (erythromycin) were anti \( P. \) acne \[22\].

The antibiotics is topical application like clindamycin, tetracycline most common to treatment of
acne but the major problems growing in resistance of *P. acnes* to antibiotics caused [23].

The acne-gel with retinol had lower effect in agar dilution test, but shown that is highly effective at high concentrations against aerobic and anaerobic bacteria including *P. acnes* [24] the antiacne more acts of oregano EO that of other evaluated including commercialized over the counter acne treatment tea tree [25].

**Conclusion**

The antibiotics play an important treatment in acne administers. Resistance *P. acnes* treatment by antibiotic compares using natural oil most affections alternative commercial washing gel in pharmacy.

**Conflict of Interest:** The authors declare that there is no conflict of interest regarding this study.

**Fund:** This project was funded by University of Baghdad, Ministry of Higher Eduction and Scientific Resaerch.

**Ethical Committee Approval:** This work was approval by the ethical committee of Department of Biology, College of Science, University of Baghdad.

Primary Prevention Program of Obesity among Primary School Children

Amina Mohamed Ismail 1, Hanaa Abdel Hakeem Ahmed2, Frial Fouad Malika3
1Research Scholar, 2Professor, 3Lecturer of Community Health Nursing, Faculty of Nursing, Ain-Shams University

Abstract

Background: Childhood obesity is a serious medical condition that affects children and adolescents. It’s particularly troubling because the extra pounds often start children on the path to health problems that were once considered adult problems: diabetes, high blood pressure and high cholesterol. Aim of the Study: assess the effect of primary prevention program of obesity among primary school children through: assessing knowledge & practices of primary school children related to obesity, Designing, implementing primary prevention program of obesity among primary school children, evaluating the effectiveness of primary prevention program on knowledge & practices related to obesity among primary school children.

Subjects and Methods: Setting: The study was conducted in four primary governmental school of El-Salam city, Cairo governorate including: (El Hussien, Osman Ben Afan, Atef El Sadat and Gamal Abdel Naser). Size: the sample composed of 144 primary school children chosen randomly through multistage sampling. Tools: Different tools were used for data collection of study and it was written in simple language to suit the understanding level of the studied primary school children First tool: Structured interviewing questionnaire, second tool: Anthropometric Measurements, physical assessment sheet Results: clarified that only few percentage of primary school children had good Knowledge preprogram while this improved to more than one third post program implementation related to their total knowledge about childhood obesity, there was highly statistically significant difference in post-program compared to pre-program according to their total practice related to childhood obesity. Conclusions: primary school children improved their knowledge and practice regarding childhood obesity after program implementation. Recommendation: primary prevention program must be provided for all primary school children to prevent childhood obesity risks.

Keywords: prevention program, primary school children, childhood obesity

Introduction

Childhood Obesity is defined as excess body fat leading to health impairment (1) (2). For boys, obesity was defined as >20% fat mass (FM). For girls, the cut-off point for obesity was >25% (3). However, FM is extremely difficult to measure in young children, because accurate techniques require a high degree of the subject compliance (4). The ideal definition, based on percentage body fat, is impracticable for epidemiological use. The measurement of change in adiposity in children is challenging because of the effects of maturation and growth on lean muscle mass, fat mass, and hydration status (5). Although less sensitive than skin fold thicknesses, the body mass index (weight/height²) is widely used in adult populations, and a cut-off point of 30 kg/m² is recognized internationally as a definition of adult obesity (6).

Corresponding Author:
Amina Mohamed Ismail,
Ain Shams, Egypt
Email: Aminaesmail051@gmail.com
Body mass index in childhood changes substantially with age. For many years, establishing an international definition of overweight and obesity among children based on pooled international data for BMI linked with adult obesity cut-off point, remained a big challenge (7).

There are many factors that influence food intake and energy expenditure in man. The following gives a brief account of these factors known to be involved in occurrence of obesity (8).

- **Genetic Factors:**

  It is a matter of common observation that obesity runs in families. It has been suggested that this is probably due to transmission of an abnormal gene from parents to child (9).

- **Socioeconomic factors:**

  Socioeconomic factors have been shown by most studies, to be correlated in one way or another, with overweight.

  Obesity is common among poor women, perhaps because food rich in protein and fat are more expensive than starchy foods which provide the bulk of cheap meals (10).

- **Psychological factors:**

  Psychological disturbances, like obesity, are very common in our complicated world today. When both are present in the same individual one may aggravate the other. Some obese children with a psychoneurosis or a personality disorder who are in happy find solace in cream buns and chocolates in the same way as others take alcohol or barbiturates and so they become more fat (10).

- **Endocrine factors:**

  Davidson, and passmore, (2018) (11) discussed the effect of endocrine factors on childhood obesity formation and declared that obesity in women commonly begins at children girls, puberty, pregnancy or in the menopausal period which suggests an endocrine factor. Cushing's syndrome arising from over secretion of adrenal cortical hormones is characterized by a special form of obesity, in which excess fat is laid down over the trunk and abdomen and usually not on the limbs (12).

- **Eating habits:**

  Obesity may occur as a result of family customs in using concentrated high caloric foods and drinks, in having to maintain social relationships including rich party foods in addition to usual meals or, in eating excessive amounts of carbohydrate foods because they are cheaper than lower caloric fruits and vegetables (12).

Generally, the community health nurse is a generalist and serves all population groups working in the clinic's setting not only utilizing principles of primary, secondary, and tertiary prevention but also serves population groups in clinics and schools. Moreover, nurses are largest segment of health care providers where, they have great opportunity to enhance client care, as well as impact health care delivery. The nursing profession has the holistic approach to client care, including a nursing process that fosters the participation and growth of clients and their significant others (13).

Comprehensive school health services are being developed to assist in meeting the needs of each community’s population of children. Intervention at primary, secondary and tertiary prevention levels are incorporated through collaboration with a diverse group of educational personnel and health care providers in the community who have fewer financial resources. The school nurse can be a central person in coordinating services (14).

**Significance of the problems:**

Worldwide in 2016 more than one-third of all school children were obese. Rates of school age children obesity have increased greatly between 1980 and 2016. It has more than doubled in school age children and tripled in adolescents in the past 20 years. Obesity is growing worldwide and becoming an emotional, psychological and financial burden on individuals and communities by
becoming a leading risk for global health problems. It has affected both developed and developing countries, and people of all socioeconomic levels (14).

Egypt has the highest percentage of obese adults worldwide as, Around 19 million Egyptians, or 35 percent of the adult population are obese – the highest rate across the globe. In addition, over 10 percent, or 3.6 million, of children are also considerably overweight (14).

Egypt, previous studies indicated that obesity is an important public health problem among school children as the prevalence of obesity among Egyptian children was 14.7 and 15.08% in boys and girls, respectively.

Furthermore, especially in Egypt, there is very little basic awareness of the problem of obesity, and so there are neither nationwide movements nor adequate documentation of initiatives dealing with obesity (15).

**Aim of the Study**

_This study aimed to_: assess the effect of primary prevention program of obesity among primary school children through:

- Assessing knowledge & practices of primary school children related to obesity.

- Designing, implementing primary prevention program of obesity among primary school children.

- Evaluating the effectiveness of primary prevention program on knowledge & practices related to obesity among primary school children.

**Hypothesis:** Primary prevention program will improve knowledge and practices related to obesity among primary school children.

**Subjects and Methods**

_Subjects and methods of this study were portrayed under four main domains as following:_

1- _Technical Design:_

_Research design:_

Quasi experimental study design (one group pre and post-test) was conducted for this study.

**Research setting:** This study was conducted in 4 primary governmental school of El-Salam city, Cairo governorate including: (El Hussien , Osman Ben AFAN, Atef El Sadat and Gamal Abdel Naser). These schools were chosen by a systematic random sample (select a random start at fixed interval) as interval (K) determining by divided the total number of primary governmental schools in El-Salam education management (N) = 32 schools , by the desired sample size (n)= 4 primary school. K = total number of primary school (N)/ desired sample size (n) =32/4=8th (every 8th school, one school was involved in sample).

**Subjects of the study , sampling:**

- **Type of sampling**: Multistage sampling was used as the following:

  Ø Stage one: selection of 4 primary governmental school by systematic random sample.

  Ø Stage two: selection of classroom from each grade from first to sixth by simple random sample.

  Ø Stage three : selection 10% of school children age (6-12yrs) from each class room by simple random sample.

- **Size of sampling** : sample was carried on (144) school children in four primary school calculated as the following: Average density of classroom equal 60 child, 10% of them was chosen randomly equal 6 child from each class room of six grade, so total number equal 36 school children in all grades in one school. Total number in four schools= 36 times 4= 144 primary school children.

- **Exclusion criteria for sampling:**

  Ø All children found to be < 6, > 12 years of age.

  Ø Children whose exact birth date was not available.

  Ø Children without written informed consent.
Sick Children and whose with chronic diseases.

Tools of data collection:

Data will be collected by using the following tools:

**First tool:** Structured interviewing questionnaire, to assess obesity among primary school children, the investigator designed questionnaire after reviewing the related literature and written in simple clear Arabic language, it included the following three parts:

- **Part I : Socio-demographic** data of primary school children
- **Part II:** primary school children knowledge related to obesity about the following items: general knowledge related to childhood obesity, knowledge related to childhood obesity risk factors, knowledge related to healthy nutrition and and finally knowledge related to health hazards and complication of childhood obesity as

**Scoring system for knowledge:**

The total items of knowledge 25 questions the scoring system was followed according to school children answers calculated as the following: complete correct was scored 2, incomplete correct was scored 1, incorrect and did not know answers was scored zero for each items of knowledge.

The total scoring of knowledge was classified according to the following:

- **Poor knowledge** if less than 60%.
- **Average knowledge** if 60-75%.
- **Good knowledge** if more than 75%.

- **Part III:** It include checklist for assessing primary school children practices related to childhood obesity consists of six main items include the following:
  - First item: food practices
  - Second item: Practices for handling fluids
  - Third item: Sleep and rest practices
  - Fourth item: Physical activities and exercise
  - Fifth item: Electronic activities practices
  - Sixth item: Behavioral activities

**Scoring system for practice:**

The check list included six main items and 34 sub items, For check list practice items, predetermined according to literature review, done items was scored one and did not do items scored zero.

The total scoring of practice was classified according to the following:

- **Inadequate practice** if less than 60%.
- **Adequate practice** if more than 60%.

**Second tool:** Anthropometric Measurements, physical assessment sheet for primary school children and laboratory investigation was conducted by trained school nurses and investigator.

- **Anthropometric measurements:** was conducted according to guidelines suggested by The WHO Expert Committee (2015).

- **Physical assessment** include the following item: Signs and symptoms of obesity, Vital signs of the primary school, physical assessment from head to toes of primary school children

- **Laboratory investigation of primary school children** as (random blood sugar, hemoglobin, total Cholesterol level).

Content validity:

Tools of study was reviewed by three expertise in community health nursing to test the content validity. Content validity was checked before pilot study and actual field work.

Content reliability:

Was done by Cronbach’s Alpha coefficient test.
which revealed that each of the two tools consisted of relatively homogenous items as indicated by the moderate to high reliability of each tool.

v Operational design

The operational design of the study entailed three main phases:

· Preparatory phase.

· Pilot study.

· Field work.

· Preparatory phase

A review of the past and current available related literature covering the aspect of the research problem was done by the investigator through using available articles, magazines, Internet, journals and text books in order to be acquainted with the research problem and develop the study data collection tools and prevention program.

· Pilot study

A pilot study was conducted for 10% of total sample size equal (14) primary school children to evaluate the clarity of the tools and its reliability used according to the analysis of pilot study results. The modifications were done in the tool according to pilot study results in order to be more applicable and changes were fulfilled by correction, omission or addition of items, until the final shape of the tool was reached. The subjects of pilot study will excluded later from main study sampling.

· Field work:

- A written consent was taken from every primary school children and their parents to share in the study.

- The investigator was started with introducing herself and explaining the aim of the study and program for the selected studied sample and assured that the data collected would be confidential.

- The investigator will complete the tool by the interviewing the primary school children.

- The investigator will visit pre mentioned schools through school daytime to collect data from 7.30 am to 1 pm, three days in the week Monday, Tuesday and Wednesday.

- Though six months duration of the program from the start till finishes the program and makes evaluation stage.

- The investigator Used different teaching methodology such as discussion, session demonstration, booklet and poster.

Program construction:

· Primary Prevention program for primary school children was conducted in four phases:

· First phase: preparatory phase

A review of recent, current, national and international related literature in various aspect of the problem was done at this phase its aim is to design and develop the study tools and to be acquainted with various aspects.

· Second phase: assessment phase

By using questionnaire based on the assessment phase (pretest) was done for (144) primary school children and (post test) was done after primary prevention program implementation.

· Third phase: planning and implementation phase

This phase at the planning and implementing the primary prevention program and its content according to its objectives, primary prevention program was designed to assess the knowledge, practices related to obesity among primary school children through using multiple session range from 4-6 session every session ranged from 1-2 hours and meeting the primary school children three days per week (individualized or group).

The program session was divided three session theory and three session practices every week and the
teaching method was used the lecture group, discussion, and role-playing, teaching material was used is Arabic booklet and audiovisual materials.

**General objective**: to assess the knowledge, practices related to obesity among primary school children.

**The program content was included the following**:  
- Meaning of school children obesity  
- Causes of school children obesity  
- Identify risk factors for school children obesity  
- Detecting knowledge about obesity among primary school children and its consequences.  
- Determining practices about obesity prevention among primary school children.

Finally: the evaluation phase

This phase aimed to evaluate the effect of prevention program to improve school children knowledge and practices related to obesity, a post-test similar to the pre-test was administered to the study subjects immediately after completion of the primary prevention program and follow up after three months.

**Administrative design**

· First approval was obtained from the authorities of the faculty of nursing Ain Shames University.

· A written letters was sent to the director of the El-salam educational management include the aims of the study.

· Official permissions were obtained from El-salam educational management authorities.

**Ethical Consideration**

Informed consent was taken from the primary school children to participate in the study after explaining the objectives of the study, it will haven’t any harmful effects on them, the information would be confidential and they could withdraw from the study at any time.

**Statistical design**

Recorded data were analyzed using the statistical package for social sciences, version 20.0 (SPSS Inc., Chicago, Illinois, USA). Quantitative data were expressed as mean± standard deviation (SD). Qualitative data were expressed as frequency and percentage.

The following tests were done:

§ Chi-square ($\chi^2$) test of significance was used in order to compare proportions between qualitative parameters.

§ Pearson’s correlation coefficient (r) test was used to assess the degree of association between two sets of variables.

§ The confidence interval was set to 95% and the margin of error accepted was set to 5%. So, the p-value was considered significant as the following:

§ Probability (P-value):

- $P$-value <0.05 was considered significant.
- $P$-value <0.001 was considered as highly significant.
- $P$-value >0.05 was considered insignificant.

**Results**

This study targeted a sample of 144 primary school children conducted in four primary school in E l - Salam city in the year 2019 -2020.

p-value >0.05 NS; *p-value <0.05 S; **p-value <0.001 HS

Table 2: reveals that primary school children, regarding body weight 58.3% of them were from 20-30kg, regarding height 38.2% of them were from >120-130cm preprogram, this percentage changed to 68.1%, 39.6% respectively after implementation of program.

Also shows that 22.9% of primary school children were Over weight (>85th -95th percentile) preprogram, changed to 21.5% after program. Also clarifies that 15.3% of them were Obesity(>95th percentile) preprogram changed to 6.9% after program.

This table shows that, there was statistically significant difference in post-program compared to pre-program according to their classification of weight BMI for age and sex, with p-value <0.05 S.

**Discussion**

The current study was carried out to evaluate the effect of primary prevention program on knowledge and practices related to obesity among primary school children. As regarding socio demographic characteristics, the present study showed that, the mean age of the studied primary school children was 8.67, regarding gender, slightly more than half of studied sample were male, regarding residence, less than half of them were urban, regarding number of sibling, more than two thirds of them had less than 3 siblings, as well as daily pocket money, less than two thirds of them take 5-10 LE Table (1).

This finding was agreed with (2), who studied (Socio-demographic factors associated with overweight and obesity among primary school children in semi-urban areas of mid-western Nigeria). And found that the mean age of the studied primary school children was 8.5, and also found that more than half of studied sample were male.

The current study disagreement with (3) who reported that in a study about Overweight and obesity in the Eastern Mediterranean Region and shows that the students aged 25 or older are at high risk and those over 30 years are at extra ordinary risk, also in contrast to (4) in a study about Socioeconomic status and obesity,” Epidemiologic Reviews., which revealed that more than one third of students affected by obesity were over age, with mean age of thirty years, which indicated that obesity and age increased the risk.

This finding agrees with the results of the study about overweight and obesity among school Children in Jordan: Prevalence and Associated Factors by (5) who find that the daily pocket money was associated with
overweight, while family monthly income associated with obesity.

The current study findings disagree with (6) who studied obesity and relation with family size cross-sectional USA study reported that the prevalence of obesity in the United States is lower among those of small family number and stated that there exists a negative correlation between family size and obesity prevalence for student. This could be due to the fact that smaller families had better food availability.

The current study finding revealed that body mass index of half of studied sample fathers were overweight while slightly less than two thirds of their mothers were overweight. As well as less than one third of studied sample fathers and mothers were obese Figure (1).

This finding congruent with (7) who studied (Prevalence and factors associated with body mass index in Brazilian children aged 9-11 years), and found that there was significant associations of individual, family, and school/family environment factors in children. Therefore, the aim of this study was to assess the individual anthropometric and behavioral, family, and school/family environment factors associated with BMI in children aged 9-11 years.

This current study clarified that only few numbers of primary school children had good Knowledge preprogram while this improved to more than one third post program implementation related to their total knowledge about childhood obesity. Figure (2)

This findings is in the same line to (A study to assess the effectiveness of Eduative supportive interventions on Knowledge, regarding Obesity among primary school children in selected schools of Mehsana city) carried out by (17) who stated that After given educative supportive intervention, half of school children had improve the knowledge. That was an effective technique in inducing the total knowledge level of primary school children regarding obesity.

Childhood obesity is determined by both genetic and environmental factors. With a dramatic increase in childhood overweight and obesity, knowledge and attitudes of the children themselves towards childhood obesity need to be placed on the frontline. Most studies have focused on knowledge and perception of parents/caregivers and health care professional about child obesity. The present study is among few that have focused on assessment of knowledge about child obesity and perceptions about body weight among primary school children and also implementation of prevention program to improve their knowledge.

the relation between primary school children total knowledge may related to obesity and dietary habits. Knowledge only not enough to change behaviors, we need also strong motivates. This may be due to less of health educations program conducted by health care providers to prevent childhood obesity.

The current study result revealed that primary school children, regarding body weight more than half of them were from 20-30kg, regarding height more than one third of them were from >120-130cm preprogram, this percentage changed to more than two thirds and more than one third respectively after implementation of program.

Also showed that less than one quarter of primary school children were Overweight (>85th -95th percentile) preprogram, changed to 21.5% after program. Also clarifies that more than one tenth of them were Obesity (>95th percentile) preprogram changed to less than one tenth after program implementation.

This table showed that, there was statistically significant difference in post-program compared to pre-program according to their classification of weight BMI for age and sex, with p-value <0.05 S. table 2

**Conclusion**

The current study findings and research hypothesis concluded that implementation of primary prevention program for primary school children was efficient in improving primary school children knowledge regarding childhood obesity, with highly statistical significant differences between pre and post prevention program
There were highly statistically significant difference in post-program compared to pre-program according to their total practice related to childhood obesity. with p-value <0.001 HS, $X^2 = 116.156$

RECOMMENDATIONS

In the light of these findings it can be recommended that:

- The primary prevention program for primary school children regarding obesity must be provided for all primary school children to improve their knowledge and practice.

- An orientation program for all parents to improve their knowledge about childhood obesity.

- Distribution of different illustration instructional booklets and brochures for primary school children using simple information including preventing childhood obesity.

- Official and policies support for school including modification of curriculums to meet primary school children needs regarding childhood obesity.

- Further researches are needed to study the childhood obesity prevention to find out the suitable solution to prevent this problem.

Abstract

Acetamiprid (ACMP) can cause neurotoxicity and induces neuronal apoptosis. The ameliorative effects of Moringa Oleifera (MO) seed extract against the neurotoxicity induced by ACMP in adult male albino rats were investigated. Forty male albino rats were divided into 4 equal groups. The first group served as a control, the second group administered ACMP 26.8mg/kg b.w. (representing 1/10 LD50) by gavage. The third group was given combination of ACMP 26.8 mg/kg b.w. and MO seed extract 150 mg/kg b.w. the fourth group was given MO extract only 150 mg/kg b.w. for 28 consecutive days. Results proved the efficacy of MO extract as a neuroprotective agent through the reduction of the oxidant parameter malondialdehyde (MDA) content by 26.9%, significant increase of reduced glutathione content (GSH) by 21.4%, and elevation of catalase (CAT) and superoxide dismutase (SOD) activities by (62.2% and 40.8%) respectively, compared to ACMP intoxicated group. Consequently, gene expression analysis for Bax and NBN genes was downregulated by 54.5% and 36.3% respectively in MO treated rats (group III) compared with ACMP intoxicated group. Moreover, restoration of the pathological tissue injuries was noticed. In conclusion, MO proved to be an effective neuroprotective and anti-apoptotic agent against ACMP-induced toxicity.

Introduction

Acetamiprid (ACMP), is one of the recently developed neonicotinoid group of pesticides, widely used against different variety of insect pests (¹). It was the second manufactured insecticide in this group after imidacloprid (²). Acetamiprid operates as a selective nicotinic acetylcholine receptor (nAChR) agonist in the central nervous system of insects (²). Over the last ten years, the expanded usage of neonicotinoid insecticides has been criticized because of the hazard associated with their toxicity (³, ⁴). ACMP was reported to have toxic effects on the thyroid, liver, respiratory and reproductive functions (⁵). Acute poisoning after ingestion of acetamiprid in humans has been documented (⁶). However, there is no satisfactory information on the neurotoxicity potential of acetamiprid on human health.
Acetamiprid may lead to oxidative damage by producing reactive oxygen species in the target tissues (7). Exposure to acetamiprid induce imbalance of oxidative stress status, and disruption of mitochondrial membrane permeability in rat’s brain through generating reactive oxygen species (8). The brain is liable to the damage caused by oxidative stress imbalance because of its comparatively low antioxidant capacity, its abundance in peroxidable fatty acid and its high-energy needs; this irreversible molecular corruption is the main cause of neuronal cell death and neurodegenerative diseases (9).

Several phytochemical expressed considerable protective effects against neurotoxicity in animal models by restoring the antioxidant capacity (10). Many plants contain natural antioxidant compounds, which used as curative agents for neuronal diseases by increasing memory; alertness and brain function in general. Moringa oleifera (MO) named a miracle tree by consisting of phytochemical, vitamins, essential amino acids and mineral. It has many therapeutic benefits such as anti-inflammatory, antipyretic, antiulcer, antidiabetic, anticancer and antimicrobial agent (11). MO extract has a role in preventing Alzheimer’s disease by reducing hyperphosphorylation and amyloid-b pathology (11). This study aimed to evaluate the neurotoxic effects induced by acetamiprid in terms of oxidant/antioxidant status, apoptosis markers and histopathological changes in male rats with studying the ameliorative effect of MO seed extract.

Materials and Methods

Chemicals:

Acetamiprid insecticide neonicotinoids (20% SP) was obtained from Starchem. Agro. Pesticides company, Egypt.

Preparation of Moringa oleifera seed extract:

Powdered seed of moringa oleifera L (1kg) was extracted with hexane (1L×5) by soaking at room temperature. The hexane extracts were concentrated under reduced pressure at 60c. The total oil from hexane were weighed and stored at -10 until analysis. The residue of moringa oleifera after hexane extract was re-extracted with ethanol. Components of MO seeds extract determined by colour test method for phenols, flavonoids and tannins (12), carbohydrates and steroids (13).

Animals:

Forty albino rats aged 12-weeks (170±10g) were obtained from the breeding unit of the Toxicology and Forensic Medicine Department, Faculty of Veterinary Medicine, Cairo University. Animals were maintained at the animal care facilities of Central Agricultural Pesticides Laboratory (CAPL) in plastic cages under controlled temperature (23±2°C), 12-h light/dark cycle and average humidity (50±5%). Water and food were available ad libitum. Rat’s acclimatization to the environmental condition were done for two weeks preceded the experiment.

Experimental Design:

Animals were divided into four groups with 10 animals each. The first group was used as a control. The second group (group II) treated with acetamiprid 26.8mg/kg b. w. (representing 1/10 LD50) by gavage. The third group (group III) given combination of acetamiprid (26.8 mg/kg b.w.) and MO seed extract (150 mg/kg b.w.), the fourth group (group IV) was given MO extract only (150 mg/kg b.w.). After treatment for 28 days, rats were anesthetized using diethyl ether, killed by capitation and the brain of each rat was collected, washed and kept for further analysis.

Lipid peroxidation and antioxidants parameters measurements:

Tissue preparation:

Brain were removed, washed with cold saline buffer, immediately stored at -80°C. For obtaining enzymatic extract, tissues were homogenized in ice cold 50mM sodium phosphate buffer (pH7.4) containing 0.1mM ethylenediaminetetraacetic acids (EDTA) yielding 10 % (W/V) homogenate. The homogenates were centrifuged at 2000 r.p.m for 30 min at 4°C. The supernatant samples were separated and used for measurement of
malondialdehyde (MDA)\textsuperscript{(15)}, reduced glutathione content (GSH)\textsuperscript{(16)}, catalase enzyme activity\textsuperscript{(17)}, superoxide dismutase (SOD) enzyme activity\textsuperscript{(18)}.

**Quantitative real-time PCR for Bax and NBN genes:**

Total RNA was extracted from fresh brain tissue using RNase Mini Kit (Qiagen) following the manufacturer’s guidelines. cDNA synthesis was done by reverse transcription of 10 μg RNA samples. Real-time PCR performed using a Real-Time PCR System (Applied Biosystems, USA) by the following primers: forward 5′-CTTCCAGGACAGCAGTGAGGA-3′ and reverse 5′-TCTTTCGAGCATGGTGACCT-3′ for NBN gene; forward ACCAAGAAGCTGAGCGAGTG and reverse CCAGTTGAAGTTGCCGTCTG for Bax gene. The cDNA amplification obtained by 40 cycles of denaturation at 95°C for 45 s, annealing at 63°C for NBN and 59°C for Bax gene for 45 s and extension at 72°C for 45 s. The 95°C step was extended to 5 min during the first cycle. 2% agarose gel electrophoresis stained with SYBR Safe DNA gel stain (Invitrogen) was used to confirm the size of the amplicons. As a reference gene, the β-actin gene amplified in the same reaction. Each measurement was repeated 3 times, and the values were used to calculate the gene/β-actin ratio, with a value of 1.0 used as the control (calibrator). The normalized expression ratio was calculated using the method described by Livak and Schmittgen\textsuperscript{(19)}.

**Histopathological examination:**

After routine histological laboratory procedures, sections of 5 μm paraffin-embedding sections were prepared and stained with hematoxylin and eosin (H&E) for histopathology\textsuperscript{(20)}.

**Statistical Analysis**

Data coded and entered using the statistical package for the Social Sciences (SPSS) version 26 (IBM Corp., Armonk, NY, USA). Data was summarized using mean and standard error of the mean (SEM) for quantitative variables. Comparisons between groups were done using analysis of variance (ANOVA) with multiple comparisons post hoc test. P-values less than 0.05 were considered as statistically significant.

**Results**

Phytochemical analysis of ethanol extract of Moringa oleifera seeds:

The total oil content of seed of moringa oleifera was 30%. Phenol, tannins, flavonoids, carbohydrates and steroids bioactive components are present in ethanol extract of seed moringa oleifera L (table 1).

Effects on MDA level, GSH, SOD and catalase activities:

As shown in table 2, significant increase in the brain level of MDA in ACMP-treated rats was observed (p ≤ 0.05) as well as significant reduction of enzymatic activity for SOD and CAT and GSH concentration compared to the control. MO extract treated group (group III) showed significant increase of all antioxidant parameters (GSH by 21.4%, CAT by 62.3%, and SOD by 40.8%) and reduction of oxidant parameter (MDA) by 26.9%, in comparison to ACMP-treated group.

NBN and Bax genes mRNA expression:

Quantification of the mRNA expression of NBN and Bax genes by real-time PCR was performed to evaluate the proapoptotic activity of acetamiprid by controlling gene expression of apoptotic pathways. The apoptosis level was significantly elevated in acetamiprid intoxicated group with a significant up-regulation of mRNA expression level for BAX gene by more than five-folds (marker of cell apoptosis) and NBN gene by four-folds compared with the control group (figure 2 A). Gene expression analysis for Bax and NBN genes in the brain tissue of MO extract treated group (group III) revealed significant downregulation by 54.5% and 36.3% respectively compared to ACMP intoxicated group.

