This study showed a 19.7 % frequency of glove use. This result was certainly lower than the majority of other studies where this action could reach 26% to 40% in a ward with high risk setting.\(^{12}\) Glove usage refers to the wearing of gloves to either prevent the hands becoming contaminated with organic matter or microorganisms, or to prevent the transfer of microorganisms to both patients and healthcare workers.\(^{13}\) Hand glove use as a component of personal protective equipment increased during a pandemic, and this was related to a personal protective equipment policy. Universal mandatory gloving in relation with the level of personal protective equipment (PPE) was not considered necessary as a policy at our research sites. Nor were we able to evaluate the increase of hand glove use during the pandemic condition due to lack of data before the pandemic.

We did not analyze the nosocomial infection rate in this study. A systematic review by Picheansanthian collected evidences of successful hand glove use to decrease contamination of health care workers’ hands.\(^{13}\) A decrease in contamination rate does not necessarily mean a decrease in nosocomial infection. The effect on decrease of nosocomial infection would only be achieved by high adherence to proper glove use. This fact has been proved by the implementation of a tight protocol as practiced by Janota in his study where participants of glove use were obliged to perform hand rub using alcohol. It was evident that this action resulted in a decrease of late sepsis in the neonatal intensive care unit (NICU).\(^{14}\) Universal mandatory gloving during RSV season was associated with significantly lower rates of bloodstream infection (BSI), central line associated blood stream infection (CLABSI) and Hospital Acquired pneumonia (HAP) in the pediatric care unit.\(^{15}\)

Our study indicates that compliance with hand hygiene at the moment of hand glove use was only 41.3%, which was lower than when gloves were not worn, where the adherence was 68.2%. Data obtained from a study before the pandemic also revealed an inversely proportional relationship between the use of hand gloves and the compliance of hand hygiene,\(^{16}\) a finding that was consistent with the present study. Cusini proved that removal of the mandatory glove program was followed by an increase in hand hygiene compliance.\(^{17}\) This previous study also showed that although the overall compliance rate for glove use was high, gloves were also overused. Gloves were worn inappropriately for tasks that did not necessitate the use of gloves, and
healthcare workers did not always remove gloves and decontaminate hands between different patients and tasks, besides non-compliance with hand hygiene which could have occurred at the moment of shifting from dirty to clean body sites of the same patient. A small increase in hand hygiene compliance especially during the moment after patient’s contact has also been reported. A converse result where hand hygiene compliance was better during glove use has been shown by a more previous study. However, this study was dealing with a far smaller number of opportunities as compared with our observation.

Another issue concerning glove use during a pandemic is glove wearing hand disinfection using alcohol-based hand rub. This protocol has been recommended in light of problems and lack of logistics at the beginning of the pandemic. Our study did not necessarily use this protocol; routine use of hand gloves was not needed because all patients have been negatively confirmed for Covid-19. The latest WHO recommendation prohibited this practice, and required hand hygiene at the moment of gloving and ungloving. At the moment this research was undertaken the scarcity has been handled by the government authorities.

This study is the first research on hand hygiene compliance in Surabaya and also East Java Regional Area. We have controlled the Hawthorne effect, high false positive compliance as a result of health workers’ awareness of being audited, by indirect evaluation using video records. Time limits and the study location were the weakness of this observation so that the overall level of long-term compliance could not be depicted.

Conclusion

Healthcare workers’ hand hygiene compliance at the moment of wearing gloves was significantly lower compared with adherence to glove use in the Pediatric Intensive Care Unit during Covid-19 pandemic.

Conflict of Interest: None declared.

Acknowledgements: The study team thank and appreciate all the other health care workers (residents, nurses, physiotherapist) involved, who willingly served as study samples, for their effort in improving hand hygiene during daily patient care. Our special thanks to Tri Budi as the independent auditor for spending the time to carry out surveillance and evaluation of the hand hygiene compliance.

Source of Funding: The authors received no specific grants from any funding agency in the public, commercial, or not-for-profit sectors.

Assessment of Self-care Among Elderly Residents at Nursing Homes in Middle Euphrates Cities in Iraq

Bashaer Mohsen Ali¹, Ali Kareem Al-Juboori²

¹Research Scholar, Ministry of Health, Kerbala, Iraq, ²Professor, University of Kerbala, College of Nursing, Karbala, Iraq

Abstract

Self-care is known to be a health resource in later life because it enables the elderly to improve their health and live at home as long as possible⁴. It is therefore essential to resolve the question of self-care in the elderly⁵. The aim of the current study was to assess the level of self-care among elderly residents at nursing homes and to find out the difference between level of self-care with regard to socio-demographic and clinical characteristics. Descriptive study design carried out among 60 elderly persons at nursing homes in middle Euphrates, they are selected by using non probability sampling. The study instrument composed of 2 parts. 1st Elderly’s Demographic Characteristics, 2nd self-care scale. The results of study reveal the overall assessment of self-care domains was moderate. In addition, there is a high significant in difference in self-care level of the elderly with regard to their age and their marital status.

Key words: Self-care, elderly, nursing homes, assessment

Introduction

Self-care is known to be a health resource in later life because it enables the elderly to improve their health and live at home as long as possible. Personal, interpersonal and external conditions influence self-care. For instance, advanced age has negative impact on self-care, while the functional capacities to perform daily activities is positively correlated to self-care. It is therefore essential to resolve the question of self-care in the elderly. Self-care is a subjective care which people use to control their activities every day and it is a key to wellness and illness care. The behaviors of self-care are learned that the individual conducts “self-care activities” to maintain life, wellbeing and health status. Self-care has emerged as a comprehensive concept constructed from a broad collection of perspectives. Alongside such developments the World Health Organization (WHO) has formed a wide notion of self-care including “what people do for oneself to establish and maintain health, prevent and deal with illness”⁶.

It is important to underline that most seniors have a positive vision of life. The elderly may take part in or conduct various activities which give a sense of independence. Moreover, life in a very residential care homes was attributed with a restricted ability for activities and elevated inactivity, resulting in deterioration of self-care activities among residents. The aim of the current study was to assess the level of self-care among elderly residents at nursing homes and to find out the difference between level of self-care with regard to socio-demographic and clinical characteristics.

Methodology

Descriptive study design carried out among 60 elderly persons at nursing homes in middle Euphrates, they are selected by using non probability sampling. The study instrument is a questionnaire designed according to the study purpose. The study instrument composed of 2 parts. 1st Elderly’s Demographic Characteristics, 2nd self-care scale. The self-care questionnaire consists of three domains which participants rate themselves on how often and how well they take care of themselves.
in recent days. Those domains include: Physical Self-Care domain, Psychological Self-care domain, Social domain (Social Life /Family /Relationships). Self-care questionnaire had been scored and rated on five levels Likert scale. The reliability of the questionnaire determined by Cronbach’s alpha for the internal consistency reliability. The data is collected by using structured interview technique. The data is analyzed by using descriptive and inferential statistical analysis.

Results

Table (1) shows descriptive statistics (frequency and percentage) of self care assessment (physical self care) for the study subjects; it shows Assessment (mean and ratio of scores) of self care assessment (physical self care) for the study subjects, it shows that the assessment of elderly residents is (moderate) for the items (1, 4, 8, 9, 10), and it is considered (high) for the items (2, 5, 6) and (low) for the rest.

Table (2) shows descriptive statistics (frequency and percentage) of self care assessment (psychological self care) for the study subjects, it shows that the assessment of elderly residents is (moderate) for the items (1, 2, 5, 6, 7, 8), while it is considered (high) for the items (3, 4, 9).

Table (3) shows descriptive statistics (frequency and percentage) of self care assessment (social self care) for the study subjects, it shows that the assessment of elderly residents is (moderate) for the items (1-7, 9), while it is considered (low) for the item numbered (8).

Table (4, 5) shows differences in overall mean of scores in self care assessment among study subgroups according to demographic data, it reveals that there is a significant increase (P<0.05) in self care assessment in subjects with optional entry to nursing home (MS=3.19) compared to those with compulsory entry (MS=2.69). The same table demonstrate that there is a high significant increase (P<0.01) in self care assessment scores in subjects that can’t perform daily activities (MS=3.56) compared to those that can perform (MS=2.62).

**Discussion**

With regard to physical self-care, the results reveal that about 43.33% of the subjects never had exercise for more than 20 minutes. Many physical, social, and psychological factors affect the ability of the elderly to perform exercises. The physical factors involve normal age-related changes, especially decrease in bone mass, muscle mass and muscle strength. The prevalence of chronic diseases also impact the ability to practice the exercise. Psychological status of residents, loss of home and relocation to nursing home, daily institutional routine, lack of motivations, absence of resource; all these factors affect the desire to perform the exercise.

This result comes along with a study\(^6\) whose findings indicate that the majority of elderly people (81.7%) did not practice any type of exercise. The findings reveal that most of elderly people (43.33%) are never take time to breathe deeply. Also, the results indicates that about 5.00% of them never engage in stress-reducing activities (excluding TV or screen time). This result reinforced by a study\(^7\) about “How residents spend their time in nursing homes”. They studies seven nursing homes in New Brunswick and found that the elderly people spend an average of (2/3) of their time in their rooms and a small percentage tend to exercise whereas watching (TV or screen time) and sitting takes up nearly 40% of their time. The findings of study appears that about 3.33% of
them never spend time outdoors. These result disagree with a study\(^{(8)}\) about the favorite activities of older adults. In addition, the percentage 3.33\% of elderly are never feel nourished, healthy, and strong. The reason may be that the homes provide for their basic needs only, while their hobbies are only supported by donations.

With regarding to psychological self-care, the results reveal that about 43.33\% of the subjects never remember to make dreams and goals a priority. This results disagree with a study\(^{(9)}\) regarding resources of life and personal goals in old age. They mentioned that the personal goals extend from simple everyday activities to grand, lifelong endeavors. Also, their results determined that about half of elderly people reported at least (one) goal in the dimension of health maintenance whereas the highest percentage of them (33\%) reported social goals. Moreover, the results of study determined the percentage (13.33\%) of elderly people are never have hope that things will get better. The reason for this result is due to their separation from their children and grandchildren and their status in the institution instead of their presence in their homes. In addition, the nursing homes does not have a good reputation, but rather is considered as the individual’s failure to “secure” his old age.

Regarding the social self-care, the results reveal that about 43.33\% of the subjects never do fun with family or friends at least once a week. This finding was in agreement with a previous study which indicates that only 31.9 percent of respondents reported regular participation in trips outside the nursing home, and 25.8 percent reported regular visits to friends or family; while, 89.9 percent claimed that entertainment with other elderly residents was a regular practice\(^{(10)}\). Also, the results of study appears that the total level of social self-care was moderate, this may be due to the elderly people in nursing home live in shared rooms, and this probably increased the chance of social interaction. Additionally, the results of study reveal the overall assessment of self-care domains was moderate. This result is reinforced by a study\(^{(11)}\) conducted in Iran which mentioned that the level of self-care among elderly people was a moderate level.

Tables (4)\&(5) reveals that there is a significant increase in self-care level (MS=3.19) in subjects with optional entry compared to those with compulsory entry (MS=2.69). According to a study\(^{(12)}\) mentioned that the elderly people who voluntarily transition into residential environments in line with their needs and goals remain in the mastery and comfort zones. They continued personal growth and a sense of meaning in life, and they experience pleasurable feelings. Also, The results demonstrate that there is a high significant increase in self-care level (MS=3.56) in subjects that can perform daily activities. This result agree with a study\(^{(1)}\) mentioned that factors of self-care ability (weather to perform activities of daily life or to achieve wellbeing) showed a positive and strong correlation with ADL (r=0.83, r > 0.50, p < 0.001). Additionally, the results of study reveals that there is a high significant in difference in self-care level of the elderly and their age. This result coincides with a study\(^{(11)}\) indicated that the level of self-care decreased significantly with age (p=0.01, r = -0.212). Finally, the results of study reveals that there is a high significant in difference in self-care level of elderly people with regard to their marital status. This finding is in agreement with a study\(^{(11)}\) about the self-care and disability of elderly Iranians people. They indicated that married women and men (P= 0.027) had significantly better self-care.

**Conclusions**

Most of the elderly people are independent in performing daily activities. The level of self-care moderate level for the elderly residents in nursing homes. Among the recommendations in this research is that the competent authorities must be encouraged to improve services in the Geriatric home especially regarding the environment, entertainment activities, safety measures and transportation services.

The Relationship between Psychological Wellbeing and Self-Care among Elderly Residents in Iraq

Bashaer Mohsen Ali1, Ali Kareem Al-Juboori2
1Research Scholar, Ministry of Health, Kerbala, Iraq, 2Professor, University of Kerbala, College of Nursing, Karbala, Iraq

Abstract

Aging is described as progressive change in psychological, biological and social structure of persons. The advanced age contributed negatively to self-care. The relocation to care homes considered as stressful event for the elderly people. The purpose of this study to find the relationship between psychological well-being and self-care among the elderly residents at nursing homes in middle Euphrates in Iraq. A descriptive-correlational design was used to gather the information from the sample of 60 participants in nursing homes. The study has been carried out from November, 1st, 2019 to August, 2020. Purposive sample used to collect the data according to some criteria. The data collected by means of Ryff scales of psychological well-being (shorten version) and self-care questionnaire as well as the socio-demographical of study sample. The data collected by using structured interview technique with the elderly residents in nursing homes. The results of study indicate that a relationship exists between psychological well-being and self-care among the elderly residents in nursing homes. As the relationship between the two variables is a high significant positive relationship (r = 0.721). The recommendations focus on managing the problems existing among the elderly and monitoring their psychological state. Establishing educational programs on how to focus on the psychological and physical aspects. In addition, increasing leisure trips to various places.

Keywords: Psychological wellbeing, self-care, elderly, nursing homes.

Introduction

The various sociocultural, biological, and genetic factors as well as personal experience determine ageing process and quality of life of elderly. Besides, it encourages the elderly to experience positive emotions and attitudes, enhancing mechanisms of self-control and self-regulation and optimizing the ability to adapt and coping with problems at this vital stage(1).

Mental health affects each part of life, from job success to relations with others, friends and family members. These can affect the ability of an individual to sleep and less tangible things, such as the likelihood that an individual takes risks, push the self intellectually, and feel emotions such as fulfillment, gratitude and happiness. Thus, caring for mental health is such a crucial part of living a healthy, happy and well-rounded life(2). According to some authors, later-life research requires to focus more than just understanding the elderly as being sick and old. The mental health of older people is affected by life experiences that can be positive as well as negative(3).
The self-care affects directly on wellbeing (4), and self-care is a matter for people to support their own health and well-being on their own account (5). A study (6) indicated self-care as behaviors that promote physical and emotional wellbeing. Research on wellness has too recorded the beneficial effects of self-care activities on physical and psychological health (7). Abilities of Self-management to maintain and achieve well-being based on who the elderly have sufficient level of cognitive, physical and social activity to meet their goals and needs for well-being. Since these, lower functioning level is predicted to contribute to weaker skills of self-management. For example, lower level of emotional, physical and cognitive functioning may adversely affect the ability to self-manage ‘to have a constructive frame of mind,’ that corresponds to the capacity to adopt and sustain a positive frame of mind or positive expectation. It is believed that the willingness to maintain a positive frame of mind can lead to wellbeing, as it increases the time span and improves motivation, that in effect allows persons to participate in activities and not easily quit (8). The level of self-care engagement may lead to increased well-being. A study (4) observed an important, positive association between the level or value of self-care and well-being. Other research shows that improved self-care practice increases well-being. Based on what was mentioned above, we aim to find out whether there is a relationship between psychological wellbeing and self-care among elderly residents at nursing home in Middle Euphrates in Iraq.

Methods

A quantitative descriptive correlation design has been utilized in this study as a way to examine the relationships among the main study variables including the predictor variables, which include the psychological wellbeing variables (9), and the dependent variable, which was self-care (3). The study has been carried out from November, 1st, 2019 to August, 2020. The study covers the elderly residents at nursing home in Middle Euphrates (Karbala, Najaf, Hilla, Diwaniya) (10). A non-probability purposive sample consist of (60) elderly persons that are selected from the total population of (100) elderly residents at nursing homes. In addition to that, a pilot study has chosen from the total number. The study sample consists of 37 men and 23 women ranging in age from 65 (National Health and Aging Trends Study) to 87 years. The purposive Sample is used in order to obtain the representative sample according to some criteria. The assessment tool has been reconstructed in a form of a questionnaire that has been adopted and modified by the researcher. The questionnaire consists of 3 parts, which are socio-demographic and clinical characteristics, RYFF psychological wellbeing scale (18 items version), and self-care scale (29 items). The instrument face validity was determining through a panel of experts. The reliability can be determined by using Pearson’s Correlation Formula (r). The result of the reliability coefficient for domains of psychological wellbeing is 0.71 and Self-care is 0.93, which is considered statistically acceptable matching with the lower bound of reliability coefficient.

</thead>
<tbody>
<tr>
<td>Psychological wellbeing</td>
<td>$r = 0.721$ **</td>
</tr>
</tbody>
</table>

*Significant at $P<0.05$; ** High significant at $P<0.01$

Table (5) shows that there is a high significant positive correlation ($P<0.01$) between psychological wellbeing and self-care of elderly residents ($r = 0.721$). The same table reveals that there is a significant positive correlation ($P<0.05$) between psychological wellbeing and Spiritual health scale residents ($r = 0.322$).

**Discussion**

Tables (1,3) indicate that the mean total score of the Ryff scale was 3.29 as well as the highest percentage of the elderly’s group have moderate level of psychological wellbeing. This indicates that the level of psychological well-being of elderly residents at nursing homes was moderate, despite the circumstances associated with the relocation to residential care and the changes inherent in aging that show a shift in the main sources that contribute to their well-being. This result is supported by a study(11) indicates that the elderly have high level of psychological well-being in social welfare institutions in Jordan. Another study indicated that the majority of elderly (59%) have moderate level of psychological wellbeing in India(12). Regarding the personal growth, which mean the process of continuous development of oneself and preparation for new challenges across life span. The results of study indicates that personal growth of elderly was high level (mean of score=3.84). This result may be due to that most of elderly feel better over the time and try to enjoy their life at nursing home, as well as, the attempt to acquire new positive behaviors and attitudes. This result is supported by a study indicates that the majority of the elderly (61%) have high level of personal growth(12).

Tables (2,4) reveal that the overall assessment of self-care domains for the study sample was moderate (mean of scores = 3.15) and the high percentage of the elderly have moderate level of self-care (68.33%). It can be suggested that the process of aging raises the level of dependence on others and, as a result, it may lead to a decline in quality of life as well as the highest percentage of chronic diseases among the elderly group.
(88.3%) and those have difficulties in walking (40%). All of these reasons may lead to a mediating level of self-care. This result is supported by a study stated that the self-care performance of elderly people was at a moderate level. When analyzing personal variables, the elderly participants had a confirmed mean age of 68.3 years old. It can be described that they are getting older and their self-care behavior performance decreases as age progresses.

Table (5) indicated that there is a high significant positive relationship (r = 0.721) between psychological wellbeing and self-care of elderly residents at P<0.01, which means when the psychological well-being of elderly people increases that will lead to increase their self-care and vice versa. This result coinciding with a study observed that an important, positive association between the level or value of self-care and well-being “(r = .228, p = .014)”. In particular, an significant positive association between self-care and wellbeing suggests that greater self-care activity is correlated with an improvement in general well-being. This result supported by a study indicates that There is a positive and significant relationship between self-care and the psychological well-being of the elderly and direct effect of self-care on the psychological wellbeing of the elderly people (standard coefficient= 0.14). Also, The result of study supported by a study found that the self-management abilities significantly affected the well-being (r =0.56; p ≤ 0.001). The present finding is reinforced by a study found that the relationship between psychological wellbeing and daily life activities was statistically significant and the ‘r’ value was 0.375.

Conclusions

There is an impact of psychological wellbeing upon the level of self-care. The relationship between psychological wellbeing and the level of self-care is confounded by the variables of age, marital status, and the health status.

Molecular Evaluation of Efficacy of Freshwater and Marine Acellular Fish Skin Matrixes in Reconstruction of Ventro-Lateral Hernia in Bucks

Bassam H. Gumaa¹, Ahmed H. F. AL-Bayati¹

¹Scholar Researcher, Department of Surgery and Obstetrics, College of Veterinary Medicine, University of Baghdad, Baghdad, Iraq

Abstract

The objective of present study is to compare between the effectiveness of freshwater and marine acellular fish skin (AFS) matrices on the reconstruction of large abdominal wall hernias in Iraqi bucks using of molecular evaluation depending on Real Time-quantification Polymerase Chain Reaction (RT-qPCR) technique to investigate the levels of basic-fibroblast growth factor (b-FGF) and vascular endothelial growth factor (VEGF) genes during the healing process of the abdominal wall hernias. Ventral-lateral abdominal wall hernias (7X7cm) were induced experimentally in 18 bucks. Thirty days post-inducing of hernias, the animals were divided randomly into two main groups (9 Bucks/group). The hernias in animals of group (A) were treated with onlay implantation of freshwater AFS sheet. While, the hernias in animals of group (B) were treated with onlay implantation of marine AFS sheet. Molecular evaluation was depended at 2, 8, and 12 weeks post-treatment of hernias. The results revealed that the significant elevation of the level of b-FGF between treatment groups was at 8th week in group B and at 12th week in group A. While, the significant elevation of level of VEGF between treatment groups was recorded in group A, 12 week post-treatment. Keywords: Hernia, Bucks, Growth factors, Biological implants, Fish skin.

Introduction

Hernia is a protrusion of the contents of a body cavity through a weak spot of the body wall. This may be from accidental or a normal anatomical opening which does not completely fulfill its physiological function (1). Repairing of large hernia is still regards as a clinical challenge for veterinary surgeons (2). The extensive hernia opening (between 7-10cm in diameter) may require repair by mesh (hernioplasty) (3). There are two types of mesh, synthetic and biologic mesh. The synthetic mesh appears more likely to develop postoperative complications, such as, mesh extrusion, bowel adherence and wound infection (4). To avoid the potential squeal of synthetic mesh, biological materials are being developed and used for abdominal wall defect repairs (5). These biomaterials are derived from varies tissues like; dermis, small intestine submucosa (SIS) and pericardium of human, porcine and bovine (6). These materials allow neovascularization and regeneration, and have ability to become remodeled into the tissue and resist infection (7). Recently, AFS has been used in a variety of clinical applications due to the physicochemical properties and amino acid compositions (8). Due to the absence of studies about the using of AFS in the reconstruction of tissues rather than cutaneous tissue, the current study designed to compare between the efficacy of freshwater and marine AFS in the reconstruction of large abdominal wall hernia through evaluation the tissue level of b-FGF and VEGF genes.

Materials and Methods

In the present study, 18 adult local apparently healthy bucks, weighing (25-30kg) and aged (1-1.5 years) were used. All animals were examined clinically and housed under the same management conditions...
in farm animals of College of Veterinary Medicine/University of Baghdad, for two weeks before starting of the experiment. The animals were numbered and classified according to the experimental design. Under the effect of sedation by intramuscular injection of 2% xylazine hydrochloride (Interchemie, Holland), in a dose of 0.2mg/kg B.W., with lateral recumbency, the right lower flank of all animals were prepared for aseptic surgical technique. Ventro-lateral hernias (7X7cm) were created in the right abdominal wall of experimental animals by using of sedation and local anesthesia using 2% lidocaine hydrochloride (Johnlee pharmaceuticals, India), in a dose of 10mg/kg, B.W. through inverted (L) shape infiltration. Thirty days post-inducing of hernia, the animals were divided randomly into two equal groups (9 Bucks/group). The hernias in group (A) were treated with onlay implantation of sheet of freshwater AFS. While, in group (B), the hernias were treated with onlay implantation of sheet of marine AFS. The animals in each group were divided into three subgroups (3 animals/subgroup) to evaluate the level of b-FGF and VEGF genes during the healing process of hernias at 2, 8 and 12 weeks post-treatment of hernias.

Molecular Evaluation

Two biopsies of (50-100mg) of native tissue were collected from each animal of the study. One of these biopsies was taken from implanted area and the second was taken from the normal abdominal muscle tissue of the same animal which considered as a control sample for each animal. The biopsies were immersed in Trizol Regent (Thermo Scientific, U.S.A.), and kept in freezing, then evaluated using RT-qPCR technique for detection the levels of b-FGF and VEGF gene expression. Analysis and calculation of gene expression levels of one or more genes depend on RNA /mRNA concentration after conversion it to cDNA. All processes including total RNA purification, qPCR amplification and data analysis. Each step of RT-qPCR for each gene of study was contained the following data as mentioned in table (1).

Primers

In this study, three primers were used including the specific gene of muscle tissue in goats according to the method described by some researchers (9), which include forward and reverse glyceraldehydes-3-phosphate dehydrogenase (FR-GAPDH) gene primer that was used as Housekeeping gene, forward and reverse b-FGF (FR-FGF-2) and forward and reverse VEGF (FR-VEGF) gene primers that were used as target genes (Table, 2). The primers were used in quantification of gene expression by using RT-qPCR techniques based BRYT Green DNA binding dye (Promega, USA).

**Relative Quantification (The DD Ct Method)**

The data of outcome of RT-qPCR for target and housekeeping gene were analyzed by the DD Ct method, also referred to as the comparative Ct method, is a means of measuring relative quantification gene expression levels (fold change), which first described by some studies (10). It determines the relative change in gene expression between a target gene under investigation, the calibrator (reference) gene, mostly, the untreated control is used as the calibrator, and the housekeeping gene (GAPDH), which considered as an endogenous control.

**Results and Discussion**

Estimation the levels of b-FGF and VEGF genes in current study was revealed the presence of differences in means values of these growth factors (GFs) among the different periods of each treatment groups and at the same period between both treatment groups. Table (3) and figure (1A) showed that the mean values of level of b-FGF gene in group A at week 2nd (1.32±0.17), then decreased at week 8th (0.35±0.08) without presence of significant differences between these two periods, while, it increased again at week 12th (6.86±2.92) post-treatment with presence of significant differences (P<0.05) with the values at weeks 2nd and 8th. Whereas, in group B, the mean values of level of b-FGF gene at week 2nd was (0.51±0.14), then, increased at week 8th (6.69±2.37) and returned to decreased at week 12th (3.82±1.87) post-treatment with presence of significant differences (P<0.05) between them. The same table and same figure showed there were differences in mean values of b-FGF gene between both treated groups at each period of following-up along the study. It was higher in group A at week 2nd without presence of significant differences between them, while, at week 8th, it was higher in group B with presence of significant differences (P<0.05) between them. At week 12th, it was higher in group A with presence of significant differences (P<0.05) between them. Table (3) and figure (1B) showed that the mean values of level of VEGF gene in group A at week 2nd was (2.65±1.09), then decreased at week 8th (1.02±0.03) without presence of significant differences between these two periods, while, it increased again at week 12th (6.08±2.53) post-treatment with presence of significant differences (P<0.05) with the values at weeks 2nd and 8th. Whereas, in group B, the mean value of level of VEGF gene at week 2nd was (0.94±0.06), then it increased at week 8th (2.07±0.30) and returned to decreased at week 12th (1.51±0.16) post-treatment without presence of significant differences between the three periods with each other. The same table and same figure showed the presence of differences in mean values of level of VEGF gene between both treatment groups at each period of study. At week 2nd, it was higher in group
A. While, at week 8th, it was higher in group B without presence of significant differences between the mean values at these two periods. At week 12th, it was higher in group A with the presence of significant differences (P<0.05) between them.

Fig. 1: Shows; the mean values of b-FGF among different periods in two groups (A). The mean values of VEGF among different periods in two groups (B).

The elevation in levels of b-FGF and VEGF genes in a tissues from the hernia sites, two weeks post-implantation in both groups with superiority in group A, may be attributed to the inflammatory response and progression of the healing process after implantation, which characterized by infiltration of inflammatory cells according to the effect of each type of AFS on the host tissue and liberation of b-FGF and VEGF (11). This process was explained by study which states that the acute host response is uniformly to all biologic
materials, which characterized by an intense MNCs infiltration (12). The liberation of b-FGF by inflammatory cells that infiltrate during wound healing was explained by many studies referred that the inflammatory cells which involved in wound healing process release cytokines and GFs like b-FGF. They indicated that the significant expression of b-FGF in wound tissue begins approximately eight day after wounding and peaks at 12–14 day (13, 14). Other studies were reported that surgical wounds are characterized by a rapid and early repair and angiogenic that is mediated in part by b-FGF, which can be selectively released by cellular injury (15, 11). Whereas, other authors observed that the gradual increase of the level of b-FGF in the tendon tissue healing from 5-30 days post operation due to the presence of inflammatory cells (16).

The liberation of VEGF by inflammatory cells that infiltrate during wound healing was explained by many studies, they indicated that the VEGF released through a various cellular responses in wound site which stimulates multiple components of the angiogenic cascade; it is up-regulated during the early days of healing when the growth of capillary is maximal associated with the releasing of VEGF by activated platelets (14, 17). Some researchers observed that level of the VEGF in wound healing of patients undergoing incisional hernia repair increasing progressively (13). While, other researchers indicated that VEGF is one of the major GFs involved in angiogenesis and produced by effector cells in the wound, and the activity of VEGF rises after the inflammatory phase, especially during the proliferative and remodeling phases (18).

At week 8th post-implantation, the levels of b-FGF and VEGF genes in group A decreased clearly than week 2nd. This fact was explained by a studies which referred that the GFs are retained in the bioimplants and their liberation will occur during gradually degradation of bioimplants post-implantation and by infiltration of inflammatory cells which bind to ECM proteins (20). In addition, some authors stated that the continuous releasing of GFs during and until complete degradation of implant, will exert their biologic effects as they are dissociated from their binding proteins and activated (21). After that, initially granulation tissue will be formed to replace the degraded part of the implant, which required a high levels of VEGF for angiogenesis to enhance granulation tissue formation, as well as, liberation of b-FGF for fibroblast proliferation and collagen deposition. While, the remodeling process required less GFs due to tissue maturity (19). The researchers indicated that the differences in the level of GFs may be related to the exact compositions and substructures of biomaterials which vary depending on many factors including; species from which materials were harvested, tissue source, method of manufacture,
efficiency of decellularization and post-processing modification (22). Many studies were referred that fish skin graft showed a high expression of FGF, VEGF and cytokines in the epithelium and underlying connective tissue when used in neovaginoplasty (23).

Review of Fungal Infection in Human Beings and Role of COVID-19 Pandemic

Batool Mutar Mahdi

Consultant Clinical Immunology, Head of HLA Research Unit, Department of Microbiology, Al-Kindy College of Medicine, University of Baghdad, Baghdad – Iraq

Abstract

Background: Fungal infections are common throughout the world. In humans, fungal infections occur when an invading fungus takes over an area of the body and the immune system is unable to handle it and eradicate it. Fungi can live in the air, soil, water, and plants and there are also some fungi that live naturally in the human body.

Aim of the Study: To search and review the current literature surrounding fungal infection in different parts of body and role of fungal infection during COVID-19 pandemic.

Methods: Henari, MEDLINE, EMBASE, PubMed, and Web of Science were searched using search criteria relating to fungal infection and relation with COVID-19 infection. Articles presenting clinical data for patients with fungal infection and coronavirus infection reported in English only were included. Data describing prognosis and outcomes were extracted.

Results: 1100 abstracts were identified. Five full texts reporting fungal infection were included. Analysis showed wide use of empirical broad-spectrum antibacterials drugs in spite of evidence for bacterial coinfection.

Conclusions: Despite frequent prescription of broad-spectrum empirical antibiotics in patients with coronavirus-associated respiratory tract infections, there is a small number of data to support the association with respiratory fungal coinfection. Generation of prospective confirmation to support development of antimicrobial antibiotics strategy and suitable stewardship specific for the COVID-19 pandemic is urgently required.

Keywords: Fungal; COVID-19; antibiotics.

Introduction

The kingdom Fungi (singular: fungus) are a kingdom of usually multicellular eukaryotic organisms that are heterotrophs that cannot make their own food and is a highly various form of eukaryotes found in all environments and fungal infections are common throughout the natural world (1). In humans, fungal infections occur when an invading fungus takes over an area of the body and is too much for the immune system especially the adaptive immunity to handle with this infection (2). Fungi can live in the air, soil, water, plants and some live naturally in the human body (3). Like many microbes, there are many useful fungi at one side and on other side there is a harmful one. When harmful fungi invade the body as opportunistic pathogen, they can be difficult to eradicate due to defect or weak in the immune system (4). Many fungi live with human host without any harm and immune systems cope with constant exposure to them; those known as commensalism (5). Like many microbes, there are helpful fungi and harmful fungi. When harmful fungi invade the body, the patient will complain from redness, itching,
swelling and foul discharge depend on what part of the body is affected like vagina, skin. Some fungi cause reoccurring surface fungal infections while others cause systemic fungal infections like blood and known as fungemia that caused by *Candida albicans* which is less common and constitutes about 70% of the cases, but can have deadly outcomes because of late diagnosis and a rareness of effective treatment present. This nosocomial bloodstream infections (fungemia) occur mainly in patients with haematological malignancies and solid neoplasms in hospitals in the USA (6).

This study tries to review and shed a light on fungal infection in different parts of the body of human beings and different methods used to confirm the diagnosis and effect of COVID-19 on increase fungal infection.

1. Classification of fungi

Fungi classified according to their appearance by microscopy and in culture, and by the method of reproduction, which may be sexual or asexual. They classify them as (7):

1- **Yeast:** form a subtype of fungus characterized by clusters of round or oval cells. These bud out similar cells from their surface to divide and propagate. In some circumstances, they form a chain of cells called a pseudomycelium. (Example: *Candida*, *Cryptococcus*, *Trichosporon*). Yeasts are unicellular fungi. The budding yeasts reproduce asexually by budding off a smaller daughter cell; the resulting cells may sometimes stick together as a short chain or pseudohypha. *Candida albicans* is a common yeast that forms pseudohyphae; it is associated with various infections in humans, including vaginal yeast infections, oral thrush, and candidiasis of the skin. C. albicans isolated from each of vaginal and oral swabs expressed the ALS1 virulence stronger gene of adhesion family (8).

2- **Mould:**

Fungi have well-defined characteristics that set them apart from other organisms. Most multicellular fungal bodies, commonly called moulds, are made up of filaments called hyphae. Hyphae can form a tangled network called a **mycelium** and form the thallus (body) of fleshy fungi. Hyphae that have walls between the cells are called septate hyphae; hyphae that lack walls and cell membranes between the cells are called nonseptate or coenocytic hyphae. Hyphae make up the mycelium (like branches are part of a tree) (9). It is divided into:

- **Septate Hyphae** which is compartmented by cross-walls (called septae). It includes Dimorphic, Dermatophytes and opportunistic Aspergillus. Arthrospores are made up of fragments of the hyphae, breaking off at the septae.

- **Aseptate Hyphae** which include Zygomycetes.

The fungus had asexual spores (conidia) forms on conidiophores and sexual reproductive phase. Reproduction of many fungi is unknown and these known as ‘fungi imperfecta’.

Some fungi are dimorphic. They are capable of changing their appearance in response to environmental changes such as nutrient availability or fluctuations in temperature, growing as a mold, for example, at 25 °C (77 °F), and as yeast cells at 37 °C (98.6 °F). This ability helps dimorphic fungi to survive in diverse environments. For example is *Histoplasma capsulatum*, the pathogen that causes histoplasmosis, a lung infection, is an example of a dimorphic fungus (9).

2. **Cell Structure of fungi**

The fungi consist of cell wall and cell membrane. There are notable unique features in fungal cell walls and membranes. Fungal cell walls contain chitin, as opposed to the cellulose found in the cell walls of plants and many protists. Additionally, whereas animals have cholesterol in their cell membranes, fungal cell membranes have different sterols called ergosterols. Ergosterols are often exploited as targets for antifungal drugs (10). Fungi are eukaryotes, non-motile life form and its basic structural unit consists of either a chain of cylindrical cells (hyphae) or an unicellular form, or both (11).
3. Epidemiology of fungal infection

A better understanding of the epidemiology and clinical presentation of fungal infection is integral to improving outcomes and treatment. Superficial mycoses account for much of the overall global prevalence of fungal infection (12). Invasive fungal infections have emerged in the last decades as an important cause of human disease in aging and immunocompromized patients who use chemotherapy (13). Epidemiology of fungal infection can be divided into Nosocomial fungal infection that occur as opportunistic mycoses and Community fungal infection that occur as Endemic Mycosis that appear in a discrete geographic area (14).

Currently about 180 hospitals participate in the National Nosocomial infections Surveillance (NNIS) system. From January 1980 through April 1990 about 27,200 fungal isolates from these hospitals; Candida species accounted for 19,621 (72.1%) of these isolates in immunocompromised patient who are particularly high risk factor for Candidemia and rapid detection of invasive candidemia in these high-risk patients is particularly important to the improvement of rates of survival and development of new methods for rapid diagnosis and monitoring should help decrease the morbidity and mortality associated with nosocomial fungal infection and invasive fungal infection (15).

4. Types of fungi

Fungi are parasites or saprophytes that live on living or dead organic matter. Mycologists identify five phyla of fungi based on the way the fungus reproduces sexually (16):

1. Chytriomycota: are usually aquatic and microscopic. They are usually asexual, and produce spores that move around using flagella.

2. Zygomycota: cause problems by growing on human food sources. One example of a zygomycete is Rhizopus stolonifer, a bread mold. The hyphae of zygomycetes are not separated by septa.

3. Glomeromycota: make up half of all fungi found in soil.

4. Ascomycota: are pathogens of plants and animals, including humans, in which they are responsible for infections like athlete’s foot, ringworm, and Candida albicans, a yeast which lives in the respiratory, gastrointestinal, and female reproductive tracts. Ascomycetes have reproductive sacs known as ascii, which produce sexual spores, but they also reproduce asexually.

5. Basidiomycota are usually club-shaped, and known as club fungi. Most reproduce sexually. Mushrooms are a common example of basidiomycetes.

5. Immunity to fungi

Most of fungal infections are opportunistic pathogens that do not cause disease unless there are alternations in immune defense mechanism by using immunosuppressive drugs, infection with human immunodeficiency virus (HIV). Fungi also cause nonlethal skin, nail, vagina and mucosal infections that are equally difficult to treat and often recurring (17).

The immune response varies with respect to the fungal species encountered. The relative importance of specific innate and adaptive defence mechanisms differs depending upon the type of fungus and anatomical site of infection. Yeast, pseudohyphae and hyphae of Candida albicans may be an important to stimulate host immune response while yeasts and spores are often effectively phagocytosed while the larger size of hyphae prevent effective ingestion. The location of some fungi intracellular can survive with in phagocytes by using them to evade fungal killing and to disseminate and invade throughout the host (18).

The first line of defense mechanism against fungal infection is innate immunity starting from neutrophils, NK cell, genetically inherited receptors, called pattern recognition receptors (PRRs) (19) on macrophages and monocytes which are important antifungal effector cells that recognize conserved pathogen-associated molecular patterns on the fungus (20). The initiating signals from
these receptors activate cellular responses and killing mechanisms. Theses effector cells are recruited to sites of infection by the action of inflammatory signals like cytokines, chemokines and complement components. Fungi are killed or damaged by production and release of reactive oxygen intermediates and antimicrobial peptides that kill the fungi\(^\text{[21]}\). Once fungal antigen within tissues, macrophages will develop into a distinct functional phenotype, which is determined by the cytokine secretion. Proinflammatory cytokines, particularly interferon gamma (IFN-gamma), drive a classically activated (M1) phenotype, whereas anti-inflammatory cytokines (e.g., TGF-beta) drive alternatively activated (M2) macrophage and macrophage phenotype can have a profound effect on antifungal immunity\(^\text{[22]}\).

Other important cell is dendritic cells that initiate both innate and adaptive immunity \(^\text{[23]}\) (Figure-1-).

These cells phagocytes and process fungal antigens and express these fungal antigen and these cells are capable of taking up fungal antigen and processing antigen for display by major histocompatibility complex (MHC) class I or MHCII molecules to naïve T cells and of mediating fungicidal activity through co-stimulatory molecules leading to migrate and proliferate other lymphocytes and secrete cytokines to initiate immune responses\(^\text{[24]}\). Dendritic cells have an instrumental role in linking innate and adaptive responses to a range of pathogenic fungi including Aspergillus fumigatus, Cryptococcus neoformans and C. albicans \(^\text{[25]}\). Signals transmitted by dendritic cells can vary depending upon the encountered fungus antigen or morphotype of the fungus resultant in differences in the nature of adaptive immune responses obtained \(^\text{[26]}\).

![Figure - 1 - Role of dendritic cell in fungal infection.](image-url)
Then the adaptive immunity will be stimulated through stimulation of naïve T cells and differentiation of CD4+T cells along a T-helper (Th) cell type 1 (Th1) or type 2 (Th2) pathway or Th17 and development of specific Th responses, is an essential determinant of the host susceptibility or resistance to invasive fungal infections. Later on development of Th1 responses is influenced by the action of cytokines, such as interferon (INF-gamma), interleukin(IL-6), tumour necrosis factor (TNF)-alpha, and IL-12, in the relative absence of Th2 cytokines, such as IL-4 and IL-10 (27). In immunocompetent hosts CD4 T-cell-mediated clearance of fungi with limited tissue damage requires a finely cooperated balance among Th1, Th17, and Treg (regulatory cell)(28). Th17 secrets IL-17 which is critical for immunity to fungal infections, particularly mucosal candidiasis (29).