Figure 1: Effect of MO extract on NBN and Bax genes expression level in brain rats intoxicated with acetamiprid pesticide. (A) Fold change of mRNA expression of Bax and NBN genes in different experimental groups using qPCR. Data showed as mean ± SEM. Groups having different superscripts letters are significantly different from each other. (B) The results of qPCR analysis were proved by agarose gel electrophoresis analysis of the PCR product compared to β-actin.
Histopathological examination:

As illustrated in figure 3, no histopathological changes of the neurons in the hippocampus were recorded in the control group (A). Degeneration and nuclear pyknosis were noticed in the neurons of group II (B). Degeneration and nuclear pyknosis were reported in few neurons of group III (C). Neurons of group IV (D) showed no histopathological abnormalities.

Figure 2: (A). Photomicograph of neurons of the control group showed no histopathological changes and normal histological structure (B). Photomicograph of neurons in ACMP treated group (II) showed degeneration and nuclear pyknosis in the neurons of subiculum of the hippocampus (C). Photomicrograph of neurons of ACMP + MO extract treated group (III) showed nuclear pyknosis and degeneration in few neurons of subiculum of the hippocampus (D). Photomicrograph of neurons of MO extract treated group (IV) showed no histopathological abnormalities and preserved normal structure of the neurons.

Discussion

The present study proved that the dried seeds of MO are great source of polyphenol compounds, such as phenolic acids and flavonoids. The flavonoids contained in MOLE are quercetin, catechin and kaempferol as reported by others \(^{(21)}\) in addition to tannins, flavonoids, carbohydrates, steroids bioactive components and vitamins \(^{(22)}\). Therefore, MOLE has a role as antioxidant, anti-apoptosis and anti-inflammatory.

ACMP–induced oxidative stress damage evaluated by quantification of MDA content, GSH, SOD and CAT activity. In the present work, Oxidative stress mediated by ACMP induced depletion in SOD, GSH, and CAT activities and induction of lipid peroxidation. This finding reflects one of the causative mechanism implicated in ACMP-induced toxicity \(^{(23)}\). Acetamiprid can cause increased reactive oxygen species (ROS) production in the cells. Excess ROS lead to increased lipid peroxidation (LPO) of the cell membrane followed by cellular damage, accumulation of MDA level and antioxidant depletion \(^{(24,25)}\). Several studies have reported the imbalance between oxidant / antioxidant status after Acetamiprid exposure \(^{(26,27)}\). The observed improvement
in the oxidative stress parameters in ACMP treated group in this study attributed to the coadministration of MO extract. The antioxidant activity of MO extract because of its content of bioactive polyphenols and flavonoids as (quercetin, catechin and kaempferol) against oxygen free radicals and its ability to prevent oxidative damage, polyphenols components of moringa seed extract such as catechin can act as an antioxidant by scavenging the free radicals and chelating the sulphyrus metal ions\(^{28}\). Moreover, quercetin contains a hydroxyl group with antioxidant capacity and other flavonoids, which suppress the production reactive oxygen species\(^{29}\).

Determination of mRNA expression level of NBN and Bax genes was performed to assess ACMP role as apoptotic and neuronal cell death provoking factor in the neurodegenerative diseases\(^{30}\). As revealed in figure 1A, ACMP intoxication induced significant upregulation of NBN and Bax genes expression level. However, there was a significant decrease of their expression level in MO extract treated group. Apoptosis is regulated by Bcl-2 family and caspase family of proteins\(^{31}\). Bax gene is a pro-apoptotic factor of the Bcl-2 gene family; encodes BCL2L4 protein that, upon activation of Bax protein, its function is to bind and induce mitochondrial outer membrane (MOM) permeabilization, leading to release of cytochrome c, followed by caspase pathway activation, hence, apoptotic cell death is accelerated in response to cell death signals\(^{32-34}\).

NBN gene plays an important role in genomic stability and repair of DNA double strand breaks. The NBN gene encodes for a protein called nibrin. This protein is responsible for several crucial cellular processes, including the repair of damaged DNA. Increased NBN gene expression indicates DNA damage\(^{35, 36}\). As proved by other authors\(^{37, 38}\), exposure to ACMP mediates apoptosis through disruption of the oxidative stress pathway. Similarly, recent studies\(^{39, 40}\) reported that, acetamiprid treatment leads to loss of mitochondrial membranes integrity and cell death through the induction of necrosis concomitantly with the generation of ROS. As shown in our results, ACMP induced neuronal cell death was significantly reduced by MO extract treatment, as revealed by significant downregulation of mRNA expression for both NBN and Bax genes in the brain tissue (figure 1A). Moringa extract used in this work as a protective agent against ACMP neurotoxicity. Treatment with MO extract significantly reduces apoptosis markers induced by ACMP; it improves mitochondrial functions, the flavonoids content of MO extract as luteolin has a powerful antioxidant activity and a protective role against DNA damage. Moringa extract contains tannins, steroids and phenols, which have free radical scavenging and anti-inflammatory capabilities\(^{41, 42}\). Moreover, MO extract contains Vit E (a-tocopherol) which inhibit programmed cell death by disrupting the activation of free radical cascade reactions in the lipid layer of the outer cell membrane\(^{43}\). Recently, Khan et al.\(^{44}\) stated that, quercetin content in MO extract could control apoptosis pathway in the mitochondria by interrupting the activation of caspases-3 and cytochrome-c.

The present study showed histopathological changes of the brain cells including nuclear pyknosis, shrinkage and degeneration in response to ACMP. The generation of ROS induced by acetamiprid result into damage of different membrane components of the cell. On the other hand, the histopathological changes were improved with MO extract treatment in comparison with ACMP intoxicated group. Results obtained by Kou et al., proved the neuronal protection effect of moringa extract\(^{45}\). Moringa Oleifera components can cross the blood brain barrier so it have beneficial effects on the neuronal system of the intoxicated-rats\(^{45}\).

Conclusion

The current findings revealed that, ACMP exposure might induce neurodegenerative disorders by induction of oxidative stress damage and apoptosis. The present study explored the role of MOLE to alleviate the ACMP-toxic effects. The protective role of MOLE is mediated through the regulation of antioxidant, and antiapoptotic signaling pathways.

Desmoplastic Fibroma of the Mandible in an Infant: A Case Report

Amr M. Ibrahim¹, Hassan Sadek², Raafat Tammam³, Mohamed R. Omar⁴
¹Lecturer of Oral Pathology Division, Basic Dental Sciences Department, Faculty of Dentistry, Deraya University, ²Lecturer of Oral & Dental Pathology Department, Faculty of Dentistry, Al-Azhar University, ³Professor of Oral & Maxillofacial Surgery, Consultant of Oral & Maxillofacial Surgery International Medical Center (IMC), ⁴Associate Professor of Fixed prosthetics Department, faculty of Dentistry, Assiut University, ⁵Associate Professor of Prosthetic Dentistry Department, faculty of Dentistry, Deraya University, Lecture of Oral Surgery Department, Faculty of Dentistry, Deraya University

Abstract

Desmoplastic fibroma (DF) is a benign tumor of connective tissue origin that is locally aggressive and of high recurrent rate. (¹) The mandible is one of the most commonly affected site with a predilection at the posterior part of the mandible, most often in the ramus-angle region. (²) DF of either the mandible or the maxilla usually occurs and is more common during the second and third decades of life. Bone destruction may progress with a tendency to invade the surrounding soft tissues. In this case report, we define the clinical, radiological, and histological features of a rare case of DF of the mandible in an eleven-months-old male. The management of the lesion consisted of mandibular resection and immediate reconstruction with rib graft. Good healing, no evidence of recurrence, excellent esthetic and functional results after six months follow up. We hope that our case report will shed new light on this special entity.

Keywords: Case report; Desmoplastic fibroma; Infant; Mandibular resection; Right mandible.

Introduction

Desmoplastic fibroma (DF) is a benign tumor of connective tissue origin that is locally aggressive and of high recurrent rate. (¹) The mandible is one of the most commonly affected site with a predilection at the posterior part of the mandible, most often in the ramus-angle region. (²) DF of either the mandible or the maxilla usually occurs and is more common during the second and third decades of life. (³) It presents as a painless firm swelling over the span of weeks to months. (⁴) A slight female predilection has been identified among jaw tumors (54:45 % = F: M). (²) The initial diagnosis of DF is often indicated by clinical and radiographic features, but a definite diagnosis can be made only by histopathological analysis. On histopathological review, DF composed of spindle cells with minimal cytological atypia and abundant production of collagen as defined by the World Health Organization. (⁵) Recurrence depends on the management protocol. (⁶) The aim of this report is to discuss the clinical, radiological, and histological characteristics and debate the optimal treatment of this rare case.

Case Report

Eleven-months-old white boy was referred by the family physician to an Oral and Maxillofacial Surgery unit, International Medical Center, Egypt, with facial asymmetry due to firm, painless swelling on the right
side of the mandible before three months. The parent of the infant reported no history of trauma and no deficits in neurologic exam were noted in regard to V and VII cranial nerves. The overlying skin was normal, no regional lymphadenopathy or tenderness were evident (Fig. 1, A).

Cone beam computed tomography (CBCT) scan of the lesion revealed a radiolucent expansile lytic lesion extending from the right ramus and angle of the mandible to the right canine area, causing destruction of both buccal and lingual cortical plates, no periosteal reaction was noted (Fig. 1, B).

Primary bone sarcomas such as osteosarcoma and chondrosarcoma, as well as other intraosseous soft-tissue sarcomas, were the differential diagnoses based on perforation of the mandibular cortex and aggressive behavior of the lesion. DF and other aggressive benign spindle cell tumors should be ruled out.

Under local anaesthesia, an incisional biopsy was performed, and the tissue mass obtained was submitted for histopathological examination. A non-capsulated spindle cell tumor with a short fascicular pattern was found in an abundant collagen with thin walled, dilated vascular channels on microscopic examination. There was no evidence of necrosis, pleomorphism, atypia, or mitotic activity (Fig. 2, A & B). The differential diagnosis included neurofibroma, DF, and low-grade sarcomas such as low-grade leiomyosarcoma or fibrosarcoma based on histopathologic features.

Immunohistochemical study was performed using β-catenin, Smooth muscle actin (SMA), S-100 protein to confirm the diagnosis, and Ki-67 to evaluate the proliferative activity. The nuclei of the tumor cells were positively labeled for the adhesion protein β-catenin (Fig.3). Negative staining was noted for both SMA except in the wall of the blood vessels (in Fig 4…), which considered as positive control, and S-100 protein (Fig. 5). The nuclei of the tumor cells showed partially positive staining with Ki-67 (only 4 % of tumor cells) (Fig. 6).

Based on the clinical, radiological, histopathological and immunohistochemical features, DF, was rendered. The patient was subsequently referred to the Oral and maxillofacial surgery unit for further management. Wide supra-periosteal mandibular resection was performed under general anaesthesia and the surgical defect was immediately reconstructed with autogenous rib graft (Fig. 7). The patient was reviewed at One year clinical and radiographical follow-up. The surgical site healed well, no signs of recurrence were detected with satisfactory functional and esthetic outcome (Fig. 8 & Fig 9).

**Discussion**

DF can affect any bone, but it is most common in the mandible (22%), femur (15%), pelvic bones (13%), radius (12%), and tibia (9%). Gnathic bone DF affects about 84% of patients under the age of 30, with a mean age of 16 years. While particular etiologic factors for DF are unknown, possible associations with trauma, endocrine factors, genetic aberrations, or multifactorial aetiology have been proposed. (4)

The maxilla-mandibular DF typically presents as a firm painless swelling that is slowly growing, rarely associated with loose teeth, it does not impact on chewing/swallowing. Facial asymmetry and irregular alignment of the teeth may be the only manifestations of the lesion. A radiolucent, multilocular lytic lesion expanding bone without any indication of periosteal reaction is a typical radiographic appearance. (7) In CT scanning, it has the characteristic “internal explosion” appearance of the lytic lesion. (8)
Histopathologically, DF is characterized by spindle shaped cells with minimal cytological atypia and abundant collagen production, the absence of a capsule, and the infiltrative nature of the lesion. (5)

To confirm the diagnosis and differentiate DF from low-grade fibrosarcoma and other sarcomas, several immunohistochemical biomarkers are essential. Low-grade fibrosarcoma did not show positive reaction with β-catenin which can support the diagnosis. In addition, low-grade fibrosarcoma and other sarcomas showed higher Ki-67 immunoreaction versus benign spindle cell tumors such as DF. In our case the tumor revealed highly positive reaction with β-catenin, which is in accordance with the results of Nedopil et al. (9)

Disagreement results were reported by Kahraman et al., where they did not detect any positive reaction with β-catenin when they studied a series of twenty-two cases of DF in jawbones, they suggested that β-catenin staining may not be used as a corroborating the diagnosis of DF. Immunohistochemical staining difference of jaw bone DF from other soft tissue and bone lesions may be related to the origination of jaw bone from the neural crest. (10)

Proliferation markers like Ki-67 can be used as a surrogate marker for evaluating the tumor’s aggressiveness. A low rate of predicted cell turnover in DF has been reported. (11) Our Ki-67 staining results are in agreement with those reported in earlier studies. (9, 11)

Other benign spindle cell tumors and low-grade sarcomas, especially fibrosarcoma, were included in the differential diagnosis. As previously stated, a positive β-catenin and a low Ki-67 immunohistochemical reactions will aid in determining a definitive diagnosis. This finding is in agreement with Mohammadi et al. (12)

Due to the aggressive behavior of DF, different treatment protocols have been proposed. (13) Higher recurrence rate (37%-72%) of DF after enucleation and curettage was reported by Gersak et al. (14) While Böhm et al., showed no recurrences after resection with wide surgical margins. (15) Radiotherapy is not recommended due to the lesion’s potential for mutagenic transformation into fibrosarcoma. (16) Therefore, wide mandibular resection was our treatment of choice.

Mandibular reconstruction is needed because the resection approach will result in loss of mandibular continuity and serious growth anomalies. In our case, reconstruction of the defect was carried out by an immediate autogenous rib graft.

Despite the fact that research suggests the therapy is successful after a 6-year recurrence-free follow-up, (1) our patient was reassessed six months after the surgical procedure. The surgical site healed well, no sign of recurrence, excellent esthetic and functional results were found. The patient parent are advised for long term follow up.

**Conclusion**

DF of the jaw is a rare fibrous tumor with an aggressive behavior and high recurrence rate. We report a rare case of DF on the right side of the mandible with good healing, no evidence of recurrence, excellent esthetic and functional results after an One-year follow up. The best treatment choice to reduce the recurrence rate of this benign aggressive tumor may be wide local resection.

**Recommendation:** The need for long term follow up is advised.

**Declaration of patient consent**

The authors certify that all required patient consent forms have been received by his parent. For his photographs and other clinical details to be published in the journal, the parents gave their informed consent prior to their infant inclusion in the study.

**Financial support and sponsorship:** Nil.

Morphometry and Sexual Dimorphism of Olfactory Fossa in Relation To Crista Galli in North Karnataka Region – A Multidetector Computed Tomographic Study

Anandagouda V Naikanur1, Balappa M Bannur2, Sanjeev I Kolagi3, Naseema Begum4

1Ph.D Scholar 2Professor, Department of Anatomy, Shri B M Patil Medical College, Vijayapura, 3Professor and Head, 4Associate Professor, Department of Anatomy, S Nijalingappa Medical College, Bagalkot

Abstract

Background: The aim of this study was to establish the morphometry and sexual dimorphism of olfactory fossa and its correlation with the types of crista galli in North Karnataka region.

Method: Two hundred and twenty Multidetector computed tomographic (MDCT) scans were collected from North Karnataka region and analyzed by using RadiAnt DICOM Viewer. The depth and width of olfactory fossa, their side symmetry, types of crista galli and correlation between the depth of olfactory fossa with types of base of crista galli were calculated in both genders. Statistical analysis was done by using Student unpaired ‘t’ test.

Conclusion: Keros type II of olfactory fossa was most common in the present study. There was significant difference (p˂0.05) in olfactory fossa depth when compared between right (mean=4.64mm) and left sides (mean=4.07mm) in females. There was no statistically significant difference found between the gender and the sides of depth and width of olfactory fossa. There was no statistically significant correlation found between the types of olfactory fossa and types of crista galli. The morphometry of olfactory fossa and crista galli would help neurosurgeons to assess these vulnerable regions of ethmoidal skull base in surgeries.

Key-words: Cribriform plate, Crista galli, Keros classification, Olfactory fossa.

Introduction

The Ethmoid bone lies in the anterior cranial fossa at the base of the cranial cavity. The cribriform plate, median perpendicular plate and two lateral labyrinths are the parts of the ethmoid bone. The orbital plate of the frontal bone and its roof joins with lateral lamellae of the cribriform plate (LLCP). [1]

The olfactory fossa is a depression in the anterior cranial fossa whose floor is formed by the cribriform plate. It is the most vulnerable site in the whole anterior skull base. It is medially bounded by crista galli and laterally by lateral lamella of the cribriform plate.[2] The depth of the olfactory fossa is determined by the height of the LLCP which is the thinnest area of the ethmoidal skull base. Thin LLCP and low ethmoidal skull base are the potential sites of injuries during endoscopic sinus surgeries.[3] Keros has classified the depth of olfactory fossa in to three types. Type I (1 to 3 mm), type II (4 to 7mm) and type III (8 to16 mm). [4]

Keros has also described the width and depth of olfactory fossa at different points and noted that type III Olfactory fossa exposes thin LLCP to injuries during
The width of olfactory fossa increases evenly from rostral to the occipital end. Measured below the wing of crista galli, the mean width is 3.8 mm on right side and 3.6 mm on left side. In the posterior one third, it is 5.2 mm on the right side and 5.1 mm on the left side at the rostral end.\textsuperscript{5}

The Crista galli (CG) is a triangular median process projecting upwards from the centre of the cribriform plate. It has a thin and slightly curved posterior border and a much thicker and shorter anterior border. It is a compact bone, but can also be pneumatized in some individuals.\textsuperscript{6} Thicker the crista galli, smaller the volume of olfactory fossa. Hajiioannou has classified the base position of crista galli into 3 types,

Type I= the base of the crista galli is located at the level of the cribriform plate.

Type II= less than 50% of the height of the crista galli is located below the level of the cribriform plate.

Type III= more than 50% of the height of the crista galli is located below the level of the cribriform plate.\textsuperscript{7}

Aim

The aim of this study was to establish the morphometry and sexual dimorphism of olfactory fossa and its correlation with the types of crista galli in North Karnataka region.

Objectives

a) To determine the gender differences in depth and width of olfactory fossa on both the sides.

b) To determine the dimensions of pneumatisation of crista galli and Hajiioannou types of crista galli in both the genders.

c) To determine the correlation between olfactory fossa depth and Hajiioannou’s classification of base of crista galli in both the genders.

Materials and Method

A prospective hospital based radiological study was done on two hundred and twenty Multidetector Computed Tomographic (MDCT) scans of the patients of all the districts of North Karnataka region of Karnataka state, India, after institutional ethics committee clearance. The study was carried out from April 2018 to September 2019.

Normal Paranasal MDCT scans of patients above the age of 16 years belonging to both genders were included in the study.

MDCT scans of Patients below the age of 16 years and MDCT scans of patients with nasal or paranasal trauma, congenital abnormalities of face, tumours or conditions involving bone destruction and surgeries were excluded from the study. While taking the MDCT of paranasal sinuses, patients were informed and instructed about the procedure before obtaining informed written consent. Axial MDCT images of 3mm thickness were taken from CT scanner (Siemens Somatom) by using bone window.

Direct coronal scan showing the maximum depth of the olfactory fossa at the centre of infraorbital foramen was taken as reference point. Depth of the olfactory fossa was determined by the length of the lateral lamella of cribriform plate (CP). The height of CP point was subtracted from the height of medial ethmoidal roof point (MERP) to measure the length of the LLCP on both sides in both genders. Figure 1 shows Line A which represents a direct horizontal line connecting the middle of the inferior orbital foramina on both sides. Line B represents direct vertical line connecting line A and to the site of communication of fovea ethmoidalis and the lateral lamella of the cribriform plate of the ethmoid bone (LLCP). Line C was drawn as a direct vertical line connecting line A to the most lateral bony boundary of the cribriform plate of the ethmoid bone at its communication with the lateral lamella which will be CP height. The height of the ethmoid roof (h) was considered as the depth of the olfactory fossa. “h” was calculated as the result of subtraction of length of line C
(“c”) from the length of line B (“b”) in millimeters (h = b - c). “h” will be representing the direct vertical height of the lateral lamella of the cribriform plate of the ethmoid bone.

FIGURE 1: Showing coronal section of Multidetector computed tomographic scan of the patient at the level of infraorbital foramen.

A(77.5mm) -Line joining two infraorbital foramen,

B (32.9mm) -Line joining medial ethmoidal roof point to line A and

C (24mm) -Line joining cribriform plate to line A.

Olfactory fossa depth was classified according to Keros classification i.e, type I (0 to 3 mm), type II (4 to 7 mm), type III (8 to 16 mm) on both sides in males and females. The side symmetry of the types of depth of olfactory fossa was then compared in both genders as shown in figure 2.

FIGURE 2: Types of depth of olfactory fossa in coronal section of MDCT scan on both the sides in the present study.
A- Line joining two infraorbital foramen,
B- Line joining medial ethmoidal roof point to line A and
C- line joining cribriform plate to line A.

The width of the olfactory fossa was measured from fovea ethmoidalis (fe) to the lateral margin of the crista galli at the level of centre of infraorbital foramina as shown in figure 3.

FIGURE 3: Measurement of width of left olfactory fossa in coronal section of MDCT scan of the patient.

The dimensions of the pneumatization of crista galli like anteroposterior and lateral to lateral diameter and types of base of crista galli according to Hajiioannous’s classification (figure 4 & 5) were noted in both coronal and sagittal section of MDCT scans.

FIGURE 4: Sagittal section of MDCT scan of the patient with type I crista galli.
FIGURE 5: Sagittal section of MDCT scan of the patient with type II crista galli.

Results and Discussion

With regard to less data available in North Karnataka region, the present study was carried out to find out any correlation between the Keros types of olfactory fossa and types of crista galli.

Comparison of the mean±SD of MERP, CP, depth of OF, and width of OF, and their significance in the present study on both sides in both genders is shown in table 1, 2 and 3.

* (n)=number, † (SD)=standard deviation, ‡ (p)=significance, § (CI)=class interval, || (MERP)= medial ethmoidal roof point, ** (ht)=height, †† (S)= significant and ‡‡ (NS)=not significant.
Among 220 MDCT scans, the mean MERP height was 26.57mm on the right side and 26.45mm on the left side. The cribriform plate height was 21.77mm on the right side and 21.28mm on the left side. The depth of the olfactory fossa was 4.76mm on the right side and 4.31 mm on the left side. The width of the olfactory fossa was 5.15mm on the right side and 4.85 mm on the left side.

Among 131 males, keros type I OF was found in 25 cases (19.08%) on the right side and 31 cases (23.66%) on the left side. Keros type II OF was found in 86 cases (65.64%) on the right side and 91 cases (69.46%) on the left side. Keros type III OF was found in 20 cases (15.26%) on the right side and 9 cases (6.87%) on the left side.

Among 89 females, keros type I OF was found in 23 cases (25.84%) on the right side and 31 cases (34.83%) on the left side. Keros type II OF was found in 54 cases (60.67%) on the right side and 51 cases (57.3%) on the left side. Keros type III OF was found in 12 cases (13.48%) on the right side and 7 cases (7.86%) on the left side.

Keros type II of olfactory fossa was most common in the present study. There was significant difference (p˂0.05) in olfactory fossa depth when compared between right (mean=4.64mm) and left sides (mean=4.07mm) in females. There was no statistically significant difference found between the gender and the sides of depth and width of olfactory fossa.

In the present study, symmetry of Olfactory Fossa depth was found in 94 cases (71.75%) in male patients and 54 cases (60.67%) in female patients. Asymmetry of Olfactory Fossa depth was found in 37 cases (28.24%) in male patients and 35 cases (39.32%) in female patients. There was no statistically significant difference found in the symmetry and asymmetry of olfactory fossa depth between the genders in the present study.

In the present study, type I Crista galli was found in 84 cases (64.12%) in male patients and 57 cases (64.02%) in female patients. Type II Crista galli was found in 47 cases (35.87%) in male patients and 32 cases (35.95%) in female patients. Type III Crista galli was not found in male and female patients. There was no statistically significant difference found between types of crista galli between the genders in the present study.

There was no correlation between the keros types of olfactory fossa and types of crista galli in the present study. Comparison of cases of keros type of olfactory fossa present in all types of crista galli in the present study on right side and left side in males and females is shown in chart 1 and chart 2 respectively.

![Chart 1](chart1.png)

**CHART 1 - Percentage of cases of keros types of olfactory fossa present in various types of crista galli in both genders on right side in the present study.**

- x axis = keros types I, II and III
- Y axis = number of cases of Keros types I, II and III of OF in seen in CG types I, II and III
CHART 2 - Percentage of cases of keros types of olfactory fossa present in various types of crista galli in both genders on left side in the present study.

x axis = keros types I, II and III

Y axis = number of cases of Keros types I, II and III of OF in seen in CG types I, II and III.

There was statistically significant difference in olfactory fossa depth when compared between right and left sides in females as shown in table no 2 and chart 3. In males, there was no such difference as shown in table 1. Keros type II olfactory fossa was predominant (64%) among the cases and keros type III olfactory fossa was rare (10%) in the present study as shown in table no.4.

CHART 3 - Comparison of MERP, CP, depth of OF and width of OF and their significance on both sides in females in the present study

n = number, CP = cribiform plate, MERP = medial ethmoidal roof point, NS = not significant and S = significant.
x axis = MERP, CP, OF

Y axis = number of cases
Comparison of keros types of depth of olfactory fossa in the present study and in various studies is shown in table 4.

Among 220 patients, the mean width of the olfactory fossa was 5.15 mm on right side and 4.85 mm on left side in the present study. There was no significant difference in the width of olfactory fossa between the sides in the present study. The study done by Daniel H. Coelho et al revealed that the mean width of OF was 4.57 mm on the right side and 4.49 mm on the left side by Digital photography. [12]

In the present study, type I crista galli was found in 64.07% of cases, type II CG was found in 35.91% of cases and type III CG was not found. In the study done by Hajiioannou, type I crista galli was found in 28.3% of cases, type II CG was found in 63.6% of cases and type III CG was found in 8.1% of cases.

In the present study, the width, height and length of pneumatized Crista galli was 3.95 mm, 9.3 mm and 7.02 mm respectively. In the study done by Gorazd Poje, [7] the width and length of pneumatized Crista galli was 5.1 mm and 8.75 mm respectively. In the study done by Ranko Mladina, [6] the width, height and length of pneumatized Crista galli was 3.75 mm, 10.35 mm and 7.8 mm respectively.

Strengths and limitations of the study:

With regard to less data available in North Karnataka region, this study will help neurosurgeons and endoscopic surgeons to assess olfactory fossa during various skull base and endoscopic sinus surgeries.

This study was carried out only in North Karnataka region and there were limited number of patients during the study period. Only adult patients were included in this study.

Conclusion

The dangerous keros type III olfactory fossa was rare in the present study when compared to the most common keros type II olfactory fossa. There was statistically significant difference in olfactory fossa depth when compared between right and left sides in females. In males, there was no such difference. The width of olfactory fossa was not significant when compared between two sides in males and females. There was no statistically significant correlation found between the keros types of olfactory fossa and types of crista galli. The knowledge regarding the keros types of
depth of olfactory fossa, width of olfactory fossa and types of crista galli will help the neurosurgeons to assess these vulnerable regions of ethmoidal skull base that are difficult to access during skull base surgeries.

Health Beliefs Related to Breast Cancer and Breast Self-Examination among Indian Women: Effect of Educational Program

Apoorva Dev.M¹, Githa Kishore², Faezeh khodadadi³
¹Asst. Professor, Department of Pharmacy Practice, PES University, ²Professor, Department of Pharmacy Practice, Visveswarapura Institute of Pharmaceutical Sciences, ³Intern, Pharm D, PES University, Rajiv Gandhi University of Health Sciences, Bengaluru

Abstract

Background: Breast cancer is believed to be the most widespread carcinoma all over the world and the most frequent type of carcinoma among females in India. Approximately 40% of breast lesions which lead to breast cancer is detectable by breast self-examination (BSE). The identification of the barriers of early detection and the baseline knowledge on breast cancer symptoms, risk factors, BSE method and also the effectiveness of a health education intervention among females in Bangalore, India are the main purposes of this research.