The predominance of Th1 (cellular immunity) over Th2 (humoral Immunity) type cytokines correlates with protection against various mycoses (30). Within this framework of interaction between innate and adaptive immunity relating to quantitative and temporal production of cytokines and the development of particular T-cell responses that modulate immunity to fungal antigen (31).

6. Diseases of fungal infections

There are millions of fungal species but only few of them cause diseases like mold and yeast that affect lung causing pneumonia with symptoms similar to flue or tuberculosis, skin causing skin rashes and nail infections. Fungal diseases can be classified as followings (32):

a- Most common fungal diseases like Dermatophytes that cause nail infection, skin ring worm infection and Candida that affect vagina and mouth.

b- Fungal diseases that affect people who live in certain areas like Blastomycosis, Histoplasmosis, Coccidiomycosis, and Paracoccidiomycosis

c- Fungal diseases that affect people who have weak immune system like Aspergelsonis, Candidiasis, Mucormycosis and Crypyococcus neoformans

d- Health problem diseases caused by fungi like fungal eye infection, Sporotrichosis and Mycetoma.

The most common fungal infection is the followings:

v Dermatophytes: Fungus that inhabit the keratinized tissue of skin, nail and scalp. These include Trichophyton rubrum, Trichphyton mentagrophytes. Microsporum canis and Epidermophyton floccosum that cause cutaneous lesion like nail infection can develop in people at any age, but it’s more common in older adults. As the nail ages, it can become brittle and dry. The resulting cracks in the nails allow fungi to enter (Figure-2-). Other factors like reduced blood circulation to the feet and a weakened immune system may play a role in development of Tinea pedis (Athlete’s foot). Toe nail fungal infection can start from athlete’s foot and it can spread from one nail to another Other fungus is tinea corporis that infect body of human and scalp ringworm that infect scalp (33).

![Figure- 2 - Nail fungal infection caused by Trichophyto.](From Dr. Batool Clinic.)

v Candida species: cause infections in individuals with deficient immune systems. Th1-type cell-mediated immunity (CMI) is required for clearance of a fungal infection. Candida albicans is a kind of diploid yeast that commonly occurs among the human gut microflora. It is an opportunistic pathogen in humans (34).
v Histoplasma capsulatum can cause Histoplasmosis in humans, dogs and cats. The fungus is most prevalent in the Americas, India and southeastern Asia. Infection is usually due to inhaling contaminated air (35).

v Aspergillus: The most common pathogenic species are Aspergillus fumigatus and Aspergillus flavus. Aspergillus flavus produces aflatoxin which is both a toxin and a carcinogen and which can potentially contaminate foods such as nuts (36).

v Cryptococcus neoformans can cause a severe form of meningitis and meningo-encephalitis in patients with HIV infection and AIDS and also isolated from burn patients then infecting C. neoformans cells are usually phagocytosed by killed by the release of oxidative and nitrosative molecules by these macrophages (37).

v Sporotrichosis: Human Sporotrichosis is an infection caused by dimorphic fungus, Sporothrix schenckii by direct inoculation. Sporotrichosis is a rare type of fungal infection that can occur in both humans and animals. Also named “rose handler’s disease,” the fungus can be found in certain plants and their surrounding soil. Sporotrichosis mostly affects people who work with soil like farmers (38).

v Tinea versicolor is a fungal infection of the skin. It’s also called pityriasis versicolor and is caused by a type of yeast that naturally lives on your skin. When the yeast grows out of control, the skin disease will appear as rash (Figure- 3 -) (39).

Figure- 3 - Tinea versicolor of the skin.(From Dr Batool Clinic).

7. Diagnosis of fungal infection

In current years diagnosing fungal infections remains a problem in the management of fungal diseases mainly in the immunocompromised patients with a massive increase in the frequency and severity of fungal infections has been found (40). Signs and symptoms of fungal infection are non-specific in diagnosis and difficult to distinguish from invasive disease particularly when blood cultures are commonly negative. This state has led
to the policy of initiating empirical therapy in the high-risk patient. At the simplest level, the clinician must be familiar with the appearance of various fungi in tissue. Early diagnosis of fungal infection is important to effective and successful treatment. There are many methods to diagnosis like traditional approaches to diagnosis include many methods starting from direct microscopic examination of clinical samples, histopathology, culture, and serology. Nowadays emerging new technologies include molecular diagnostics tests and antigen detection in clinical samples. Rapid and early diagnosis of fungal infections is a key factor for patient outcome and cure. Traditionally, the following are the diagnostic methods to early detect the fungus:

1- Direct microscopic examination of clinical samples under light microscope using KOH preparation and demonstration of broad based budding organisms and hyphi in the sputum or skin. Stains also used like lactophenol cotton blue stain is good for identification mold, Grocott Methanmine Silver (GMS) stain, Periodic acid-Schiff (PAS) stain and Pap stain or Papanicolaou’s stain used in cervical specimen, Hematoxylin and Eosin stain in detection Aspergillosis through finding typical hyphae on staining of respiratory secretions has highly predictive value.

2- Histopathology of biopsy for example coccidioidomycosis of the lung. Histopathologic examination can usually distinguish Aspergillus from other fungi. Tissue biopsy of skin or other organs may be required in order to diagnose extra-pulmonary disease like Blastomycosis is histologically associated with granulomatous nodules.

3- Culture from fungal lesion from lower respiratory tract like bronchoalveolar lavage of leukaemic patients is also very useful which highly predictive of invasive fungal disease like Aspergillosis and Candidiemia. The culture media used are Sabouraud dextrose, malt extract and less commonly brain heart infusion. Culture may take many days to a result with several of the filamentous fungi. In the case of disseminated candidiasis, blood culture used. All above methods depend on the quality of the clinical specimens and the experience of the laboratory personnel. Moreover, these classical methods have previously shown lower sensitivity in fungal detection.

4- Non-culture methods include antibody and antigen based assays for detection fungal infection like cryptococcosis and coccidioidomycosis. Galactomannan antigen testing of blood is used in some European Centres using ELISA or EIA methodology or agglutination method. Tests for mannan antibodies and antigenaemia are also used.

5- Metabolite assays appeared promising but have not been used commercially.

6- Molecular method like PCR based assays that do not require viable cells and have the ability to identify the increasing number of fungi that are clinically relevant pathogens in humans’ and identification of fungal DNA from body fluid samples using specific genome sequences. PCR used genus-specific probes with 100% sensitivity and specificity.

7- Fungal ribosomal genes are multi copy targets enabling early detection using PCR and 18S rRNA gene enables accurate sequence and identification.

8- Detection of glucan in blood has been achieved using crab amoebocyte lysate.

9- CT scan findings enable diagnosis (Figure- 4-).
8. Treatment of fungal infection

Early diagnosis of infection would enable administration of drugs when treatment is most to be effective. Drug like Ketoconazole is an effective treatment for chronic superficial candidiasis and chronic dermatophytosis like for example patients with tinea corporis. Azoles group like Fluconazole is good treatment option for candida albicans and also used for prophylactic antifungal therapy in prolonged neutropenic situations. Other drug like Griseofulvin is also used as antifungal drug. It is possible to maintain some patients with chronic mucocutaneous candidiasis in remission without using prophylactic ketoconazole, although relapses may occur. Empiric treatment of fungal infections like aspergillosis, cryptococcosis, mucormycosis, and invasive candida infections normally doesn’t require species specific identification. Other medication like Creams and ointments are often sufficient to treat many cases of ringworm. Basic hygiene can help treat and prevent ringworm as well. Keeping the skin clean and dry can help avoid infection and wearing sandals into public showers or locker rooms and avoiding shared items and towels (50,51). Some fungal infection like Mucormycosis and Zygomycosis involves a combination of surgical debridement of involve tissues and antifungal therapy like Amphotericin B intravenously with elimination of predisposing factors for infection (52).

Role Of Fungal Infection In COVID-19 Pandemic

Many reports demonstrated that fungal infection had low rate in hospitalized COVID-19 patients but high use of empirical broad-spectrum antimicrobials in hospitals and difficulty in clinically differentiating between COVID-19 and bacterial infection and its progression to fungal infection provides a major challenge to clinicians (53,54). Fungal infection in COVID -19 patients was increased due to immune suppression by viral infection, prolonged length of using ventilators, contaminants in blood and line culture, and excessive empirical use of high dose antimicrobial drugs. Study was reported that fungal infection constitutes 0.7% of infection in Cohort study. Three patients were diagnosed with Aspergillus fumigatus tracheobronchitis and other four patients with Candida albicans bloodstream infection (55). Few data are available about that and any links between them and candidaemia have yet to be explored in details. The WHO recommends against the prescribing of antimicrobials in mild to moderate COVID-19 cases without clear indication of bacterial infection (56). Prospective studies are required to provide greater insight into the risk factors and outcome of fungal infection in COVID-19 and to give evidence-based recommendations. Other report showed no antimicrobial stewardship interventions were described (57).

Conclusions

Fungal infection is a common disease world -wide especially after dissemination of diseases with immune suppression like human immune deficiency diseases and patients on chemotherapy due to transplantation and cancer. It was diagnosed by many methods and treated by many medications.

Abstract

Background: Patients’ satisfaction is a person’s feeling of pleasure or disappointment resulting from a service’s perceived performance or outcome to his or her expectations. As this definition makes it clear, satisfaction is a function of perceived performance and expectations. This study was undertaken to evaluated patients’ satisfaction level with the hospital services and health care providers among four government hospitals in sulaimani city. The data from 311 inpatients admitted to and stay in the hospital for any medical condition were collected by a face-to-face interview from November 2019 to February 2020. Standardized 4-point Likert scales ranging from satisfying to dissatisfying (1 to 4points) were used for all the 24 items in the questionnaire. Data analysis was performed using a statistical package of Stata (14.version). A frequency analysis was used for demographic data analysis. A person Chi-square test was employed to determine the association between the categorical independent variables. The participant’s mean age was 37.9 SD 13.5 years with ages ranged from 14-85 years. The majority (86.5%) of the study participants were satisfied with the hospital services and environment while a small number 42 (13.5%) of them were dissatisfied with the issue. Almost 275 (88.4%) of the patients were revealed excellent nurse care and a very small number 36 (11.6%) was showed dissatisfaction. Also, 245 (79.1%) of the patients were satisfied with doctor care. Only 65 (20.9%) of them have a negative aspect of doctor care. A significant difference was found between the level of education and patients’ satisfaction with doctor care (coefficient 0.88, p<0.05). Besides, a significant association was found between residence and hospital services (coefficient 0.63, p =0.05). In general, we have discovered a satisfaction level among our sample is considered high and indicates good care provided by health facilities in all hospitals. Further study required seeking the least satisfactory factor regarding doctor care.

Keywords: Satisfaction, Shar hospital, nurse, Sulaimani, patients, physician

Introduction

Patient satisfaction has been described as the value and reaction of patients towards the care they received in the hospital and the medical care was performed (¹). Patient satisfaction is a central indicator of health care quality and reflects the ability of the provider to meet the patients’ needs (²). So, it is a process as much as an attitude, so it must be, monitored continuously, and frequently measured. Patient satisfaction is essential and must be taken into account in assessing the quality of health care delivered particularly when decisions are being made about changes and enhancement in services. It also is used as an instrument in determining payment rates, especially in the context of a competitive healthcare atmosphere and consumerism (³, ⁴). Gradually, patients’ satisfaction became an essential component of health care services quality monitoring and improvement processes (⁵). Patient satisfaction with nursing care is of great importance to any health care agency because
nurses comprise most health care providers and they provide care for patients 24 hours a day (6). Assessing to what extent patients are satisfied with health services is clinically relevant, as satisfied patients are more likely to comply with treatment, take an active role in their care, continue using medical care services, and stay within a health provider (where there are some selections to be made) and maintain with a specific system (7). Nurses are the frontline people that patients most likely meet up with, spend the highest amount of time with and rely upon for recovery during their hospitalization. Nursing care plays a prominent role in determining the overall satisfaction of patients’ hospitalization experience (2). Furthermore, maintaining good technical as well as interpersonal skills is essential for doctors to satisfy their patients (8). Besides, the demonstration of professionalism and ethical practice are also required to meet the expectations of patients. The technical expertise of physicians is regarded as consisting of maintaining an appropriate level of experience, ability to diagnose, the performance of clinical procedures, prescribing medicine, and learning about the latest medical developments. Moreover, the success with technical procedures, treatment, and medication depends upon favorable communication with patients (9, 10). Unlike developed countries, doctors are not made to comprehend the importance of ethical practice and communication skills during medical training. Physicians working in public hospitals deal with patients of a lower socio-economic class with negligible health awareness and poor hygiene. Understanding the patients and making them understand is the big challenge with which physicians are confronted in public outpatient clinics in developed countries (10, 11). Patients’ satisfaction of their relation with their doctors is a key element in the efficiency and usage of health services and varies depending on patient characteristics. Each patient has expectations when meeting a doctor and the difference between these expectations and what he obtains represent the perception of the satisfaction (12). Many previous studies have developed and applied patient satisfaction as a quality improvement tool for health care providers. Thus, patient satisfaction is an important issue both for the evaluation and improvement of healthcare services (13). The aims of the study: first, to analyze patient satisfaction with a doctor and nurse-patient interaction and relationship. Second: to determine patient satisfaction with the quality of hospital and services performed to patients during their hospital stay in Sulaimani.

**Methodology**

This cross-sectional study was conducted from November 2019 to February 2020. The study population consisted of all patients admitted to four government hospitals (Shar Hospital, Shahid Hemen Hospital, Teaching Hospital, and Maternity Teaching Hospital) during the period of study. The four hospitals are located in the center of Sulaimani City. Shar, Shahid Hemen, and Teaching hospital are provided a wide range of care and treatment to adult people. Maternity Teaching Hospital is provided a wide range of care and delivers to women. In this study, the participation of the patients was voluntary. The data from 311 inpatients admitted to and stay in the hospital for any medical condition were collected. Convenient sample size was chosen because this is conservative and adequate when the proportion of participants is unknown. Patients selected for the study included those who were at least 2 days of experience of hospitalization and aged 14 years and over. The patient was interviewed when they were in a good situation and conscious. Accompanying patients were excluded from the study. The authors personally visited the hospitals and all of the respondents (patients) after informed consent was taking were told about the aim of the study and they were encouraged to contribute. Furthermore, the authors guaranteed the privacy of the responses of the participants. However, face-to-face interviews were conducted with patients with no education and education. Each interview session took about 10 to 15 minutes and the data collection process was conducted over a period of 16 weeks.

The questionnaire was originally developed in Kurdish for a better understanding of the local people. The questionnaire was shared with the experts to ensure face validity, revised and a pre-tested questionnaire...
was used in this research. A pilot study was done before administering it to a representative sample. The aim was to find out if the questions are clear enough, clearly understood, in the right order and the provided answers are sufficient and detailed enough. The fill-in time was also determined. The questionnaire consists of four sections, the first section include Sociodemographic characteristics (age, gender, residence, occupation, marital state, and education), the second section consists of 11 items on the hospital services and environment, third and four-section each consist of 7 items on physicians and 6 items for nurses care. The study was approved by the ethics committee of the Technical Institute of Sulaimani and permission was also taken from Sulaimani Directory of health and all hospitals.

Data analysis was performed using a statistical package of Stata (14.version) after the data was entered into the Epidata (3.1). A frequency analysis was used for demographic data analysis. A person Chi-square test was employed to determine the association between the categorical independent variables. Standardized 4-point Likert scales ranging from satisfying to dissatisfying (1 to 4 points) were used for all 24 items. Internal consistency was tested using Cronbach’s alpha coefficient. Scales 1, 2, and 3 were interpreted as being satisfied Patients’ and 4 dissatisfied. Binary logistic regression was subsequently conducted to predict the factors which influence the level of satisfaction.

**Results**

A frequency analysis was used for the demographic data analysis and general information about the survey participants. The results of the frequency analysis or demographic assessments are presented in Table1. This includes age, gender, education, residence, marital status, occupation, and education of the participants. One-third of the participants (83.3%) aged 25 and over. The mean age was 37.9 SD 13.5 years with ages ranged from 14-85 years. The majority of the study participants were women (81.1%). A very slight difference was found between inside and outside participants (49.8% and 50.1%) respectively. Of (80.1%) the participants were married while the rest (19.9%) was unmarried. The larger part of respondents had no employment (20.3%). However, most of them were educated (60.1%).

**Patient satisfied with hospital services and environment**

Analyses of patients satisfied with hospital services and environment were shown in Table 2. A large number of the patients were satisfied with four hospital services 280(90%) out of 311 patients. We noted most of the respondents were satisfied with the patient’s ward and bedding (61.1%), ward cleanliness (91%), ward comfortable and calmness (71.4%). Of (81.7%) participants were satisfied with providing medical requirements by the staff while only a small number were dissatisfied (18.3%). One-third of the respondents (84.6%) answered that hospital departments (laboratory, radiology, and pharmacy....) can be easily found by the patients. Over half (68.8%) of the patients were satisfied with ward water facilities and sanitary while (31.2%) have a negative aspect. The majority of the patients (89.4%) were satisfied with the patient’s system registration. More than half (59.5%) of the patients were satisfied with the availability of medical requirements (drugs and medical items). A large number of the participants (92.3%) were satisfied with the doctor’s performance for medical procedures at the time needed. A high percentage (90%.vs 91.6%) of the respondents was satisfied with the time patients examine by the physician and the finding of laboratory results respectively.

Patient satisfaction with nurse care

Regarding patients satisfied with nurse care was shown in Table 3. The majority (90.7%) of the respondents were satisfied with nurse behavior and patient respect. Of (89.7% vs 91.6%) were satisfied with nurse responsibility at any time. We noted a participant (92.3%) recorded that nurses have implemented each medical procedure adequately, (89.4%) of them providing a good explanation about the situation to the patients, and (87.5%) of respondents were answered that nurses were medically qualified.

**Patient satisfaction with physician care**

The study findings showed that (91%) of the 282 patients were satisfied with the doctor’s behavior and dealing respectfully with patients during an examination. (87.8%) respondents during visiting hospitals were strongly satisfied with the doctor responded to the patient’s condition and hear them. Also (84.2%), were mostly satisfied with doctors providing a good explanation about the disease condition and the best medical care requirements. Of 90% of the patients were satisfied with the time of examination by the physician. The majority of the patients (91.6%) were satisfied with the easy access to the physician as needed at night shift. Of these (87.5%) were satisfied with physician clarity of drug use and dose. We noticed that (75.6%) of patients were satisfied with the physician’s exam, while (24.4%) of the patients were unsatisfied.

The score level of patients’ satisfaction with the study subject was presented in Figure 2. The satisfaction score was ranged from 0-10 on a scale of 10. Two hundred ninety-six (86.5%) of the study participants were satisfied with hospital services and environment, while a small number 42 (13.5%) of them were showed dissatisfied with a mean score of 9.5, SD ±1.8. The majority of patients 275 (88.4%) were revealed excellent nurse care while a very small number 36 (11.6%) was dissatisfied, a mean score of 5.4, SD ± 1.3. Patients’ satisfaction with doctor care was 245 (79.1%) and a negative aspect was found among a small number of 65 (20.9%) with a mean score of 4.5, SD ± 1.7.
Chi-square analysis was performed to find the correlation between socio-demographic factors and patient satisfaction level with hospital services and health care (doctors and nurses). Table 5: We found no significant correlation between the participant’s age, gender, marital state, and occupation with the level of satisfaction. Except significant association was found between participant’s residence with hospital services (P-value= 0.04) and between education level with doctor care (P-value= 0.002).

Discussion

This study examined the level of patient satisfaction with a health care provider (nurses and physicians) and services performed in the non-private hospitals in Sulaimani city. We evaluated 311 Patients among whom were highly satisfied with the nurse’s care (88.4%), physician’s care (79.1%), and hospital services (86.5%). The findings of our study are corresponding with the Saudi experience study and the study of Lagos University Teaching Hospital reported that patients with high levels of satisfaction with nurse care \(^2, 14\) and the study of Southern Saudi Arabia \(^15\). A lower number of patient’s dissatisfaction with hospital services and health care was recorded in this study. Such a low perception of satisfaction with staff care and hospital services by patients may create problems in the health system by decreasing trust and less utilization of services as well as delayed health-seeking with subsequent poor health.
outcomes of the public. We found the study participants were more satisfied with nurse care compared to doctor care. The result of this study appeared consistent with the study done by the Kingdom of Saudi Arabia (16) while is inconsistent with the study reported by Southern Saudi Arabia (15). The study discovered that there were no significant differences between patients’ satisfaction and age and gender. Indeed, older respondents did not affect satisfaction values. However, several studies indicated that older participants are generally more satisfied with the health care provider and hospital services compared to younger respondents (17, 18). More females were participated in this study (81%) but no relationships were found between gender and level of satisfaction. Our results are similar to the study that reported patient gender did not affect satisfaction values (18). The Ha’il City, Saudi Arabia study also reported no relationships were found between gender and patient satisfaction levels (19). The results of this present study indicated that there was a significant difference between the level of education and patients’ satisfaction. Patient with a lower level of education was more satisfied with doctor care services than the higher education the P=0.002. The finding of this study is similar to some studies that reported lower education level was greater satisfaction with health care service (20, 21) and also is consistent with a study that reported a higher level of education was less satisfied with health care (22). This can occur because patients with high educational levels possess more information about treatment alternatives and expect higher care standards and therefore are more critical in this regard. In regression analysis, significant associations between place of residence and patient satisfaction were identified, respondents in the rural area remained significantly associated with respect to satisfaction with hospital services the coefficient 0.63, p=0.05. The result of this study is in line with the study (23). This may be due to that some of the rural places they don’t have large hospitals and if they found, the quality of the services may be at the lowest level compared to urban a place. Our study has much strength including the use of validated measures of patient satisfaction, nurses and physician’s care, hospital services, and environment across four large government hospitals. The study has limitations as well. Data from both health care providers and hospital services are cross-sectional, thus limiting causal inferences about the associations found. The open bedside interview we use to collect data might also influence the participants’ responses to some extent even if the data collectors were not part of the treating team. According to our knowledge, this is the first quantitative study to determine the level of patient satisfaction with health care providers (nurses and doctors) and hospital services in Sulaimaniyah city.

Conclusions

In general, the study revealed that patients were highly satisfied with hospital service and health care providers in Sulaimani city. The proportion of patients satisfied with nurse care was found to be higher than the proportion of patients satisfied with doctor care and those with a lower level of education was more satisfied with doctor care than a higher level of education because the second group have adequate treatment information and predicted adequate care they received. Besides, respondents with rural residents are more satisfied with hospitals’ quality and services because some of the respondents living in rural areas have a lack of large hospitals and inadequate health system services. If we improve the quality of hospital services and health care, it is clear that evaluating patients’ satisfaction should be constant to reformulate the baseline and regulation and to be able to assess interventions and changes in the health system. Further study is suggested on patient satisfaction with doctor care to find factors that influence low patient satisfaction compared to nurse care if we must improve the quality of health.

Acknowledgments

We would like to extend our gratitude to the Sulaimani directorate of health and Sulaimani polytechnic university for their permission. Furthermore, our gratitude also goes to all participants who voluntarily agreed to participate in this study and helping to complete this study.

Combined Effect of Physical and Psychological Stress Exposure during Pregnancy on the Expression of Caspase-3 Cerebrum and Cerebellum of Newborn Mus Musculus

Binta Dwi Novitasari1, Hermanto Tri Joewono2, Widjiati3

1Postgraduate Student of Reproductive Health Science, Airlangga University, Surabaya, Indonesia 2Lecturer at Department of Obstetrics and Gynecology, Faculty of Medicine, Airlangga University, Surabaya, Indonesia, 3Professor at Department of Embryology, Faculty of Veterinary Medicine, Airlangga University, Surabaya, Indonesia

Abstract

Background: Prenatal stress affects fetal development including brain development. When a stressor is felt, the brain as the main target for stress will release a hormone that stimulates the release of pro-apoptotic proteins and activate caspase-3 which acts as an executioner caspase in the cell death process. The aim of the study was to analyze the effect of combined stress during pregnancy on the expression of caspase-3 cerebrum and cerebellum of newborn Mus musculus. Methods: An experimental study using 24 pregnant mice (Mus musculus). Subjects were randomized into four groups, consisting of physical stress exposure group (forced swimming) (G1), psychological stress exposure group (noise) (G2), combination stress exposure group (forced swimming + noise) (G3), and control group (G4). Stress exposure was given on 6th-15th days of pregnancy. From each mother, three newborn of Mus musculus were taken to make preparations from brain tissue. Immunohistochemical examination was performed to assess caspase-3 expression. Results: The study shows that the mean and standard deviation of the expression of caspase-3 cerebrum and cerebellum in the physical stress exposure group is 5.70 ± 0.99 and 5.80 ± 1.35, the psychological stress exposure group is 7.23 ± 1.39 and 7.40 ± 1.24, the combined stress exposure group is 8.67 ± 1.09 and 9.30 ± 1.12, and the control group 4.17 ± 1.18 and 3.90 ± 1.06. ANOVAs statistical test results show significant differences among groups with a value of p = 0.000 in the cerebrum and p = 0.000 in the cerebellum. Conclusion: Exposure to physical and psychological stress during pregnancy increases the expression of caspase-3 in the cerebrum and cerebellum of newborn mice.

Keywords: Mus musculus, pregnancy, stress, cerebrum and cerebellum, caspase-3

Introduction

Stress in pregnancy not only has a negative impact on the survival of the pregnancy, it can also affect fetal development and maternal well-being. Prenatal stress affects the fetus resulting in low birth weight, prematurity, and impaired brain development. Studies report that the prevalence of stress during pregnancy in the world ranges from 5.5 to 78%, while in developing countries it ranges from 6% to 52.9%.

The brain is the main organ that interprets, responds to, and becomes the target of stress marker hormones. When a stressor is felt, the hormone (CRH) which acts on the anterior pituitary to promote the secretion of adrenocortico-tropic hormone (ACTH). This hormone then stimulates the adrenal cortex to release glucocorticoids (GCs) into the bloodstream. High glucocorticoids will reduce BDNF expression and

stimulate cell apoptosis \(^{(19)}\).

Caspase-3 acts as the executioner caspase in the cell apoptosis process \(^{(12)}\). Caspase-3 when activated has the function of controlling cell death \(^{(21)}\), causing cleavage of protein kinases, cytoskeletal proteins, DNA repair proteins, endonuclease inhibitory subunits and ultimately to deterioration of cellular function \(^{(9)}\). Increased apoptotic activity of brain cells will reduce the number of cells making up the central nervous system in the fetal brain where there are two main types of cells that make up the central nervous system, namely neurons and glial cells \(^{(9)}\). The cerebellum is a part of the brain that contains more neurons than other parts of the brain \(^{(7)}\), the cerebrum and cerebellum are interconnected by means of polysynaptics, forming a system related to cognitive function and neuropsychiatric disorders \(^{(1)}\). There is little literature and researches on the impact of stress and neurobehavioral studies on the impact of stress on the cerebrum or cerebellum.

This study identifies differences in caspase-3 expression in the cerebrum and cerebellum of newborn mice (Mus musculus) whose mothers are exposed to physical and psychological stress during pregnancy.

Materials and Methods

This research is an experimental study on mice (Mus musculus) which was conducted from January to March 2021 at the Laboratory of the Faculty of Veterinary Medicine, UNAIR, Surabaya. This study used 24 adult female mice (Mus musculus) aged 2-2.5 months of pregnancy which were exposed to stress during pregnancy on the 6th until 15th days of pregnancy. The research subjects were divided into 4 groups which were randomly selected (G1, G2, G3, and G4) with 6 mice in each group.

First group: Exposure to physical stress in the form of forced swimming for 5 minutes once a day in a special box measuring 50x30x25 cm filled with water with a height of 18 cm with a water temperature of 24 °-28 °C and put in a dark box cage, exposure time is 09.00 am.

Second group: The group of exposure to psychological stress by giving noise with an intensity of 90 dB once a day for 1 hour successively in a dark and soundproof enclosure measuring 1x1x2 m, TrueRTA software (real time audio analyzer) was used to produce noise. Noise intensity was measured with a real time sound analyzer (TES 1358) each day prior to exposure to experimental animals, by placing the analyzer in animal cages at several locations, and taking the average of the different readings.

The third group: The stress exposure group, a combination of physical and psychological, was given a noise of 90 dB for 1 hour, then given a break of 5 minutes and then be swam for 5 minutes per day, exposure time starts at 09.00 am.

Fourth group: Control group with standard treatment without stress exposure.

Sampling Inspection

Mus musculus mothers were anesthetized then the pups were born by sectio caesarea (SC) on the 16th day of pregnancy. The pups of Mus musculus which were to be sacrificed were anesthetized first, and then the cranium was cut in the sagittal direction from caudal (occipital) to rostral (frontal), right between the two hamisters of their brain. Furthermore, the brain was released. The separated brain was weighed, and then put in a 10% formalin solution for organ preservation; the cerebrum and cerebellum were taken. Furthermore, immunohistochemical preparations and Hematoxylin-Eosin (HE) staining were made.

Data Analysis

To see the normality of the data, the Shapiro-Wilk test was used. If the data obtained are normally distributed, then the ANOVA test is used followed by LSD (Least Significant Difference) to see the differences in all groups. If the data obtained are not normally distributed, the Kruskall Wallis test and the Mann Whitney test are used. This study uses a significance level of P<0.05. To simplify statistical calculations, researchers used the SPPS tool version 21.
Results and Discussion

Results

The results show the highest expression of caspase-3 in the cerebrum and cerebellum in the combination of physical and psychological stress exposure group compared to the physical stress exposure group, psychological stress exposure group, and the control group (Table 1). The results of the normality test using the Shapiro-Wilk test on the treatment group obtained a significance value (p-value) > 0.05, which means that the data distribution is normally distributed, so the Analysis of Variance (ANOVA) test was used to test whether there were differences in the treatment groups on the expression of caspase-3 in the cerebrum and cerebellum.

Based on the ANOVAs test results in table (2), it is known that there are significant differences among the groups in the expression of caspase-3 in cerebrum and cerebellum of newborn *Mus musculus*.

The combination of physical and psychological stress exposure group (G3) is the strongest among the physical stress group (G1), psychological stress group (G2), and the control group (G4). The expression of caspase-3 in the control group is the weakest. IHC is with a magnification of 400 times.
Discussion

The developing brain is the most sensitive organ to the effects of stress during the prenatal period, due to substantial changes in structural growth and connectivity during fetal life (2). During the gestational period, there are process of proliferation, differentiation, migration, and aggregation of fetal neurons which are strongly influenced by environmental factors (2). Prenatal stress exposure shows a long-term effect that includes both behavioral and molecular changes (6, 13).

When a stressor is felt, the hypothalamus will release the hormone cortisol. During pregnancy, fetal exposure to maternal cortisol is limited by the placental enzyme 11β-HSD-2 which functions to convert cortisol to cortisone, an inactive glucocorticoid (17). High glucocorticoids under stress reduce placental expression of 11βHSD2 which is associated with intrauterine growth restriction (20).

In acute stress, the binding of glucocorticoids and glucocorticoid receptors increases the tissue-plasminogen activator (tPA) which helps the process of converting proBDNF to mature BDNF (mBDNF) and increases proteolytic processing of proBDNF in mBDNF which can increase BDNF levels during stress, but in chronic stress due to decreased tPA hence the process of proBDNF to mBDNF is inhibited and BDNF expression is reduced. If proBDNF is not processed into mBDNF then proBDNF will bind more highly to the p75NTR receptor which induces a pro-apoptotic signaling pathway (3). The proBDNF binding to the p75NTR receptor will activate the apoptotic pathway through the co-receptor bond, namely sortilin. Sortilin will activate jun-N terminal kinase (JNK) which will then phosphorylate C-Jun which will activate pro apoptotic proteins such as p53, Bad, BIM, BAX so that it will stimulate mitochondria to release cytochrome-C which then activates caspase (12).

It is known that there are two types of caspases that have been identified, namely the initiator caspase and the effector / executioner caspase. Caspase 8 and 9 are the initiator caspases, while caspase-3 is the effector / executioner caspase (23). Caspase executioner mediates cell death during apoptosis, caspase-3 has the ability to partially cleave caspase substrates and its activity is required to induce cell death (10).

The results of our study indicate that there are significant differences in the expression of caspase-3 in cerebrum and cerebellum of newborn mice among treatment groups. Combined stress exposure show the strongest expression of caspase-3 compared to the physical, psychological, and control stress exposure groups. This finding is supported by a study by Qiao Y et al in 2020, where the combination of stress exposure caused significantly more hyper-activity of the HPA system as indicated by increased serum cortisol, CRH and ACTH levels (16).

High caspase-3 expression can cause an increase in apoptotic activity of brain cells and will decrease the number of cells making up the central nervous system in the fetal brain (9). A study conducted by Kinsella et al in 2009 shows that chronic stress during the prenatal period interferes with fetal neurodevelopment (11). Sandman et al, found that prenatal stress impaired cognitive performance during infancy and decreased brain volume (18).

Conclusion

Stress exposure during pregnancy increases the expression of caspase-3 in cerebrum and cerebellum of newborn Mus musculus.

Case Study in Fatal Motorcycle Injury Patterns

Budiatri Retno Noormaningrum1, Idha Arfianti Wiraagni1, Dhiwangkoro Aji Kadarmo2

1Researcher, Department of Forensic and Legal Medicine, Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia, 2Researcher, Department of Forensic, Bhayangkara Hospital, Yogyakarta, Indonesia

Abstract

Crash injury is one of the leading causes of premature death globally. In Indonesia, a motorcycle crash is the main cause of road traffic injuries. As a city with a high number of motorcycles, Yogyakarta needs the right mitigation approach based on the local characteristics. The aim of this study was to evaluate the patterns of injury in a fatal motorcycle crash in Yogyakarta. Data were described from five dead motorcyclists that were brought to the mortuary of Bhayangkara Hospital.

Key words: injury; injury patterns; motorcycle accident.

Introduction

Motor crash makes an abundance of needless deaths and disabilities. WHO reported 1.35 million deaths a year or nearly as 3700 deaths every day from road traffic accidents1. In Indonesia, road injuries are the eighth and tenth leading cause of premature mortality and when combined with morbidity, respectively2. As a popular vehicle, the motorcycle demand in Indonesia is very high. Data from 2016 showed that more than 5 million motorcycles were produced annually3.

Yogyakarta is a city in Indonesia that motorcycles were extensively used. Hence, a crash is the greatest cause of road traffic injuries in Yogyakarta4. The right mitigation approaches are needed based on local characteristics. Therefore, we conduct this study to describe the patterns of injury in a fatal motorcycle crash in Yogyakarta.

Material and Methods

All of the deceased that would be discussed was brought to the mortuary of Bhayangkara Hospital in Yogyakarta from the scene of the crash, from April 1st to June 30th, 2020. The deceased were motorcyclists that had perished at the crash scene without received any medical attempts beforehand. The details had been summarized in Table 1. Approval of this study was given by the Medical and Health Research Ethics Committee (MHREC) Faculty of Medicine, Public Health and Nursing University Gadjah Mada/dr Sardjito General Hospital.

Results

Case 1: contusions on the chest

On Monday, April 6th, 2020, the body of 37 years old male was brought by the police after a motorcycle crash that took place in a rural area at 12 PM. The deceased was still wearing an intact helmet on its head, no wounds were found underneath. From the examination, we found bruises, 8x4.2 cm on the right and 1.1x1 cm on the left side of the chest. There was bluish color on the face and nail beds.

Case 2: an app-based motorcycle taxi driver

A dead body of a 25-year-old male was brought to the mortuary on Thursday, April 9th, 2020. The motorcycle crash happened at 5:15 AM in a rural area. The deceased was still wearing an app-based taxi driver jacket and

Corresponding Author:
Idha Arfianti Wiraagni
Email: arfianti.idha@gmail.com
helmet. The examination revealed some abrasions, 10x5 cm on the left side of the chest, 19x15 cm on the left side of the abdomen, and 3x2 cm on the back of the left hand, and also closed fractures on the left upper arm, and left upper leg.

**Case 3: open fracture of the head**

An examination was conducted on Tuesday, May 26th, 2020, on a dead body of 36 years old male. The guy was wearing a helmet while crashed a house wall fence that day, at 2:30 AM under clear weather, as the rider. The pillion passenger was a 19 years old male that survived while suffered from lacerations on the left cheek and the right foot. The crash scene was a dimly lit rural area. The examination exposed an open fracture on the front part of the head that extended to the backside. There was amputation at the first segment of the fifth finger of the left hand, and closed fractures with deformities on the nose, left upper arm, right upper leg, and left knee. We found multiple lacerations on the left side of the head, right and left cheek, and lower lip. There were multiple abrasions on the right shoulder, right hand, left upper leg, right and left knee, and left lower leg.

**Case 4: multiple fractures**

On Sunday, May 31st, 2020, at 10:30 PM, in a rural area, a fatal road crash happened to a 69 years old male. The deceased was brought to undergo a forensic examination. The examination came out with multiple closed fractures on the lower jaw, upper left arm, the right side of the chest, left wrist, left ankle, and right knee. There was a laceration on the back part of the head 3x0.5 cm. We found numerous abrasions on the right side of the head, left knee and left upper arm.

**Case 5: the broken helmet was still attached**

On Monday, June 22nd, 2020, the dead body of 51 years old male that was still wearing a broken helmet on its head was brought by the police. When the helmet had been released, we found an open comminuted depressed fracture 15x13 cm on the frontotemporal region of the skull, with brain tissues scattered around. Other injuries were abrasions and bruises that were spread out on the neck, right elbow, right lower arm, right knee, left lower leg, upper right chest, and back. The crash happened in an urban area that day at 9:55 AM.

**Discussion**

**Demographical characteristics**

All of the cases that were discussed involved male motorcyclists, agreed with other studies that the majority of motorcycle crash casualties were male. This finding happened because there were more male motorcyclists than females, that in accordance with Indonesia’s condition. But for a head injury, there was no considerably different risk for both sexes.

Four from 5 cases (case 1, 3, 4, 5) associated with age $\geq$35, parallel to finding from Malaysia that this age was a significant predictor of death in a motorcycle crash. This similar outcome could be because of the similarity of Indonesia and Malaysia that both countries have large numbers of motorcycles as transportation vehicles for working-class citizens.

**The patterns of injuries**

The main objective of this study was to evaluate the patterns of injury in a fatal motorcycle crash in Yogyakarta. Studies from other countries showed that the most frequent cause of death in a fatal motorcycle crash was head injury. In this study, we described 2 cases (case 3 and case 5) with a devastating fracture on the head that could be easily recognized from external examination.

The actual number of head injuries in this study could be bigger, considered that internal examination had not been done because of the police request. The study in Spain showed that when the internal examination was conducted, the prominent causes of death in a motorcycle crash were subarachnoid hemorrhage, followed by cerebral contusion and skull base fracture. The past study found that the position as the rider had a higher head injury risk, compared to the pillion passenger.
Helmet use had been reported to lower head risk injury, in the amount of 69%, 71%, and 53% reduction in skull fractures, cerebral contusion, and intracranial hemorrhage, respectively\textsuperscript{13}. Contributing factors to the helmet’s failure in preventing injuries in case 1, 2, 3, and 5 could be speeding, or using helmet without proper fixation. As the past studies showed that the helmet protective effect only effective when the speed of the motorcycle was less than 30km/h\textsuperscript{14}, and securely fixed\textsuperscript{15}.

For facial injury, the helmet had a protective effect against maxillary fracture, but for mandible fracture (case 4) was not significantly proven\textsuperscript{16}. This finding might be because there was no consideration to the helmet types. Another study found that the full-face and modular helmet had a higher protective effect against head injury compared to open-face, half-helmet, and novelty helmets\textsuperscript{7}. A study from Thailand reported that a full-face helmet reduced head injury risk by 64% compared with a half-coverage helmet, and 36% compared with a half-coverage helmet\textsuperscript{17}. In Indonesia, wearing a national standardized helmet for motorcyclist was made mandatory\textsuperscript{18}, but the resident’s habit of wearing a helmet while riding a motorcycle was just 33.7% and 41.8% in Indonesia and Yogyakarta in particular based on the report in 2018, respectively\textsuperscript{6}.

Results from the past study showed that the majority of injury types were abrasions or bruises, followed by lacerations and bone fractures. Nearly agreed with our findings that all of the cases involved abrasions or bruises, 3 cases showed lacerations (case 3, 4, and 5), and bone fractures in 4 cases (case 2, 3, 4, 5). Amputation was relatively rare but happened in case 3, which might be because of the crushed effect during the collision\textsuperscript{12}.

After the head injury, injuries in the chest and abdomen caused significant numbers in motorcycle crash mortality\textsuperscript{5}, as we suspected from case 1, 2, and 5. But the actual cause of death could not be defined without internal examination.

Other factors

The crashes in this study happened at various times and days, with the only case that occurred at the weekend was case 4. A past study in Pakistan found that crash happened on weekdays and during rush hour (6 AM-9 AM in the morning and 3 PM-6 PM in the evening) had more fatal probability than minor injuries that might be because of the high traffic of daily commuters. From this study, there was no crash that happened in rush hour, case 2 befell early in the morning, case 3 before dawn, and case 4 late at night, might have an association with speeding and off-peak hours that increased the probability of fatality.