Methodology: The study was composed of totally 500 female participants from five different institutions in urban and rural of Bangalore in 2020. Assessing baseline knowledge on breast cancer and BSE using self-administered questionnaires as well as administering interventional health education in the form of a lecture, pamphlets and illustration of proper method of conducting breast self-examination using video tutorials.

Conclusion: The baseline knowledge about breast cancer and BSE practice among participants for early detection was found to be insufficient. However, we witnessed a great progress after immediate and follow up intervention. Periodic interventions are essential to prevent relapsing of certain types of barriers.

Key Words: Breast cancer, Breast self-examination, Educational intervention, Early Diagnosis, Follow up.

Introduction

Cancer is considered to be the number one cause of death in many countries. Countless number of people are annually diagnosed with cancer all over the world, and more than half of the patients ultimately lose their lives due to this awful disease. Breast cancer is considered as the most common cancer in women. Globally, it was estimated that 2.1 million females were diagnosed with breast cancer in 2018, the last year of incidence data collection ¹. It is a significant collective hurdle in both low-health expenditure and mid-level countries. In India, the rate of breast cancer in women, was 27.7% in 2018 with mortality rate of 23.5% ². It is the most wide-spread cancer among women who were residing in the urban areas of India ³. Patients who were diagnosed at an early stage of breast cancer have a better prognosis and good survival rate ⁴. However, the majority of the women in India present with an advanced stages of breast cancer, which declines the survival rates in India, which stems from the failure of early detection programs, causing a great number of females presenting with late-stage disease ⁵.
Lack of education on breast cancer and breast screening techniques used for early diagnosis is recognized as one of the major barriers to early detection of breast cancer. In the United States, the survival rate has increased which might be related to improvement in preventive measures and diagnosis of breast cancer in early stages. However, the mortality rate of breast cancer is increasing in most regions of the world particularly in low-income countries. Among different types of breast screening, Breast self-examination (BSE) is an easy, fast and free, non-invasive procedure that requires no special materials/equipment. It is also an effective diagnostic method for breast cancer that only takes five minutes to inform. There is evidence that women who correctly practice BSE on monthly basis are more likely to detect breast cancer in the early stages of its development, and early detection has been confirmed to influence early treatment and to yield a better survival rate. These findings highlight the importance of imparting proper knowledge on breast cancer and BSE and the barriers to early detection and implementation of preventive strategies, including education of the target population about breast cancer and BSE. Hence, this study is planned with the aim to assess and identify the barriers of early detection and the baseline knowledge on breast cancer symptoms, BSE method and risk factors of breast cancer and also the effectiveness of education on breast cancer and BSE in the Indian metropolitan women residing in Bangalore, Karnataka.

Material and Methods

Participants:

The study included women from Bangalore in the age group of 17 to 65 years and with no history of breast cancer. Non-random sampling method was used in this study and 500 women who gave their consent to participate in the study were included.

Study tools, techniques and procedure:

The research was carried out in order to investigate the knowledge of participants that was in association with breast cancer symptoms, risk factors, BSE technique and timing as well as obstacles for finding medical assistance. The efficacy of educational interference (in form of lecture, pamphlets and demonstration of suitable way of implementing BSE using video tutorials) in three phases (Pre-intervention phase and the post intervention phase itself is divided into two sections; immediate phase and three-month period). The following four steps describe the complete research procedure:

Step I:

A pre-designed, structured, and self-administered questionnaire was utilized for data collection. The first section of the questionnaire constituted demographic details of participants [Table 1]. The second section was comprised of 19 questions, the first 16 questions concentrated on knowledge evaluation of symptoms and risk factors of breast cancer and BSE method and training [Table 2, 3, 4]. The other three questions described the obstacles for seeking medical help [Table 5]. At the pre-intervention phase, participants were evaluated for baseline knowledge of breast cancer and BSE and then pamphlets were given out in which importance of breast cancer sign and symptoms, risk factors of breast cancer, importance of early detection by BSE and the proper method of conducting BSE were discussed. The study participants’ communication addresses were collected to avoid a loss to follow up.

Step II:

This was followed by a brief workshop as well a presentation concerning the sign and symptoms, risk factors of breast cancer and its screening methods with more focus on BSE method. The attendees were shown a brief instructive video. The content of the film revolved around the significance of BSE, ways of executing and the best time for BSE. Enquiries from the participants have been invited.

Step III:

After education, first post-interventional assessment was done to evaluate the increased awareness level of breast cancer and BSE using the same questionnaire.
among respondents.

**Step IV:**

After a three-month period, second post-interventional assessment regarding breast cancer and BSE knowledge was done.

**Statistical analysis:**

The statistical software for social sciences (IBM SPSS statistics 20) was used to analyses data. Descriptive statistics (i.e., frequencies, percentages, mean, standard deviation) were used to describe the demographic features and the Chi-square test was used to explore associations. P-value less than 0.05 was considered significant in all analyses.

**Ethical statement:**

Before entering the study, all the study participants were required to give their informed consent regarding the study benefits, risks, significance. The signed consent of every participant was recorded before the administration of the questionnaire. The study was approved by the Ethics committee of PES College of Pharmacy (PESCP/2015-16/PPD-PHD-01).

**Result:**

**Sociodemographic data:**

The survey involved a community-based research that included 500 women. The median age of women who participated in the study was 23.41 ± 5.063 years. The majority of the respondents 438 (86%) were in the age group of 17 to 25 years. The vast majority of the respondents 359 (71.8%) were students. Only 37 women (7.4%) were married and 463 (92.6%) were unmarried [Table-1].

**Awareness of Breast Cancer symptoms and risk factors:**

[ Graph 1] provides an evaluation of the knowledge of breast cancer manifestations and risk factors, and showed that the perception of common breast cancer symptoms (pain, discharge or bleeding from the nipple, a lump or thickening in the breast) and seven risk factors (the use of HRT, alcohol consumption, smoking, pregnancy in old age, overweight, positive family history and physical activity) improved significantly after the intervention. 71.4 % of them did not have any knowledge whatsoever that pain cannot be attributed as one of the main causes of breast cancer. In addition, at the pre-intervention stage, roughly 51.4% and 31.8% of women stated that only discharge and lump formations were the signs of breast cancer respectively and the remaining half had no knowledge of the fact that lump or thickening of breast is one of the major symptoms of breast cancer [Graph 1].

**BSE Skill Evaluation:**

After the comparison of correct percentage of pre-training and post-training responses in regards to the knowledge of immediate and a three-month follow-up BSE method and timing, it was determined that there was a statistically significant difference between the pre-training and post-training knowledge levels. When comparing the percentage of pre-training and the three-month follow-up awareness, an improvement in the correct response percentage was determined in the three-month follow-up period. The overall BSE knowledge increased from approximately (38.5%) to (83%) i.e., a twofold improvement was seen in the BSE knowledge even after three months of the intervention, due to the impact of health education provided for the respondents [Table-2], which has been found to be statistically significant (P < 0.05).

**Barriers in seeking medical help:**

The most significant obstacles to find medical care were multiple being too scared to go and visit doctor 361 (72.2%), followed by lack of confidence to speak about symptoms 357 (71.4%) and being too ashamed to go to see a physician 342 (68.4%) [Table-3].

Graph-1. Percentage of correct answers to knowledge assessment about breast cancer symptoms and risk factors.

**Discussion**

Study participants were evaluated for their knowledge of breast cancer under four different concerns, such as warning signs and risk factors of breast cancer, BSE method and timing and barriers to seek medical help in case of any warning sign.

Knowledge of women on breast cancer symptoms and risk factors:

It is sad to say that the prior knowledge of women participants regarding breast cancer manifestation and risk factors was determined as medium-low level. After the training however, these values increased significantly. This indicates another important aspect of our research, which highlights the importance & effectiveness of the training regarding the knowledge level among female participants after the training on breast cancer and BSE."
Regarding risk factors, Smoking (57.8%) was the most reported risk factor while the vast majority of participants (80.6%) were not aware of the fact that obesity and having children later on in life (over 40) were also important risk factors for breast cancer [Graph 1]. Prusty RK et al., approved that women in Mumbai were weakly aware of breast cancer risk factors. Obesity was the most common cited risk factor (19%) while early menstruation (5.6%) and late menopause (10%) were among the least common risk factors. Another study by Millat WA, respondent with family history of breast cancer had a slightly higher level of awareness regarding BSE compared to respondents with no family history.

### Knowledge on BSE Method and Timing:

Our participants were also questioned about BSE practice. It was observed that the majority of the participants in the present study had moderate to poor knowledge when it came to BSE practice. However, it has been significantly improved up to 90% after the education, which highlights the positive changes on the BSE knowledge due to the training regarding BSE [Table 2]. According to Abdul Nazer Ali’s research, the general awareness score on BSE knowledge was moderate at baseline and improved drastically after educational program. A similar study by Mehrnoosh assessed the knowledge of women at baseline, 6, and 12 months and reported that education modules of BC and BSE method improved the knowledge scores in the intervention group.

### Barriers to seek medical help:

In our study, we found various barriers. During the pre-intervention phase it was found that almost 45% of women did not have the confidence to notice a change in their breast, 68% were embarrassed to consult a doctor, 72% were scared, and almost 72% were not confident enough to visit the physician for discussion. Acquiring finally helped to remove obstacles such as embarrassment, fear and lack of self-confidence. After all, cultural characteristics may be treated as the main barriers that can be influential. After education, it was noticed that above 65% of women got confidence and were freed of negative attitudes towards their physician for consultation. Education brought a significant change in their attitude and improved their confidence levels towards breast health [Table 3]. According to Saleha Qasim study, shows the most commonly prominent reasons of not visiting a doctor in time were: busy schedule, embarrassment, anxious to see a doctor, finding it hard to speak with the doctor.

Some limitations need to be addressed, when interpreting the results, first of all, a great number of the participants (87.8%) were identified at the age group of 17-25 years and may not be representative of all female of different age group; hence it is recommended to conduct further studies using a wider range of age. We therefore highly recommend that the appropriate and practical training programs should be provided for women through India’s health care system.

### Conclusion

We witnessed participants’ awareness towards breast cancer manifestation, risk factors and BSE for early detection insufficient at the pre-intervention phase, but we found a great advancement in the first and second post-intervention phase. The study emphasizes the fact that breast cancer awareness needs to be raised and individuals must be educated about the significance of BSE practice, which allows breast cancer to be detected in a much earlier stage. The presented data demonstrates a significant perceptual barrier and baseline knowledge regarding breast cancer and BSE among Indian females and demonstrates the ability to provide guidance for seeking the techniques to enhance awareness among Indian females according to their needs.

### Acknowledgment:

We thank the participants of the study for their valuable time and interest shown in our study.

### Conflict of Interest:

The authors declare that they have no conflict of interest.

### Funding support:

The authors declare that they have no funding support for this study.

Abstract
Maternal mental health considered as an important subject among leading public health experts. It has been shown that women are two to three times more likely to be diagnosed with mental illness compared to men. Chronic stress, experiencing war, and history of abuse are the most effective factors that associated with mental illness. Iraq has experienced years of challenging circumstances due to the political and social environment as well as due to physical barriers to health care services. This paper presents findings of previous literatures in relative to mental illness among Iraqi women. In the current study, we are aiming to determine the mental illness symptoms and effects in pregnancy during a period of all trimesters. Moreover, we try to assess risk factors’ effects on mental illness symptoms in order to have better understanding of the occurrence and associated factors in pregnancy. Type of study comparative cross-sectional study with analytic component. A cross section study was conducted from 2018/9/5 to 2019/8/25. Observations of present study show that there is a relationship between some factors like domestic violence, unplanned for pregnancy, previous miscarriage, psychological trauma before or during pregnancy. Our study mainly focusing on women with maternal mental illness and inform strategies that would help to reduce and manage maternal mental problems in order to promote their general health status.

Key words: Mental illness, Pregnant, Teaching Hospital, Kut 2019.

Introduction
Mental illness is a syndrome characterized by clinically significant disturbance in an individual’s cognition, emotion regulation, or behavior that reflects a dysfunction in the psychological, biological, or developmental processes underlying mental functioning. Mental illness are usually associated with significant distress or disability in social, occupational, or other important activities. Mental health problems may be a result of an excessive stress. As with cancer, diabetes and heart disease, mental illnesses are often physical as well as emotional and psychological. Furthermore, mental illnesses may be caused by a reaction to environmental stresses, genetic factors, biochemical imbalances, or a combination of all mentioned factors. Notably, with proper care and treatment many individuals learn to cope or recover from a mental illness or emotional disorder. Although the incidence of mild mental health problems is not significantly different during pregnancy, the risk of bipolar or severe depressive illness is greatly increased postpartum and this period represents perhaps the highest risk period in a woman’s life for the development of a psychiatric disorder. Furthermore, women with previous serious mental health problems are at high risk of recurrence during both the antepartum and postpartum periods. Previously, it has been illustrated that the most common types of mental illness are Anxiety disorders, that including panic disorder, obsessive-compulsive disorder, post-traumatic stress disorder, and phobias. Moreover, Depression, bipolar disorder, and other mood disorders have also been described as types of mental illness.
illness. In addition, same study has referred to eating, personal and psychotic disorders as other types of mental illness. Moreover, Neurotransmitters (brain chemistry), are naturally occurring, as brain chemicals that carry signals to other parts of your brain and body. When the neural networks involving these chemicals are impaired, the function of nerve receptors and nerve systems change, leading to depression. Common risk factors: Family history of mental health problems, Complications during pregnancy or birth, Personal history of Traumatic Brain Injury, Chronic medical condition such as cancer or diabetes, especially hypothyroidism or other brain-related illness such as Alzheimer’s or Parkinson’s, Use of alcohol or drugs, Poor nutrition and lack of sleep. Furthermore, there is a wide range of symptoms could be categorized as indicators of mental illness. For instance, anxiety: excessive worry or fears. Persistent sad or low mood, unusual or illogical thoughts, unreasonable anger or irritability and poor concentration. Previously, it has been shown that diagnosing a mental health disorder is a multi-step process. During a first appointment, doctor may perform a physical exam in order to look for signs of physical issues that could be contributing symptoms. Some doctors may order a series of laboratory tests trying to screen for underlying or less obvious possible causes. Moreover, doctor may ask to fill out a mental health questionnaire. Patients may also undergo a psychological evaluation. You might not have a diagnosis after your first appointment. In some cases, doctor may refer patient to a mental health expert, because mental health can be complex and symptoms may vary from person to person, it may take a few appointments to get a full diagnosis. However, these are widely believed to be underestimates, due to poor diagnosis (especially in countries without affordable access to mental health services) and low reporting rates, in part because of the predominant use of self-report data, rather than semi-structured instruments such as the structured clinical Interview for DSM-IV (SCID); actual lifetime prevalence rates for mental disorders are estimated to be between 65% and 85%. In the current study, we are aiming to determine the mental illness symptoms and effects in pregnancy during a period of all trimesters.

**Methodology**

Describe mental illness in Iraqi women during pregnancy a cross section study was conducted in 2019 depending on many references. The time of study from 2018/9/5 to 2019/8/25. The study included women in 2018 and 2019 who are visited Al-Zahra hospital's gynecology outpatient clinic, to identify women who are needed for psychological support or suffer from sign and symptoms of mental illness during pregnancy.

Risk factors for mental illness during pregnancy, risk of history of psychological trauma on pregnant women was also measured. In this study 250 cases collected in age group ranged from 19 – 35 years, in any gestational age. We collected samples from Al-kut depending on questioners. Actually, pregnant women have been asked many questions that relative to signs and symptoms of mental illness and depend on psychiatry classification the questioner contain 20 questions. If the number of positive questions is seven in number or below there is no mental illness. If the number of positive questions is eight or above there is mental illness.

**Results**

We took 250 cases from Al-kut to estimated prevalence of mental illness during pregnancy and its risk factors.

* Correlation is significant at the 0.05 level (2-tailed).
In our study were 203 cases unemployed (81%) and (19%) employers. We found that there is a high risk of developing signs and symptoms of mental illnesses among unemployed pregnant women (table 3).

In the present study, prevalence of sign and symptoms of mental illnesses in low income more than high income (table 3), there was 55 cases with low income (22%), 180 cases with moderate income (72%), and 15 cases with high income (6%).

In the is study, there was 167 cases with no any complication (66%), 83 with complication most of them hypertension and bleeding (33%). We found that there is high risk of developing mental disorders in complicated pregnancy comparing to those with un complicated pregnancy (table 4).

*. Correlation is significant at the 0.05 level (2-tailed). **. Correlation is significant at the 0.01 level (2-tailed).

Present study also shows that 243 cases with no family history of mental illnesses (97%), 7 cases with family history (3%). All women with family history of mental illnesses suffer from some signs and symptoms of mental illnesses but not related to pregnancy (table 6).

In the current study, we determine that 196 pregnant women with good family support (78%), 41 with moderate support (16%), and 13 cases with poor family support (6%). It was strong correlation between family and social support in relative to developing of signs and symptoms of mental illnesses in those with poor or moderate family and social support (table 6).

Discussion

This cross-section study presents detailed description of women’s maternal mental health in Al-kut. Many systematic reviews have suggested that
women are at high risk of mental illnesses because of social and cultural customs. There are also significant barriers to receive mental health services due to infrastructure challenges and perception of stigma at population level. WHO estimates that prevalence rate for mental illnesses is higher in low income countries (20%) compared to women in high income countries (16%), this provides to be true in Iraq, especially since 2003. Previous studies have demonstrated that Iraqi women present high rates mental illnesses compared to women in other countries. Actually, global prevalence rate for maternal depression and anxiety is between 15-20%. Moreover, it has been shown that depression and anxiety are highly indicated during antenatal period. The most relevant factors associated with antenatal depression or anxiety (ranked according to the number of studies that have found the factors to be significant predictors, and presenting also the number of studies who did not) are: lack of family or social support, history of abuse or domestic violence, personal history of mental illnesses, unplanned pregnancy, high perceived stress, present or past pregnancy loss or complication, low education level, low income, dissatisfied relationship with partner. Consistently, numerous previous studies revealed that young women are significantly associated with antenatal depression and anxiety. Whereas, 10 studies found that old age to be a significant risk factor. Another 10 researchers did not find any association with age. In agreement with previous studies, current study shows that there is no significant of age correlation. Strikingly, no studies regarding the psychopathology of the partner as potential risk factor for antenatal mental illness. In our study, we found that majority of the participants are in low income group. Our interpretation is that low income increases the likelihood of poor living conditions, financial struggle and influences interpersonal relationship. Moreover, we also found among pregnant women observed that patients being educated but not employed could predispose to depression during pregnancy (antenatal depression) and its associated Risk factor. Among women in Bangalore. In the current study and in agreement with aforementioned studies, we showed that the chance of getting depressed is significantly high in case of unplanned pregnancy. Furthermore, our study shows significant correlation between domestic violence and antenatal depression as well as anxiety. The linkage between poor social and family support and antenatal depression has been well documented. In fact, low social support may increase mental stress by inducing feeling of insecurity, predispose to substance abuse, and promotes interpersonal conflict. Other studies have reported that negative life event may lead to persistent higher levels of depressive symptoms since positive life event would reduce the severity of depression over time. It is important to mention that body mass index was not linked with the risk of prenatal depression in this study, even other research have indicated an interconnection between obesity and depression, the causal pathway could include inflammation, hormonal imbalance or sleep disturbance.

**Conclusion**

In summary we can conclude that there is a correlation between the mental illness in pregnant women and the following risk factors; domestic violence, not planned for pregnancy, house wife, previous miscarriage, history of psychological trauma before pregnancy. These factors affect the mental health of the mother.

Challenges in Maternal and Child Health Routine Data Administration in Indonesia: A Qualitative Study

Arief Priyo Nugroho¹, Diyan Effendi¹, Zulfa Auliya Agustina², Asep Kusnali¹, Siti Maimunah³, Irfan Ardani¹, Ratna Widyasari¹

¹Researcher, National Institute of Health Research and Development, Ministry of Health of Indonesia, Jl. Percetakan Negara No. 29 Jakarta, Indonesia, ²Researcher, Health Technology Innovation, Ministry of Health of Indonesia, Indrapura 17, Surabaya, ³Legal Drafter, National Institute of Health Research and Development, Ministry of Health of Indonesia, Jl. Percetakan Negara No. 29 Jakarta, Indonesia

Abstract

Background: Maternal and child health (MCH) routine data is essential in making a good health-related policy. However, the quality of MCH routine data in Indonesia is doubted, and thus the Indonesian government relies heavily on the survey data for policymaking. This condition raises questions about where the problems exist in routine data recording stages. This study aims to explore the barriers and strategies of MCH routine data recording by the administrators in the primary healthcare center.

Method: This study was qualitative research conducted in Buru Regency, Ambon City, Purworejo Regency, and Surakarta City from May to November 2020. The data collections were intended to understand administrators’ efforts to deal with the data recording problems. Data triangulation was performed through in-depth interviews with primary healthcare center staff and observations on daily routine data administration practices.

Results: The study demonstrated challenges in the MCH routine data administration context. The first problem is behavioral contexts lead to incorrect input and delay data submission. Second, technical determinant shows the lack of integration that leads to repetitive data recording and data fragmentation. The third was the organizational problem such as lack of inter and intra-departmental coordination in data sharing, infrastructure, and human resource shortage.

Conclusion: The findings elucidate the problem of administrative structures in the implementation of routine data policy. A comprehensive response to cope with routine data policy implementation context is needed. Existing maternal and child healthcare routine data requires structural administration refinement that provides a context for implementing reliable routine data recording of maternal and child health.

Keywords: Maternal and Child Health, routine data, administrative structure

Introduction

Routine data is inherent in the health efforts being carried out. Therefore, routine data would describe the achievements of health programs. Health routine data in Indonesia is sourced from the healthcare facilities reports. However, in practice, routine data generated by the bodies responsible for the health services are not reliable. Routine data generated in Indonesia is still questioned for its validity.

The question of validity arises when routine data has not maximally supported the health policy or there is a huge gap between reported data and the concurrent data source such as survey data.[¹,²] In Indonesia, there is a gap between the health-facilities-sourced data and...
the survey data. For instance, the health-facilities-sourced data reported that KN1 coverage was 97.4%, in 2019 but the data of Basic Health Survey (Riskesdas) showed KN1 coverage was 84.1%.[3] This data gap has potentially caused an error in the government’s response to health problems for pregnant women.

The presence of data gaps shows that routine data management is experiencing various obstacles. Routine data registration is facing inadequate supervision and alternate workload by local Midwives were cited as factors resulting in inconsistent reporting of data.[4]

This paper focuses on how the MCH data are routinely recorded and reported by the administrator in the primary healthcare center. This administration scheme has a primary role in MCH routine data. It shows how the data recording is administrated and explains the context of routine data policies implemented.

**Method**

This study used a qualitative approach which was conducted from May to November 2020. The data were collected through focus group discussions (FGDs) and in-depth interviews with the related stakeholders. The FGDs and interviews were designed to get a deeper understanding of the context of the MCH routine data problems both from the policymaker and implementer perspectives.

The research was carried out in four areas: Buru Regency, Ambon City, Purworejo Regency, and Surakarta City. The selection of these regions was intended to capture the diversity of region-related problems in carrying out routine data recording.

Data triangulation was performed through in-depth interviews with primary healthcare center staff and observations on daily routine data administration practices. Both FGDs and in-depth interviews were audio-recorded. The recordings were transcribed and analyzed into behavioral, technical, and organizational determinants categorization.

**Results and Discussion**

Routine Data Circumstances in Four Regions

The implementation of MCH routine data recording in the four regions that were the locus of the study had the same budgeting conditions. Routine data recording is still relatively minimal, having a separate budget
and supporting existing activities. There is no budget specifically allocated for data recording. It is still embedded in the activities that are carried out.

Most of the budget came from deconcentration funds from the central government. Although in the regional budget, several were allocated for routine data management, in general, the funds allocated specifically for recording routine MCH data were still insufficient.

The implementation of routine data recording on maternal and child health had also experienced constraints due to the lack of human resources. The staff in charge of data at the Primary healthcare center often had to carry out more than one task. Apart from recording routine data, she was also responsible for other tasks such as delivery services. As such, the workload increased and there was an impression that the human resources in the primary healthcare center were insufficient.

Table 2. Resources in implementing MCH routine data recording

Routine data recording infrastructure was relatively minimal to support the implementation of maternal and child health routine data recording. Despite having very little budget allocation, the Surakarta city government had adequate infrastructure support. This infrastructure adequacy was caused by the implementation of the ‘one data’ policy in Surakarta.

MCH Routine Data Recording Problems

Behavioral problems

In routine data recording, problems often encountered in this study were input errors and delays in data transmission. The two problems by the implementer were included in the category of behavioral problems. Behavioral problems in routine data recording were caused by high and varied workloads. First, the high workload is caused by a large number of recording applications and diverse types of data. Second, the staff in charge of data recording not only had the function of recording routine data but also responsible for delivering health services. Also, there were other duties and functions which were the responsibility of the staff who carry out data recording, such as administrative duties as treasurers.

“There are many cohorts recordings, so there is a possibility that it will be wrong” (PHC A1)

“Yes, it was already reported but forgotten not to be written in the cohort. The midwives have the cohort book but sometimes they forget to write in the cohort book. I’ve done the monitoring and evaluation and rarely found that condition. Maybe there was a delivery or other activity, so they forgot to write in the cohort.” (PHC A2)

Experiences in other regions in Indonesia also found similar problems with the routine data recording.
Other countries also face similar experiences in carrying out routine health data recording. This problem is considered a daily problem encountered in routine data implementation. This daily problem cannot be underrated because it affects the quality of the routine data being produced.

Technical problems

Incorrect input and delay submission of data experienced by routine data recording implementers occurred due to inadequate technical support in the routine data recording system. Technically, the routine data recording application was not integrated, so there was data fragmentation. Data fragmentation caused by the unintegrated recording application made performance inefficient. Often the same data must be inputted into two or more different applications. Repetition of similar data recording was an inefficiency in carrying out routine data recording. In addition to increasing the workload, this problem also likely to cause input errors. The same problem was also found in previous studies which showed that the error rate of data recording increased and the compliance of recording staff decreased due to a large number of MCH data recording forms. This condition was not unnoticed by the data recording staff. They realized what they were doing was a repetitive job that could have been made more concise. But in reality, it returns to the recording system which did originate and was aimed at separate management.

“We at the family health directorate, have no application and manually operated. There are some apps for nutrition routine data. There is no MCH application. The problem in this city is the internet, the staffs have overlapping work, and the high workload…” (City health department informant)

The shortage of human resources that were experienced became an operational burden when the routine data recorder at the primary healthcare center was a staff who did not only have responsibility for recording routine data only. Mostly the staff responsible for recording routine MCH data were midwives who had more than one program responsibility. From the interviews conducted with a director of a primary healthcare center, one midwife bears three or more responsibilities. This burden did not include the responsibility for health services.

“Honestly we feel overburdened. The workload is too high. Imagine, 15 midwives have to handle 32 villages and our jobs are not only about MCH but also other duties not related to MCH. If we may focus on MCH only then the outcomes would be better.” (PHC C1)

Behavioral problems in recording routine MCH data at the primary healthcare center showed that the division of tasks has not been carried out with the principle of a clear separation of functions. The staff at the primary healthcare center has many functions at once. Midwives, for example, not only provide delivery services, but they are also responsible for other programs. This problem prevents staff from honing expertise in one particular area.
Organizational problems

Lack inter and intradepartmental coordination in data sharing

Routine data recording at the health center includes the MCH program (pre and post-natal care), immunization, surveillance, and several other programs. The recording is carried out by the Primary healthcare center staff, who is usually a village midwife. Each program had its data recording application.

Most of the MCH routine data recording applications were not integrated, indicating that there was a technical problem. Data recording was done repeatedly because each MCH program had different applications even though they had the same data. Regarding maternal and child health, there were at least two applications, namely “e-ppgbm” [13] and “simpus KIA”[14]. This condition showed the weak coordination between policymakers in the Ministry of Health.

Human resource shortage

Of the four research loci, the lack of human resources had always been a problem in carrying out routine data recording. This problem has become the main topic in health services in Indonesia. Even in urban areas,

The problem of lack of human resources was not only caused by a lack of quantity but also due to maldistribution. The uneven distribution contributed to the constant lack of health workers at the primary healthcare centers[15]. This phenomenon can be seen in the findings of this study, in Buru District, the number of midwives was sufficient even though they were not permanent employees. In other findings, in urban areas such as Surakarta or Purworejo, the human resources at the primary healthcare center were not excessive but they were sufficient. The problem faced was the high workload, especially for midwives who were responsible for more than one program.