Application-based taxi drivers (case 2) had a higher risk of mobile phone-related crashed, associated with the high prevalence of mobile phone use while riding. A factor that also contributed to motorcycle crashes was riding under alcohol influence, as it could increase the risk of losing control, and associated with non-helmet use. There were no data related to blood alcohol level obtained from this study.

Conclusions

Knowing injury patterns and associated factors are important in developing mitigation strategy to reduce motorcycle crash fatalities. The demographical characteristics gave us knowledge of the people at risk. Some measures had been made, but the implementation seems still lacking. This study could be developed for a future investigation, with the additions of more samples and variables. Internal examinations and laboratory tests will give objective value that will enrich the study.

Prevalence of Internet Gaming Disorder (IGD) in University Students and its Relationship with Depression

Bandana Bisht1, Navdeep Kaur2, Sandeep Kumar Goyal3

1Professor & Principal, 2Associate Professor & Vice-Principal, Chitkara University College of Nursing, Chitkara University, Himachal Pradesh, India, 3Senior Consultant, Department of Psychiatry, SPS Hospitals, Ludhiana, Punjab, India

Abstract

Introduction: Internet gaming disorder (IGD) is the emerging disorder in adolescents. The most common motivators behind IGD is coping with stressors, escapism, control over one’s life, excitement and challenges.

Aims: The current study was done with the aims: 1) To find the prevalence of IGD in university students 2) To find the prevalence of depression among university students 3) To find the association of IGD with depression among university students.

Settings and Design: A descriptive research design was used to collect data from a private university. Setting of the study was food court of the selected university.

Methods and Material: A total of 91 college students were recruited from a selected university. Purposive sampling method was used to collect the data. Internet Gaming Disorder addiction was checked with the help of DSM-5 criteria. Depression was checked with the help of PHQ-9 questionnaire.

Statistical Analysis Used: Chi-square was used to check the association between IGD and depression.

Results: Twenty-one (23%) respondents were found to have IGD. Out of 21 respondents who had IGD, 9 were having mild depression, 4 were having moderate and 3 were having severe depression. Out of 70 respondents who did not suffer from IGD, 28 showed no signs of depression, 36 had mild depression and only 6 reported moderate depression. None of them had severe depression. The results demonstrated that internet gaming disorder was significantly associated with depression (p<0.005).

Conclusions: Majority of the respondents having IGD had also reported co-morbid depression on PHQ-9 questionnaire. Thus depression needs to be identified and treated in clients suffering with Internet gaming disorder.

Key words: Internet Gaming Disorder (IGD), Depression

Introduction

The digital world was still in past, is changing dramatically now and will be changing rapidly then. In the past two decades, owing to exponential growth in technology and digital usage, internet gaming has become one of the most popular online activities. Despite its entertainment purpose, excessive engagement in online gaming can cause devastating effect on an individual’s health. In 2013 Diagnostic and Statistical Manual of Mental Disorders, 5th edition (DSM-5) has labeled it as separate entity ‘Internet Gaming Disorder’ (IGD) with the definition ‘persistent and recurrent use of internet to engage in games, often with other players, which leads to clinically significant distress or impairment.’ Moreover, ‘Gaming Disorder’ has been included as a mental health disorder in International classification of diseases 11th revision (ICD-11) by World Health Organization. Internet gaming disorder is a growing
public health threat that usually affects the adolescents and young adults across the globe and causing a significant decline in an individual’s well-being not only to physical, psychological but also to social and occupational functioning. [4]

Prevalence of Internet Gaming Disorder is increasing worldwide and has been estimated to be between 0.7-27.5 percent. It varies across countries and regions due to difference in various sample characteristics and screening tools being used. As per previous researches, Internet Gaming Disorder is found to be more prevalent in Asian countries than western ones. [5, 6] Further, one of the market surveys quotes India as one of the top five countries for downloading games globally. Also, India being a country with largest youth population and fastest growing smartphone user base, new insights regarding India are being uncovered continuously that it would exceed other countries and become biggest gaming market in future. This would result into more vulnerability to dangers associated with online gaming especially to adolescents in overall population of India. [7, 8, 9, 10] The available literature suggests that Internet Gaming Disorder is more prevalent in males and in adolescents brought up by divorced parents and reared up in broken homes. It is reported that increasing age, low self-esteem and poor daily life satisfaction usually cause more severe online gaming addiction particularly among males. [11, 12, 13, 14]

The predictive factors associated with problematic online gaming are not well established. However, researchers state that Individual factors (gender and age), social interactive factors (family atmosphere, social anxiety and self-esteem), cognitive factors and psychopathological conditions deeply influence the development of Internet Gaming Disorder. Depression, ADHD, anxiety and impulsivity are considered as the strongest risk factors. [15, 16] Also, an individual with higher psychopathology is more prone to online gaming addictions in an attempt to escape through emotional difficulties. [17, 18, 19] Furthermore, Addicted gamers often exhibit more irritability, aggression, low mood, and confusion between real and virtual world. Problematic gaming is also associated with low academic performance and substance abuse. [20]

In India, there is a scarcity of studies regarding prevalence and associated factors with digital gaming despite of the fact that internet usage is rising day by day in the country. Therefore, exploring the field of research regarding online gaming disorders will provide necessary hub of knowledge in an order to formulate health policies to prevent and treat Internet Gaming Disorder. With this background, present study was conducted to know Internet Gaming Disorder prevalence among university students and its association with depression.

**Aim of the Study**

1) To find the prevalence of Internet Gaming Disorder in college students

2) To find the prevalence of depression

3) To find the association of Internet Gaming Disorder with depression, if any

**Materials and Methods**

**Setting & Participants**

A total of 91 college students were recruited from a selected university. The setting of the study was Food court of the selected university. Purposive sampling method was used to collect the data. For the present study, those students were enrolled who gave the consent for the study and who met the inclusion criteria which was: a) The volunteer college students studying in undergraduate program of any stream b) Students using mobile phones or/laptops and also having access to internet since last one year.

The design of the study was descriptive research design.

**Tools**

1. Socio-demographic Performa: A socio-demographic performa was used.

2. PHQ-9:PHQ-9 [21] is a subset of Patient health
questionnaire. PHQ is a self-report version of Primary Care Evaluation of Mental Disorders (PRIME-MD). The PHQ-9, a tool specific to depression, simply scores each of the 9 DSM-IV criteria based on the mood module from the original PRIME-MD. PHQ-9 total score for the nine items ranges from 0 to 27. Scores of 5, 10, 15 and 20 represent cut points for mild, moderate, moderately severe and severe depression, respectively.

3. IGD Assessment tool: Internet gaming disorder was assessed by the researchers according to DSM-5 criteria by clinical interview.\[24\] There were nine items related to gaming behavior. Participants were supposed to respond in Yes or No. For every “Yes”, score of 1 was given. Any participant having score 5 or more was categorized as having IGD. The data so generated was subjected to statistical analysis.

The assessment was made on the basis of above instruments and scales, supplemented with a clinical interview.

**Results**

Table 2 depicts that out of 33 students who did not have depression, 28 students were also not having IGD. Similarly, students with mild depression also have less cases of IGD. Out of 10 students who had moderate depression, 4 were having co-morbid IGD. All the students who were having moderately severe depression also had co-morbid IGD. Chi-square analysis found that there is a significant association between Depression and IGD.

Discussion

The current study, to the best of our knowledge,
is the first study to report prevalence of IGD and its association with depression among university students in India. This study found that overall prevalence of IGD was 23% in students of university. Similarly, a review literature conducted by Mihara and Higuchi found a prevalence of IGD ranging from 0.7% to 27.5%. In contrast to developed countries where the prevalence of IGD is reported only between 0.3%-1% by Przybylski AK et al.[25] It is hypothesized that unlike the western countries, students of Asian countries face more academic and societal competition. Thus, digital gaming provides an escape into a virtual world where they can relieve stress from such competitions.[10, 26]

Individuals with internet addiction exhibit more psychopathology, as revealed by Yen J et al.[27] For instance, Whang et al,[28] found significant association between degree of depression, anxiety and problematic internet use. A systemic review on the association between disordered online gaming and mental health issues found the correlation of 92% between anxiety and IGD, 89% between depression and IGD, and 85% between ADHD and IGD.[29] Hence, Depression is considered as a co-morbid psychiatric symptom of disordered digital gaming. Similarly, in current study, relationship between IGD and depression was also examined and it was found to be significantly associated (p value ≤ 0.005) as majority of the respondents had reported co-morbid depression on PHQ-9 questionnaire. These results are in line with the existing researches on relationship between pathologic internet gaming and psychiatric symptoms.[30, 31, 32,33,34] The literature has consistently demonstrated that online game addicts report more depression, loneliness, anxiety and lower psychological well-being.[28, 35]

Furthermore, in past, it was proposed by investigators that an individual with depression use Internet excessively as the means of self-medicating and Internet addiction itself can lead to depression symptoms because of social isolation resulting from spending much time in online gaming, which, in turn, causes undermined psychological health.[36, 37] Achab et al[38] compared the characteristics of addict vs non-addict online gamers and found significantly higher rates of irritability, emotional changes, low mood since online gaming onset. In addition to this, online gaming disorders and depression may share common risk factors, like, genes, environmental, educational, deficit social support, stress coping skills, and each might serve to aggravate of severity of other.[36,39] However, more researchers are needed to explicate the common mechanism underlying IGD and depression.[40]

Conclusions

In conclusion, this research demonstrated the most recent prevalence of Internet gaming disorder and its association with depression in University students of India. It shows continuous increase in prevalence of digital gaming and has strong association between depression and IGD. Thus depression needs to be identified and treated in clients. Furthermore, the direction of relation between IGD and depression needs to be explored.

Limitation

- Sample size was small
- Randomization was not done

Pattern of Drowning Cases at a Tertiary Care Hospital, Khammam

Pondurthi Srinivas Rao¹, Bharath Kumar Guntheti²
¹Asst Professor, Government Medical College, Siddipet; Telangana, ²Professor, Dept. of Forensic Medicine & Toxicology, Mamata Medical College, Khammam; Telangana

Abstract

The diagnosis of death by drowning is one of the hardest challenges in forensic pathology. Circumstantial factors and physical evidence such as autopsy findings are both important in drowning. There were 68 cases of drowning deaths during one-year study period from Jan 2019 to Dec 2019, at dept of Forensic Medicine MMC&MGH, Khammam, consisting of 60 male and 8 female victims. The largest number of victims, 26 [38.23%] were found in the age group 31 to 40 years. Males [n=60, 88.23%] were predominantly affected. 37 [54.41%] cases were married, in which 32 were males (47.05%) and females were 5 (7.35%) and 31 cases are unmarried out of which 28 [41.17%] are male and 3 females. Most of the victims were follows Hindu belief, habitat of rural. Approximately 30 [44.11%] of victims come from the student unemployed group. Incidence of fresh water drowning is more than sea water drowning. The wet drowning accounted more than dry drowning. Highest number [n=32, 47.05%] occurred in afternoonthan other timings. The incidence of drowning was more in summer. Major fatalities occurred within one to three days of hospitalization. Accidental falls 56 [82.35%] were the commonly occurring incidents that leads to drowning death and most of drowning deaths 58 [70.58%] occurred in the lakes. Majority of victims died at the place of drowning. Most of the victims witnessed respiratory complications [55.2%]. 10.00% of the deceased were the tested positive for alcohol, while 4 [6.66%] were confirmed as drug abusers. Non swimmers were victims more than swimmers. Decomposition changes on the body were found in 10 % cases. Externally, frothy or blood-stained discharge at mouth and nostrils and “washer-women” appearance on the hands and feet were the common postmortem findings; while internally, congestion, edema of the lungs and presence of foreign bodies in an airway, were the common findings. Out of 68 cases 62 [91.17%] cases were showing positive results for same diatoms in bone marrow and sample water, in 45.88% cases, only sample water showed positive results, 22.94% cases were showing no diatoms in bone marrow and sample water. The aim of the study is to analyzed different main objective of the study is epidemiological factors and pattern of drowning, contributing factors, and arriving diagnosis of ante mortem drowning by diatom test.

Keywords: Pattern of Drowning, River, Canals, Wells, Diatoms, Fresh water

Introduction

Drowning is a type of asphyxia due to aspiration of fluid in to air passages, caused by submersion in water or any other fluid.

There are four types of drowning:
1. Wet [primary] drowning
2. Dry drowning
3. Secondary drowning [Post immersion syndrome or near drowning]
4. Immersion syndrome [Hydrocution, submersion inhibition]¹.

Corresponding Author:

The main question in case of a body recovered from water is whether the individual was alive at the time he/she entered water. Circumstantial evidences, external appearances like cutis anserine, washer woman feet, and internal findings like emphysema aqueosum and froth in airways up to the terminal bronchioles give substantial amount of evidence for the diagnosis of ante mortem drowning. The discovery of diatoms and its application in diagnosis of drowning has increased the corroborative evidences for drowning².

During autopsy, one must focus attention to distinguish between changes that are due to drowning and those that are otherwise, i.e., those that occur in bodies immersed/submersed/disposed in water after death from causes other than drowning. The autopsy diagnosis of drowning is one of the major problems in forensic medicine, especially when there is delay in recovering the corpse. In advanced decomposed and skeletonized bodies, the only method of identifying the classical ante mortem drowning is estimation of the diatoms from the bone marrow and of comparing them with the diatoms available in the water².

Drowning is the third leading cause of unintentional injury death worldwide, accounting for 7% of all injury related deaths worldwide³.

According to National Crime Records Bureau, about 12 people end life every hour, and 83 people drown every day in India. The total number of accidental drowning deaths in India was 32,671[7.9%] during 2019.⁴

Accidental deaths due to drowning are common in India and suicidal drowning is one of the most common means to commit suicide. Homicidal drowning occurs less commonly. Some murderers dispose of the dead bodies of their victims in the rivers, seas and wells to simulate death due to drowning. Sometimes unwanted bodies are thrown into water.

The main objective of this retrospective study is profile, pattern of drowning, circumstances, location, month wise, contributing factors for drowning, and arriving diagnosis of ante mortem drowning by diatom test and suggestive preventive measures.

**Aims & Objectives**

Study of sociodemographic profile, pattern & present trends in drowning.

Types of submersion media and seasonal variation

Study the water diatoms and tally them with sternal bone marrow diatoms.

To know the validity of diatom test.

Cause and manner of death.

**Materials & Methods**

The present study was conducted in the Dept of Forensic Medicine, Mamata Medical College, Khammam, between January 2019 to December 2019. A total of 68 cases of drowning were statistically analyzed with regard to general incidence, profile, pattern, and drug/alcohol abuse, contributing factors after complete and detailed postmortem examination. Viscera were preserved for chemical analysis. Intact sternum and two-liter control sample of water from site of drowning was also preserved for comparative study with diatoms test. The diatoms from the sternal bone marrow of the cases were analyzed by acid digestion and were compared with the water diatoms from the same source.

**Result and Discussion**

Total 768 autopsies were conducted during the period of one year in the Dept of Forensic Medicine, MGH, Khammam. Out of these cases, drowning was concluded as cause of death in 68[8.85%] cases. These are similar to studies by authors.⁴⁻⁶

When identity is taken in to consideration, nearly all the cases were of known type. The above distribution may be because most of the accidental drowned deaths occurred in a close place from their residence, where they were brought to the mortuary as known bodies. 4[5.88%] cases are brought to the mortuary as unknown identity by investigating officers and in stage of decomposition, in those cases the early signs of drowning, postmortem
examination was masked and diatom test becomes the only means of knowing whether death was due to antemortem drowning or postmortem disposal. These are similar to authors.5, 6

In this study, peak incidence is observed during second [n=27, 39.70%] and third [n=26, 38.23%] decades of life, after which a gradual decline was evident. 2nd and 3rd decades together accounted for 77.94% of the total cases. These are consistent with authors1-6. Young people are at greatest risk of drowning owing to their energy and curiosity that can easily lead them to jump into water source from which they cannot escape. In teenagers and adults, drowning has been associated with drugs and intoxication.

In our study, deaths were more among males by drowning [n=60, 88.23%] as compared to females [n=8, 11.76%], male-female ratio being 7.5:1. This may be because of extensive outdoor activity of men. These are similar to another authors1-8. Married victims [n=37, 54.41%] outnumbered unmarried [n=31, 45.58%]. A total of 37 married people out of which male were 32 [47.05%] and 5 [7.35%] were female. Whereas unmarried males 28 [41.17%] were more than the unmarried females 3 [4.41%]. Amongst female victims the percentage of married are more. In the males no much difference between married and unmarried. As depicted in table no.1. Same findings were noted by authors.6-8

44 [64.70%] constituted from rural population. This distribution is because of the area under our jurisdiction consists of mostly rural, sub rural area surrounding the Khammam. Which are supported by authors.5, 7

Occupation wise, students were top among the victims. Whereas laborer was 19 [27.94%], employees were 10 and house wives were 5. This might be because of over enthusiasm of students in swimming and lack of proper supervision as felt by authors4-6. Chart no.1

Majority of people drowned in daytime as compared with night. Highest incidences reported in afternoon [n=40, 58.82%] followed by evening [n=23, 33.82%] and least [n=4, 5.88%] in night time. Same findings were made by authors7-9.

In this study, the incidence of drowning was more in summer [n=46, 67.64%] when compared to other seasons. These are consistent with authors6-9.

The month wise occurrence of drowning was more [n=46, 67.64%] in April-June months followed by July-August months [n=10, 14.70%] and Sept-Nov months [n=9, 13.23%] and least in Dec-Feb months [n=34.41%]. The high incidence of drowning in summer season might be because, victims being students in vacation, high temperatures in this season forced them into swimming to beat the heat and lack of proper supervision. These are consistent with authors6-9.

The commonest place of submersion was well/lakes [n=40, 70.58%] followed by river [n=10, 14.7%] and canals [n=7, 10.29%]. The reason might be due to jurisdiction of Khammam being surrounded by rural and semi-rural habituation. Place of incident and media of submersion was known in 68 cases. Chart no.3

Fresh water drowning was more commonly encountered with drowning in wells/lakes predominating 67 [98.52%] when compared with sea water drowning 1 [1.47%]. The reason might be due to presence of no sea in this jurisdiction. Similar observations were made by other studies.5-9

Pattern of drowning, 56 [82.35%] of deaths occurred due to accidental drowning, while swimming in wells/lakes, canals and river water. The victims are usually children, fisherman, and waterfront workers, intoxicated or epileptic subjects. Unintentional drowning was reported in maximum studies2-10. Chart no.4

Suicidal drowning was seen in about 8 [11.76%] of the cases. Drowning remains a relatively popular method of suicide in this region. This trend is because of increasing social, family, financial responsibilities and adjustment problems in the society, which might lead to increased suicidal tendencies. Suicidal episodes are fairly common amongst women or disabled persons.
These are consistent with studies by authors 7-10.

In our study only four homicidal cases [5.88%] of drowning was reported. The reason is intentionally persons being drowned by others with various grounds such as business, financial problems, extra marital affairs, family quarrels, and property disputes. Same results are obtained by authors 7-10.

In this study, wet drowning 54[79.44%] is commonest type of drowning, followed by dry drowning [n=10, 14.70%] and post immersion syndrome [n=4, 5.88%] in present study. These are consistent with authors 9-11.

In this study non-swimmers [n=58, 85.29%] dominated swimmers [n=10, 14.17%]. These are supported by authors 8-12.

In our study, most [n=64, 94.11%] of the persons were alive at the time drowning when compared with post mortem drowning 4[5.88%]. We could prove scientifically by positive diatom test and similarity of diatoms in test sample of bone marrow and control sample of water as ante mortem drowning, especially in putrefied corpses where no other signs of ante mortem drowning are present. We have also made an attempt to find out that in four cases the cause of death was not drowning, in the bodies recovered from water, as the victims were thrown into the water after killing them by some other means. These are consistent with authors 9-18.

In this study, out of 68 cases, 62(91.17%) cases are showing positive results for same diatoms in bone marrow and sample water, in 4[2.94%] cases, only sample water showed positive results, 2 (3.3%) cases showed no diatoms in bone marrow and sample water. The analysis of diatoms found in body may draw a fairly sound conclusion related to drowning as a mode of death. These are consistent with studies by authors 8-18. We analyzed the relationships between the numbers of the diatoms in the lung tissues and the drowning medium. Also, we made a comparative analysis between the diatoms in the lung tissues and the drowning medium using the ratio of diatom numbers in both samples. Quantitative diatom analysis in the lung tissues, especially combined with the diatom analysis of the drowning medium, provides supportive evidence in determining if a body recovered in water was due to drowning or not.

We observed associated injuries in 12 cases. This is supporting that the person was alive at the time of drowning. Middle ear hemorrhage was present in 72% of cases. Similar findings were made by authors 14-17.

Duration of hospital stay, we observed that the maximum number [n= 6, 8.82%] of victims stay in hospital for 1-2 days, followed by 2-3 days [n= 4, 5.88%] and up to seven days [n=22.94%] while spot dead were 56[82.35%] cases and brought dead were 2 [2.94%] cases. These are consistent with authors 9,16-20. Period of survival in fatal cases varied from 2 -7 days. The chances of survival depend on the duration of submersion, the water temperature, the person’s age, and how soon resuscitation begins.

In this study, 8[11.76%] people were positive for alcohol in their body. People who have consumed alcoholic beverages before submersion are more prone to develop brain or lung damage. Similar findings are made by authors 9,11, and 21.

Respiratory complications were encountered in maximum number of cases [n=50, 73.52%] followed by 10[14.70%] victims who did not aspirate water but died of asphyxia due to laryngospasm, neurological complications were seen in 3[4.41%] cases and post immersion syndrome in 4[[5.88%] cases. While seven victims [10.29%] died in the hospital. These are consistent with authors 18-22. The original concept of drowning deaths was that they were asphyxial in nature with water occluding the airways, death was due to electrolyte disturbance and or cardiac arrhythmias, produced by large volume of water entering the circulation through lungs. Chart no.8
Conclusion

Drowning deaths were more common in males, among 21 to 30 years of age group. A majority of them were married rural people and unemployed. Majority of drowning deaths were accidental in nature by falling into the wells/lakes and fresh water drowning deaths. Accidental drowning deaths were more common in males and children, suicidal drowning deaths were more in females. Almost all the deceased died at the scene and day time drowning deaths. Maximum number of drowning deaths were reported in summer and non-swimmer victims.

Froth or blood-stained discharge at mouth and nostrils, congested, edematous and voluminous lungs were common autopsy findings. Alcohol intake, disease status was found in 7.2% and 10.29% of cases respectively. Middle ear hemorrhage was present in 72% of cases. Postmortem aquatic bite marks and ante
mortem ingestion of water was found. The diatom test was still considered as golden standard. As drowning is a major cause of mortality among teenagers after road traffic accidents, all over the world, more in developed countries, this matter should not be overlooked.

**Recommendations:** Preventive measures need to be taken, based on the risk factors that had been identified. Therefore, a more comprehensive and strict approaches should be amended to prevent drowning death.

Supervision and surveillance of any child in proximity to any aquatic environment, including swimming pools, baths, beaches, buckets containing water, etc., is an essential strategy for the prevention of drownings ...

The presence of a lifeguard is the best way to avoid water accidents that end in drowning.

The Pattern of Physical Injuries among Victims of Fatal Accidents in Bhopal, Madhya Pradesh

Brinda Patel¹, SK Asawa²

¹Senior Resident, Dept of Forensic Medicine & Toxicology, AIIMS, Bhopal, M.P., ²Professor & Head, Dept of Forensic Medicine & Toxicology, Government Medical College, Dungarpur, Rajasthan

Abstract

Background: The pattern of injuries is unique to the mode of the accident as well as to the causative agent. The objective of the present study was to describe the pattern of injury among victims of a fatal accident and draw a medicolegal conclusion from the pattern of injury. Methods: A total of 145 dead bodies brought for autopsy at the two selected post-mortem centres were included in the present study. The socio-demographic data like age, sex, religion, occupation as well as the circumstances leading to the death of the individual were gathered from documents and detailed interview of the friends/relatives/eyewitnesses etc. Among study participants, burns were the single largest category of accidents closely followed by road traffic accidents. The brain was the most common internal organ injured and the skull was the most common major bone fractured among the victims. One-fourth of all study participants were dead before being brought to hospital and one-third of all study participants survived for more than 48 hours after the incident. Conclusion: Septicaemic shock and craniocerebral injury were the most common cause of death among study participants.

Keywords: Accidents, Injury, Burns, Fall, Fatal, India.

Introduction

Trauma is an injury inflicted on a living tissue caused by the application of external force.¹ As per section 44 of the Indian Penal Code, an injury is defined as any harm illegally caused to any person in body, mind, reputation, or property.² Injuries can be classified as physical (or mechanical), chemical, thermal & miscellaneous depending on the nature of the causative agent.³ For medico-legal purposes, injuries can also be classified as suicidal, homicidal, accidental, fabricated, self-inflicted & defence. Traumatic instances can be unintentional (accidental) or intentional (suicidal or homicidal).⁴ It is estimated that worldwide about five million people die each year due to some type of injury.⁵ Moreover, different types of injuries collectively account for about 9% of global mortality & 12% of DALY (disability-adjusted life years).⁵

An accident is the occurrence of a series of events resulting in unintended injury, death, or property damage. It is an unplanned event, occurring suddenly, unexpectedly & inadvertently in an unforeseen circumstance.⁶ An accident is a result of defects laying either in the host (victim), agent (vehicle) & environment (road condition, traffic, weather conditions etc.) or a combination of defects at each of these three levels. Accidents represent an endemic of the modern and fast-changing world. There are different types of accident viz. road traffic accidents (RTA), railway accidents, falls from height, accidental fires, occupational accidents. In India, RTAs has the maximum share of unnatural deaths followed by burns.⁷ Globally, RTAs are considered as the 3rd leading cause of death after heart disease & cancer⁸ & the 3rd major preventable cause of unnatural deaths.⁹ ‘Fall from height’ is defined by ICD-9 as an event where a person falls to a ground-level from an upper level, whereas FICSIT (Frailty & Injuries Cooperative Studies) defines them as unintentionally coming to rest on the ground or lower level.¹⁰ The frequency, type & extensiveness of an injury depend on body weight, velocity, height, nature of surface impacted, body’s orientation at impact.¹¹ The most important among all these factors is the ‘height’ of
the fall.[11] During the autopsy, the most important thing to do is to determine the primary site of impact to permit the forensic reconstruction of the event to form a medico-legal opinion whether the fall was suicidal, homicidal, or accidental.

The objective of the present study is to identify and describe the pattern of injuries sustained by victims of fatal accidents.

Material and Methods

Study Setting: The present study was carried out at the mortuary of People’s College of Medical Sciences, Bhopal and Medico-legal Institute of Madhya Pradesh, Bhopal. Study Duration: The total duration of the study was one & a half year; from 1st January 2014 to 30th June 2015. Sample Size: For this study, we sampled and collected data from a total of 145 dead bodies on which the autopsies were conducted during the period of data collection.

Inclusion Criteria: Deaths due to accidents (e.g., road traffic accidents, falls from height & thermal injuries), who either died before reaching the hospital or were admitted to hospital before their death. Exclusion Criteria: (I) deaths due to non-accidental trauma (interpersonal or self-harm)(ii) Decomposed bodies preventing a valid autopsy, (iii) deaths due to causes other than trauma.

Data collection: The detailed medico-legal postmortem examination was carried out in the two selected centres after receiving requisition from the concerned police official, the inquest report & the dead body challan. The socio-demographic data like age, sex, religion, occupation as well as the circumstances leading to the death of the individual were gathered from documents like inquest report, dead body challan and through detailed interview of the friends, relatives, neighbours, eyewitnesses, and police officials accompanying the dead bodies. In cases where the death of the victim occurred in the hospital, the treatment records available were also studied. All medico-legally important findings were documented by taking scaled photographs, whenever & wherever possible.

Data Analysis: All the data were collected in a paper-based data collection form. Thereafter, the data will be coded and entered in Microsoft Excel. The coded data were imported into Stata 15.1 version for analysis. For the continuous data, the author calculated the mean, median, and standard deviation. For discrete data, the author calculated and reported frequency, proportion, and percentage.[12] Any statistical difference between the two proportions will be estimated using the Chi-square test.[13] Any statistical difference between the two means will be estimated using the T-test.[13]

Results

During the period of data collection, a total of 145 dead bodies fulfilling the selection criteria were brought to the mortuaries for autopsy. Table 1 gives details about the type of accident. As can be inferred from table 1, burns were the single largest category of accidents followed by road traffic accidents resulting in death among study participants. There was only a single case of death due to lightning.

Table 2 give details about the socio-demographic details of the study participants. The mean and the median age of the study participants was 38.6 and 28 years, respectively. Most participants were between 10-30 years of age followed by 30-60 years of age. Occupationally, most of the study participants were field workers and met with an accident while on their job. This was closely followed by females working as a homemaker.

***- Includes study participants without burn injury.
^- sample exceeds 145 because of multiple injuries.

Table 3 illustrates the injury sustained by bones and internal organs among victims of the non-burn accident. Among study participants, skull & facial bones were the most commonly (26.2%) injured major bones closely followed by bones of lower limb (25.7%), neck & thorax bones were least commonly injured bones (9.8%). Similarly, the brain was the most commonly injured organ (30.4%). Collectively, the hollow viscera of the abdomen were the second most common organ injured among the victims.

</tbody>
</table>
Table 4 highlights the cause of death and the time for which the victim survived after the accident. Among study participants, septic shock was the most common cause of death. This is hardly surprising as most study participants suffered a burn injury. This was closely followed by cranial injury. In our study, most victims survived for more than 48 hours and about one-fifth of victims were declared dead on arrival at the hospital. Most participants who survived for more than 24 hours after the incident suffered from burn and most participants who were dead before reaching hospital suffered from poly-trauma.

**Discussion**

The present study included data from a total of 145 victims of fatal accidents whose dead bodies were brought to the mortuary of People’s College of Medical Sciences & Research Centre (PCMS & RC), Bhopal and Medicolegal Institute of Madhya Pradesh (MLI), Bhopal, for autopsy, during the period of data collection. The participants included victims of road traffic accidents, falls from height, railway accidents, accidental burns & other accidents. Most deaths were attributed to burns (44.8%), followed by road traffic accidents (36.6%), falls from height (12.4%), and railway accidents (4.8%).

In our study, out of a total of 145 victims, the majority were males (69.0%). In Indian society, men are generally the more active group (both economically and physically), thereby exposing themselves to various injury-causing agents. This may explain the observed male preponderance among study subjects. In our study, the single most common age group was 20-60 years, which also corresponds to the age group of maximum economic and physical activity. Children <10 years of age constituted the least common age group among study participants. All these participants (children) exclusively suffered from either burn or fall from height. The majority of the victims belonged to the Hindu community followed by Muslims. Similar results of Hindu predominance followed by Muslim were also reported by Gowri S et al. and Mazumdar A et al.

In the present study, most of the victims were married (54.5%), followed by unmarried (38.6%). This is easily understood as the most common age group in the present study was 21-40 years and this represents the bulk of the married population. Similar findings were also reported by other researchers e.g., Gowri S et al., Harish D et al. & Mangal HM et al.

In cases of death due to burn injury, women (61.53%) outnumbered men (38.46%). This female preponderance can be explained by the fact that in
our study most accidental burn were kitchen related. Furthermore, in our study about 23% of all participants were homemaker. Such female predominance among victims of accidental burns injuries is also reported by other researchers viz. Dhillon S et al (2005) [18], Gowri S et al, [14]& Bharadwaj SD et al [19]. In contrast,Rani A et al [20]and Chaudhary BL et al [21]reported a slight male preponderance among burn victims. In our study male predominance was seeing among victims of accidents that happened outdoors such as RTA. Moreover, in our study all the victims of fall from height were men. Similar findings were also reported by Kumar M et al [22], Naik BV et al [23], and Satish NT [24].

In the present study, we observed that the most commonly affected region,bearing external injuries was head, neck & face/HNF, involving 74 cases(26%), followed by lower limb (25%), and upper limb (21%). Involvement of HNF & extremities was most common because of the obvious facts that all these are exposed & projecting body parts & most active parts at the time of infliction of trauma.Khan MK et al. observed a similar pattern of distribution, having a larger proportion of injuries in HNF & extremities as compared to thorax & abdomen.[25] Merchant SP et al, Patil AM et al,also describes quite a similar pattern of injuries in conformity as observed1 in the present study. [26, 27](Out of all the internal organs, the brain was the most injured organ (30%). Both lungs and heart were injured in 17% of cases each, whereas the liver was injured in about 12% of cases. The brain was found to be the most injured organ in many studiesMandal BK et al (2012) of RTAs, falls from height & assault.[28]

Most cases of fracture were noted in the skull (26%), followed by lower limb (25%) followed by upper limb fractures (21%). As the head is the most prominent of the exposed parts of the body under its situation, it bears the brunt of violence in traumatic cases. Bairagi KK et al. (2010) also reported that most fractures were seen in the skull and face.[29] Similarly, Ravikumar R (2013) found skull fractures in 67.75% of cases of RTA, especially among two-wheeler accidents.[30] Mandal BK et al, also found the skull to be mostly fractured, followed by thoracic bones & long bones respectively in RTA cases. [28] Kumar JVK et al (2013) observed that there were skull fractures in almost all cases of fall from height wherever primary head impact was present.[31]

In the present study, one-third of all participants remained alive for >48 hours after the incident and about one-fourth of participants were declared dead on arrival at the hospital. The longest period of survival was predominantly seen among the victims of burn injury whereas in cases of head injury most victims survived <48 hours. Patil AM et al had more or less similar results. [27] Khan MK et al. in their study on fatal head injury victims found that the greatest number of victims survived for 1-6 hrs (27.17%).[25] Manish K. et al (2012) found that the maximum number succumbed to death within 6 hours.[32] The variation noted may be due to the difference in the type of trauma, type of organs involved & time of medical attention etc. Among burn-related deaths, the majority survived for 3-7 days (48.64%); followed by spot deaths (22.97%). Such a long survival period was because the burnt tissue acts as a nidus for infection & sepsis sets in as a delayed complication leading to death in approximately 3-7 days. This was consistent with the results of Gadge SJ et al (2014).[33] Chaudhary BL et al [21] state that the maximum victims died on the spot, followed by a survival period of 3-7 days. Harish D (2013) on the other hand found that maximum victims survived for more than 1 week (24%).[16]

**Conclusion**

Accidents constitute a major chunk of preventable deaths. Most of the participants in our study were either physically or economically active or both. The burn injuries were most common among housewife as most burn accidents were domestic incidents. Among victims of non-burn trauma, the most common injured internal organ was the brain and the most common major bone fractured was the skull.

Demographic Characteristics as Predictors of Medicine and Health Services Access Difficulties and Economic Problems during Covid 19 in Java, Indonesia

Cati Martiyanat, Leny Latifaht, Yusi Dwi Nurcahyant, Diah Yunitawatit, Marizka Khairunnisat

1Magelang Health Research and Development Center, Ministry of Health, Indonesia

Abstract

Background. The very rapid spread of COVID-19 infection, causing large-scale social restriction in many parts of the world. A lot of businesses and working places closed. Health services and medicine were in high demand. Objective. This study aims to determine the demographic characteristics that predict medicine and health services access difficulties and economic problems. Method. This was cross-sectional research conducted in Java, Indonesia. The research sample was 1,385 individuals aged 15 years and over who lived in Java and had filled out a survey via a google form. Data analysis using multivariate logistic regression. Results. The risk of difficulty accessing medicine and health services and economic difficulties was higher for males, had income < 3 million per month, and do not have health insurance. Conclusion. Male, had low income, and do not have health insurance are at higher risk for having difficulty accessing medicines/health services and experiencing economic difficulties. Meanwhile, respondents under 25 years of age have a higher risk of experiencing difficulties in accessing medicines and health services. The government needs to implement a strategy to reduce health and economic problems due to COVID-19 and pay attention to individuals under 25 years of age to access health services/medicines.

Keywords: Covid-19, medicine and health services, economic difficulties

Introduction

COVID-19 has spread widely in the world, at least in 216 countries and other territories with confirmed numbers of COVID-19 were 6,057,853 people and the number of deaths as many as 371,166 people as of June 1, 2020. After almost 3 months of mass social distancing, on 1st June 2020, Indonesia entered the new phase of transition into new normal or called new habit adaptation. A study showed timely control strategies using epidemiological measures in reducing social mixing, closely related to the outcomes of the COVID-19 epidemic. Despite the epidemiological concern, Indonesia has to juggle with economical calculation when declaring transition into the new normal phase. It is explained why the relaxing distancing control measures took place in a time of the still-raising confirmatory person contracting COVID-19.

During the COVID-19 pandemic, a lot of businesses and working places closed, mainly in the informal work sector. This made people lose their job and impacted on financial income. The increase in unemployment, poor households, the problem of people’s purchasing power, and the empowerment of micro, small and medium enterprises has become the focus of the Indonesian government. The vaccination program for certain age groups has begun to be carried out by the Indonesian government starting in early 2021, however, the economic sector in Indonesia has not shown significant progress. COVID-19 and its countermeasures have caused economic shocks that have an impact on unemployment, poverty, economic crises, and health inequalities. The government is faced with controlling the rate of cases and the economic situation to address health disparities and economic impacts due.
to the COVID-19 pandemic.\textsuperscript{11}

Research in several countries has identified mixed results for groups that are vulnerable to a more severe economic impact than for other groups. Economic health problems that arise due to COVID-19 are various, such as work and income problems\textsuperscript{12}, job losses and increased poverty \textsuperscript{13}, access to health services\textsuperscript{14}, inequality of health services between rural\textsuperscript{13}, and fulfillment of basic or daily necessities\textsuperscript{14}. Identification of vulnerable groups is important so that interventions in dealing with the economic and health impacts of COVID-19 are right on target and according to needs. So far, no research has been found on demographic characteristics that are predictors of access to medicines and health services and economic difficulties due to COVID-19 in Java, Indonesia. Given the diversity of vulnerable groups affected and indicators of economic problems that arise in various countries, studies are still needed on predictors of access to medicines and health services and economic difficulties due to COVID-19. This study aims to determine the demographic characteristics that predict economic impacts and community groups that require special attention regarding the economic impact of COVID-19 in Java, Indonesia. The demographic variables including age, gender, education level, employment status, monthly income, and marital status. Economical difficulties including questions about decreased income, difficulty in meeting daily needs, health insurance ownership, and difficulty accessing medicine and health services. The age variable is categorized into 3 categories: \( \leq 25 \) years old, 26-45 years old, and > 45 years old. Gender consists of males and females. The education level consists of 2 categories: high school and below and bachelor and above. Work status is divided into categories of health workers and non-health workers. Monthly income consists of 3 categories: < IDR 3 million, IDR 3-10 million, and > IDR 10 million. Marital status consists of the categories of non married and married. Statistical analysis used descriptive analysis and multivariate logistic regression using SPSS v.16.

\section*{Method}

This research is a quantitative study with a cross-sectional design. The research sample is individuals aged 15 years and over who live in Java, Indonesia and have filled out a survey via google form which is distributed by the research team through various cellular networks and social media. The number of samples obtained was 1,385 people. The study was conducted from June - July 2020. The inclusion criteria included individuals aged 15-64 years, willing to be respondents, able to read and understand questions. This study aims to determine demographic characteristics that predict economic impacts and community groups that require special attention regarding the economic impact of COVID-19 in Java, Indonesia. The demographic variables including age, gender, education level, employment status, monthly income, and marital status. Economical difficulties including questions about decreased income, difficulty in meeting daily needs, health insurance ownership, and difficulty accessing medicine and health services. The age variable is categorized into 3 categories: \( \leq 25 \) years old, 26-45 years old, and > 45 years old. Gender consists of males and females. The education level consists of 2 categories: high school and below and bachelor and above. Work status is divided into categories of health workers and non-health workers. Monthly income consists of 3 categories: < IDR 3 million, IDR 3-10 million, and > IDR 10 million. Marital status consists of the categories of non married and married. Statistical analysis used descriptive analysis and multivariate logistic regression using SPSS v.16.

The total number of respondents who filled out the questionnaire was 1415 people. A total of 30 people filled out the double questionnaire so that the remaining 1385 respondents could be processed. The majority of the sample were women (74.0%), aged 26-45 years (63.2%), married (70.5%), and highly educated (86.2%). Most of the respondent’s occupations as a government employee (36.0%) with the type of occupation as non-health workers (65.8%), earn <10 million per month (45.5%), and do not have health insurance (84.3%). The next table presents a multivariate logistic regression test to describe demographic characteristics as predictors of access to medicines and health services and economic difficulties due to COVID-19 in Java, Indonesia.