Maldistribution of human resources and high workload showed a lack of efficiency. A primary healthcare center was not designed as an organization that encourages specialization in every function it carries out. According to Indonesia Minister of Health Regulation No. 43 of 2019, primary healthcare center management does not emphasize efforts to increase staff professionalism by encouraging the specialization of duties and functions. Primary healthcare centers are managed to cover a wide range of areas and are deliberately encouraged to holistically address public health problems.

The holistic approach does provide the benefits of integrative and coordinative services. However, if this approach is not implemented properly, it will reduce the efficiency of the management of the primary healthcare center. These potential problems were found in the implementation of routine data recording. The integration between the data recording process and health services meant that there was no separation of the duties and functions of the staff which results in a double burden of work. This problem is a manifestation of inefficiency in human resource management in the primary healthcare center.

Lack of infrastructure

The last problem identified was the inadequate infrastructure for MCH routine data recording. This problem arose as a result of the lack of allocation for carrying out routine data. Even regions with adequate fiscal capacity, such as Surakarta and Purworejo, also experience the lack of infrastructure, although to a different degree compared to regions with low fiscal capacity. Especially for areas such as Buru Regency and Ambon City, infrastructure became the main obstacle after human resource problems. Regional budget allocations in the health sector are strongly influenced by the subjectivity of regional mayors. Often curative efforts get more budget allocations because their impact could be immediately measured. So that success in the curative sector is expected to increase the electability of the incumbent regional head-bearing party.[16]

Routine data recording that has adopted information technology has made the adequacy of infrastructure
an obstacle. These constraints are mainly faced by regions that are still struggling with basic problems such as electricity supply and the availability of internet connections. This problem directly hinders the implementation of a routine MCH data recording and reporting system. The constraints of MCH routine data recording found in this study were formalized in the following conceptual model (figure 1).

![Diagram](image)

**Figure 1 Determinant in MCH Routine Data Obstacle in Buru, Ambon, Purworejo, and Solo – Modified from Hoxha et al. (2020).**

The organizational problems had caused the occurrence of technical problems. Whilst technical problems were the root of behavioral problems endured by the MCH routine data administrators.

**Potential Solutions**

The results of this study indicated that the problems of implementing the MCH routine data recording including behavioral and technical problems. These problems were formed as a result of the organizational culture that drives them.

Therefore, efforts to improve routine data recording require at least two keys of improvements. The first is about the simplification of data recording. This simplification is needed to reduce the workload. Second is the improvements in the management structure. Improved management of routine data recording is required for the sustainability of records.

**Routine data recording simplification**

The first solution that can be taken is to simplify the routine MCH data recording system. As discussed above, the number of recording systems both online and offline has caused a decrease in the level of compliance in filling in data and increased input errors, many of which with the same variables cause the workload of
midwives at the primary healthcare centers to increase. Not only the number of forms that must be filled in, but the village midwife also has many help books to use manually. Assistive book for midwife personal records which also means that the existing system is not yet effective and efficient.\textsuperscript{[18,19]}

**Routine data administration enhancement**

Primary healthcare center needs to have skilled and competent human resources in data recording. The success of recording and reporting routine data is largely determined by human resources that implement routine data information systems. Staffs who are in charge of data recording and reporting must have an awareness that the data generated is indispensable for policymaking\textsuperscript{[20,21]}

If the solutions-focused only on the lack of human resources, the problem of routine MCH data recording will not be resolved properly. First, in the delivery of health services, the problem of resources including human resources is a classic problem.\textsuperscript{[15,22]} Second, the complexity of the problem of inequality in health services even at the subnational level.\textsuperscript{[23]} Therefore, optimal management of human resources is a rational choice in improving services.

In the modern bureaucracy, specialization is needed to increase the efficiency of results. In the Weberian framework of thought, efficiency results from the existence of specialization in work.\textsuperscript{[24,25]} This specialization requires a supportive organizational structure. The organizational structure of the primary healthcare center in Indonesia has not been able to answer this need. Human resource management is still based on the Health program which is carried out without paying attention to the specifications and specializations of work required.

Primary healthcare centers have not implemented the separation of staffs’ functions and duties. So that health workers at the primary healthcare centers carry out very diverse duties and functions. Human resource management in such an organizational structure makes employees unable to develop job specializations. This phenomenon is because they are not required and are not encouraged to specialize in work.

**Conclusion**

Constraints on the implementation of MCH routine data recording were evident that problems that occurred were mostly due to organizational problems. The organizational context has resulted in technical issues and eventually leading to behavioral issues. Behavioral problems were derived from the issues of insufficient human resources, a lack of coordination in both inter and Intra departments, and inadequate infrastructure.

These research findings showed that the routine data administrators were trapped in a situation that did not allow them to increase the efficiency and quality of MCH routine data. Challenges regarding the diverse job function of routine data administrators were the context of problems that prevent optimum routine data recording.

Superior Semicircular Canal Dehiscence Syndrome in a Woman: A Case Report

Arif Surgana¹, Haris Mayagung Ekorini²
¹Resident, ²Lecturer, Department of Otorhinolaringology Head and Neck Surgery, Faculty of Medicine, Universitas Airlangga – Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Abstract

Background: Superior semicircular canal dehiscence (SSCD) syndrome is a disease that occurs very rare. Clinical presentation consists of Tullio’s phenomenon and Hennebert’s sign. This case presentation is atypical and clinician should be aware. Purpose: to present the rare case of Superior semicircular canal dehiscence (SSCD) Case presentation: A 65-year-old woman with complaints of dizziness from 2 years ago and her recurrence. The audiogram showed bilateral sensorineural deafness with a mean hearing threshold of 58 decibels (dB) of the right ear and 48 dB of the left ear. There is also an air-bone gap in the right ear at low frequencies (250 Hz). The tympanogram revealed a type A result in both ears. Positive results were obtained on the examination of Romberg sharpened, positive Fukuda step to the right, and the Gans test. CT scan showed dehiscence of the right superior semicircular canal. Therapy in patients was given conservative therapy because the participants refused to undergo surgery. Conclusion: SSCD has a specific symptom of Tullio’s phenomenon and CT scan shows dehiscence of the superior semicircular canal. Keyword: Superior semicircular canal dehiscence, Tullio’s phenomenon, vertigo

Introduction

Superior semicircular canal dehiscence (SSCD) syndrome was a disorder in which symptoms of vertigo induced by loud noises (Tullio’s phenomenon) or intracranial pressure (Hennebert’s sign) due to dehiscence of the bone lining the superior semicircular canal¹. The prevalence of developing SSCD was 3% on the computed Tomography (CT) scan survey of the temporal bone². Tullio’s phenomenon and Hennebert’s sign are characteristic sign because of the formation of a third window in the superior semicircular canal. The third window appears due to dehiscence of the superior semicircular canal. Sound stimulation and intracranial pressure on this third window cause excitation or inhibition of the superior semicircular canal leads to symptoms of vertigo. Bone conduction will lead to hyperacusis, leading to symptoms of autophonia³.

Temporal CT scan of SSCD can show dehiscence of the semicircular canal. The CT scan is about 0.5 mm thick to see the structure of the inner ear. Clinical symptoms combined with appropriate CT scan images can increase SSCD specificity by 99%⁴. Audiometric examination of SSCD can give results of conduction hearing loss, especially low frequencies and tympanometry examination yields normal values⁵. Based on the description above, we are interested in reporting a case of SSCD that we had in a 65 year old woman.

Case Presentation

A 65-year-old woman with complaints of vertigo since 2 years ago has disappeared. Vertigo is not triggered

by change in head position. The patient has undergone medical rehabilitation therapy but the complaints persist and when she hear loud sounds feel uncomfortable and dizzy. Hearing loss since 1 year ago in both ears. Previous medical history is hypercholesterolemia. The patient has seen several doctors and finally to a neurosurgeon, then a Magnetic Resonance Imaging (MRI) examination is recommended before being referred to a specialist in otorhinolaryngology head and neck surgery.

On both ears Rinne’s examination and Weber’s examination were no lateralization and Bing’s examination was positive in both ears. The audiogram showed bilateral sensorineural deafness with hearing threshold pure tone average of 58 decibels (dB) of the right ear and 48 dB of the left ear. There is also an air-bone gap in the right ear at low frequencies (250 Hz). The tympanogram revealed a type A result in both ears. The acoustic reflex was not continued because the patient experience vertigo during examination. When the acoustic reflex was performed, nystagmus appeared but the direction could not be determined because the patient asked to stop the examination. The valsalva test was not performed in these patients because of vertigo.

Vestibular examination was carried out including the Romberg test, the Romberg sharpened test, the Fukuda step test, the Gans test, and the Dix Hallpike test. Positive results were obtained on the examination of Romberg sharpened, positive Fukuda step to the right, and the Gans test. Negative results were obtained on the Romberg, Dix-Hallpike examination and the coordination examination in the form of dysdiadokinesia and finger nose tests. In conclusion, the results of the vestibular examination showed that Vertigo with non-Benign Paroxysmal Positional Vertigo (BPPV) type.

A CT scan of the temporal bone with suspicion of SSCD was performed on the patient. CT scan showed dehiscence of the right superior semicircular canal. The left semicircular canal appeared normal. The cochlea and vestibule appeared normal. Bilateral normal internal acoustic canal. Both patent of vestibular aqueduct and facial nerve. Osicles and scutum were normal, no erosion found. The foramen ovale and rotundum were normal bilaterally (Figures 1 & 2). Therapy in patients was given conservative therapy because the participants refused to undergo surgery.

Figure 1. CT scan of the coronal temporal cut shows dehiscence of the right superior semicircular canal (black arrow). Left superior canal appears normal (white arrow).
SSCD syndrome was a disorder due to dehiscence of the roof of the superior semicircular canal occurs. Symptoms that arise involve hearing and balance problems. In general, the symptoms that arise are divided into two, related to sound and pressure changes. Symptoms associated with sound are vertigo triggered by loud noises (Tullio’s phenomenon), autophonia (can hear sounds from one’s own body), hyperacusis, fullness in the ears, tinnitus, low frequency conduction deafness, while symptoms related to pressure changes are vertigo when the intracranial pressure increases (Hennebert’s sign) eg when coughing, valsalva, and lifting heavy objects\(^{(5)}\). The age of SSCD patients in this case is in accordance with previous studies where many SSCD patients were found to be over 60 years of age\(^{(2)}\) and other studies stated that the incidence of SSCD increases with increasing age\(^{(6)}\). In this case there was dehiscence of the superior semicircular canal in the right ear. Dehiscence often occurs unilaterally but can also be obtained bilaterally\(^{(7)}\).

The Tullio phenomenon can produce vertigo when hearing loud sounds especially at low frequencies\(^{(8)}\). The Tullio phenomenon was found in 96% of these SSCD sufferers. The symptom description is characterized by vertigo or nystagmus on hearing a loud sound\(^{(7)}\). The symptoms of Tullio’s phenomenon are not given enough attention as a result of the patients are misdiagnosed with psychiatric disorders. Vertigo in SSCD can also result from the Valsalva maneuver\(^{(9)}\).

Low frequency (250 Hz) air bone gap in the right ear corresponds to hearing loss in SSCD usually conduction hearing loss at low frequencies below 1000 Hz\(^{(3)}\). This conduction hearing loss results from the presence of a third window of the superior semicircular canal. Sound energy that enters the cochlea through the foramen ovale will partially go to the dehiscent semicircular canal, resulting in an increase in the threshold with air conduction. This results in an air-bone gap without pathology in the middle ear\(^{(10)}\). Electronistagmography (ENG) can help diagnose SSCD where nystagmus occurs when tympanometry and valsalva are performed. A 100-110 dB stimulation examination at 125-4000 Hz will show vertical and torsional nystagmus. Fistula examination revealed vertical and torsional nystagmus with a slow phase moving away from the side of lesion, but valsalva examination revealed nystagmus in the opposite direction\(^{(11)}\).

The results of temporal CT scan in this patient showed dehiscence of the right superior semicircular canal. Temporal CT scan is the main modality in diagnosing SSCD, especially if the patient is planning for surgery. Normal view of the superior semicircular canal has 3 layers of roof, namely the otic capsule, trabecular bone and bone cortex. These three layers can be clearly seen on a temporal CT scan with 0.5 mm thickness. The recommended CT scan is multi-axial with a parallel image of the coronal, sagittal and axial slices with a thickness of 0.5 mm. Superiority the picture of dehiscence when viewed from the coronal slice. Temporal reconstruction CT scan with multiple slices can increase the sensitivity and specificity in detecting the presence of SSCD. Dehiscence that appears on one slice can not confirm the presence of dehiscence in other slices\(^{(4)}\).
SSCD therapy can be both conservative and surgical. Conservative is aimed primarily at SSCD patients with mild symptoms. Conservative therapy by avoiding increased intracranial pressure such as straining, blowing hard, air travel, lifting heavy weights, or bending over. These activities can worse the vertigo. Surgical therapy has had high success in reducing vestibular symptoms and autophonia. Hearing symptoms rarely improve after surgical therapy\(^{(12)}\).

Surgical therapy may involve window reinforcement, resurfacing, and plugging / occlusion techniques. The reinforcement window has a high recurrence rate in the long term and is less effective in reducing symptoms of autophonia. This technique is usually combined with resurfacing and occlusion techniques. Resurfacing technique is to give flap over the dehiscence of the canal with a special material to prevent the transmission of intracranial pressure into the inner ear. The materials used can be bone, cartilage, fascia or ceramic implants. This technique can be effective in reducing the symptoms of vertigo and autophonia. The occlusion technique is clogging the canal thereby eliminating the function of the semicircular canal\(^{(12)}\).

The operation can be performed by trans cranial medial fossa, transmastoid, and transcanal approaches. The cranial media fossa approach is a traditional technique with first craniotomy to find arcuate eminence and areas of dehiscence. The transmastoid approach is less invasive than craniotomy. This approach also allows for plugging and resurfacing through a mastoidectomy. The success rate for this approach is also quite high at 94%. The transcanal approach is the newest technique by strengthening (reinforcement) the foramen ovale or rotundum. This technique can reduce the risk of complications of facial nerve paralysis, cerebrospinal fluid leakage, and intracranial hemorrhage\(^{(13)}\).

**Conclusion**

A 65 year old woman diagnosed with SSCD showed symptoms of the Tullio phenomenon, namely vertigo when hearing loud sounds, especially low frequencies. On audiogram examination, bilateral sensorineural deafness and air-bone gap of the right ear were found at low frequency (250 Hz). Temporal CT scan showed dehiscence of the right superior semicircular canal. Romberg’s test results, Gans test and Fukuda’s step test gave positive results to the right. Therapy in patients is carried out conservatively.

Estimation of Stature by Measuring Ring Finger Length in Young Adults

Arijit Datta¹, Manish Kumar Singhal², Rachna Agarawal³, Preeti Tiwari⁴
¹Associate Professor, Forensic Medicine, Manipal Tata Medical College, Jamshedpur; ²Associate Professor, Pathology, Government Medical College, Bharatpur; ³Assistant Professor, Anatomy, Government Medical College, Bharatpur; ⁴Assistant Professor, Community Medicine, Manipal Tata Medical College, Jamshedpur

Abstract

Background: The “anatomical” and “mathematical” methods are the two main types of adult stature estimation methods available. Till date, most of the studies on stature estimation have used the length of bones such as femur, humerus, radius, etc. Very limited work has been done to estimate stature from finger length, as there is very little literature available for the same.

Aim: Measurement of ring finger to estimate the stature in young adults

Material and Methodology: A correlation study was conducted with the approval of institutional Ethical Committee during the period of May 2017 to October 2014 among 500 adults. All the right handed males and females in the age group of 22 to 40 years were included in the study. Individuals having congenital defects on right upper limb, congenital defects on right lower limb, pregnant woman, previous history of fracture in upper limb or lower limb or any bony malformation due to rickets, osteomalacia was excluded from the study. Data analysis was done using SPSS 17.

Results: In the study 49.8% of the participants were males with mean age of 31.18 ± 5.54 and females with mean age of 32.14 ± 6.36. Mean stature among males was 162.51 ± 7.56 cm and in females it was 153.59 ± 5.21 cm. The mean value of ring finger length in males and females were 7.02 ± 0.42 cm and 6.40 ± 0.67 cm respectively.

Conclusion: Ring finger length showed higher and better correlation coefficient values among males as compare to females.

Key words- stature, height, ring finger, young adults

Introduction

Dwight proposed in 1894 that because human populations differ in physical features, it is only natural that their bones should differ as well. Dwight’s theories and discoveries influenced the foundation and development of a new field in psychology. Dwight’s ideas and discoveries influenced the foundation and development of a new field of forensic science known as forensic anthropology, earning him the title of “Father of Anthropology”. The study of ante mortem histories of people using skeletonized remains is referred to as forensic anthropology. In suspected cases of infanticide, murder, or suicide, it is thus useful in a medicolegal context. Disaster Victim Identification is the process of determining the identity of dismembered or otherwise unidentified human remains in the cases of mass disasters such as explosions, bomb blasts, mass killings, transportation crashes, and natural calamities (DVI). The methods used to positively identify deceased victims of a multiple casualty event are referred to as disaster victim identification. The practice of estimating stature began in the late twentieth century. The “anatomical” and “mathematical” methods are the two main types of adult stature estimation methods available. Dwight first
proposed the anatomical method in 1894, which entails articulating the entire skeleton on a measuring board, correcting for the curvature of the spine, and then adding a correction factor for soft tissue and skin to estimate stature\textsuperscript{5}. Folly\textsuperscript{6} reintroduced anatomical method with minor variations in 1956, which he called Fully’s procedure. The major disadvantage of the anatomical method of estimating stature is that it requires a nearly complete skeleton. Regression formulae (or ratios) based on the correlation of individual skeletal components to living stature\textsuperscript{7} are used in the mathematical method. In 1899, Karl Pearson\textsuperscript{8} succeeded in developing the first formal stature regression formulae for estimating stature from long bone measurements. The femur and tibia are the most precise long bones to use for this analysis\textsuperscript{9, 10}. Anthropologists may measure long bones found in human remains and apply their measurements to mathematical linear regression equations, which were first proposed by Allbrook in 1961.\textsuperscript{13} These equations were created specifically to estimate the stature of an unclaimed cadaveric body or a missing individual, where long bone data from a particular population can be used to calculate the estimated stature using a linear regression equation, which is then compared to the missing individual’s reported stature. Age, sex, and race are all factors in experiments that use a mathematical method to estimate stature\textsuperscript{11, 12, 13, 14}. Trotter contributed to the development and refinement of mathematical methods for calculating stature\textsuperscript{15}. They compared the data collected from American soldiers to cadaver lengths and came to the conclusion that 0.06 cm would be multiplied from calculated body length for subsequent years after the age of 30. The estimated stature (age 30) should be used as a correction formula\textsuperscript{16}. They had the opportunity to test and assess their previously established formulae after conducting additional research on soldiers following the Korean War. They could also assess differences in growth and proportion among American soldiers. These experiments were performed on the humerus, femur, tibia, and fibula, and the researchers determined that stature estimation formulae should be recalculated within appropriate time intervals, even for the same racial population. When a full dead body is discovered, determining the individual’s stature is relatively simple; however, when only parts of the body are available, determining the individual’s stature is difficult.\textsuperscript{17} Till date, most of the studies on stature estimation have used the length of bones such as femur, humerus, radius, etc. Very limited work has been done to estimate stature from finger length, as there is very little literature available for the same. Hence this study intends to fill this lacuna and looks into the possibility of estimation of stature by measuring the length of ring finger, to estimate the stature using the mathematical method among native adult population of a village in Dakshin Kannada district, Karnataka, India, which will be of great importance to anthropologists and forensic experts.

**Aim**

Measurement of ring finger to estimate the stature in young adults

**Methodology**

**Materials**

The material used to conducted this study includes stadiometer to measure height, digital sliding calliper to measure ring finger length

**Methods**

A correlation study was conducted in Harekela village with the approval of institutional Ethical Committee during the period of May 2017 to October 2017 among 500 adults constituting 250 males and 250 females falling in the age group of 22 years to 40 years.

To calculate the sample size, correlation coefficient value (r value) was selected which was least among all the previous studies. The correlation coefficient value found was 0.546\textsuperscript{26} at 5% of level of significance with power of study as 90%. Considering the r value as 0.546, sample size was found to be 152. To increase the impact of the study correlation coefficient value was anticipated as 0.3 at 5% of level of significance at 80% of power. The sample size was found to be 438 but for the feasibility to conduct the study round figure of 500 sample size was taken where 250 were males and 250 were females.
The sample size of the present study was calculated using the following formulae

\[ n = \frac{2(Z_{\alpha} + Z_{\beta})^2}{C^2} + 3 \]

Where

\[ Z_{\alpha} = 1.96 \text{ at 5\% level of significance} \]
\[ Z_{\beta} = 0.8416 \text{ at 80\% power} \]
\[ C = 0.5 \ln \left( \frac{1+r}{1-r} \right) \]
\[ r = 0.30 \]

Required sample size = 438

Sample size taken by investigator = 500

All the right-handed males and females in the age group of 22 to 40 years (ref) were included in the study; systematic random sampling method was adopted to select the participants for the study. Individuals having congenital defects on right upper limb, congenital defects on right lower limb, pregnant woman, previous history of fracture in upper limb or lower limb or any bony malformation due to rickets, osteomalacia was excluded from the study.

The procedure and purpose of the study was thoroughly informed and explained to the study population. Information sheet was given to the study group where detail information regarding the importance of study was mentioned and a written informed consent was taken from all study subjects. Measurements of female participants were taken in presence of female colleague.

**Technique of measuring Stature**

Stature was measured accurately using stadiometer where participants were made to stand in erect posture on the board of standard stadiometer platform by keeping the foot in close contact without any footwear and arms hanging by the side, the trunk braced along the vertical board and eyes looking straight ahead and face adjusted in Frankfurt plane. The measurement was taken as maximum distance from floor to vertex of the head by bringing the horizontal sliding bar to vertex 19.

**Technique of measuring ring finger length**

Ring finger length was also calculated using the digital sliding caliper. Participants were advised to extend their hand and to keep it on flat table then the distance between the midpoints of the proximal crease of ring finger to the tip of the ring finger was measured 20.

To avoid diurnal variation all the measurements were taken during the same time period 21.

**Results**

The study population consisted of 249 males (49.8\%) with mean age of 31.18 ± 5.54 and 251 females with mean age of 32.14 ± 6.36 (fig 1). Mean stature among 500 individual was found to be 158.03 ± 7.87 cm. Mean stature among males was found to be 162.51 ± 7.56 cm and in females it was found to be 153.59 ± 5.21 cm. The mean value of ring finger length in males and females were 7.02 ± 0.42 cm and 6.40 ± 0.67 cm respectively. Males had an average height of 162.51 ± 7.56 cm while females had average height of 153.59 ± 5.21 cm. There was statistically significant difference across the group (p<0.001) (table 1). Significant correlation was found across ring finger length with stature (table 2). Males showed better correlation than females across stature and ring finger length and it was found to be statistically significant (table 3). Table no 4 provide the R square value of the predictor for RFL in case of males and females along with whole population. It is also showing the ring finger length as a predictor to determine stature is better in males than females.

Formula derived by using regression analysis to estimate stature from RFL (table 5)-

In case of males, \( \text{Stature} = 88.91 + 10.481 \times \text{RFL} \)

In case of females, \( \text{Stature} = 142.723 + 1.697 \times \text{RFL} \)

In case of whole population, \( \text{Stature} = 114 + 6.554 \times \text{RFL} \)

Dependent variable: Stature

Discussion

Mean age of study population

Present study was conducted among 500 individuals among rural Mangalore population with mean age of 31± 5 years, out of those 249 were males and 251 were females with mean age of 31±5 years and 32±6 years respectively. In the study done by Bardale R.V et al.
the mean age of male population was 21.52 years and the mean age of female population was 20.08 years. While in the study conducted by Krishan K to estimate the stature from index and ring finger length subjects were in the age group of 14 to 18 years.

**Mean stature of study population**

We found that in our study mean stature among 500 individual was found to be 158.03 ± 7.87 cm. Statistically significant stature difference between males and females was found in our study, mean stature among males was found to be 162.51 ± 7.56 cm and in females it was found to be 153.59 ± 5.21 cm. But in the study conducted by shivakumar AH in South India and Chikhalkar BG in Mumbai mean stature was found quite high in their studies as compared to the present study which was 167 ± 0.10 cm and 167.26 ± 8.494 cm respectively. Study conducted by Bardale RV et al found that the mean height of men was 171.6 cm and mean height of women was 157.3 cm his study. The mean height for Oriya males was observed to be about 162 cm and 152 cm for females respectively Studies done on international platform too showed varying results like in the study done by Habib SR et al showed mean stature in Egyptian males to be 174.61 ± 7.34 cm and among Egyptian females to be 160 ± 5.45 cm. Ahmed AA found mean stature among Sudanese males to be 174.71 ± 5.72 cm and 160.43 ± 5.49 cm among Sudanese females.

**Discussion on ring finger length**

In the present study the mean ring finger length of the study participants was 6.71 ± 0.64 cm. Significant difference was observed between ring finger length of males and females which was found to be 7.02 ± 0.42 cm in males and 6.40 ± 0.67 cm in females. In a study conducted by Krishan K the mean ring finger length was 7.26 cm in males and 6.73 cm each in females respectively. Bardale R.V et al found that the ring finger showed significant difference (P < 0.001) between stature of male and female subjects. Amongst males, correlation was higher between the ring finger length and stature (r = 0.546). Raju GM et al found that in his study there was significant difference between stature and ring finger length (p< 0.001), the correlation coefficient value in males was 0.57 and in females 0.43. Krishan K et al showed that ring finger length measurements was significantly larger in males than females (P-value < 0.001), statistically significant correlation was observed between stature and ring finger lengths.

In present study, Table no 4 provide the R square value of the predictor for RFL in case of males and females along with whole population. It is also showing the ring finger length as a predictor to determine stature is better in males than females.

Formula derived by using regression analysis to estimate stature from RFL (table 8)-

In case of males, Stature= 88.91 + 10.481 x RFL

It shows that per unit increase in RFL there is 10.481 cm increase in stature of males

In case of females, Stature= 142.723 + 1.697 x RFL

It shows that per unit increase in RFL there is 1.697 cm increase in stature of females

In case of whole population, Stature= 114 + 6.554 x RFL

**Conclusion**

- Ring finger length showed higher and better correlation coefficient values among males as compare to females

**Conflict of Interest**- Nil

**Source of Funding**- Nil

Abstract

Annotation. The article reveals validation studies of the method of quantitative analysis of high-performance liquid chromatography of a complex and multicomponent original sedative drug produced in the Republic of Uzbekistan. Criteria for repeatability, accuracy, precision, intermediate accuracy and correlation coefficients for drug validation were determined. The analytical method for determining the number of tablets covered with a film “Sedarem” from the proportion of valeric acids in the main active ingredients of the drug was determined on the basis of the 5th series of the “Accuracy” indicator. The accuracy of valeric acid is judged from at least 5 data obtained for each of the 3 levels lying within the analytical domain of the quantification method. Comparing the results of determining the amount of valeric acid, it turns out that there is no statistically significant difference between them, that the three time points for each series are mutually compatible.

The analysis procedure for determining the amount of phenolic compounds in the preparation, when comparing “Precision” with the results of determining the amount of phenolic compounds at different intervals and on different days, which characterizes repetition and “intermediate precision,” it was found that there is no statistical reliable difference between them, and three time points for each series are mutually compatible. Study of drug linearity from flavanoid fraction was carried out in the range from 80 to 120% of nominal value of analytical parameters.

Keywords: “Sedarem”, tablet, high performance liquid chromatography, repeatability, accuracy, precision, intermediate precision and correlation coefficient.

Introduction

Due to the high efficacy of sedatives and the absence of side effects, these drugs are widely used in everyday medical practice, especially in the treatment of elderly patients. According to the classification, drugs based on medicinal plant raw materials are widely used among sedatives. Progress, life growth at a rapid pace further increases the need for sedatives1,3.

An effective technology for preparing dosage forms with optimal technological indicators of the proposed original sedative has been developed, standardization methods, quality and validation standards have been established.

The validation criteria of the Sedarem sedative tablet quantitative analysis method, coated with cladding, were determined by the following indicators: accuracy, repeatability, linearity, precision, intermediate accuracy and correlation coefficient3.

Aim of the Research: Study the possibility of determining the validation criteria for Sedarem with a coating.

Materials and methods: Quantitative analysis of the sum of the main active ingredients in the coated
tablet, i.e., carboxylic acids with respect to valeric acid, flavonoids with respect to routine, as well as phenolic compounds with respect to rosmarinic acid, was carried out on an Agilent Technologies 1200 liquid chromatograph with a UV detector.

A suitable chromatographic column S-18 is Zorbax Eclipse with a particle size of 5 μm, filled with a sorbent of 4x100 m.

The validity criteria of the method of quantitative analysis of sedative tablets “Sedarem” coated with the shell were determined on the following parameters: accuracy, repeatability, linearity, precision, intermediate precision and correlation coefficient. To study the possibility of determining the criteria for validation of the drug “Sedarem” coated with the shell. Quantitative analysis of the sum of carboxylic acids relative to valerian acid, flavonoids relative to routine, and phenolic compounds relative to rosemary acid was performed on Agilent Technologies 1200 liquid chromatograph, UV detector. A suitable chromatographic column S-18 is a Zorbax Eclipse filled with 4x100 mm sorbent with a particle size of 5 mm.

The results were processed in the method of variance statistics, according to the Student’s criterion, at p = 0.05. The tables show the arithmetic mean (M), the corresponding standard error of error (m), the Student Criterion (t), the number of choices (n), and the confidence limit (lower confidence limit ÷ high confidence limit) 4.

Results and Discussion

Validation of the method of quantitative determination of the medicinal form of the tablet coated with a shell, “Sedarem” on valerian acids “Correctness”. It is known that the accuracy of the method is characterized by the deviation of the average result of its definitions from the values obtained as correct 1. The tested method is considered valid if the values obtained as true are at reliable intervals corresponding to the average results of the analyses obtained as a test for this method. After determining the quantity of the preparation by the fraction of valerian acids in different series, the following results were obtained, and the results are given in Table 1. If we compare the results of determining the quantity of valerian acids in five different series of the preparation under test, there seems to be no statistically significant difference between them, the results of exactly five series are mutually compatible. The analytical method for determining the amount of Sedarem tablets coated with valerian acid corresponds to the requirements of validation on the indicator “Accuracy”.

The accuracy of the method is explained by the dispersion of the results obtained using it relative to the average result value. The criterion of such dispersion is the value of standard deviation of the result of a specific unit obtained to select a sufficiently large volume 2,3. For any method of quantification of accuracy, the quantification method is estimated from the results of at least 5 data obtained for each of the 3 levels (low, medium and high) lying in the analytical domain of the method.

Repetition (similarity). Repeatability of the analytical method has been evaluated based on independent results obtained in a short time in the same laboratory under the same conditions. Intermediate precision in the laboratory. Intermediate accuracy in the laboratory of the approved method was evaluated in one laboratory 5. Five sets of Sedarem-coated tablets were used in the analysis. After analyzing the tablets on the indicator “Precision”, which characterizes the similarity of the repeatability of the results of quantitative determination of the drug, the following results are given in Table 1.

If we compare the results of testing valeric acids of five different series of drugs, it becomes clear that there are no statistically reliable differences between them, exactly five series are mutually compatible 6.

After checking for intermediate precision, the following results were obtained and are presented in Table 1.
Table-1.: The results on the accuracy of the quantitative determination precision analysis repeatability and intermediate precision of the results of quantitative determination of the drug on the presence of valeric acids (M±tm; p=0,05; n=5)

If the results of determining the amount of ivaerian acids in different time intervals are compared, it appears that there is no statistically significant difference between them, that the three time points for each series are mutually compatible. The method of analysis for quantitative determination of valeric acid content of cedarem shell-coated tablet meets the validation requirements on the indicators of “Precision”, which characterizes the repeatability (similarity) and “Intermediate precision”. The linearity of the method is that the method of the analytical signal depends on the concentration or amount of the analyte detected in the sample under analysis, within the scope of the analysis. In method validation, its linearity in the field of analysis is verified by testing, by analytical measurements for at least five samples with complete amounts or concentrations of the analyte.

To determine the linearity of the range in the analytical field (80–120%), we calculated a correlation coefficient (R), which should be R ≥ 0,99.

Research results. Due to the requirements for the size of the analytical area of the methodology in the range of 80 to 120% of the nominal value of the analytical indicator to be determined, the following results obtained are given in Table 2.
Table 2. Results of the study of the preparation linearity by the fraction of valerian acid, (in the analysis the area is 80-120% (n = 5)

In accordance with the requirements of the 12 edition of GPh, in the joint venture “Remedy group” shell-coated tablets “Sedarem” meet the linearity of the drug in five series, in the field of analysis (from 80 to 120%).

The methods of analysis for determining the amount of valerian acid in a cedar-coated tablet met the validation requirements for the “Analysis Area” and “Linearity” indicators.

The validation of the method for determining the amount of phenolic compounds in shell-coated tablets “Sedarem”. After determination of the quantity of the pharmaceutical form by the fraction of phenolic compounds in different series, the following data were obtained. The obtained results are presented in Table 3.

If the results of determining the amount of phenolic compounds in five different series of the tested drug are compared, there is no statistically significant difference between them, the results of exactly five series are mutually compatible. The method of analysis for the determination of the amount of phenolic compounds in the drug “Sedarem” coated tablets meets the requirements...
of validation on the indicator “Accuracy”. Following the determination of the drug on the indicator “Precision”, which characterizes the repeatability of the results of the determination of the amount of the drug, the following data were obtained (Table 3).

If we compare the study of five different series by the

If we compare the results of determining the number of phenolic compounds at different time intervals and on different days, it turns out that there is no statistically significant difference between them, that three time points for each series are mutually compatible.

The method of analysis for determining the number of phenolic compounds in the form of shell-coated tablets “Sedarem” meets the requirements of the validation for “Accuracy”, which characterizes the reproducibility and “Intermediate Accuracy”.

In connection with requirements to the size of the analysis methodology area in the range from 80 to 120% of the nominal value of the identified analytical indicators, the following results were obtained (Table 4).
Table-4: Results of the study of linearity of the preparation in terms of the share of phenolic compounds, when the analysis area is 80-120% (n=5)

In accordance with the requirements of the 12 edition of GPh, in the joint venture “Remedy group” shell-coated tablets “Sedarem” meet the linearity of the drug in five series, in the field of analysis (from 80 to 120%). The method of analysis for determining the amount of phenolic compounds in shell-coated tablets “Sedarem” meets the requirements of validation on the indicators “Area of analysis” and “Linearity”.

Validation of the method of quantitative determination of cedarem shell-coated tablets by flavonoids

After determining the amount of flavonoids in different series of the drug, the following data were obtained (Table 5).

If the results of determining the amount of flavonoids in five different series of the tested drug are compared, there is no statistically significant difference between them, the results of exactly five series are consistent. The analytical method for determining the amount of flavonoids in the shell-coated tablets “Sedarem” met the validation requirements on the indicator “Accuracy”.

After checking the dosage form on the indicator “Precision”, which characterizes the repeatability of
the results of quantitative determination of the drug, the following results were obtained (Table 5).

Determining the proportion of flavonoids of the drug in five different series, there is no statistically significant difference between them, the results of exactly five series are mutually compatible.

The following data were obtained after the intermediate precision test analyzes (Table 5)

Study to Assess the Prevalence of Mobile Phone Addiction Among Adolescents with Selected Demographic Variables

Arti1, Rahul Gusian2, Anamika Gautam2
1Assistant Professor, 2Nursing Tutor, Department of Mental Health Nursing, Shree Guru Gobind Singh Tricentenary University, Gurugram, Haryana, India

Abstract

Introduction: Adolescence is a time of moving from immaturity of childhood to maturity of adulthood. Technologies especially the mobile phone has considerably the new epidemic in century. It has become an essential part of the modern community and necessities in the people’s lifestyle over the past decade and gained unparallel fame because it facilitates communication between individual and shortening distance, a good investment of time.

Method: It was a Descriptivestudy conducted amongst 100 consented students of age 13-18yr of Gurugram schools. Data was collected through a self – structured questionnaire to assess the prevalence of mobile phone addiction among adolescents.

Result: Prevalence of smartphone addictions shows majority 65% adolescent are at high risk to develop smartphone addiction, 26% are at mild level of addiction and remaining 9% are at severe level of addiction. The chi square association of prevalence of mobile phone addiction among adolescent with selected demographic variables (0.003) was found to be statistically significant with standard only, whereas showed know no statistically significant association with other demographic variables

Conclusion: Study concludes that Prevalence of smartphone addictions shows majority 65% adolescent are at high risk to develop smartphone addiction, 26% are at mild level of addiction and remaining 9% are at severe level of addiction.

Keywords: - Adolescence, smartphone, addiction

Introduction

Adolescence is uniquely different from all other stages of human development, especially from physiological and cognitive perspectives, and it can be argued that it is the most challenging of all developmental periods. Addiction is considered by WHO (WHO Expert Committee – 1964) as dependence, as the continuous use of something for the sake of relief, comfort or stimulation which often causes cravings when it is absent.1

Technologies especially the mobile phone has considerably the new epidemic in century. It has become an essential part of the modern community and necessities in the people’s lifestyle over the past decade and gained unparallel fame because it facilitates communication between individual and shortening distance, a good investment of time.2 The mobile phone is a two-edge sword; it has both positive and negative

aspect. Excessive mobile phone use tends to lead to the certain of a non-chemical addiction, most commonly known as “mobile phone addiction”.

Smartphone offers several conveniences in our life, but we also need to be aware of the negative effects of smartphone use, the most concerning aspect being smartphone addiction. Smartphone addiction is a phenomenon that pertains to uncontrollability of smartphone use. People with this problem encounter social, psychological and health problems.

Students may disturb others through ring tones and they also misuse cell camera. They can use their cell phones to write and send text messages, take and send digital photos, and even take and send short digital video clips, in addition to making phone calls. Nearly all the user can become inappropriate and undesirable in middle and high schools classrooms.

A conducted a cross sectional observational study on 382 students to know the magnitude of Smartphone addiction among students of the medical university at Yenepoya university campus, Mangalore, Karnataka state, south India. Study concludes that 46% of students using Smartphone 4-6 hours per day and main use of Smartphone were for social networking. Based on cut off values, 36.8% of students were addicted to Smartphone.

A conducted a descriptive study to assess the risk of developing nomophobia among adolescents in selected PU colleges at Bangalore. The study revealed that there is a statistically significant association between the risk level and selected socio demographic variables. There was a moderately positive correlation between pattern of mobile phone usage and risk of nomophobes ($r = +0.83$) which was significantly associated at 0.05 levels.

A conducted a study to assess the severity score of mobile phone use and internet use among 114 Bsc. Nursing students at Manipal college of Nursing, Manipal. Result revealed that most of the subjects 50 (43.9%) belongs to 19-20 years of age. 1.8% subjects reported of having mild addiction to mobile phone use. 2.6% subjects had moderate and 30.7% had mild internet addiction.

**Methodology**

The study was done with quantitative approach and non-experimental design was adopted. The setting of the study was in Gurugram, Haryana. The sample was 100 students and convenient sampling was used for study. Self-structured questionnaire was prepared to assess the prevalence of mobile phone addiction among adolescents. The researcher had conducted a pilot study on minimum 10% of the sample and that sample was excluded from the main study. Approval from the research and ethical committee of SGT University, faculty of nursing was taken to conduct the research to assess prevalence of mobile phone addiction among adolescents. Permission for data collection was taken from Principles of various schools of Gurugram. Written consent was taken from students before asking questions and confidentiality of information was maintained.

**Statistical Analysis**

The collection of data were appropriate descriptive statistics using frequency, percentage, mean, mode, median and SD of different variables. The Chi-square test were used for the analysis of data. Value of $P< 0.05$ was considered statistically significant. The IBM statistical Package for the Social Sciences (SPSS) Version 16 was applied to analyse the data.

**Results**

The findings are summarized as follows: Majority (64%) of the samples belong to age group is 15-16. 53% of the total samples were studying in 10th standard. 59% of the total samples were male. Mostly i.e. 89% samples were living in urban area and belong to nuclear family (72%). Majority of parents of samples were graduated.

Prevalence of smartphone addictions shows majority 65% adolescent are at high to develop smartphone addiction, 26% are at mild level of addiction and remaining 9% are at severe level of addiction.
Chi square association of prevalence of mobile phone addiction among adolescent with selected demographic variables (0.028) was found to be statistically significant with standard only, whereas showed know no statistically significant association with other demographic variables.

**Discussion**

The Study concluded that the majority (64%) of the samples belongs to age group is 15 -16. 53% of the total samples were studying in 10th standard. 59% of the total samples were male. Prevalence of smartphone addictions shows majority 65% adolescent are at high to develop smartphone addiction, 26% are at mild level of addiction and remaining 9% are at severe level of addiction

The findings of the study were supported by the study done by Prekshaa Jai 1, Sachin Ratan Gedam2Pradeep S Patil3 (2019). Objectives of the study were to estimate the prevalence of smartphone addiction, to understand its pattern of use, and to determine association of smartphone addiction with pattern of use and personality dimensions among medical students. Study revealed that the prevalence of smartphone addiction was found to be 24.65% with high risk of addiction being 7.53% and 17.12% among males and females respectively.

The smartphone addiction was associated with smartphone use duration on a typical day, frequency of use, and most personally relevant smartphone function (p<0.05). The personality dimensions, such as assertive-submissive, depressive-non depressive, and emotional instability-emotional stability also had significant association with smartphone addiction (p<0.05); and these dimensions were also found to be predictors along with duration of use on multivariate analysis.7

In other study done by Ashwini dongre et al (2017) a cross sectional exploratory study to assess the prevalence of nomophobia among mobile phone users; to study the cell phone dependence pattern among adults; and to study the health effects of mobile phone usage. Study conclude that a higher proportion of males (82.91%) were dependent on mobile phone compared to females (31.25%). The most common 13 selfperceived symptom due to increase mobile phone usage was lack of sleep (70.61%) followed by eyestrain (42.46%).8
The study done by Arpita kumari et al (2013) to assess the severity score of mobile phone use and internet use among 114 Bsc. Nursing students at Manipal college of Nursing, Manipal. Result revealed that most of the subjects 50 (43.9%) belongs to 19-20 years of age. 1.8% subjects reported of having mild addiction to mobile phone use. 2.6% subjects had moderate and 30.7% had mild internet addiction. 

The present study of concluded that the chi square association of prevalence of mobile phone addiction among adolescent with selected demographic variables (0.028) was found to be statistically significant with standard only, whereas showed know no statistically significant association with other demographic variables.

The findings supported by the study done by Seonq-soo cha, Bo-kyunseoa(2018) on 1824 middle SCHOOLS student in South Korea to examine smartphone use patterns, smartphone addiction characteristics, and the predictive factors of the smartphone addiction. Result revealed that among 1824 participants, 563 (30.9%) were identified as a risk group for smartphone addiction and 1261 (69.1%) were classified as a normal user group according to their scores on the Smartphone Addiction Proneness Scale.

Our study concluded that majority of the adolescent students were prone to develop smartphone addiction. The study also concluded that there is association between smartphone addiction and standard class. It can be concluded that 9th and 10th standard students are prone to develop smartphone addiction.

There is a considerably debate on addiction and abuse to smartphone among adolescents and its consequent input on their health not only in a global context, but also specifically in the Indian population. The adolescents between 14-18 teens 96% of them have at least one mobile phone and 22% of them own multiple mobile phones.

Over usage of mobile phone leads to physiological and psychological health hazards. Apart from the various benefits of cell phones, it’s over usage leads to mobile phone addiction. It is the biggest non drug addiction in the world. The world health organization confirmed that mobile phone use may represent a long term health risk, classifying mobile phone radiation as a “carcinogenic hazard” and “possibly carcinogenic to human”.

**Conclusion**

This chapter present conclusion drawn based on the present study. The study attempts to assess the prevalence of mobile phone addiction among adolescents in selected schools of Gurugram. Study concludes that Prevalence of smartphone addictions shows majority 65% adolescent are at high risk to develop smartphone addiction, 26% are at mild level of addiction and remaining 9% are at severe level of addiction.

**Future implications**

In service and continuing education programs should be organized for schools as well as college students regarding mobile phone addiction. This aids to prepare the school going students to prevent themselves from the addiction. Schools teachers need to lay emphasis on the mobile phone addiction.

**Limitation**

The study was limited to only one setting. The time duration for the study was limited.Only prevalence was assessed no attempts was made to identify other attributes.

**Ethical Statement**

Approval from the research and ethical committee of SGT University, faculty of nursing was taken to conduct the research to assess prevalence of mobile phone addiction among adolescents. Permission for data collection was taken from Principles of various schools of Gurugram

**Declaration of participants consent**

Written consent was taken from students before asking questions and confidentiality of information was maintained.

Comparison of Gender Prediction Accuracy between Regression Models Derived from Hand, Foot Measurements and Long Bone Measurements in a Sample of Kolhapur Population

Arun S. Karmalkar¹, Vasudha R. Nikam²

¹Associate Professor ²Professor and Head, Department of Anatomy, D.Y. Patil Medical College, D. Y. Patil Education Society (Deemed University), Kolhapur, Maharashtra, India

Abstract

Introduction: Here, we aim to compare the accuracy of the regression formula derived to predict gender using data on measurements of foot and hand with the formula derived to predict gender using the length measurements data of the long bones (tibia and ulna).

Methods: Patients attending the outpatient services at the Orthopedic Department, and between the age range 18 to 50 years were recruited (n=1000; 500 males and 500 females). Subjects suffering from any kind of bone deformity were excluded. Vallois method was used to estimate the measurements of hand, foot, tibia, and ulna. Regression formulas were obtained from the hand, foot-long bones measurements; to predict gender, using multiple logistic regression.

Results: Differences between male’s and female’s measurements of hand (P<0.001), long bones (P<0.001), and foot (P<0.001) were significant. The accuracy of the model used to predict gender, which was calculated from the dimensions of hand and foot was 81.5%. The accuracy of the model used to predict gender calculated from the long bone measurement was 78.3%.

Conclusions: Dimensions of hand and foot are a better predictor (81.5%) of gender vs the length of long bones (tibia and ulna) (78.3%) in the Kolhapur population.

Keywords: Tibia, Ulna, Foot, Hand, Foot deformities.

Introduction

Measurements of length of bones, hand, and foot vary across both sexes as is established in numerous studies. Consequently, these measurements have been successfully used for the gender estimation of a population.¹,² Sex determination from bone measurements are ofmedico-legal and forensic importance. Experts from forensic fields are called to decipher age, sex, and stature of whole or fragmented skeletal material from many different populations.³ Gender estimation has been done using the measurements of various bodyparts such astrunk, vertebral column, limbs, long and short bones, hand, foot, frontal bone, etc.⁴,⁵ However, pelvis remains the commonly used bone for gender identification, due to its accuracy.⁶,⁷ Other important bones where sexual dimorphisms are distinct and are used for gender assessment are from the postcranial and craniofacial region.⁸,⁹
The advantage of hand and foot measurements for the estimation of gender is that these are easily accessible and would be the most convenient and feasible option for the estimations. Currently, the data on estimation of gender in the population of south-western region of Maharashtra is scarce. The objective of the study was to compare the accuracy of gender prediction model derived from the measurements of hand and foot with the accuracy of a model derived from the measurements of long bones.

Material and Method:
This study was designed to be a prospective, observational study. The participants were recruited from the outpatient service of the Orthopedic Department at a Tertiary care center in Maharashtra. Sample size calculation was done on the R software (version 1.2.5001) using the formula pwr.t.test (d=0.098, power=0.85, sig.level=0.05, type= “one.sample”) where, d = effect size, power = 85%, significance level= 5%. The sample size was calculated to be 937 and therefore a total of 1000 subjects (500 males and 500 females), between the age range 18 to 50 years were recruited. The study was undertaken after the Institutional Ethics Committee approval, and after obtaining a written informed consent from the study participants. Subjects with any kind of bone deformity, injury, fracture of either foot or hand were not included. Standard anthropometric apparatus, a digital Vernier calipers (Mitutoyo, Japan), were used for the measurements. To avoid diurnal variations measurements were performed at approximately same time of the day (3:00-6:00 PM). Height of the cases were recorded as the vertical distance between vertex and floor, using a stadiometer. Foot length measurements were recorded as the distance from the tip of the hallux to the most prominent point of the back of the heel. Foot breadth measurements were recorded as the distance from the most anterior point of the skin on the middle finger to the midpoint of the distal crease of the wrist joint. Hand breadth measurements were recorded as the distance from the most medially placed point located on the head of the 5th metacarpal to the head of the 2nd metacarpal. Length of tibia was recorded as the distance from the farthest upper point of the medial part of condyle to the lowest point on the medial malleolus. Similarly, ulnar length was measured from the olecranon to the styloid process with elbow being fully flexed and palm spread over the opposite shoulder. Markings were made using a skin marking pencil. Continuous data were analysed using the Mann Whitney U-test test. Multiple logistic regression analysis was performed to derive the equation for gender prediction using R software v 1.2.5001. A P-value of <0.05 was considered as statistically significant.

Results
The Mean±SD age of male volunteers was 32.9±8.9 and the median was 32 years. The Mean±SD age of female volunteers was 33.8±9.4 and the median was 33 years. The average heights (Mean±SD) of the males and females were 166.6±5.6 cms and 157±6.4 cms, respectively. A significant difference (P<0.05) between the heights of participants of different sexes was detected. All the measurements were significantly higher in males when compared with females (P<0.001) (Table 1, 2, 3).

The gender prediction was done with the usage of logistic regression models; one model derived from the measurements of long bones and the other model derived from the data of foot and hand measurements. The odds of the gender being male increased 17.3 times with every unit increase in the right tibial length (P<0.001). The odds of the gender being male decreased 0.06 times with every unit increase in the left tibial length. The odds of the gender being male decreased 0.06 times with every unit increase in the left tibial length (Table 4).

The odds of the gender being male increases 108.21 times with unit increase in length of right foot, 8.94 times with unit increase in hand length of left side, and 53.53 times with unit increase in breadth of left hand. The odds of the gender being female increases 0.012 times with unit increase in length of left foot, 0.49 times with unit increase in length of right hand, and 0.14 times with unit increase in right hand breadth. (Table 5).
The regression equations are presented below for the estimation of gender by long bones, hand and foot measurements:

**Gender estimation by long bones:**

\[-20.8259 + 2.8507 \times \text{Length of Tibia Rt} - 2.8097 \times \text{Length of Tibia Lt} + 0.1480 \times \text{Length of Ulna Rt} + 0.5779 \times \text{Length of Ulna Lt}\]

Equation 1

**Gender estimation by hand and foot dimensions:**

\[-48.5756 + 4.684 \times \text{Foot Length Rt} - 4.4053 \times \text{Foot Length Lt} - 0.4276 \times \text{Foot Breath Rt} + 0.3341 \times \text{Foot Breath Lt} - 0.7048 \times \text{Hand Length Rt} + 2.1906 \times \text{Hand Length Lt} - 1.9575 \times \text{Hand Breath Rt} + 3.9802 \times \text{Hand Breath Lt}\]

Equation 2

The accuracy of the formulae in predicting the gender was found to be 78.5\% (equation 1) and 81.5\% (equation 2) respectively at a cut-off point of 0.5. The cut-off points of 0.5 implies that for values above 0.5, the predicted sex is male and for values below 0.5 the predicted sex is female. Results suggest that measurements of the hand and foot provides a superior prediction of gender as compared to the prediction of gender which was calculated from the lengths of tibia and ulna.

Discussion

Bone dimensions ranging from skull to hands and foot have been effectively used to predict gender in the past for themedico-legal cases and forensic applications. Measurements of hand and foot provide the most feasible options to estimate gender as they are in most cases easily accessible. Here we studied whether measurements of hand and foot could predict gender with an accuracy comparable to that of the long bone dimensions (tibia and ulna).

This study report that gender can be predicted by measurements of hand and foot; with an accuracy of 81.5% and the findings are in line with similar studies reported from other nations. Zebek et al. predicted gender by utilizing measurements of foot with an accuracy of 95.6% in the Turkish population. Similarly, Jowaheer et al., identified gender from the dimensions of hand and foot with an accuracy of 90-92% in an Indo-Mauritian sample.

This study reports the accuracy of gender prediction from the lengths of tibia and ulna was 78.5%. Other studies have already reported excellent data for gender prediction using long bones. Tibia was used to predict gender with an accuracy of 80-84%. In 2019, another study among a Ghana sample showed that gender could be predicted by height of a person with an accuracy of 80.7 %, by ulnar length with an accuracy of 82.3% and by radial length with an accuracy of 75.3 %. A derived equation from a combination of all measurements predicted gender with an accuracy measurement of 82.4%. Likewise, in 2017, among Poland population with the accuracy of gender estimation by radial length
was 84 %. Other long bone such as humerus was also reported to predict gender with the accuracy of 93.3% in an Egyptian sample. Gender prediction has also been calculated by femur dimensions with the accuracy of 72.5% in males, and 85% in females.

Surprisingly, dimensions of hand and foot seems to be a better predictor of gender, than long bones (tibia and ulna) length in the Kolhapur population. The major strength of this study is that it is one of the largest studies conducted to predict gender using data on the measurements of hand and foot. Though other accurate methods of measurements of bone such as radiographs, scanograms, computerized digital radiographs and computerized tomography (CT) are available, measurement methods adopted in the present study; is easily reproducible and cost effective as it does not require costly equipments.

This study is a first-time report on the approximate dimensions of foot and hand, and their utility in the prediction of gender in a sample of Kolhapur population.

**Conclusion**

The regression equation derived in the study can be used to predict gender in the Kolhapur population. Dimensions of hand and foot are better predictors of gender when compared to the length of bones (tibia and ulna) in Kolhapur population.

Biochemical and Histopathological effects of Acetaminophen and Protective Effects of Naringin on Liver Rats

Aryaf Mahmood Sabea1, Ahlam J. H. AlKhamas2, Bashar Sabah Sahib3, Jawad Kadhim Faris4

1Assist. Lecturer, Department of Medical Laboratory Techniques, AL-Hilla-University College, Iraq, 2Assist. Prof., Department of Anatomy and Histology, College of Veterinary Medicine, Al-Qasim Green University, Iraq, 3Assist. Lecturer, Department of Medical Basics Sciences, Faculty of Nursing, University of Al-Qadisiyah, Iraq, 4Prof. Department of Physiology, College of Veterinary Medicine, Al-Qasim Green University, Iraq

Abstract

This study was conducted to find out liver protective activity of naringin (NRG) 40-80 mg/kg body weight (b.w.) against acetaminophen (ACN) 2 g/kg induced liver damage in rats. Thirty two male rats were divided into four groups: group I: negative control, (1 ml/kg Saline orally) group II: positive control ACN (2 g/kg), orally as single dose at first day, group III: ACN (2 g/kg), orally as single dose at first day, plus NRG (40 mg/kg) orally for (8) consecutive days, group IV: ACN (2 g/kg), orally as single dose at first day, plus NRG (80 mg/kg) orally for (8) consecutive days. All the rats were anesthetized to collect blood then killed on the (9) day of the experiment to take the liver samples. ACN induced liver damage was proved by a significant (P<0.01) reduction in the body weight, total protein (TP), albumin (AB), superoxide dismutase (SOD) and catalase (CAT) enzymes and a significant (P<0.01) increased in liver weight, serum aspartate transaminase (AST), alanine transaminase (ALT), alkaline phosphatase (ALP), total bilirubin (TB), direct bilirubin (DB), malondialdehyde enzyme (MAD) and histopathological changes. Protective liver toxicity effect and oxidative damage caused by ACN significantly (P<0.01) increasing in body weight, TP, AB, SOD and CAT and significantly (P<0.01) decreasing in liver weight, AST, ALT, ALP, TB, DB and MAD and improving tissue morphology by a meliorative in NRG 40, 80 mg/kg b.w. These results confirm that NRG antioxidant effects can protect ACN induced hepatic toxicity in rats.

Key words: Naringin, Acetaminophen, Anti-oxidants, liver damage

Introduction

Acetaminophen (N-acetyl-p-aminophenol; APAP), popularly known as paracetamol, is a most common and widely used as analgesic and antipyretic drug that is safe at therapeutic dosages for a wide range of treatments (1). Acute overdose of acetaminophen is known to cause hepatic and renal damage in both human and experimental animals. Nephrotoxicity is less common compared to hepatotoxicity in acetaminophen overdose, but renal damage and acute renal failure can occur even in the absence of liver injury and can even lead to death in humans and experimental animals (2). Paracetamol has been used as a non-narcotic analgesic and antipyretic drugs. This drug works by inhibiting the synthesis of prostaglandins in the central nervous system (3). It is widely used to treat muscle pains, arthritis and acute headaches. It is safe at therapeutic levels, but at high doses it can lead to undesirable side effects such as hepatotoxicity and nephrotoxicity (4). Naringin is a plant flavonoid of great human value. Flavonoids are ubiquitous polyphenolic secondary metabolites isolated from vascular plants (5). They have a general structure of 15-carbon skeleton that contains two phenyl rings A, B and a heterocyclic ring C. Flavonoids are the most important flavonoids participating in the stress responses of plants (6). Approximately 8000 flavonoids have been identified from various citrus fruits, vegetables and beverages (7). They behave as chemical messengers, pollinator attractants and stress regulatory
elements of plants (8). Flavonoids also exhibit human health promoting abilities like antioxidant and free radical scavenging potential (9). They act as antiviral, antibacterial, anti-inflammatory, vasodilator, anticancer and ant ischemic agents(10). Flavonoids can undergo various metabolic transformations such as methylation and sulfation to change their structures and hence their biological activities (11).