Logistic regression results showed that male (AOR 1.754; 95% CI: 1.281-2.402; p <0.000), had low education (AOR 2.233; 95% CI; 1.525-3.268; p <0.000), had income <3 million per month (AOR 5.069; 95% CI: 2.753-9.334; p <0.000), and do not have health insurance (AOR 1.683; 95% CI: 1.201-2.360; p <0.05) are more at risk of experiencing difficulties in meeting daily needs. Being male (AOR 1.380; 95% CI: 1.056-1.805; p<0.05), had income < 3 million per month (AOR 3.643; 95% CI: 2.429-5.463; p<0.000), and do not have health insurance (AOR 1.639; 95% CI: 1.162-2.311;p<0.05) are more at risk of experiencing decrease income. The risk of losing a job is higher for people with low education (AOR 1.945; 95% CI: 1.343-2.816; p<0.000) and had income < 3 million per month (AOR 2.444; 95% CI: 1.503-3.975; p<0.000).

The risk of difficulty accessing medicines and health services is higher for male (AOR 1.789; 95% CI: 1.294-2.474; p<0.000), had income < 3 million per month (AOR 2.035; 95% CI: 1.128-3.672; p<0.05), and do not have health insurance (AOR 1.446; 95% CI: 1.003-2.086; p<0.05). But, older age (25-45 years old), AOR 0.540 95% CI: 0.330-0.884, p<0.05; > 45 years old, AOR 0.335 95% CI: 0.181-0.621, p<0.001) become protective variable in facing difficulty accessing medicines and health services.

**Discussion**

This study found that the risk of accessing drugs and health services was higher for men, had income < IDR 3 million per month, and not having health insurance. The absence of health insurance generally occurs in low-income. Populations that are vulnerable to COVID-19, including those in low socioeconomic groups are at risk of difficulty accessing health care services. Low-income families have 3 main barriers to accessing health care including lack of insurance coverage, poor access to health care facilities, and unaffordable costs. The results of Shadmi’s research in Zambia found that primary health services are free, but other costs must be borne by patients when accessing health services such as transportation costs, medicines, and diagnoses that cannot be carried out in health facilities that have the potential to continue to increase as the spread of
COVID-19 and poor households in urban and rural slum areas are the vulnerable groups to this financial risk. In this study, older age (25-45 years old) and 45 years old become protective variables in facing difficulty accessing drugs and health services. Previous research has found that access of young adults to health services is lower. The reasons that young people do not access health care include feeling unneeded, awareness of seeking treatment, structural weaknesses and existing care systems, or economic factors. Different from the results of this study, Bambra’s study found that lockdown policies had an impact on women’s access to health care, such as preventive care against breast cancer or cervical cancer screening, which was restricted in European countries.

This study found that male, had low education, had income < IDR 3 million per month, and do not have health insurance are more at risk of experiencing difficulties in meeting daily needs. lower-income earners are twice as likely to experience economic difficulties as those in the top income quintile. Wolfson’s research also found that households in the low-income, low-educated (not university) group, and who do not have health insurance are struggling to meet their basic needs because of COVID-19. Karpman’s study suggests that low-income people spend less on food, delay buying expensive goods, use up savings, or increase credit card debt at the start of the COVID-19 pandemic. Power’s research also found that people with low incomes employ complex food management and shopping strategies to maintain food security by buying goods at low prices, choosing local produce, shopping at multiple supermarkets for the cheapest items, and budgeting for the long term. Sarma’s survey in the United States found 6.3% of respondents were concerned about financial stability, 42.5% about jobs, 69.4% about food availability, 31.0% about housing stability, and 35.9% about access to health care due to COVID-19.

This study found that male, had income < IDR 3 million per month, and do not have health insurance are at higher risk for having difficulty accessing medicines and health services and experiencing economic difficulties. Meanwhile, respondents under 25 years of age have a higher risk of experiencing difficulties in accessing medicines and health services. This research identifies groups that need special attention because they are more economically affected and have difficulty accessing health due to the COVID-19 pandemic. The government needs to implement a strategy to reduce health and economic disparities because COVID-19 in male groups with low-income who do not have health insurance and pay attention to individuals under 25 years of age to access health services and medicines.

**Conclusion**

The male gender with low income (<3 million per month), without health insurance are at higher risk for having difficulty accessing medicines and health services and experiencing economic difficulties. Meanwhile, respondents under 25 years of age have a higher risk of experiencing difficulties in accessing medicines and health services. This research identifies groups that need special attention because they are more economically affected and have difficulty accessing health due to the COVID-19 pandemic. The government needs to implement a strategy to reduce health and economic disparities because COVID-19 in male groups with low-income who do not have health insurance and pay attention to individuals under 25 years of age to access health services and medicines.

The Association of Adiponectin Serum Level and Body Mass Index among Javanese Obese Adolescents

Christine Florens¹, Nur Aisiyah Widjaja², Roedi Irawan³, Meta Herdiana Hanindita²

¹Resident, ²Senior Staff, ³Head of Department, Division of Nutrition and Metabolic Diseases, Child Health Department, Faculty of Medicine, Airlangga University, Dr. Soetomo General Hospital, Surabaya, Indonesia

Abstract

Introduction: The adiponectin level should decrease in obese people, however, many previous studies’ results about its role in obesity still remain controversies. The present study aimed to evaluate the profile of adiponectin serum level among obese adolescents in Javanese population and its correlation with body mass index (BMI).

Methods: A cross-sectional study involving obese adolescents aged 13-18 years old from some schools was conducted from May to September 2020. The subject were determined by using a total population sampling method that met inclusion and exclusion criteria. Anthropometries were measured to count BMI and determine obesity according to CDC 2000. The adiponectin serum level was examined by ELISA from blood samples. Data were analyzed using Mann-Whitney Test and Spearman correlation, with a significance value at \( p < 0.05 \).

Results: There were 240 obese adolescents involved (52.1% boys) in the present study. There were significant differences in the mean of body-weight and body-height according to gender (\( p<0.05 \)), however, there was no significant difference in BMI based on genders. The median of adiponectin serum level was 13.9 (1.5-46.6) µg/ml, which had no correlation with BMI (\( p=0.98; r=0.002 \)).

Conclusion: The adiponectin serum level had no significant correlation to body mass index. More studies are suggested to find out several factors that might influence the adiponectin serum level in Javanese population.

Keywords: Adiponectin, Body Mass Index, Obese Adolescents, Javanese

Introduction

Adiponectin is an endocrine factor that is synthesized and released from adipose tissue, especially in subcutaneous and visceral fat.¹ Several studies have shown that adiponectin serum level has negative correlation with body fat mass.²,³ However, others still show controversial results.⁴,⁵

In obesity, there are adipocytes hypertrophy. This condition, accompanied with high fat diet, might cause DNA methylation. DNA methylation is the addition of methyl group to the atom carbon number 5 from cytosine ring or atom nitrogen number 6 of adenine. Furthermore, it will decrease the adiponectin expression. The same methylation might be happened in adiponectin receptor (AdipoR1 and AdipoR2), thus, it will prevent...
the adiponectin to bind its receptor.\textsuperscript{6}

The adiponectin increases insulin sensitivity and glucose uptake, decreases gluconeogenesis, decreases triglyceride production and lipogenesis on the liver and skeletal muscle.\textsuperscript{7}

Adiponectin and insulin resistance in obese adolescents will increase glycolysis, gluconeogenesis, hyperlipidemia, and endothelial dysfunction. The process, at last, results in metabolic syndrome.\textsuperscript{8} The obesity management and decreasing body weight hopefully will increase adiponectin serum level.\textsuperscript{9}

Therefore, it is essential to see the profile of adiponectin serum level in obese adolescent. In conjunction with its association to metabolic syndrome from previous studies, the obese children with lower adiponectin serum level will be more susceptible to develop metabolic syndrome.\textsuperscript{10}

The correlation of adiponectin serum level and BMI might differ according to race, age, and gender. To the best of the researchers’ knowledge, the study of adiponectin serum level among obese adolescents in Javanese population, Indonesia, is still limited.

**Materials and Methods**

*Cross-sectional research* was conducted on obese adolescents from 12 junior and senior high schools in Surabaya and Sidoarjo city, East Java, Indonesia, from May to September 2020. The subjects were determined using a total population sampling method that met the inclusion and exclusion criteria. The inclusion criteria were adolescents aged 13-18 years old with obesity problems. Moreover, both students and their parents voluntarily participated in the study. Adolescents with a history of corticosteroid consumption for more than two to six months before the study was carried out or the subjects got sick were excluded.

Obesity was established based on the CDC 2000 criteria, which was body mass index (BMI) for age and gender above the 95\textsuperscript{th} percentile. Body weight was measured using a digital weight scale (Seca, Germany No ref. 224 1714009) with a precision of 0.1 kg. The subjects were standing with barefoot and using thin clothes during bodyweight measurement. Height measurement was performed using stadiometers (Seca, Germany No ref. 224 1714009), with an accuracy of 0.1 cm. During height measurement, the subjects were standing with barefoot without using hat. The stadiometer was used to measure the height from heel to vertex. The results were presented as ‘meter’. BMI was calculated by the following formula:

\[
BMI = \frac{\text{Body weight (kg)}}{\text{Body height (m)}^2}
\]

The subjects had been fasting for 12 hours before the blood samples were taken. The adiponectin serum level was examined using 5 ml venous blood. The blood samples were centrifuged until the serum were achieved and saved in -70\textdegree C for further analysis. The analysis of adiponectin serum level used ELISA (Enzyme Linked Immuno-Sorbent Assay) of DBS (Diagnostic Biochem Canada CAN-APN-5000) kit and presented as µg/ml.

Bodyweight, body height, and adiponectin were described as ± mean (\(M\)) and standard deviation (\(SD\)). The correlational analysis between adiponectin serum level with gender and age group was carried out using Mann-Whitney test. The correlation between BMI and adiponectin serum level was analyzed using spearman rho, \(p<0.05\) considered as significant. All statistical analysis were conducted using SPSS 21.0.

This study had got permission from the ethics committee of The Faculty of Medicine, Airlangga University No. 115/EC/KEPK/ FKUA/2020. Before the subject recruitment, the researchers had explained to the subjects and their parents about the general research information and the consent.

**Results**

There were 240 obese adolescents involved in this study, consisting of 125 (52.1%) boys and 115 (47.9%) girls. Based on age group, there were two groups namely those less than 15 years old and those 15 years old or older. 44.6% subjects were less than 15 years old.
Table 1. Characteristic of the subjects.

The median of adiponectin serum level from all subjects was 13.9 (1.5-46.6) µg/ml and the mean amounted of 15.7 µg/ml±7.6. Table 2 shows that the mean of adiponectin serum level among boy adolescents was lower than girls and it was not statistically significant. Furthermore, from the classified age, the mean of adiponectin serum level in less than 15 years old group was slightly lower than the others. Figure 1 confirms that there was no correlation between adiponectin serum level with body mass index ($p=0.98; \ r=0.002$) from this study.

Discussion

The decrease of adiponectin serum level in obesity is caused by the failure of transcription regulation with unclear mechanism. Generally, the adiponectin expression is ruled by transcription and translation process. In obesity, adipocyte hypertrophy and inflammation disturb the process. The DNA-methyltransferase-1 (DNMT1) expression is increasing and causes hyper methylation on adiponectin promoter. As a result, it can inhibit adiponectin production.11

This study gave the result of median adiponectin serum level of 13.9 (1.5-46.6) µg/ml and the mean of 15.7 µg/ml±7.6 from all subjects. This value was higher than previous studies conducted by Asayama et al, who stated 6.4 µg/ml±0.6, Lanas et al with 9.9 µg/ml±3.2, and Widjaja et al with 7.84 µg/ml±3.8.

Several factors might influence adiponectin serum level such as gender, obesity, physical activity, dietary pattern, and genetic.13,14 Ethnicity is one of the independent factor that might influence adiponectin level. The adiponectin serum level was significantly different between Iranian, Indian, and European although they were living in Australia. The Europeans had the highest mean of adiponectin serum level of 16.8 (14-20.2) µg/ml.15

Similar to the result of the present study in adiponectin serum level according to gender, several previous studies also showed that it was lower in boys than girls.13,16,17 The insignificant difference of our result was the same as Woo et al, and might be happened due to our samples only included obese adolescents.18

Meshkini et al found the adiponectin serum level was initially lower in boys. However, after it was corrected with age, BMI, and fat mass, and waist circumference, there were no differences between both genders. Based on that result, the adiponectin serum level might be influenced by percentage of fat mass and pubertal state. The percentage of fat body mass in girls is increasing during puberty. On the contrary, it is constant in boys.19

Estrogen might increase subcutaneous fat, on the other hand, testosterone is more influencing the visceral fat. Cnop et al observed that visceral fat had association with lower adiponectin level.20,21

The adiponectin level in this study was not significantly different according to age classification.
In contrast, other studies could describe the decrease of adiponectin level during puberty. Thus, the older adolescent would have lower adiponectin serum level. Otherwise, on adults, Obata et al found the positive correlation between adiponectin and age, either in healthy or patient with type 2 diabetes mellitus.

In this study, there was no significant correlation between serum adiponectin and body mass index. Awede et al found the same result in west African without diabetes. In male subjects, the lower adiponectin level was in subjects with normal BMI and obesity. On the other hand, on female group, subjects with overweight had the highest adiponectin level but subjects with obesity had the lowest adiponectin serum level. Study in Indian population also portrayed the same result. Our result was in contrast with other studies that stated the BMI had negative correlation with adiponectin serum level.

The racial distinction might play an important role. Mente et al found negative correlation between BMI and adiponectin serum level on subjects from Chinese, European, and Aborigin population, whereas the same correlation did not find in South Asian population. Khoo et al, also found different rate of negative correlation between BMI and adiponectin serum level in the Chinese, Malay, and Indian population that lived in Singapore. The most significant decrease of adiponectin serum level based on BMI happened in Chinese population.

The insignificant correlation from this study might be caused by the difference of fat mass distribution, dietary patterns, and genetic factor among our subjects with other studies. The limitation of this study was only involved obese adolescents. Moreover, the physical activity and dietary patterns have not assessed in this study yet. Further studies should include normal and overweight adolescents, evaluation of physical activity and dietary patterns.

Conclusion

The concern to adiponectin serum level in obese adolescent is increasing due to its impact on insulin resistance and developing metabolic syndrome. Results of the decrease of adiponectin level related to obesity is still controversy. The adiponectin serum level in this study had a wide range, with no significant correlation to body mass index.

Our average result of adiponectin serum level among obese adolescents was higher than other previous studies. It also did not have significant correlation with age and gender. More studies are needed to find out several factors that might influence the adiponectin serum level in Javanese population such as physical activity, dietary patterns, and genetic.

Acknowledgements: Authors are grateful to the 12 high schools in Surabaya and Sidoarjo who volunteered to become the research respondents. Moreover, they would thank all headmasters and counselling teachers who gathered our respondents and their parents with us before and during the data collection.

The Gloves as Effective Personal Protective Equipment (PPE) of Indonesian Batik Workers

Cita Rosita Sigit Prakoeswa, Damayanti, Sylvia Anggraeni, Menul Ayu Umborowati, Sri Awalia Febriana

1Professor, 2Researcher, Department of Dermatology and Venereology, Faculty of Medicine Universitas Airlangga/ Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Abstract

Background: Batik substances may increase the risk of biological function disruption to batik workers.

Objective: To Determine the effectiveness of using test gloves in transepidermal water loss (TEWL), skin hydration level, and skin acidity (pH).

Methods: This study was one group pretest-posttest design of 16 batik workers. Subjects use test gloves made from neoprene on right hands and personal gloves made from thermoplastic polymer of vinyl chloride on left hands in first and second week. Washed out for 2 weeks, last 2 weeks use test gloves on left hand and personal gloves on right hand. TEWL, skin hydration level, and pH was examined by Cutometer dual MP-580

Result: First and second week using test gloves on the right hand, significantly differences of TEWL level on extensor and dorsum manus; skin hydration level on flexor, extensor, palmar, and dorsum manus; pH on extensor, palmar and dorsum manus (p<0.05; CI 95%). Fifth and sixth week using test gloves in the left hand, significantly difference of TEWL level on dorsum manus, all area of skin hydration level and pH results (p<0.05; CI 95%). No significant differences of comparison right and left hand in the first, second, fifth, and sixth week, that showed any types of gloves can protect batik workers from skin barrier disruption.

Conclusion: Personal gloves and test gloves usage for protection doesn’t have much significant difference. Wearing gloves may also give risk to trigger contact dermatitis if not used properly or using incompatible material.

Keyword: gloves, Indonesian batik workers, skin barrier function
During the production of batik, synthetic dyes usage increases exposure to harmful pollutants such as heavy metals, suspended solids, or organic substances. These exposures might enter human’s body through the skin and respiratory mucosa. That exposure can be contact dermatitis. Occupational contact dermatitis is the most common in occupational skin disease in developed countries for between 70% and 90%. The incidence in Europe reported that 0.5 to 1 per 1000 workers. In Indonesia, study that had been conducted by researchers in batik workers population in Yogyakarta shows that the contact dermatitis prevalence due to work is quite high (10.36%). This shows the importance of personal protective equipment (PPE) in batik workers.3–6

PPE is important to prevent contact dermatitis. One of the most important PPE item in batik industry is gloves, that is recommended when wet work is performed. The wearing of gloves may improve hydration and pH of the skin.6,7 The purpose of this study was to determine the effectiveness of using test gloves which can provide protection for skin, especially for batik workers, from irritation due to long-term working.

Methods

Sixteen female batik workers who were involved in dyeing process from batik center in Tanjung Bumi District, Paseseh Village were included as samples in this clinical trial. Inclusion criteria in this study were age 15-50 years, involved in dyeing process, and were willing to participate in this study. There were 2 types of gloves evaluated in this study. The first type was personal gloves (their own gloves that batik workers had worn, made from thermoplastic polymer of vinyl chloride). The second type was test gloves that made from neoprene. In the first 2 weeks, the subjects were asked to use test gloves on their right hands and personal gloves on their left hands. Daily usage of the gloves were 8 hours a day and they were changed every 3 days. Washed out period was conducted for 2 weeks, it was a period when subjects were given with no gloves. Finally, in the last 2 weeks the subjects were asked to use test gloves on their left hand and their personal gloves on their right hand. At the beginning and end of each treatment clinical examination as well as skin biological function tests (TEWL level, skin hydration level and skin acidity) were conducted on both flexors, extensor, palmar, and dorsum of the hands. Biological function of the skin (TEWL level, skin hydration level, and skin acidity) was examined using Cutometer dual MP-580, the examination takes three times per examination and the final result is an average. Analysis will be carried out to compare skin function between batik worker who wore test gloves and personal gloves. The correlation between pre and post exposure of the right/left hand was analyzed by t dependent test, while the correlation between right and left hand was analyzed by independent t-test.

Results

This study involved 16 batik workers who were involved at dyeing process as subjects. Subjects were both male and female, aged 15-50 years. The results for mean TEWL level on flexor, extensor, palmar, and dorsum of right hands that used test gloves on the first week of study were 27.99 g/m2/h, 26.07 g/m2/h, 48.57 g/m2/h, and 40.78 g/m2/h, respectively; meanwhile mean TEWL level on flexor, extensor, palmar and dorsum of left hands that used personal gloves from the workers on the first week of study were 29.64 g/m2/h, 27.09 g/m2/h, 47.05 g/m2/h, 33.16 g/m2/h, respectively.

Skin hydration level measurement results on flexor, extensor, palmar and dorsum of right hands on the first week were 58.77 AU, 63.80 AU, 46.53 AU, and 63.93 AU, respectively, meanwhile on the left hands the results were 61.61 AU, 59.74 AU, 45.40 AU, and 61.88 AU, respectively. Furthermore, the skin pH measurement results on flexor, extensor, palmar and dorsum of right hands were 5.18, 5.22, 5.25, and 5.04, respectively; meanwhile on the left hands the results were 5.19, 5.25, 5.36, and 5.16, respectively (Table 1, Table 2).

On the second week after the use of test gloves on the right hands for two weeks, TEWL level results on flexor, extensor, palmar, and dorsum manus of right hands were 24.66 g/m2/h, 19.77 g/m2/h, 54.49 g/m2/h and 23.61 g/m2/h, respectively; meanwhile on the right
hands the results were 27.24 g/m²/h, 18.72 g/m²/h, 50.98 g/m²/h and 20.54 g/m²/h, respectively. Skin hydration level results on right and left hands flexors were 44.13 AU and 38.74 AU; extensor 35.38 AU and 37.06 AU; palmar 29.47 AU and 27.98 AU; and dorsum 36.67 AU and 39.11 AU. The skin pH measurement on right and left hands’ flexor were 5.37 and 5.40; extensor 5.49 and 5.43; palmar 5.81 and 5.83; and dorsum 5.51 and 5.51 (Table 1, Table 2).