Materials and Methods

This study was conducted during November 2020 in the Physiology Department of Veterinary Medicine of AL-Qassim green university.

Drugs

Naringin (NRG) 100% Natural was purchased from BULK Supplements.com USA. Paracetamol, (Qnardol –SR 1g) from Star biomed -India. Ketamine 10% inj. from KEPRO- HOLLAND. Xylazine, XYL- M2, VMD- Belgium.

Experimental Rats

The number of laboratory animals used in the experiment are thirty two healthy male rats at aged (170-180) days and weighted (200-210) grams, obtained from the animal house of the College of Veterinary Medicine, AL-Qadisiya University, were kept for (10) days as acclimatization period before the starting of the experiment, all rats were feed on concentrated food (pellets) and were given plain water, the animals room temperature was (19-23)°C, and the humidity was (45-55), that room was washing and sterilization once a week.

Experimental design

After a quarantine period of (10) days, the animals were divided into four equal groups, each group consist of (8) rats, and they received the treatment as follows:

Group I: Negative control received normal saline (1 ml/kg b.w orally by stomach tube), daily for (8) days. Group II: Positive group were treated ACN (2g/kg) orally by stomach tube as single dose at first day, then NRG (40 and 80 mg/kg b.w) orally by stomach tube, per day, respectively, for (8) days. The doses of treatment are according to Kumar et al., (13).

Body and liver weight

All animals were weighed before and after treatment, changes in the body weights of rats were recorded, in addition to the weights of rat livers, with using digital electronic balance.

Sacrifice Animals and Serum Preparation

At the end of experimental period, rats were fasted for (10) hrs, rats were anaesthetized with ketamine (75 mg/kg) combined with xylazine (2.5 mg/kg). Blood samples were collected by heart puncture in non-heparinized tubes, centrifuged at (4000) rpm for (10) minutes. After separation the serum from the clot, using a sampler, the samples were used to measurement of serum biochemical parameters for liver function tests AST, ALT, ALP, TP, AB, TB, DB and oxidative stress parameters in liver MAD, SOD and CAT. The rats were sacrificed by cervical dislocation and the abdominal cavity was immediately opened, liver tissues were excised and weighed immediately after sacrifice. livers were processed for histopathological and immunohistochemical studies.

Histopathological techniques

Sections were taken from livers of the animals in each group immediately after sacrificed. These tissues were washed with the normal saline solution to remove blood, then fixed in 10% neutral formalin for (24) hrs, dehydrated in different concentration of alcohol, and processed for paraffin embedding. Sections of (5) µm thickness were cut using a rotary microtome. The sections were processed and passed through graded alcohol series stained with Haematoxylin and Eosin, cleared in xylene and examined microscopically according to (15).
Statistical Analysis

The statistical results of the data were analyzed according to Complete Randomized Design (C.R.D.) (16). The mean differences between the averages of the studied traits were determined at the probability level of (0.01) using the Duncan test (17).

Results

Body, liver weight after treatment

Oral administration of ACN at a dose of 2g/kg caused a significant (P<0.01) decrease in body weight and a significant (P<0.01) increase in liver weight. Treated rats with NRG 40 mg/kg and NRG 80 mg/kg showed significant (P<0.01) increase in body weight and significant (P<0.01) decrease in liver weight was observed (Table 1).

Serum biochemical analysis

The administration of ACN to rats resulted in a significant (P<0.01) reduction in serum TP, AB, and a significant (p > 0.01) increased ALT, AST, ALP, TB, DB, when compared with that in control. Preventative treatment with NRG ameliorated these altered biochemical parameters toward normal values in comparison with the ACN group in (Tables 2).

Antioxidant Enzymes

The MAD activity was significantly (P<0.01) increased and SOD and CAT were significantly (P<0.01) decreased in the ACN group when compared to the control group. In the treated groups with NRG 40-80 mg/kg, ameliorated these altered biochemical parameters toward significantly (P<0.01) decreased in the MAD and significantly (P>0.01) increased in SOD and CAT this result shown in (Table 2).

Histopathological Examination

Light microscopic of liver examination using (H&E 400X) stain in control rats, showed normal histological structure of the liver tissue was observed with the central vein and cords of hepatocytes radiating toward the periphery, bile duct were surrounded by connective tissue and normal sinusoids were observed. (Fig:1a). Histopathological section of rat liver group II which treated with ACN (2g/kg), orally by stomach tube as single dose at first day, showing severe fatty degeneration and necrosis into the surrounding cells in the central vein. (Fig:1b). Histopathological section of rat liver group III treated with ACN (2g/kg), orally by stomach tube as single dose at first day, then NRG (40 mg/kg b.w) orally by stomach tube, per day, respectively, for (8) days, showing moderate fatty degeneration arranged of hepatic cells around central vein (Fig:1c). Histopathological section of rat liver group IV, which treated with ACN (2g/kg), orally by stomach tube as single dose at first day, then NRG (80 mg/kg b.w) orally by stomach tube, per day, respectively, for (8) days, showing hepatoocyte arranged around the central vein, normal sinusoids and nuclei with no signs of necrosis (Fig:1d).

Discussion

This study is to show that NRG could alleviate ACN induced liver toxicity, NRG has an ameliorative effect against liver toxicity induced by 2g/kg body weight of ACN as explained by reduction in the body weight and increased in liver weight when compared to control. Our results are in acceptance with prior findings of (18). Mentioned that the oral administration of 800mg/kg of paracetamol for seven days, it causes significant loss in weight among the liver damaged rats than the control. According to (19), increased catabolism and anorexia are responsible for decreased food intake and causes body weight loss further, following loss of the tubular cells, involved in renal water reabsorption leads to dehydration and decreases body weight (20). While previous study of Ali et al., (21) that the paracetamol administration did cause significant increase in the average liver weight when compared to the normal control group. The enlargement of livers in ACN - treated rats suggested hepatic lesions and liver injury associated with the toxic effects of ACN. These significant changes in the liver weights may be attributed to the accumulation of extracellular matrix protein and collagen in liver tissue. Treatment of ACN causes histopathological and immunohistochemical changes, sever fatty degeneration and necrosis into the surrounding cells in the central vein and significant increase in the serum level of liver function markers such as ALT, AST, ALP, TB, DB levels in addition to a significant reduction TP and AB levels. These results are in acceptance with those obtained by other investigators (22). These enzymes are originally present in the cytoplasm, when there is hepatopathy, these enzymes and molecules leak into the bloodstream and serve as an indicator for the liver damage (23). ACN is a widely used drug, produce N-acetyl-Pbenzoquinone-imine at overdoses and covalently binds to sulphhydryl groups causing cell necrosis and lipid peroxidation by depleting reduced glutathione in the liver, subsequently leading to liver toxicity. Oxidative stress is considered an important contributing factor to the development of liver and kidney diseases. Oxidative stress mainly develops due to increased generation of Reactive Oxygen Species (ROS) and a decrease in ROS scavenging capacity (24). The significant increase in MAD and significant reduction SOD and CAT are
attributed to increased production of ROS. Excessive lipid peroxidation causes lipid degradation that impairs cell membrane function, resulting in tissue damage and failure of antioxidant defense mechanisms to prevent the formation of excessive free radicals in paracetamol-intoxicated rats (25). The results of the present study suggest that, the accumulation of free radicals, and that increased oxidative stress is a basis for cellular damage. Through the aforementioned findings, we conclude that there is liver damage due to the use of ACN. Treatment with NRG for (8) days reduced the ACN injured liver produces a significant increased in body weight, TP, AB, SOD and CAT and significant decrease in weight of liver, ALT, AST, ALP, TB, DB and MAD. The results of this study are in agreement with (26). Flavonoids are an important group of secondary metabolites and a source of bioactive compounds in plants (27). Our results demonstrate the protective effect NRG on ACN for (8) days induced liver toxicity in the rats. This can be demonstrating on the anti-inflammatory effects, such as pathogens, damaged cells or irritants (28). NRG, Phenolic phytochemicals are thought promote health partly via antioxidant activity and free radical scavenging effects (29). Also has antioxidant properties and confers protection against H2O2-induced chromosome breakage and loss and DNA damage. NRG may avoid H2O2-induced oxidative damage not only by decreasing DNA damage but also by increasing the DNA repair capacity (30). NRG an anti-inflammatory, antioxidant and anti-apoptotic potential effect at colorectal sites as it modulates the production and expression of oxidative mediators by reducing DNA damage (13). Also has beneficial effects on many CNS diseases, including Alzheimer’s disease, Parkinson’s disease and epilepsy (31). Based on the advance findings, it can be conclude that, ACN had adverse effects on the liver. NRG administration showed a marked hepatic protective activity. The protective effects of NRG may be due to the its anti-inflammatory effects or antioxidant effects or ant apoptotic effects individually or synergistically.

**Conclusion**

This study explained that NRG declines ACN induced hepatotoxicity. The effect of NRG against ACN induced hepatotoxicity could be mediated through its antioxidant, antiinflammatory, antimicrobial and antiapoptosis action. However, NRG treatment was able to alleviate liver damage associated with ACN treatment and this is assign to its antioxidant activity and its ability to prevent inflammation.

Investigation the Role of IL-17 rs2275913 Gene Polymorphism with the Risk of Osteoporosis in a Sample of Iraqi Pre and Postmenopausal Women

Asmaa Mahmoud Salman¹, Da’ad A. Hussain¹

¹Scholar Researcher, Institute of Genetic Engineering and Biotechnology, University of Baghdad, Iraq

Abstract

Objective: This study aimed to investigate the relationship between the genetic polymorphism and alleles frequencies of IL-17 rs2275913 G/A with the risk of low bone mineral density (osteoporosis and osteopenia). Furthermore studying the relation between some immunological and biochemical parameters with this disease in a sample of Iraqi pre and postmenopausal women. Methodology: In this study, we investigated about the IL-17 rs2275913 G/A polymorphisms and the risk of low bone mineral density (BMD) among 30 patients with osteopenia, 30 patients with osteoporosis and 30 healthy controls. Serum IL-17 level and its correlation with the IL-17 rs2275913 G/A genotypes were analyzed. The study was carried out from November 2020- January 2021 in Baghdad Teaching Hospital/ Bone density examination unit/ in Baghdad-Iraq. Conclusion: It is concluded that the IL-17 rs2275913 G/A genotype was not associated with increased risk for development of low (BMD) in Iraqi pre and postmenopausal women. Recommendation: Based on study conclusion, during menopause, it is important for women to have a DEXA scan to detect low BMD and receive appropriate care to prevent degradation of the micro-architecture of bone tissue, which increases the risk of bone fractures.

Keywords: Low Bone Mineral Density, IL-17, Single-nucleotide polymorphism Susceptibility, Baghdad Teaching Hospital.

Introduction

Bone mineral density (BMD) is a measure of the inorganic mineral content in bone, and is one of the more informative assessments of bone quality in both clinical studies and forensic investigations. Several factors, such as age, sex, disease, genetics, and lifestyle, affect BMD measurements, and normative standards must be applied for specific groups and individuals. One of the most common disorders associated with low BMD is osteoporosis and increased fracture risk, due to a decrease in bone strength and an increase in bone fragility (1).

Osteopenia is a clinical term used to describe a decrease in BMD below normal reference values, yet not low enough to meet the diagnostic criteria to be considered osteoporotic. It is, as defined by the World Health Organization (WHO), is a t-score between -1 to -2.5 (2). This condition happens when the body disposes of more bone than it is making. It is transform into osteoporosis so far as that is concerned isn’t unavoidable. Diet, work out, and in some cases prescription can help keep the bones thick and solid for quite a long time. Furthermore Osteopenia as a rule doesn’t have any side effects. This makes it difficult to analyze except by a bone mineral thickness test (3).

Postmenopausal osteoporosis is a chronic disease associated with age-related declines in bone mass, changes in bone microarchitecture, and skeletal fragility. These changes place postmenopausal women at increased risk of fragility fractures, which are linked to significant morbidity, economic cost, and negative impact on health-related quality of life (4).
Interleukin-17 (IL-17) is characteristic cytokines of CD4+ cells and the group of Th17 cells secrete, showed that IL-17 plays an important role in the formation of osteoclast. IL-17 is secrete factors that can work together with tumor necrosis factor alpha (TNF-α) enhance the process of the development of inflammation and bone transformation (5). IL-17 is a recently discovered family of cytokines composed of six members. Additional isoforms homologous to IL-17A designated as IL-17B, IL-17C, IL-17D, IL-17E, and IL-17F were discovered afterwards (6).

Material and Method

Study population: This study was conducted with 30 osteopenia patients and 30 osteoporosis patients with pre and postmenopausal Iraqi women who attended Baghdad Teaching hospital in Baghdad/Iraq between November 2020- January 2021. Osteopenia and Osteoporosis was defined according to the conventional World Health Organization (WHO) definition. Subjects with a history of bone disease, metabolic or endocrine disorders such as diabetes mellitus, hyperthyroidism, hyperparathyroidism, renal disease, liver disease, medications known to affect bone metabolism (e.g. anticonvulsants, corticosteroids, heparin sodium) were excluded. The control group comprised 30 healthy volunteers for the general health checkup in our hospital during the same period. After obtaining written informed consent, 5 mL of peripheral blood was collected for DNA extraction and ELSA test. Each participant was interviewed using a standard questionnaire by a trained nurse, to collect demographic characteristics and medical histories. All the specimens we recruited were of Arabic/ Iraq ethnicity and were filtered based on their clinical characteristics. Before the assay, we obtained a written informed consent from each participant in our study.

Bone mineral density measurements: Area BMD (g/cm²) was measured by dual energy X-ray absorptiometry (DEXA). Densitometers were calibrated daily. Left hip and posterior–anterior lumbar spine (L2–L3–L4) scans were performed with the patient lying supine on the imaging table using the protocols recommended by the manufacturer.

DNA extraction and genotyping: Genomic DNA was isolated from EDTA anticoagulated peripheral blood with a commercially available extraction kit (Geneaid/ Taiwan) according to the manufacturer’s instructions. Genotype determination for one SNP in the IL-17 gene (rs2275913 G/A) was performed by real-time polymerase chain reaction (RT-PCR). The polymorphisms within IL17 rs2275913 G/A were genotyped with TaqMan genotyping assays using the Roto-Gene Q apparatus Real-Time (Roto-Gene Q, Italy). Probes and primers designed for RT-PCR shown in Table 1.

Serum level measurement of IL-17: The interleukin-17 (IL-17) level were determined by enzyme-linked immunosorbent assay (ELISA) using a commercially available ELISA quantitative kit (Shanghai Yehua/ China) according to manufacturer’s instructions.

Statistical Analysis

The Statistical Analysis System- SAS (2012) program was used to detect the effect of difference factors in study parameters. Least significant difference –LSD test (Analysis of Variation-ANOVA) was used to significant compare between means. Chi-square test was used to significant compare between percentage (0.05 and 0.01 probability) (7).

Result

This study included 30 osteopenia, 30 osteoporosis patients and 30 healthy controls, the mean ages of osteopenia, osteoporosis patients and healthy controls were 36.46 ±1.36, 55.80 ±1.48 and 41.33 ±1.81 years, respectively. The genotype and allele frequencies of the IL-17 rs2275913 G/A polymorphisms for all the studied variations are shown in Table2.

* (P≤0.05), ** (P≤0.01).

There were no association in the genotypes between patients and controls, and the allele frequencies of IL-17 rs2275913 G/A for the three study groups appeared that there were no significant different between patients and controls. Compared GA genotype between control and patients, heterozygous GA genotype was associated with significantly increased in control (43.33%) and decreased in osteoporosis (36.67%) and osteopenia (33.33%). AA genotype was higher in osteopenia (33.33%) and control (23.33%) then decreased in osteoporosis (13.33%). In addition, GG genotype was higher in osteoporosis (50.00%) and less in osteopenia (33.33%) and control (33.33%). While in the allele frequencies G and A there were no significant different between patients and controls.

Serum IL-17 level and its correlation with the IL-17 rs2275913 G/A genotypes. There were no statistically significant associations between IL-17A gene polymorphisms and Serum IL-17 Level in osteoporosis and osteopenia, while there were statistically significant differences between IL-17A gene polymorphisms and Serum IL-17 Level in control group p-value (0.038). In
contrast IL-17A plasma levels were significantly higher in patients (31.72-16.37)) comparatively to controls (15.05), and this result due to our study and another studies that the serum IL-17 level related to osteoporosis but the IL-17 G/A (rs2275913) genotypes has no related to osteoporosis (Table 3).

Table 3: Serum IL-17 level and its association with the IL-17 G/A (rs2275913) genotypes.

Discussion

In the present study, we selected, one SNP IL-17 rs2275913 G/A to evaluate their association in patients with Iraqi pre and postmenopausal women with osteopenia, osteoporosis and healthy controls. Inflammatory processes and cytokines play essential roles in the pathogenesis of women osteoporosis. Variations in cytokine levels among individuals are a plausible explanation for differences in disease susceptibility and severity, and are principally attributable to single nucleotide polymorphisms (SNPs) in cytokine-encoding genes (8).

Interleukin-17 (IL-17) is a proinflammatory cytokine produced by the memory CD4 + T cells after activation and has been shown to be involved in amplifying inflammatory response by recruiting immune
cells such as neutrophils and monocytes and inducing other proinflammatory molecules (9). IL-17 is essential to both the adaptive and innate immune systems. It has five confirmed receptors (IL-17RA-RD and SEF) and six members (IL-17A-F). Moreover, IL-17, as a pro-inflammatory cytokine, can trigger the release of chemokines and cytokines (10).

**Conclusion**

It is concluded that there were no significant differences in the allele frequencies of IL-17 rs2275913 G/A for the three study groups osteopenia patients, osteoporosis patients, and controls. So IL-17 rs2275913 G/A genotype and A allele, was not associated with increased risk for development of low BMD in Iraqi pre and postmenopausal women and there were no association between Serums calcium, alkaline phosphatase (ALP), BMD and IL-17 rs2275913 G/A genotype. Also it is concluded increase IL-17 level play an important role in the development risk of osteoporosis and osteopenia in pre and postmenopausal women (11) (12).

**Recommendations**

During menopause, it is important for women to have a DEXA scan to detect low bone mineral density and receive appropriate care to prevent degradation of the micro-architecture of bone tissue, which increases the risk of bone fractures. a.To increase bone density and reduce the risk of osteoporosis, it is critical to consume calcium and vitamin D3-rich foods, as well as get enough sunlight for a sufficient period of time to promote production of vitamin D3. It is also critical to exercise regularly to maintain bone density and reduce the risk of low bone mineral density.

Treatment of Lupus Nephritic with Severe Preeclampsia: A Case Report

Asri Insanur Rahma¹, Lita Diah Rahmawati²
¹Resident, ²Rheumatologist, Department of Internal Medicine, Universitas Airlangga/Dr. Soetomo General Hospital, Surabaya, Jawa Timur, Indonesia

Abstract

A 25 years-old pregnant woman with history of Systemic Lupus Erythematosus (SLE) complained shortness of breathing and swelling legs. Physical examination showed hypertension, tachycardia, tachypnea, anemic conjunctiva, and pitting edema in both legs. Workup examination found anemia, hypoglycemia, hypoalbuminemia, proteinuria, metabolic acidosis, strong positive dsDNA, trivial MR, mild TR, PR, dilated LV, decrease of LV systolic function, hypokinetic global LV, eccentric LVH, and severe oligohydramnios. The patient was diagnosed with severe preeclampsia, severe oligohydramnios, SLE, Lupus Nephritic (LN), stage II JNC VII hypertension, and peripartum cardiomyopathy.

An emergency caesarean section was planned as the main management to prevent infant and maternal morbidity and mortality. MgSO₄ was given to prevent eclampsia. Methylprednisolone and azathioprine were given to control SLE and LN activity. Furosemide, spironolactone, ramipril, methyldopa and nifedipine were given to control blood pressure, help normalizing heart function, and prevent organ failure. The patient was suggested to postpone next pregnancy until 1 year after LV function turns to normal.

Keywords: Lupus Nephritic, Pregnancy, Systemic Lupus Erythematosus, Severe Preeclampsia

Introduction

LN developed during conception or pregnancy increases the risk of preterm birth (34%), pre-eclampsia (10-35%), maternal mortality, fetal death, neonatal death (12-38%), intrauterine growth delay (30%), chronic kidney disease (CKD) and end-stage renal disease (ESRD).¹

Pre-eclampsia causes risk of stroke, premature birth and even death. Severe pre-eclampsia can develop into eclampsia with grand mal seizures.²

Differentiating active lupus nephritis from pre-eclampsia becomes one of the biggest challenges in managing SLE patients with pregnancy. They both present with proteinuria, hypertension, leg edema and systemic effect, yet the treatment of these two diseases is different. Pre-eclampsia will improve once the pregnancy terminated and active SLE requires immunosuppression as treatment.³

Case Report

A pregnant woman, 25 years old housewife living in Gresik, Jawa Timur, Indonesia, visited Dr. Soetomo General Hospital with a chief complaint of shortness of breathing.

The patient suffered from shortness of breath starting from early pregnancy worsened 1 week before admission with exertion or while walking long distances and improved with rest. The patient also complained of
swelling in both legs since early pregnancy, worsened in the last week before admission.

It was her third pregnancy aged 39 weeks. There was no history of hypertension in the previous pregnancies. During the third pregnancy, the blood pressure was always normal, except 1 month before admission.

The patient was diagnosed with SLE in 2017 in other hospital due to malar rash, photosensitivity, joint pain, hair loss, mouth sores and positive result of ANA test and routinely consumed methylprednisolone 4 mg once per day, azathioprine 50 mg twice per day, and calcium lactate 1 tablet once per day. The therapy was continued during this pregnancy.

Physical examination found hypertension (170/100 mmHg), tachycardia (104 beats per minute), tachypnea (24 times per minute). The conjunctiva was anemic. There was pitting edema in both legs.

Laboratory tests resulted anemia (Hb 9.3 g/dL, Hct 28.1%). Complete urine examination showed proteinuria (3+). ANA profile test showed strong positive dsDNA. Echocardiography examination found trivial mitral regurgitation (MR), mild tricuspid regurgitation (TR), mild pulmonal regurgitation (PR), dilated left ventricle (LV), decrease of LV systolic function (EF by Teich 44%), hypokinetic global LV, eccentric LV hypertrophy (LVH). Obstetric USG showed severe oligohydramnios.

According to the history taking and examination, the patient was diagnosed with severe preeclampsia, severe oligohydranmios, SLE, LN, stage II JNC VII hypertension, and peripartum cardiomyopathy (PPCM).

A CITO caesarean section was planned due to severe preeclampsia and severe oligohydramnios. The patient was given MgSO4 40% intravenously 1 gram every hour up to 24 hours postpartum, nifedipine 10 mg every 8 hours orally if blood pressure ≥ 160/110 mmHg, methyldopa 500 mg every 8 hours orally, furosemide 20 mg every 8 hours intravenously, isosorbide dinitrate 5 mg every 8 hours orally, methylprednisolone 62.5 mg once 3 hours before C-section continued by methylprednisolone 62.5 mg 3-6 hours post C-section and calcium 500 mg per day. The patient was also given furosemide injection 20mg intravenously every 8 hours, spironolactone 25mg every 24 hours orally, and ramipril 2.5mg every 24 hours orally to help normalizing heart function. The dose of methylprednisolone was tapered down to 16 mg every 8 hours and azathioprine 50 mg twice per day was given.

The patient was discharged on the eight day of care and suggested to postpone next pregnancy until 1 year after LV function turns to normal. The patient was also planned to visit out-patient clinic after discharged, but she did not.

**Discussion**

Pregnancy and SLE influence each other. Hormonal and immunological changes in pregnancy can affect SLE activity in general, causing both short-term and long-term adverse effects on renal function. On the other hand, SLE leads to pregnancy complications such as preeclampsia, premature birth and fetal loss. Women with SLE are able to control their pregnancy if they choose the optimal time for conception and have proper management during their pregnancy.1,4

Distinguishing LN flare and pre-eclampsia is challenging due to similar symptoms and possibly simultaneous occurrence.5

Diagnosis criteria of SLE according to ACR are: (1) malar rash: (2) discoid rash (3) Photosensitivity (4) inflammation of the mouth or nose (5) non-erosive arthritis in two or more joints accompanied by tenderness, swelling or effusion, (6) heart-lung involvement (7) neurological disorders (8) kidney disorders (9) hematological disorders (10) immunological disorders (11) nuclear antibody (ANA) positive test if no known drugs can trigger.6

The patient had been diagnosed with SLE in 2017 in other hospital due to malar rash, photosensitivity, joint pain, hair loss, mouth sores and positive result of ANA test before admission.
Criteria of LN based on ACR are persistent proteinuria more than 0.5 mg per day or more than 3+ by dipstick, and/or cellular casts including red blood cells, white blood cells, hemoglobin, granular casts, tubular casts, or mixed casts. According to the Italian Nephrology Society, renal flare-ups are defined as an increase in proteinuria of at least 2 g per 24 hours if the basal proteinuria is less than 3.5 g every 24 hours, or doubled if the basal proteinuria is more than 3.5 g per 24 hours, accompanied with concurrent microhematuria and cell cylinders in the urine sediment. Active LN is defined as the appearance of active urine sediment and/or proteinuria more than 0.5 g per day with or without an increase in serum creatinine. Other results found are increase in ds-DNA antibodies and decrease in complement levels. Meanwhile, inactive LN lupus was defined as proteinuria less than 0.5 g per day without urine sediment.

Complete urine examination in this patient resulted proteinuria (protein 3+). C3 and C4 examinations showed low values (C3 27.4 mg/L C4 7 mg/dl). And obtained high ds-DNA antibody results on the ANA profile examination. Therefore, this patient was categorized into active LN based on criteria mentioned.

SLE disease activeness in pregnancy is assessed by modifying the SELENA-SLEDAI score. The score of 3 or less is not counted as a flare, 2-12 is counted as mild to moderate flare, and more than 12 is counted as severe flare. The score of this was 2, so that the patient did not undergo flare.

Diagnostic criteria of preeclampsia are persistent systolic blood pressure of 140 mmHg or higher, or a diastolic blood pressure of 90 mmHg or higher after 20 weeks of gestation in women with previously normal blood pressure, may accompanied by proteinuria 300 mg or more in a 24-hour urine collection. Proteinuria is not absolute criteria for preeclampsia. According to the criteria of the American College of Obstetricians and Gynecologists (ACOG), if preeclampsia is accompanied by systolic blood pressure ≥ 160 mmHg or diastolic blood pressure ≥ 110 mmHg while resting, thrombocytopenia, elevated liver enzymes, severe right upper quadrant pain or epigastric pain that does not respond to treatment, progressive renal insufficiency, pulmonary edema, visual disturbances or brain disorders, it is classified into severe preeclampsia. In this case, he patient was classified into severe preeclampsia due to blood pressure of 170/100 mmHg and edema in both legs.

Termination is the main therapy for preeclampsia. Those who have not reached term and have no severe manifestations are still evaluated with a non-stress test 2 times a week. Therapy for severe preeclampsia includes corticosteroids for fetal lung maturation, MgSO4 for eclampsia prophylaxis, and anti-hypertension. The systolic blood pressure target is less than 160mmHg and diastolic less than 110mmHg. The first-line treatment for anti-hypertension in preeclampsia is nifedipine, hydralazine, and labetalol with alternative nitroglycerin and methylldopa.

Patients with severe preeclampsia should be treated with expectative care. If there are contraindications to expectative care, delivery of the pregnancy should be prepared and carried out in stable condition. Contraindications for expansive treatment include eclampsia, pulmonary edema, dissemination of intravascular coagulation (DIC), severe and uncontrolled hypertension, fetal emergency, placental solution, and intrauterine fetal death. Complications of expected treatment include persistent symptoms, HELLP syndrome, IUGR, severe oligohydramnios, premature rupture of membranes, and severe kidney problems. If there are complications, corticosteroids should be given for lung maturation and delivery must be prepared. The patient was then planned for a caesarean section with indications of severe pre-eclampsia and severe oligohydramnios. Patients were also given injection therapy of 40% MgSO4 intravenously 1gram every hour up to 24 hours postpartum, nifedipine 10mg every 8 hours orally (if blood pressure ≥ 160/110 mmHg), methylldopa 500mg every 8 hours orally.

The treatment of LN consists of two phases: induction and maintenance. Induction therapy refers
is purposed to cure active disease while maintenance therapy to continuously maintain the remission and prevent organ damage.

Corticosteroids the main treatment of LN. They are effective in controlling kidney flares, but not to improve long-term results alone. However, steroid exposure should be limited to a minimum during pregnancy. High doses during pregnancy are associated with an increased risk of diabetes, hypertension, pre-eclampsia, premature rupture of membranes and congenital fetal abnormalities. Nevertheless, short doses and/or high doses of intravenous methylprednisolone can be used in the case of flares.\textsuperscript{12}

Azathioprine may be the safest immunosuppressant drug to take during pregnancy. This drug is recommended especially if it has been consumed before pregnancy.\textsuperscript{2} Apart from azathioprine, other immunosuppressants that can be used during pregnancy are cyclosporin A and hydroxychloroquine.\textsuperscript{3}

The patient had taken 3x8mg Methylprednisolone orally, Azathioprine 2x50mg orally, 1x1 calcium lactate before admission. Then, the patient was then given methylprednisolone 1x62.5mg intravenous therapy 3 hours before cesarean section then followed by injection of methylprednisolone 62.5 mg intravenously every 3-6 hours postoperatively. Methylprednisolone therapy was continued and tapered down on the third day. Azathioprine 2x50mg was continued.

SLE in pregnancy should be monitored by an obstetrician and rheumatologist.\textsuperscript{5} Pregnancy should be postponed until the disease is said to be inactive, at least 6 months before conception.\textsuperscript{2} Basic laboratory tests should be repeated at the first prenatal visit and must be checked if no preconception counseling has been done. Monthly prenatal visits are necessary. The frequency of laboratory examinations depends on SLE or LN activity. Serial fetal ultrasound examination is planned to monitor fetal growth.\textsuperscript{1}

A kidney biopsy is only indicated to rule out or classify LN if the results will affect management, due to risk of bleeding after biopsy in pregnancy.\textsuperscript{5} A kidney biopsy is not recommended after 32 weeks of gestation.\textsuperscript{1}

**Conclusion**

LN is often superimposed severe preeclampsia, which could end up with maternal and fetal mortality. This case showed early diagnosis and proper treatment. This kind of case commonly happens in pregnant women with LN.

Knee Osteoarthritis Severity in Relation to Neutrophil-Lymphocyte Ratio

Auday Hussain Hassan Al-Janaby
Orthopedic Surgeon, Orthopedic Department, Al-Zahrawi Hospital, Misan Health Directorate, Ministry of Health/ Environment, Misan, Iraq

Abstract

Background: Osteoarthritis is a disease with a significant inflammatory component. Neutrophil-lymphocyte ratio (NLR) level is a marker to determine inflammation. The study aimed to evaluate the association between severity of knee osteoarthritis and NLR.

Methods: A case-control study conducted in Al-Zahrawi during June 2017 to June 2018. A total of 100 knee osteoarthritis were recruited and 50 healthy subjects as a control group.

Results: NLR was significantly higher in knee osteoarthritis than controls, the mean value was (2.19±0.72) and (1.97±0.88), respectively. Older age, chronic pain, prolong onset of diagnosis and high NLR were significantly associated with severe osteoarthritis.

Conclusions: Knee osteoarthritis had higher NLR compared to healthy people. Higher NLR is associated with severity of knee osteoarthritis and it is a poor indicator.

Key Words: Neutrophil-lymphocyte ratio; osteoarthritis; bone sclerosis; osteophytes

Introduction

Osteoarthritis (OA) is the most common form of arthritis, and it is a leading musculoskeletal cause of disability in elderly persons\(^1\). OA is chronic multifactorial disease with progressive joint degeneration accompanied by sub-chondral bone sclerosis, bone cysts formation, marginal osteophytes, knee flexibility decrease, arthralgia, joint effusion, crepitus, and deformities\(^2\). It is likely to increase due to the aging and obesity\(^3\). The diagnosis confirm by history, physical examination, imaging studies and laboratory testing\(^4\). X-rays reveal marginal osteophytes, narrowing of the space, increased density of the subchondral bone, subchondral cyst formation, bony remodeling and joint effusions\(^5\). NLR is the ratio between the absolute neutrophil and lymphocyte counts\(^6-8\).

Methods

Study design and Setting

This was a case-control study conducted in Al-zahrawi during June 2017 to June 2018. A total of 100 knee osteoarthritis were recruited and 50 healthy subjects as a control group.

Participants

A total of 100 patients with OA according to the American College of Rheumatology clinical criteria \(^9\), who attended the outpatients clinic. A total of 50 healthy subjects who agreed to participate in the study.
Exclusion criteria

1. History of knee trauma.
2. Post infection arthropathy.
3. Tumor.
4. Rheumatoid arthritis.
5. Systemic lupus erythematosus (SLE).

Data collection

Data were collected including age, gender, BMI, smoking, drug history, and medical history. The clinical and laboratory data including the radiological findings and NLR. The OA grade was assessed according to the Kellgren-Lawrence (KL) grading system\(^{10}\).

Statistical Analysis

Data entered and analyzed using the statistical package for social sciences (SPSS) version 24, International Business Machines Corporation (IBM), United states (US), 2015. Descriptive statistics presented as frequencies, percentage (%), mean and standard deviation. Analytic statistics performed using Chi-square to compare frequencies for student’s t test and ANOVA test were used to compare means. Level of significance was set at < 0.05.

Results

No statistically significant differences had been found between the groups in demographic variables, (Table 1). The value of NLR; patients with OA had significantly higher NLR than controls, the mean NLR was \((3.02\pm0.87)\) and \((1.86\pm0.9)\), respectively, \((P=0.001)\), (Table 2). Regarding the distribution of the knee osteoarthritis patients according to their KL grading scale, \((18\%)\) grade I, \((32\%)\) grade II, \((21\%)\) grade III and \((29\%)\) grade IV, (Table 3). Regarding to the severity, among these variables, age, and NLR were significantly different, (Table 4).

Discussion

The demographic data are similar to the clinical picture of OA documented previously, where majority of the patients were old age and females were the dominant gender\(^{(11, 12)}\). There is no statistically significant differences in all hematological parameters except NLR. Despite that there were very few studies available about the association between NLR and OA. The findings were consistent with Tasoglu, et al.\(^{(13)}\).

Recently, Hira and Tamam\(^{(14)}\), reported the mean NLR was significantly higher in OA group than controls. There was inconsistency about the predictive role of NLR in diagnosis, prognosis or as a marker for disease activity for other diseases\(^{(15-17)}\).

The correlation between severity of OA and the variables that showed significant association on univariate analysis, older age and higher NLR were still significantly associated with severe OA. Previous studies mentioned that old age is a significant risk factor of OA and associated with severe OA\(^{(11-13, 18)}\). The explanation beyond could be attributed to the general incidence and prevalence of OA has been reported to increase by ten times in older age than younger, particularly > 65 years who are commonly affected by OA. Also, there is a change in behavior, lifestyle, diet and other factors. In addition, the cells and extracellular matrix of joint
tissues increase the susceptibility of older adults to OA (18, 19).

Conclusions

Osteoarthritis had higher NLR compared to healthy subjects. NLR is a poor predictor of OS severity. Age was a stronger risk factor of severity.

Bronchodilator Effect of *Crataegus azarolus* var *aronia* Unripped Fruit Extracts on Rat’s Tracheal Smooth Muscle

Aveen A. Mohammed¹, Omar A. M. Al-Habib²

¹Lecturer, Department of Biology, Faculty of Science, University of Zakho, Zakho, ²Professor, Department of Biology, College of Science, Nawroz University, Duhok, Kurdistan Region, Iraq

Abstract

**Objectives:** The present study aimed to investigate the bronchodilator effect of different *Crataegus azarolus* var *aronia* unripped fruit extracts on tracheal smooth muscle of rats and to study the roles of K channels and EDHFs in produced responses.

**Background:** *Crataegus* is widely used in Kurdistan Region for the prevention of several diseases such as respiratory, cardiovascular, hypertension …. etc. due to its content of several bioactive compounds like aromatic amines, phenolic acid, flavonoids, and proanthocyanidins.

**Method:** The bronchodilator effects of various *Crataegus* fruit’s extracts on rat’s tracheal rings and the roles of K⁺, Ca²⁺ channels and EDHFs in bronchodilation using specific blockers.

**Results:** Most of *Crataegus* fruit’s extracts used showed a potent bronchodilator effect on trachea, in which the HME produced a highly significant dilation, followed by methanol and ethyl acetate extracts which showed a considerable relaxant effect. The results confirmed that the induced dilation was NO and PGI₂ dependent, along with activations of K<sub>ATP</sub> and Kir and Kca while Kv plays a minor and limited role.

**Conclusion:** The novel results indicate that HM, M, EA extracts prepared from *Crataegus* unripped fruit produce a potent bronchodilator effect, which was NO and PGl₂ dependent along with the activation of K<sub>ATP</sub>, Kir and Kca<sup>2⁺</sup> channels.

**Key Words:** *Crataegus*, trachea, bronchodilator, methanol, hydromethanol, ethylacetate, extracts.

Introduction

A widespread use of herbal formulations throughout the world has increased due to their cultural acceptability, availability, affordability, efficacy, and safety claims<sup>(1,2)</sup>. Surveys on the therapeutic uses of *Crataegus aronia*, the dominant species which populate the Mediterranean Basin Mountains, has been used in the traditional medicine to treat diabetes, cancer, as well as cardiovascular and respiratory diseases<sup>(3)</sup>. During the past two decades, herbal medicine have received a great concern as novel options of therapy for human disease treatment<sup>(4)</sup>. It is widely agreeable that the presence of various bioactive compounds such as aromatic amines, essential oils, phenolic acids, flavonoids, proanthocyanidins and triterpenes<sup>(5,6,7)</sup>. These Components are responsible for most of the pharmacological effects of the medicinal plants<sup>(8)</sup>. The most promising among which are edible plants, due to their negligible adverse effects<sup>(9,10)</sup>. Medicinal plants have been used as primary sources in treatment and prevention of several diseases such as congestive heart failure<sup>(11)</sup>, angina pectoris, hypertension, and arrhythmias<sup>(12)</sup>, blood thinning effect<sup>(13)</sup>, lower the total cholesterol in plasma<sup>(11)</sup>. In addition, it also acts as antioxidant<sup>(14)</sup> and in cardio-myogenesis and angiogenesis from stem cells<sup>(15)</sup>. However, due to the availability of limited studies on its effects on pulmonary diseases, especially obstructive pulmonary diseases, (<sup>(16)</sup>) and since most of the studies related to the use of *Crataegus* in the treatments of various diseases
focused on the use of leaf and root extracts, whereas very little is known about the effect of *Crataegus* fruits. Thus, the current research project is adopted to study the bronchodilator effect of *Crataegus aronia* unripped fruit extracts to explore the possibility of its use in the treatment of respiratory diseases and its mechanism of action.

**Materials and Methods**

**Preparation of *Crataegus aronia* unripped fruit Extracts**

The shade-dried powder (500g) prepared from *C. aronia* was soaked in 2.5 L of 99.98% ethylacetate, methanol and hydromethanol (60% methanol) repeatedly 5 times, each for 10 days with occasional shaking. The extract was filtered through muslin clothes and then through Whatmann No.1 filter paper. The filtrates of each extract were combined and concentrated by thin film rotary evaporator at 40 °C under reduced pressure. Thick crude extracts of *C. aronia* fruits were stored at −4 °C for future use. For the preparation of desired serial dilutions, a needed amount of the extract was dissolved in deionized water from which serial dilutions were prepared and warmed up at 37°C.

**Animals**

Wister male Albino rats, weighing 210–310 g used in this study were obtained from Animal House (Department of Biology, College of Science, University of Zakho). Animals were reared in PCV cages kept in a well-ventilated animal house room. During the experimental period, four to six animals were kept in each cage, kept under controlled laboratory conditions at 25 °C and photoperiod of 12 hours’ light–dark cycle. Rats had free access to dechlorinated tap water and standard rodent pellets.

**Isolated Tracheal Preparation and Experimental Protocol**

After anesthetization of the rat, the trachea was removed, cleaned, and transferred into a petri-jar containing aerated physiological solution. The trachea cut into small rings (each consists of 3-4 cartilaginous ring). The ring was fixed in a 10 ml glass chamber containing Krebs solution at 37°C and the two stainless-steel wires were used to connect the ring to the bottom of glass chamber from one side and to force transducer from the other side and subjected to 1 gm tension. The preparation allowed to equilibrate for 1 h before the addition of any drug. Meanwhile, it was washed with buffer solution every 15 min during the equilibration period. The pH of the buffer was maintained at 7.4 by continuous aeration of the physiological solution with a carbogen gas (consists of 5% CO<sub>2</sub> and 95% O<sub>2</sub>). To study the effect of *Crataegus* unripped fruits extracts, a dose response curve was established for each extract by cumulative addition of different concentrations of each extract and the response was recorded. To find out the role of various ion channels and hyperpolarizing agents, the tissues were pre-incubated either with desired blocker or inhibitor such as TEA, BaCl<sub>2</sub> and 4-AP (1×10<sup>-3</sup>M), GLIB (1×10<sup>-5</sup>M), nifedipine (1x10<sup>-5</sup>M) for 20 minutes or L-NAME (3×10<sup>-4</sup>M), methylene blue (1x10<sup>−5</sup>M) and indomethacin (3x10<sup>-3</sup> M) for 30 minutes prior to the application of ACh.

**Statistical Analysis**

Data are presented as Means ± SEM. The IC50s values (the concentration of the agonist or extract that produced 50% reduction in the maximal relaxant responses) were determined from the concentration–response curves by non-linear regression analysis using GraphPad Prism™ software, version 6.0 (GraphPad Software, USA).

**Results**

**Effect of Ethyl Acetate Extract on Isolated Rat’s Trachea**

1. Effect of Pre-Treatment of Tracheal Rings with L-Name, Methylene blue and Indomethacin on EAE-Induced Relaxation

Both L-NAME and Indomethacin produced a mild and non-significant inhibition in the in the DRCs
of EAE induced relaxation in tracheal ring, which reflect the limited participation of NO and PGI\textsubscript{2} in the induced relaxation (Table 1); while methylene blue produced a reverse response in the induced relaxation since the DRC was significantly enhanced, especially at the last three doses used.

Table 1: The LogIC\textsubscript{50}, (LogIC\textsubscript{50} of 95% CI) and Emax ± SEM induced by EAE in trachea pretreated with L-NAME, methylene blue and indomethacin.

2. Effect of Pre-Treatment of Tracheal Rings with K\textsuperscript{+} and L-type Ca\textsuperscript{2+} channel blockers on EAE-Induced Relaxation

The DRCs induced by EAE in tracheal rings were inhibited to a variable extent in the presence of K channel blockers since TEA, GLIB and BaCl\textsubscript{2} caused inhibition in induced relaxant responses. Thus, the inhibition was significant (P<0.05-0.1) in the presence of TEA at high doses, whereas both GLIB and BaCl\textsubscript{2} produced non-significant inhibition (Table 2). In contrary, 4-AP produced non-significant enhancement in the induced relaxation since the Emax was increased from 44.1 in the control to 55.17 %. This indicate that Kca\textsuperscript{2+} plays a significant role in the EAE induced relaxation, while both Kir and K\textsubscript{ATP} channels played a limited role in the induced responses. However, Kv channel showed no role in this relaxation at all. The presence of Nifedipine also showed non-significant inhibition in the relaxant response, which also reflects the limited and indirect role of L-type Ca\textsuperscript{2+} channel in the induced response.

Table 2: The LogIC\textsubscript{50}, (LogIC\textsubscript{50} of 95% CI) and Emax ± SEM induced by EAE in trachea pretreated with TEA, GLIB, BaCl\textsubscript{2} and 4-AP.

Effect of *Crataegus* Fruit's Methanol Extract on Isolated Rat's Trachea

1. Effect of Pre-Treatment of Tracheal Rings with L-Name, Methylene blue and Indomethacin on ME-Induced Relaxation

Pretreatment of tracheal rings with Indomethacin and L-Name inhibited the relaxant effect induced by ME, but not to the same extent since the inhibition produced by high doses of ME was highly significant, while L-Name produced a non-significant inhibition (Table 3). In contrast, the DRC in presence of methylene blue was slightly and non-significantly enhanced as indicated by changing Emax from 71.40 ± 0.13 in the control to 74.48% in MB treated rings. These results indicate that the induced relaxation by ME is partially produced by PGI2 through COX pathway (P<0.001), but the role of NO pathway was limited. On other hand, cGMP inhibitor (MB), slightly and non-significantly enhanced the induced relaxant response.

2. Effect of Pre-Treatment of Tracheal Rings with K+ and L-type Ca2+ channel blockers on ME-Induced Relaxation

The results of the effect of preincubation with K+ channels blockers on ACh precontracted tracheal ring revealed that K_{ATP} channels played a highly significant (P<0.001) role in the induced relaxation whereas Kir played a limited role in the relaxation as indicated by the inhibitory effects of GLIB and BaCl2 on DRCs. In contrary, both Kca^{2+} and Kv played no role at all in the induced relaxation responses since their blockers enhanced rather than inhibiting the relaxant responses (Table4). Nifedipine (L-type Ca^{2+} channel blocker) produced no effect on the relaxant response produced by ME, this indicate that L-type Ca^{2+} channels plays no role in the induced relaxation.

Effect of *C. aronia* unripped fruits HME on Isolated Rat’s Tracheal Rings

1. Effect of Pre-Treatment of Tracheal Rings with L-Name, Methylene blue and Indomethacin on HME-Induced Relaxation

   Typical DRCs from representative experiments on the effect of L-Name, methylene blue and indomethacin on the relaxation induced by HME in tracheal smooth muscle precontracted against ACh are shown in figure (Table 5). The results showed that all the DRCs are shifted to the right hand but to variable extents. The relaxation response for ACh precontracted tracheal rings showed a highly significant (P<0.01) inhibition in the presence of L-NAME at a concentration 0.42 mg/ml with Emax inhibition from 91.63 ± 0.09 in the control to 67.46% (Table 5). However, both Indomethacin and methylene blue caused a mild and non-significant inhibition in their DRCs. The mild inhibitory effect of methylene blue was diminished at high doses of ME. This indicates that NO pathway playing an important role in the induced relaxation, whereas the roles Indomethacin and MB were limited.

2. Effect of Pre-Treatment of Tracheal Rings with K⁺ and L-type Ca²⁺ channel blockers on HME-Induced Relaxation

Preincubation of ACh precontracted tracheal rings with both BaCl₂ and GLIB caused significant (P <0.01 to 0.05) inhibition in DRCs at high doses (0.54 & 0.58mg/ml) of HME (Table 6). This reflecting the major role of K<sub>ATP</sub> and Kir channels in the relaxant effect produced by HME. In addition, Kv channels also offered a limited participation in the induced relaxation, while Kca2+ played no role at all in this relaxation since the presence Kv blocker (TEA) did not affect the DRC which was very close to that of the control. Preincubation of the tracheal rings with L-Type Ca²⁺ channels blocker (Nifedipine) caused a mild and non-significant inhibition in DRC, which reflect the limited role of L-Type Ca²⁺ channels in the relaxation induced by HME.

**Discussion**

Pretreatment of the tracheal rings with L-NAME, (NO synthase inhibitor), reduced the relaxant effects induced by HME, EAE and ME against ACh precontracted tracheal rings, indicating that this relaxant effect involves the synthesis and release of NO by nNOS which has beneficial effects in asthma, causing bronchodilation by relaxing airway smooth muscle via NANC nerves activation (17). Nitric oxide causes relaxation in smooth muscle via both cGMP dependent and -independent mechanisms depending on the levels of NO. At intermediate NO level, it activates Kca channel whereas at higher NO levels is accomplished by a cGMP – dependent mechanism (18). This pathway also includes the activation of cGMP-dependent protein kinase (PKG) by cGMP, which in turn, regulates numerous target proteins, e.g., Kca channel (IKCa), L-type Ca²⁺ channel (ICaL), sarcolemma Ca²⁺-ATPase pump (ICaP) currents, and myosin light chain phosphatase (MLCP), that lead to SMC relaxation. Prakash et al., confirmed that NO donors inhibit Ca²⁺ ion liberations by blocking sarcoplasmic reticulum Ca²⁺ release and promoting Ca²⁺ extrusion in porcine tracheal rings causing tracheal smooth muscle cells relaxation and subsequent bronchodilation (19). While cGMP did not participate in HME induced relaxation in tracheal SMCs; which was confirmed by using methylene blue (cGMP inhibitor) that did not alter the HME induced relaxation. This indicates that the relaxant effect of NO in rat tracheal smooth muscle is due to the activation of guanylate cyclase and production of the second messenger cGMP which reduces intracellular Ca²⁺ in smooth muscle.
cells. This mechanism was confirmed by (20), who concluded that cGMP activates intracellular effectors, such as PKG, which decreasing the intracellular Ca$^{2+}$ and dissociation of actin and myosin filaments and finally leading to SMCs relaxation.

The relaxant effect of ME, HME and EAE in association with production of the prostaglandin (PGI$_2$) was confirmed in trachea by inhibition of cyclooxygenase on its preincubation with indomethacin, which highly inhibited the relaxation responses. This clearly reflects the important role of PGI$_2$ in the induced relaxation which diminished in the presence of PGI$_2$ blocker Indomethacin. A similar effect of PGI$_2$ was exhibited by rat’s aorta in response to quercetin (21) and euscaphic acid (6) which are the important constituents C. aronia extracts (22).

Voltage-gated potassium (Kv) channel had an important role in relaxation induced by HME, because it decreased maximum relaxation response in tracheal rings pre-incubated with 4-AP (Kv channel blocker). This suggesting that the transient increase of cytosolic Ca$^{2+}$, activate calcium channels in the plasma membrane to influx Ca$^{2+}$ from extracellular fluid and to produces depolarization which in turn activate Kv channels to hyperpolarize membrane and facilitate smooth muscle relaxation (22, 23).

Calcium activated potassium (Kca) channel also plays an important role in the relaxation mediated by EAE and HME since KCA channel blocker) that significantly inhibited the induced relaxation. This clearly indicate that Kca channels playing an important role in the relaxation induced by both EAE and HME, whereas in ME-mediated relaxation, plays a limited role in the induced relaxation which was mildly inhibited. Depending on K$^+$ influx through the activation (Kca) channel because TEA (Kca channel blocker) highly inhibited EAE-induced relaxation and non-significantly inhibited ME-induced relaxation effects. A similar trend of response was reported for C aronia active ingredients such as quercetin induced relaxation of coronary arteries (24) and euscaphic acid induced relaxation (6) since both studies reflecting the important role of Kca channel in inducing smooth muscle relaxation.

The results of the current research indicated that HME, ME, and EAE -mediated relaxation partially dependent on the activation of K$_{ATP}$ sensitive channels since in the presence of GLIB (K$_{ATP}$ sensitive channel), the HME and ME induced relaxant responses in tracheal rings were strongly inhibited. However, EAE induced relaxation was non-significantly inhibited. K$_{ATP}$ channels are stimulated by its openers, such as pinacidil and cromakalim, so the opening of these channels causing K$^+$ efflux, hyperpolarization in the smooth muscle cell membrane and subsequent vasodilation and drop in blood pressure (25).

Inward-rectifier potassium (Kir) channel also involved in relaxation induced by HME. This was confirmed by pre-incubated of tracheal rings with BaCl$_2$ (Kir channel blocker), which strongly inhibited HME-mediated relaxation. The importance of this type of channel is confirmed by (26) who found that Kir channel has an important role in the organizing the resting membrane potential and resting tone in smooth muscle. Similarly, (27) reported that Kir channels have an important role in determining the resting potential of the cell.

Pre-incubation of trachea with nifedipine (L-type Ca$^{2+}$ channel blocker) non-significantly decreased the relaxant effects of HME, EAE extracts or not changed at all on preincubation with ME. However, (28) found in mouse that the relaxation induced by NO in lung’s smooth muscle cells occurs through cGMP-PKG pathway, decreasing the frequency of agonist-induced Ca$^{2+}$ oscillation and inhibiting the release of Ca$^{2+}$ via IP3 receptors, leading to the activation of K$^+$ channels and relaxation of smooth muscle cells.

**Conclusions**

Ethyl acetate, methanol and hydromethanol extracts Crataegus unripped fruit’s produced a potent bronchodilator effect in rat’s trachea in which hydromethanol extract produced a highly significant
dilation followed by methanol and ethyl acetate extracts which produced considerable relaxant effects. This potent relaxant effect on the bronchial smooth muscle cells was depending on NO and PGI2 along with the activation of dependent on $K_{\text{ATP}}$ and Kir and Kca channels.

Effect of Murotal Sound Stimulation during Pregnancy on the Number of Neuron Cells of Cerebrum and Cerebellum of the Newborn Rattus norvegicus

Ayu Putri Yani1, Hermanto Tri Joewono2, Widjiati3

1 Postgraduate Student of Reproductive Health Science, Airlangga University, Surabaya, Indonesia, 2 Lecturer at Department of Obstetrics and Gynecology, Faculty of Medicine, Airlangga University, Surabaya, Indonesia, 3 Professor at Department of Embryology, Faculty of Veterinary Medicine, Airlangga University, Surabaya, Indonesia

Abstract

Background: The human development index (HDI) illustrates how superior human resources are. The stimulation of Murotal during growth and development has been shown to increase cell growth in plants. The aim of the study was to analyze the effect of the differences against the number of neuron cell’s in the cerebrum and cerebellum Rattus norvegicus offspring between those who received Al-quran Murottal surah Ar-Rahman stimulation, Qori and Qoriah sounds voice in pregnancy day of 6th.

Methods: An Experimental study using 30 pregnant (Rattus norvegicus). Subjects were randomized into three groups, control group (Q1), voice of Qori group (Q2), and voice of Qoriah group (Q3). sound stimulation was given on 6th-17th days of pregnancy. From each mother, two Newborn of Rattus norvegicus were taken to make preparations from brain tissue. Eosin Hematoxylin was performed to assess number of neuron cells.

Results: The study shows that the mean and standard deviation of the number neuron cells cerebrum and cerebellum in the control group is 9.88 ± 1.71 and 21.10 ± 2.11, the voice qori group is 10.16 ± 1.01 and 22.46 ± 1.71, and the voice qoriah group 11.12 ± 1.52 and 22.50 ± 1.76. ANOVAs statistical test results show there is no significant differences among groups with a value of p = 0.152 in the cerebrum and p=0.183 in the cerebellum.

Conclusion: Murotal sound stimulation during pregnancy increased the number of neuron cells in the cerebrum and cerebellum of newborn rats.

Keywords: neurons; cerebrum; cerebellum; murotal; sound

Introduction

Global challenge in all countries is competition for human resource development, not only related to material functions, but directly related to the intelligence function of the brain intelligence to intelligence competitive, brain to brain competition. preparing the next generation needs to be done, especially creating quality human resources, has adequate intelengensi prepare for life in an increasingly competitive[1].

Integrated management of brain intelligence will produce human resources who are intelligent, have high competence, ability, skills, and competitiveness. Intelligence is related to the efficiency of the information transfer process in the brain that can be attempted since the prenatal period. Indonesian Child Doctors Association, the first day of life is called the golden age, the period from early pregnancy until the child is born and 2 years of age is an important period, determining the quality of health in life next. At that time the brain development has reached 80% of the brain[2].

The development and growth of the brain as well as the maintenance of intellectual health in the fetus affect cognitive, social and emotional abilities for the foundation of development and development of future generations. The cerebral cortex is a part of the brain that has cognitive function, but recent research has shown that the cerebrum (cerebrum) and cerebellum (cerebellum) contain more neuron cells than the cerebral cortex which allows them to be involved in cognitive function\[^3\].

Demonstrated that the cerebrum and cerebellum are interconnected via polysynaptics, forming a system associated with cognitive function and neuropsychiatric disorders. So it can be ascertained that the cerebrum and cerebellum play an important role in motor, cognitive, emotional and behavioral development\[^4,5\]. Therefore, stimulus and nutrition provided during pregnancy play an important role in fetal brain function. The fetal brain at that time undergoes proliferation, migration, differentiation, myelination, synaptogenesis, and apoptosis which are influenced by environmental and genetic factors. environment such as nutrition and stimulation\[^6,7\].

Efforts that can be made during pregnancy are to provide adequate nutrition and stimulation. Stimulation that is easily accepted by the fetus is stimulation in the form of sound. Experts claim that sound stimulation in the prenatal period is an environmental factor that can affect the growth of the fetus in the womb and that there are certain parts of the brain that are affected by familiar music rather than music unknown to listeners\[^3,4,8,9\]. In Indonesia, the majority of people are Muslim so that the murotal voice is often heard. Listening to murotal has a calming and relaxing effect on a person, so that it will also contribute to lowering blood pressure\[^10,11\]. Murotal both sung by men and women can be distinguished by type frequency and sound intensity. The accuracy of the voice in women reaches 100% while in men 95.47% this happens because the male voice is detected to be similar to the female voice so that the accuracy of the male voice is reduced\[^12–14\].

This study identifies differences the effect number neuron cells of stimulating the murotal quran in the cerebrum and cerebellum of newborn mice (\textit{Rattus norvegicus}) whose mothers to murotal qori voice stimulation and murotal qoriah voice stimulation during pregnancy.

**Materials and Methods**

This research is an experimental study on mice (\textit{Rattus norvegicus}) which was conducted from February to April 2021 at the Laboratory of the Faculty of Veterinary Medicine, UNAIR, Surabaya. This study used 30 adult female mice (\textit{Rattus norvegicus}) aged 2-3 months of pregnancy which were exposed to stress during pregnancy on the 6th until 17th days of pregnancy. The research subjects were divided into 3 groups which were randomly selected (Q1, Q2, and Q3) with 10 mice in each group.

The first group: the group was not given any treatment, the rats were only pregnant and were allowed to eat and drink like pregnant rats in general.

Second group: qori sound stimulation group, pregnant rats on days 6-17 in a soundproof room for 1 hour playing ar rahman letters with sound intensity close to 65 dB at night.

The third group: the qoriah sound stimulation group, pregnant rats on days 6-17 in a soundproof room for 1 hour playing ar rahman letters with a qoriah sound with a sound intensity close to 65 dB at night Fourth group: Control group with standard treatment without stress exposure.

**Sampling Inspection**

\textit{Rattus norvegicus} mothers were anesthetized then the pups were born by sectio caesarea (SC) on the 17th day of pregnancy. The pups of \textit{Rattus norvegicus} which were to be sacrificed were anesthetized first, and then the cranium was cut in the sagittal direction from caudal (occipital) to rostral (frontal), right between the two hamisters of their brain. Furthermore, the brain was released. The separated brain was weighed, and then put in a 10% formalin solution for organ preservation; the cerebrum and cerebellum were taken. Furthermore,
Hematoxylin-Eosin (HE) staining were made.

**Data Analysis**

To see the normality of the data, the Shapiro-Wilk test was used. If the data obtained are normally distributed, then the ANOVA test is used followed by LSD (Least Significant Difference) to see the differences in all groups. If the data obtained are not normally distributed, the Kruskall Wallis test and the Mann Whitney test are used. This study uses a significance level of P<0.05. To simplify statistical calculations, researchers used the SPPS tool version 21.

**Results and Discussion**

**Results**

The results showed the highest number of neurons in the cerebrum and cerebellum on murotal sound stimulation compared to the control group, the qori sound murotal stimulation group, and the qoriah sound murotal stimulation group (Table-1).

The results of the normality test using the Shapiro-Wilk test in the treatment group obtained a significance value (p-value)> 0.05, which means that the data distribution was normally distributed, so the Analysis of Variance (ANOVA) test was used. Tested whether there were differences in the treatment group in the number of neuron cells in the cerebrum and cerebellum.

Based on the results of the ANOVA test in table-2, it is known that there is no significant difference between groups in the number of neurons in the cerebellum and cerebellum in the newborn *Rattus norvegicus*.

Discussion

The highest mean number of neuron cells cerebrum and cerebellum was in the qoriah sound stimulation group followed by qori sound stimulation and the control group. Female voices tend to have better frequency intensity and are familiar to fetal ears so they are most easily captured by the fetal brain. However, there was no significant difference between the treatment group and the control group on the number of neuron cells in the Cerebrum and Cerebellum Rattus norvegicus offspring then continued in the test. post-Hoc LSD which showed that there was no significant difference in the number of Cerebrum and Cerebellum neuron cells between the treatment group and the control group.

Sound can resonate with cell organelles, one of the cells is brain nerve cells, where the brain tissue has main cells, namely neurons that function to convey signals from one cell to another\cite{15,16}. Sound containing the tone - the tone harmonious and orderly able to generate rhythmic stimulation to the central nervous system because the performance of the brain that can coordinate and control all activities of the body into homeostasis\cite{14}. In contrast to murottal, music will sound beautiful as created by the tool or the human voice sounds carefully structuring can form a specific pattern\cite{17}.

In pregnancy nuclei in the brain stem have formed at the beginning of the second trimester. At 20-22 weeks of gestation, some neurons in the hearing center have formed dendrites and axons, with the physiological and behavioral responses of the fetus to sound, including brainstem reflex activity, indicating that the auditory stimulus has reached the center of the auditory system in the brain\cite{9,18,19}. The growth of children has been started since I was in the womb it is not surprising that Islam says education has started since the baby still in the womb. The fetus begins to hear clearly at the age of 6 months in the womb so that the fetus can move its body according to the rhythm of the mother’s tone of voice\cite{20}. Factors the environment in the form of sound on fetal brain development in the form of sound affects the growth of neural connections and causes the process of neurons to adapt to the stimulation given\cite{21}.

There was a difference in the results of the study, but it was not significant because of the fetus being able to hear sounds from outside apart from treatment, sounds from outside and from within. Sounds from the inside are hidden and can be heard more in low frequencies such as the mother’s heart sound, the sound of the mother’s intestinal peristaltic movements and the sounds around the mother, and the similarity of the voice of women/qoriah to the voice owned by the mother.

Stimulation for fetal hearing is the easiest form to do because it is automatic more often hear sounds in the mother’s body such as the sound of the heartbeat, body fluids and digestion. A report found similarities in the accuracy of women’s voices and men’s voices tested with a sound frequency detection system with a backpropagation neural network, for the type of voice it was known that the accuracy of women’s voices reached a value of 100% while in men 95, 47% of this happens because male voices are detected to be similar to women’s voices so that the accuracy of men’s voices is reduced\cite{12}. The research conducted which compared the mother’s voice with the recorded voice of the father and played in the fetus showed no significant difference in fetal heart rate, number and duration of fetal movement\cite{22}.

Sounds from the outside and the inner environment that the fetus can hear can activate neurotransmitters in neuron cells that have ionic ions such as glutamate and Ca\textsuperscript{2+} influx which will bind to CAMK then phosphorylate with CREB which will then stimulate BDNF mRNA to become BDNF, then BDNF will bind to its receptors, namely TrKB which will affect the process of proliferation, differentiation, migration, synaptogenesis, apoptosis and myelination which will increase the number of neuron cells.

Conclusion

In conclusion, our data show that there is a difference in the mean number of neuron cells in the cerebrum and cerebellum. However the it is not significant. The highest
mean number of neuron cells was in the qoriah voice stimulation group followed by qori voice stimulation and the control group. Female voices tend to have better frequency intensity and are familiar to fetal ears so they are most easily captured by the fetal brain.

Abstract

Introduction – Systematically, obesity was associated with low-grade inflammation indicated by abnormal adiponectin secretion, thereby activating inflammatory signaling pathways that could impact chronic inflammation and increased the risk for causing cancer cells. The exercise was an effective and efficient strategy in maintaining pro and anti-inflammatory homeostasis. Exercise performed regularly could increase adiponectin levels as anti-inflammatory markers and decreased pro-inflammatory cytokines, such as Tumor Necrosis Factor-alpha (TNF-α).

Objective – This study aimed to prove the effect of acute aerobic exercise in the decrease of TNF-α levels on obese adolescent females.

Material and Methods – A total of 14 obese adolescent females were participated in this study and were randomly divided into two groups, namely CG (n=7, control group), AEG (n=7, acute aerobic exercise group). ELISA was used to measure TNF-α levels in all samples. Statistical analysis was performed using the Paired Samples T-Test and Independent Samples T-Test.

Results – The results of the Paired Samples T-Test on CG showed that there was no significant difference between the mean of TNF-α levels in pre-exercise and 10 min post-exercise (p>0.05). However, AEG showed a significant difference between the mean of TNF-α levels in pre-exercise and 10 min post-exercise (p<0.05). The results of the Independent Samples T-Test showed that there was no significant difference between the mean levels of TNF-α pre-exercise in CG and AEG (p>0.05), while the mean TNF-α level of 10 min post-exercise among CG and AEG showed a significant difference (p<0.05).

Conclusion – Our data showed that TNF-α levels were decreased by 10 min post-acute aerobic exercise. Therefore, acute aerobic exercise could be used as a method to decrease the level of inflammation in obese adolescent females.

Keywords: Acute aerobic exercise, TNF-α levels, obese adolescent females

Introduction

Obesity was a world health problem that must be noticed¹, because obesity increased the risk of various chronic diseases such as type 2 diabetes (T2D), hypertension, and cardiovascular disease (CVD)²-³, and several types of cancer⁴. Obesity was also associated with bad impact on health quality including metabolic complications which involved many cytokines and hormones¹. One of the cytokines that played a role in obesity was Tumor Necrosis Factor alpha (TNF-α)⁵. TNF-α was a pro-inflammatory cytokine that found increased in obese condition⁶-⁷. Research conducted by
Dahlman et al.\textsuperscript{8} reported that there was a correlation between TNF-\(\alpha\) polymorphism and obesity-related phenotypes. The increased TNF-\(\alpha\) could cause hyperlipidemia and insulin resistance, especially in the presence of single nucleotide polymorphisms (SNP) on the promoter (-308 G/A and -238 G/A)\textsuperscript{9}. In addition, TNF-\(\alpha\) was also an insulin receptor antagonist, so that increased TNF-\(\alpha\) production could interfere with the signaling of insulin and inhibited glucose absorption\textsuperscript{10}, which could lead to insulin resistance\textsuperscript{11}.

Systematically, obesity was associated with low-grade inflammation indicated by abnormal secretion of adiponectin, so that could activate inflammatory signaling pathways\textsuperscript{12} which could impact chronic inflammation\textsuperscript{13} and increased the risk for causing cancer cells\textsuperscript{14}. That was proved by an increase in inflammatory markers, such as TNF-\(\alpha\) in obese individuals compared to normal and lean individuals\textsuperscript{5-6}. The high level of TNF-\(\alpha\) was the characteristic of many malignant cancers, including breast cancer, and was often associated with cancer cell aggressiveness and poor prognosis\textsuperscript{15}. Therefore, a specific strategy was needed to prevent the increase of inflammation in obese individuals through non-pharmacological therapy based on exercise. The exercise was an effective and efficient strategy in maintaining pro and anti-inflammatory homeostasis in the body\textsuperscript{16}. Exercise performed regularly could increase adiponectin levels as a marker of anti-inflammatory\textsuperscript{17-18} and decreased pro-inflammatory cytokines, such as TNF-\(\alpha\)\textsuperscript{19}, so that exercise could be used as a strategy in maintaining the balance of inflammation level. However, several previous studies reported controversial results. Such as research conducted by Dos Santos et al.\textsuperscript{20} reported that moderate-intensity continuous exercise (55% \(\text{VO}_2\text{max}\)) did not significantly change TNF-\(\alpha\) levels in obese adolescents aged 15-18 years. Study conducted by Gerosa-Neto et al.\textsuperscript{21} found a decrease in TNF-\(\alpha\) levels in obese subjects who were exercised with 70% \(\text{HR}_\text{max}\) intensity for 16 weeks and increased in 90% \(\text{HR}_\text{max}\) intensity. Meanwhile, research conducted by Mokhtarzade et al.\textsuperscript{22} also reported that aerobic interval exercise significantly decreased TNF-\(\alpha\) levels. Research conducted by Salamat et al.\textsuperscript{5} reported that there were no significant decrease in TNF-\(\alpha\) level after endurance, resistance and concurrent (endurance–resistance) exercises.

Based on those exposures, this study aimed to prove the effect of acute aerobic exercise on decreasing TNF-\(\alpha\) levels in obese adolescent females. We hypothesize that acute aerobic exercise could decrease TNF-\(\alpha\) levels in obese adolescent females.

**Materials and Methods**

**Study design**

This study was true experiment with the pretest-posttest control group design. The total subjects were 14 obese adolescent females, aged 20-23 years, body mass index 27.5-35 kg/m\textsuperscript{2}, normal blood pressure, normal resting heart rate, fasting blood glucose <100 mg/dL, hemoglobin 13-17 g/dL and randomly divided into two groups, namely CG (\(n\)=7, control group), AEG (\(n\)=7, acute aerobic exercise group). All subjects received information verbally and written about this research. Subjects filled out and signed informed agreements before participating in the study. All procedures in this study have approved by the Health Research Ethics Commission of the Faculty of Medicine, Universitas Brawijaya Malang by number 26/EC/KEPK–S1/02/2020.

**Exercise protocol**

The intervention was given at the Malang City Health Office Fitness Center. The intervention of aerobic exercise was performed by running on a treadmill with an intensity of 60-70% \(\text{HR}_\text{max}\) for 40 minutes with details of 5 minutes for warming-up (50-60% \(\text{HR}_\text{max}\)), 30 minutes of the core performed continuously (60-70% \(\text{HR}_\text{max}\)) and 5 minutes for cooling down (50-60% \(\text{HR}_\text{max}\))\textsuperscript{23-25}. The intervention was performed at 07.00-09.00 A.M. using a treadmill (Pulsar 4.0 HP Cosmos Sports & Medical, Nussdorf-Traunstein, Germany). The heart rates were monitored during exercise using a polar heart rate monitor (Polar H10 Heart Rate Sensor, Inc., USA). The research environment had a room temperature of 26±1 °C and a humidity level of 50-70%\textsuperscript{26-27}. 
Anthropometric measurements and physical fitness

Measurement of body height used stadiometer (SECA, Chino, CA, USA). Measurement of body weight used electronic scale (Tech 05®, China). Body mass index (BMI) was measured by calculating body weight (kg) divided by body height in meter quadrat ($m^2$). Blood pressure was measured using an OMRON automated device (OMRON, HEM-7130 L Model, Omron Co., Osaka, Japan). Maximum measurement of oxygen volume ($VO_2\text{max}$) used Astrand 6-minute cycle test method using Monark 828 E tools Version 1010 ergo cycle (Monark, Vansbro, Sweden).

Blood collection and analysis

The blood sample was taken 3 ml from cubital veins. At the time of blood taking, the subject was in a sleeping position. Blood was taken two times, before exercise and 10 minutes after exercise. The blood was centrifuged for 15 minutes at a speed of 3000 rpm. Measurement of TNF-α levels used Enzyme-Linked Immunosorbent Assay (ELISA) kit (Catalog No. E-EL-H0109; Elabscience, Inc., China) by standard curve range 7.81–500 pg/mL and sensitivity 4.69 pg/mL. Blood was taken to check FBG and Hb levels performed on the capillaries located at the tip of the middle finger. FBG was measured in mg/dL using an Accu-Chek Performa (Roche, Mannheim, Germany), while Hb was measured in g/dL by Easy Touch GCHb (Easy Touch, Hsinchu, Taiwan).

Statistical Analysis

Data were analyzed using Statistical Package for the Social Sciences (SPSS) for Windows, version 17 (SPSS Inc., Chicago, IL, USA). The normality of data was tested using Shapiro-Wilk. To compare the results, we used Paired Samples T-Test and Independent Samples T-Test. All data were presented as mean ± standard error of the mean (SEM), and $p<0.05$ was considered significant.

Results

The basic profiles of the samples, including age, body height, body weight, body mass index (BMI), systolic blood pressure (SBP), diastolic blood pressure (DBP), resting heart rate (RHR), maximal oxygen volume ($VO_2\text{max}$), hemoglobin (Hb), fasting blood glucose (FBG), were displayed in Table 1.

Based on Table 1, the results of the Independent Samples T-Test showed that there was no significant difference in the mean data of the research subject’s characteristics between CG and AEG ($p>0.05$). The analysis results of TNF-α levels between pre-exercise and 10 minutes post-exercise could be seen in Figure 1.

**Figure 1. TNF-α level pre-exercise vs. 10 min post-exercise.** CG: Control group; AEG: Acute aerobic exercise group. Data were presented as mean±SEM. $p$-values was obtained using Paired Samples T-Test to compare 10 min post-exercise and pre-exercise TNF-α level.

Based on Figure 1, the results of Paired Samples T-Test on CG showed that there was no significant difference between the mean TNF-α levels in pre-exercise and 10 min post-exercise (19.30±1.10 vs. 19.41±0.77 pg/mL, ($p$-values=0.940). However, the results of AEG showed a significant difference between the mean of TNF-α levels in pre-exercise dan 10 min post-exercise (19.50±1.31 vs. 16.35±0.29 pg/mL, ($p$-values=0.038)). The analysis results about the mean TNF-α levels in pre-exercise (CG*AEG) dan 10 min post-exercise (CG*AEG) could be seen in Figure 2.

**Figure 2. TNF-α level CG vs. AEG.** CG: Control group; AEG: Acute aerobic exercise group. Data were presented as mean±SEM. $p$-values was obtained using Independent Samples T-Test to compare AEG and CG TNF-α level.
Based on Figure 2, the results of the Independent Samples T-Test showed that there was no significant difference between the mean of TNF-α levels in pre-exercise of CG and AEG (19.30±1.10 vs. 19.50±1.31 pg/mL, (p-values=0.909). Meanwhile, the mean between TNF-α level in 10 min post-exercise of CG and AEG showed a significant difference (19.41±0.77 vs. 16.35±0.29 pg/mL, (p-values=0.003).

**Discussion**

Based on the results of the study, it showed that the acute aerobic exercise which was performed for 40 minutes/exercise session significantly decreased TNF-α levels. These results were in line with the results of research conducted by Jahromi et al.19 reported that resistance exercise significantly decreased pro-inflammatory cytokines, such as TNF-α. Likewise, exercise with an intensity of 70% VO2 max significantly decreased TNF-α levels28. However, these results were opposite with the research conducted by Bernecker et al.29 which reported that heavy-intensity exercises exactly increased pro-inflammatory markers while circulating, such as TNF-α.

These different results might be due to the differences in the intensity of the exercises performed. In our research, exercise was performed in moderate-intensity (60-70% HRmax) meanwhile the previous studies used heavy-intensity. Exercise with an intensity of 70% VO2 max could significantly decrease TNF-α21. Based on a review article conducted by Gonzalez-Gil et al.16 also reported that moderate-intensity exercise could increase the anti-inflammatory environment, so that could decrease systemic inflammation indicated by the decreased pro-inflammatory cytokines such as TNF-α and the increase of adiponectin as anti-inflammatory markers. Moderate-intensity exercise could be an effective strategy in maintaining the anti-inflammatory environment16, because moderate-intensity exercise could decrease pro-inflammatory cytokines such as TNF-α30 and increased the level of adiponectin as the anti-inflammatory marker31, so the moderate-intensity exercise could be used to maintain the balance of inflammatory level.

Exercise played a role in regulating the level of systemic inflammation because exercise could increase muscle contraction so that it could suppress pro-inflammatory activity through the release of myokines and cytokines30. The increase of muscle contraction regularly could produce and released cytokines to the circulation and other body areas, including the immune system30. Interleukin-6 (IL-6) was a cytokine produced and released by binding the skeletal muscle fibers to affect the other organs32. The production and the release of IL-6 was believed that had a correlation with the decrease of TNF-α level induced by exercise, so it could activate the anti-inflammatory response, which was affected by the increase of interleukin-10 (IL-10), interleukin-1 receptor antagonist (IL-1RA), and the level of tumor necrosis factor-soluble receptor (sTNFr), so that caused pro-inflammatory cytokines, such as TNF-α decreased33-36. When inflammation occurred in the human body, IL-6 could limit the gen expression which coded pro-inflammatory cytokines, such as TNF-α, Interleukin 1 beta (IL1β), Nitric Oxide Synthase 2 (NOS2), and activated terminal c-Jun N kinase (JNK), so that could add the responsiveness of macrophages on interleukin-4 (IL-4) to decrease the inflammation level37. Besides, exercise could also increase adiponectin levels17-18. When adiponectin levels increased and binded to adiponectin receptor 1 (ADIPOR1) or adiponectin receptor 2 (ADIPOR2) there would be activation of AMP-activated protein kinase (AMPK) and peroxisome proliferator-activated receptor alpha (PPARα)16, caused a decrease in liver gluconeogenesis and lipogenesis, and increased glucose uptake in skeletal muscle (SKM) and white adipose tissue (WAT). This directly suppressed the secretion of TNF-α and monocyte chemoattractant protein-1 (MCP-1), and also increased interleukin 10 (IL-10) and macrophage polarization (M2)16,28-29.

**Conclusion**

Based on the results, it could be concluded that acute aerobic performed for 40 minutes/session exercise significantly decreased TNF-α level compared with the control group. Acute aerobic exercise could be one of the effective non-pharmacological methods to decrease
inflammation level indicated by the decrease of pro-inflammatory cytokines, such as TNF-α.

Acknowledgments

We would like to express our gratitude to the Faculty of Sport Science State University of Malang that has provided facilities in the screening process of a prospective research subject and the Fitness Center of the Health Ministry of Malang that has provided facilities well. Also, we greatly appreciate and wish to thank Palang Merah Indonesia (PMI) Blood Transfusion Unit (UTD) Malang that has assisted the blood sampling and blood centrifuge processes. This includes but is not limited to all the parties of to Physiology Laboratory Faculty of Medicine Universitas Brawijaya Malang who has helped the analysis process of TNF-alpha level and all-volunteer who have participated in this study.

Funding: The fund that used for this research is came from personal cost.

Abstract

Background: The condition of Covid-19 pandemic potentially influences hand hygiene compliance as a result of workload changes, increased awareness of healthcare workers (HCWs) and personal protective equipment procedures, especially in terms of hand glove use.

Objective to know the adherence of healthcare workers at the pediatric intensive care unit (PICU) to comply with hand hygiene and glove use during the pandemic.

Methods An observational prospective study was carried out including all HCWs stationed at the PICU Dr Soetomo General Hospital during January 2021. All participants were to sign an informed consent before the study took place. A target of 500 opportunities was estimated during the observation, and recorded using infra-red cameras placed at ten points. Hand hygiene compliances were evaluated according to the video surveillance records by an independent auditor. Compliance was measured by dividing total number of observed appropriate hand hygiene by the sum of opportunities. Data were analysed using Chi Square test at a significance of p<0.05.

Results: A total of 28 HCWs were eligible for the study; 9 were excluded. The majority were female (21; 75%), the mean age was 37.9 (SD 5.2) years. During 72 hours’ observation among 526 glove-use opportunities 104 (19.7%) actual glove-use episodes were evident. The hand hygiene compliance was lower (41.3%) when wearing gloves as compared to those with no glove use (68.2%) (p<0.001).

Keywords: hand-hygiene compliance, hand-gloves, pediatric intensive care unit, Covid-19 pandemic

Introduction

Healthcare workers have been facing increased risk of Covid-19 occurring in hospitals during the pandemic condition, consequently leading to increased awareness to comply with hand hygiene due to concerns for Covid-19 transmission. Moreover, it was also apparent that there was an increased workload related to higher number of patients and responsibility for personal protective equipment procedures at a higher rate of duration and quality. On the other hand, the working comfort while wearing high-level personal protective equipment would certainly be low, which could in turn lead to bad influence on hand hygiene compliance.¹,²

Reports on the prevalence of nosocomial infection especially in the pediatric ward globally varied, ranging
from 4.8% in developed countries to 48% in developing countries, where the mortality rate also varied from 5% - 33.8%. Many cases hospital-acquired Covid-19 infection have been detected, where approximately 12.5% has been reported among the total cases in Europe. There has been no distinct data on total Covid-19 nosocomial infection in Indonesia.

The latest recommendation during a pandemic condition related to hand hygiene protocols and covid-19 infection control for HCWs has been issued. Local China guidelines accommodated additional hand hygiene moments to the process of putting on and removal of personal protective equipment. Use of gloves as part of personal protective equipment also increased along with the contact risk level.

Some experts expressed the hypothesis that there would be an increase in hand hygiene compliance during the pandemic. However, evidences measuring compliance have been scarcely published so far, globally as well as domestically. Although there has been a lot of research which concerned the relationship between hand hygiene compliance and glove use, the level of hand hygiene compliance and glove use during the pandemic has never been studied. Accordingly, this study was conducted to explore the profile of hand hygiene compliance related to glove use at the pediatric intensive care unit during the pandemic.

**Material and methods**

This observational prospective study, conducted during January 2021, took place at the pediatric intensive care unit (PICU) Dr Soetomo General Hospital, a third level teaching hospital of the Airlangga University. The PICU of this hospital consists of three parts, namely PICU 1, PICU 2, and the nurse station, bearing a capacity of 8 beds. Patients admitted were all negatively confirmed for Covid-19 by PCR swab. Health workers wore a level 1 protective equipment. Most of the patients were of respiratory and hematology emergencies. The bed occupancy ratio during the study was 50%, which did not significantly differ from the previous months.

Eleven doctors (1 consultant, 10 residents) and 16 nurses were occupied in the PICU. The study was performed only by doing an observation using video surveillance without any intervention. The cameras were of the eyeball type infra-red camera (Daihua technology, made in the People Republic of China) DH-HAC- T1A21P series, along with a size of 3.6 mm, which were placed at 10 points. The devices provided a high definition video picture of 1080 pixels and 30 frames per second, subsequently able to show the details of hand hygiene movements performed. One sink was provided in each part of the PICU, along with standard operational procedures (SOP) about hand hygiene in the PICU.

A 24 hours’ recording was obtained without the need for an operator. Records were sorted and edited to produce a short video clip and further evaluated for hand hygiene compliance by an auditor of the Infection Prevention and Control (IPC) committee at a certified hospital, and entitled as an Infection Prevention control Nurse (IPCN), certified by the Indonesian Association of Infection Prevention Control Nurses (HIPPII). Evaluation of hand hygiene compliance was carried out by referring to the 5 moments for hand hygiene concept as well as adherence with proper hand hygiene procedures.

A minimum number of 500 opportunities was targeted. Audit was performed using an observation sheet similar to that used by the hospital team for Infection Prevention and Control, adapted from the WHO module.

All health professionals (doctors, nurses, physiotherapists) stationed at the PICU served as study samples, and were to sign an informed consent before the study commenced. Statistical analysis applied to judge differences in hand hygiene compliances related to glove use was the Chi-Square’s test at a significance level of P<0.05.

**Operational Definition**

Hand Hygiene is a practical management of
handwashing as outlined by the 2009 WHO Guidelines, consisting of hand rub (alcohol-based) and hand wash (with water and common soap or antimicrobial soap).

Hand hygiene related to glove use is handwash or hand rub before wearing gloves, hand rub while wearing the same gloves, handwash or hand rub after glove removal.

Hand hygiene compliance is the accuracy of the hand hygiene procedures performed when indicated as outlined by the WHO. The number is measured using the formula: \((\text{the action of proper hand hygiene/oppotunity}) \times 100\), and stated as percentage.

Opportunity is the moment of requiring the action of hand hygiene. Example: A doctor intends to do physical examination on a patient, which will be counted as 2 opportunities, before and after touching the patient.

Missed is failure to perform proper hand hygiene in the form of hand rub or handwash when there is an opportunity. Repeated hand rub of a glove-wearing hand is considered as missed.

**Ethical Clearance:** This study was approved by the medical researched ethical Health Research Ethics Committee, Dr. Soetomo Hospital Surabaya No. 0271/LOE/301.4.2/1/2021. Access to acquire CCTV records has also been gained from the Director of the Dr Soetomo Hospital.

**Results**

During the study period video recording in the PICU Dr Soetomo General Hospital took place using a total time of 72 hours, where 526 opportunities for hand hygiene were identified. A total of 37 subjects were recorded doing the activity necessitating hand hygiene in the PICU. However, 9 were excluded due to missing informed consent. Subjects studied consisted of 7 males (25%) and 21 females. Mean age of the studied subjects was 35.7 (SD 5.2, 95% CI) years. Studied subjects who were a doctor by profession comprised of residents and a consultant, who did the rounds and activities in the PICU. Among the 16 nurses considered as study subjects the majority have had a period of employment for more than 10 years. One physiotherapist stationed at the PICU was also a candidate for this study subject. Characteristics of the study subjects are shown in table 1. Total compliance was 62.9%. Among the total opportunities 104 (19.7%) of glove use opportunities was evident. Hand hygiene compliance when wearing gloves was 41.3%, which was significantly lower as compared with a 68.2% adherence to hand hygiene not using gloves. (p<0.001). (Table 2).

**Discussion**

This study involved health workers as subjects consisting of 28 study subjects. The majority were nurses with a year-service for more than 10 years. Bin Ibrahim in his study found that seniority, profession being a nurse, and female gender were positively associated with good hand hygiene compliance, and that seniors, nurses, and women were more likely to perceive a need for improvement. They more likely have the ability to influence other healthcare workers to achieve a better hand hygiene behavior.\(^{11}\)