On the fifth week after washed out, the test gloves were used on the left hand and the personal gloves were used on the right hands. TEWL level results on right and left hands flexor were 35.99 g/m²/h and 26.80 g/m²/h; extensor 28.00 g/m²/h and 27.31 g/m²/h; palmar 52.29 g/m²/h and 53.18 g/m²/h; and dorsum 35.91 g/m²/h and 38.16 g/m²/h. Skin hydration level results on right and left hands flexor were 77.00 AU and 70.66 AU; extensor 73.30 AU and 72.51 AU; palmar 55.62 AU and 64.02 AU; and dorsum 72.43 AU and 69.35 AU. Furthermore, pH results on right and left hands flexor were 5.43 and 5.32; extensor 5.32 and 5.31; palmar 5.54 and 5.52; and dorsum 5.32 and 5.38 (Table 1, Table 2).

On the last week of measurements, TEWL level results on right and left hand’s flexor were 27.92 g/m²/h and 27.53 g/m²/h; extensor 23.12 g/m²/h and 22.06 g/m²/h; palmar 56.48 g/m²/h and 56.67 g/m²/h; and dorsum 30.84 g/m²/h and 33.30 g/m²/h. Skin hydration level results on right and left hand’s flexor were 57.95 AU and 57.93 AU; extensor 54.38 AU and 54.31 AU; palmar 59.62 AU and 59.60 AU; and dorsum 53.84 AU and 53.73 AU.
AU and 56.66 AU; extensor 55.64 AU and 56.59 AU; palmar 54.76 AU and 55.18 AU; and dorsum 50.50 AU and 50.88 AU. The skin pH results on right and left hand flexor 5.57 and 5.48; extensor 5.46 and 5.52; palmar 5.56 and 5.74; dorsum manus 5.63 and 5.60 (Table 1, Table 2).

In this study, the results at fifth and sixth on the TEWL level measurement were not significantly different except for the left dorsum (p=0.040; CI 95%). Meanwhile there were significant differences of skin hydration level results in all area (p<0.05) except the right palmar (p=0.795; CI 95%). There were significant differences of skin pH on the right dorsum manus (p=0.000; CI 95%), left flexor (p=0.029; CI 95%), left extensor (p=0.022; CI 95%), left palmar (p=0.006), and left dorsum manus (p=0.009; CI 95%).

Discussion

Batik workers are directly and indirectly exposed to irritant materials of dyes. Batik candles consist of coconut oil, bee hive, animal fat, paraffin. This ingredient may increase the risk of skin dryness and irritant contact dermatitis. Clinical manifestations of contact dermatitis are pruritus, roughness, tightness, burning sensation and pain, followed by lack of elasticity, texture coarsening, and skin wrinkle.\(^8\)\(^9\) Occupational contact dermatitis is the most common occupational diseases. That can be prevented by elimination, substitution, engineering controls, and personal protective equipment (PPE).

Using gloves is one of prevention modality, that may reduce the risk of chemical exposure.\(^8\)\(^,10\)

In second week after using test gloves in right hand there were significant difference in TEWL level, skin hydration level, and pH results except TEWL level on flexor, TEWL level on palmar and pH on flexor. Not only in the right hand in first week, but also left hand using personal gloves showed significant difference on TEWL level, skin hydration level, and pH results, except TEWL level on flexor and palmar. This suggests that the use of gloves on batik workers can improve the skin barrier function. Some literature showed clinical
improvement of contact dermatitis after using PPE. PPE can vary in form such as gloves, aprons, overalls, hats, safety boots and masks. There are many types of gloves such as type I (disposable gloves), type II (household gloves), type III (industrial gloves), and type IV (special gloves). There are also various kinds of gloves materials, made from rubber, plastic, textile, or combination. Some literatures said that protective gloves may give protection for working, involving direct contact with solvent for several hours.

Protective gloves must be periodically checked and inspected if any holes are found, that condition can absorb the allergens or irritants. Effectively prevention of contact dermatitis may use disposable gloves and frequent changes; but as long as the gloves are intact, frequent changes are not necessary to prevent contact dermatitis. Any substances in the gloves that should be used for dry work are fabric gloves (e.g., cotton or leather), and for wet work should are cotton gloves which absorb sweat. Furthermore, gloves that can protect from solvents and inks are nitrile and neoprene gloves.

However, the use of waterproof gloves over period time must be considered hazardous to the skin, due to occlusive effect in moist chamber. Some literatures reported although the gloves can protect from irritant, allergen and microbial agents, gloves can be a etiologic factor in occupational contact dermatitis if not used properly. Kwon et al, reported a case of irritant contact dermatitis caused by chronic cutaneous exposure to solvents on the inner surface of gloves.

Some mechanisms by which gloves can be exposed to chemicals are contamination, permeation, and penetration. When workers open the gloves incorrectly without first cleansing of the hand and the contamination of gloves interiors are very common problems. The physical defect of gloves can be a process of solvent penetration, like a hole in the gloves. One study shows evidence that the use of cotton gloves liners can prevent form contact dermatitis rather than wearing occlusive gloves. In other studies reported that appropriate PPE use is highly recommended due to batik workers might be exposed any substances and materials. There are many factors can be a protective gloves include gloves material, the additive used in manufacturing, the manufacturing process, and the thickness and homogeneity of the material. Choosing suitable gloves for chemicals or solvent is very important, that there are some chemicals for which no gloves can provide protection for long periods time.

This study showed that any types of gloves may give protection for batik workers in batik production, since there were no significant difference between the skin barrier function after wearing test gloves and personal gloves. However, the length of the gloves may also play role in the protection itself. Short gloves may increase the risk of allergens or irritant contamination inside the gloves.

**Conclusion**

Personal gloves and test gloves usage for protection doesn’t have much significant difference. Glove usage can reduce TEWL that can give a protective effect, however, there is a risk of contact dermatitis because it can increase pH and reduce skin hydration. Wearing gloves may also give risk to trigger contact dermatitis if not used properly or using incompatible material.

Abstract

The resistance of pathogenic bacteria is a global health dynamic and the time is now to find alternative solutions from plant secondary metabolites. Ageratum conyzoides L. is a plant known as akaziraruguma in Rwanda and used to treat wounds and ulcers. This study aimed to evaluate the phytochemical profile and germicidal efficacy of ethanolic and aqueous leaf extracts of Ageratum conyzoides L. grown in Rwasave wetland. The leaves were collected and dried under the shed for 10 days, blended into powder by electric blender and macerated with water and 96% ethanol. Phytochemical screening was performed by following the standard procedures and antibacterial activity of the extracts was examined by agar well diffusion method and the inhibition zones were recorded. Phytochemical screening revealed the presence of different secondary metabolites including alkaloids, tannins, flavonoids, steroids, terpenoids and saponins. In this assessment, aqueous and ethanolic extracts exhibited significant inhibitory activity against tested pathogens with inhibition zones that ranging from 6 ± 0.9 mm to 20 ± 0.5 mm of diameter. The minimum inhibition concentrations range between 0.47 mg/mL and 15.00 mg/mL. The results confirm that the leaves of akaziraruguma could be the credible source of antibacterial agents that should be used for therapeutic purposes and in production of pharmaceuticals.

Keywords: Ageratum conyzoides L., Antibacterial, Phytochemical screening, Zone of Inhibition

Introduction

Akaziraruguma (Ageratum conyzoides L.) is an ethnomedical plant by which one or more parts can be used for therapeutic intentions. It was named akaziraruguma by Rwandan citizens due to the fact that it is mostly employed to treat wounds. It is believed to have originated from America yet, nowadays it is able to be cultivated all over demographic areas including tropical and subtropical regions.

The leaves of Ageratum conyzoides L. contain flavonoids (eupalestin, kaempferol, sinensetin, quercetin), alkaloids (echinaline and lycopsamine), steroids (β-sitosterol, stigmastanol, brassicasterol) and sesquiterpenes (linalool, limonene, eugenol) which possess various medicinal importance including antioxidant, analgesic, anti-inflammatory, anti-malarial, anti-cancer due to its potent hepatotoxic and carcinogenic nature associated with pyrrolizidine and antihyperglycemic, anti-ulcerogenic, antimicrobial and insecticidal properties.

This plant has an ability to heal wounds and the haemostatic effects by decreasing the bleeding time through the production of vasoconstriction, precipitate proteins at the bleeding sites and promote the natural
process of blood coagulation. The hemostatic activity of *Ageratum conyzoides* L. could be observed through the lowering of prothrombin and clotting times and also by increasing plasma fibrinogen concentration in rats of the experimental group. Indeed, this treatment is not only used in modern medical treatment but also people are familiar with it in traditional ways to cure different types of diseases.

It has been used to treat pneumonia in Cameroon, to cure tetanus, itchiness and leprosy in India and it is as well considered as an anti-gynecological disease in Vietnam. The leaves of this plant are used to treat headache and skin diseases, ringworm infections and have anti-nematocidal activities against *Taenia solium*. The leaves of this plant have active pharmacological substances such as chromenes and chromans. Chromans consist of 6-amino and 6-acetamido derivatives, which can help to relieve the symptoms of depression and also demonstrated the ability to reduce fever by causing the hypothalamus to override a prostaglandin-induced increase in temperature. They also used to treat the infections caused by worms that are classified in the order of trematodes. The other secondary metabolites that are available in *Ageratum conyzoides* L. are the derivatives from 2,2-dimethyl chromene like 6-(1-hydroxyethyl)-7,8-dimethoxy-2,2-dimethylchromene and 6-hydroxy-7,8-dimethoxy-2,2-dimethyl chromene which demonstrate the capability to impede the life processes of various microorganisms.

The polyhydroxyflavones include scutellarein-5,6,7,4’-tetrahydroxyflavone, quercetin, quercetin-3-rhamnopyranoside, kaempferol-3-rhamnopyranoside and kaempferol3,7-diglucopyranoside which have virustatic ability to inhibit HIV syncytium and viral p24 antigen formations. They also contain afzelin and quercetin 3-O-α-arabinopyranoside which have repulsive potential against herpes simplex virus type 1, Aujeszky’s disease virus and adenovirus type-3 by inhibiting acyclovir-resistant HSV-1. The leaf extracts of this plant have demethoxyageratochromene with antifungal activity against *Penicillium chrysogenum* and *Paphiopedilum javanicum* and antibacterial potential against *Vibrio cholerae*, *Streptococcus pyogenes*, *Corynebacterium diphtheriae* and *Salmonella typhi*. By considering all scientific researches done in different parts of the world, there are no published findings on phytochemical evaluation and germicidal efficacy of ethanolic and aqueous leaf extracts of *Ageratum conyzoides* L. grown in Rwase wetland, Rwanda. The novelty of this study is to provide the primary data on medicinal profile of this plant by taking into account that the abundance of bioactive substances in plants depend on seasonality, climate, geographical location and other environmental conditions. From that standpoint, the current study is specifically aimed to evaluate phytochemical constituents and antibacterial activity of *Ageratum Conyzoides* L. leaves grown in Rwase wetland, Rwanda.

### Materials and methods

#### Collection of plant materials

The mature healthy fresh leaves of *Ageratum conyzoides* L. were collected from Rwase wetland which is located in Huye district, Southern province, Rwanda. The plant was independently authenticated by Chief Herbarium Officer at National Herbarium of Rwanda which is located in Huye district, Rwanda. The leaves were washed thoroughly with running tap water and rinsed properly with distilled water. The leaves were air-dried at room temperature for 10 days and blended into powder using electric blender.

#### Plant material extraction

During extraction, twenty grams of *Ageratum conyzoides* L. leaf powder was macerated with 100 mL of 96% ethanol (1:5) and water for 3 days using rotary shaker for better extraction. After extraction, the extracts were decanted and then filtered through Whatman filter paper N°1. Ethanolic crude extract was obtained by evaporating the solvent using rotary evaporator. Aqueous crude extract was obtained by lyophilization process and the yielded thick
extracts were dissolved in 10% DMSO and kept in labelled containers at 4°C for future use.

**Sterility proofing of the extracts**

To be sure about the sterility of the extracts, 2mL of the extracts were introduced into 10 mL of Mueller Hinton broth and incubated at 37°C for 24 hours. The absence of microorganism growth on the broth after the period of incubation signifies the presence of a sterile extract. After such observations, sterilization of the extracts under UV light was not carried out.

**Phytochemical screening**

Qualitative phytochemical screening was carried out to evaluate the presence of bioactive components in crude leaf extracts according to standard method. Qualitative analysis tests were performed for various phytoconstituents such as flavonoids (Shinoda’s test), steroids (Salkowski test), tannins (Ferric chloride test), alkaloids (Wagner’s test), saponins (Froth’s test), proteins (Xanthoproteic’s test), and terpenoids. The formation of brown ring confirmed the availability of terpenoids in the examined extracts.

**Source of test bacteria**

*Staphylococcus aureus*, *Escherichia coli* and *Pseudomonas aeruginosa* are the bacteria that were used in this work and they were obtained from University Teaching Hospital of Butare. Each bacterium was tested for viability by reviving it in peptone broth and finally sub-cultured into nutrient agar followed by incubation at 37°C for 24 hours. A single colony of each microorganism was diluted in 9 mL of peptone water and eventually acclimatized to give the equal concentration of bacterial cells to density of 10⁴ CFU/mL.

**Antibacterial and antifungal assay of extracts**

The antibacterial assay of extracts was examined by agar well diffusion method according to National Committee for Clinical Laboratory Standards. About 20 µL of diluted bacterial cultures were swabbed on respective nutrient agar plates. After spreading, Pasteur pipette was used to create 3 wells in the inoculated agar and filled up with 20mg/mL, 40mg/mL and 60 mg/mL, respectively. During this experiment, 30 µL of 30mg/mL vancomycin was used as a standard antibiotic. The plates were incubated in the upright position at 37°C. *Staphylococcus aureus*, *Escherichia coli* and *Pseudomonas aeruginosa* plates were incubated for 24 hours. Following the incubation, the antifungal and antibacterial assays of the extracts were evaluated by observing and measuring the inhibition zones. These assays were repeated three times each and the data were noted as mean±standard deviation. The ration between inhibition zone of the sample and the inhibition zone showed by the standard antibiotic was reported as the activity index of the extracts.

**Determination of minimum inhibition concentration (MIC)**

The MIC is explained as the lowest concentration that inhibits the observable growth of microorganism after nightlong incubation. In this study, the MIC was examined by preparing the inoculum of microorganisms from nutrient broth cultures. With broth dilution technique, the extracts were serially diluted from 60mg/mL to 0.0585mg/mL with 2mL of distilled water.1 milliliter suspension of the test microorganisms was inoculated with Mueller Hinton broth as a positive control and Vancomycin as a standard reference antibiotic. It was incubated for 18-20 hours at 37°C and determined the MIC by observing the presence or absence of turbidity in the test tubes. The least concentration where no turbidity observed was noted as the MIC value.

**Results**

**Phytochemical analysis**

The yields of the ethanol and water extraction were 12.5 and 7.5mg/g, respectively. Ethanol disclosed the highest capability to extract bioactive substances from plant leaves. In reference to the results presented in table 1, phytochemical screening clearly confirmed the
presence of alkaloids, proteins, terpenoids, tannins, flavonoids and steroids in ethanolic extracts and absence of terpenoids and tannins in aqueous extracts.

The findings of antimicrobial assay revealed that vancomycin had more potential compared to ethanolic and chloroform extracts. Both extracts were able to inhibit Gram positive bacteria (*Staphylococcus aureus* ATCC 25923) stronger than Gram negative bacteria (*Pseudomonas aeruginosa* ATCC 27853 and *Escherichia coli* ATCC25922) in Table 2. This potential was also confirmed by their activity indexes presented in Table 3 and their respective MICs as shown in Table 4.

**Discussion**

The current investigation was carried out to evaluate the phytoconstituents and antibacterial activity of ethanolic and aqueous leaf extracts of *Ageratum conyzoides* L. grown in Rwasave wetland, Rwanda. The core findings of this study revealed that leaf extracts of *Ageratum conyzoides* L. contain secondary metabolites with antiseptic properties.

The results disclosed the availability of tannins, steroids, saponins, alkaloids and flavonoids in ethanolic extract which have ability to inhibit the visible growth of various pathogens. These findings are in conformity with the results published by other researchers which highlighted that the secondary metabolites from plants have ability to hinder the cell wall synthesis of different microorganisms by creating substances that are rich in prolene growth factor. 24

Once the plant extracts associate with the compounds that do not have slightly negative and positive charges in the water-fearing interior of the membrane, they impede the microbial growth. This growth should also be hindered through the formation of hydrogen bonds between the polar lipids and the hydrophilic flavonoids at the interface of the membrane. The antimicrobial activity of flavonoids is explained by the fact that they decrease elasticity in hydrophilic and hydrophobic regions of cell membrane and induce biofilm disturbance. 25

The observed outstanding antibacterial capacity of flavonoids is attributed to the presence of 3-O-octanoyl-epicatechin which enhance membrane affinity of their long acyl chains. The absence of hydroxyl groups on the B rings of the flavonoids play major role to inhibit microbial membranes than the flavonoids which have hydroxyl(OH) groups on their B rings. 26

The plant derived antimicrobials control bacterial growth by altering their membrane permeability or decreasing their pH. 8 These membrane disruptions along with the activity of β-lactams on the transpeptidation of the cellular membrane increase the inhibitory activity of the extracts. 28 The extracts evidently demonstrated extensive capability to cause leakage of different growth factors and enzymes from the cell. These plant secondary metabolites perform antibacterial activity by agitating cellular binary fission, interacting with extracellular proteins and by damaging the integrity of bacterial cell walls. 29,9

The differences in antimicrobial potential of the extracts is also attributed to the amount of secondary metabolites available in tested plant parts. This finding could be explained by the fact that the distribution of bioactive substances in roots, leaves, fruits, stems and seeds are different. 31 The abundance of the bioactive compounds in plants depends on the stage of maturity, rainfall, seasonality, soil salinity and other agroecological
conditions which repress or induce water absorption, physiological and chemical processes during plant metabolism.

Both ethanolic and aqueous extracts demonstrated great antimicrobial activity against tested microorganisms but organic solvents demonstrated high ability to dissolve plant secondary metabolites due to their polarity. This finding is as well in agreement with the findings of Idris who published that the ability of extractants to extract the compounds from the leaves plays a pivotal role during extraction of plant metabolites. This finding is in contrast with the research published by Cowan which highlighted that water may not be able to extract aromatic and saturated antibacterial compounds that can inhibit the growth of microorganisms.

The results obtained from this study showed that all leaf extracts exhibited high antibacterial activities against Gram-positive than Gram-negative bacteria. This statement could be explained by the fact that cell wall make-ups of Gram-positive and Gram-negative bacteria are slightly different. Gram-negative outer membrane consists of phospholipids and lipopolysaccharides that act as a barrier which block the entrance and reaction of antimicrobial agents through cell envelope. The diversity in antimicrobial activity of extracts to Gram-positive and Gram-negative bacteria can be as well explained by the fact that catechins induce an oxidative stress due to reactive oxygen species (ROS) that cause changes in the membrane porosity and its destruction.

Gram-negative were not highly sensitive due to the liposomes which contain high amounts of negatively charged lipids which make catechins weak to inhibit Gram-negative bacteria due to negatively charged lipopolysaccharides of the outer bacterial membrane. Staphylococcus aureus ATCC 25923 as a Gram-positive bacterium was more sensitive to the ethanolic extracts with the activity index of 0.83. This finding is absolutely correlated with the results of Zaika who reported the significant sensitivity of Staphylococcus species due to their cell walls and outer membranes. This result is also in line with the research of Bravo and Anacona which demonstrated that Mn\(^{2+}\), Hg\(^{2+}\), Co\(^{2+}\), and Cd\(^{2+}\) complexes of quercetin exhibit bactericidal upshot against Staphylococcus aureus, Bacillus cereus and Klebsiella pneumoniae.

In this research, antibiotic disc of vancomycin manifested high inhibitory activity than the prepared plant extracts. This outstanding effectiveness of antibiotic than the plant extracts is obviously correlated with the fact that antibiotics are refined and naturally purified while plant extracts are crude states.

**Conclusion**

The conclusion that can be drawn from the findings of the current study is that *Ageratum conyzoides* L. has high medicinal importance and also give a great promise that the leaves of this plant should be considered in production of antibacterial agents to fight off the pathogens that are resistant to typical antibiotics in current use.

A Review of the Use of Strategic Management Tools in the Health Sector

Dani Sahirul Alim¹, Nur Wening²

¹Doctoral Student, ²Associate Professor, Post Graduate Program of Management, University of Technology Yogyakarta

Abstract

This paper is a review and study of various research related to tools of strategic, and factors that influence both of internal and external strategic in medical facilities research. The purpose of the review is to explore and connecting theories from various research. This paper identified 51 articles with related topics published the last decade. The results of this study that research related to implementation tools of strategic in health facilities still rarely. The use of SWOT (strengths weaknesses opportunities threats) analysis is the most popular tool used (42.86%), followed by Break-even analysis (28.56%), Balanced scorecard (BSC) and PEST (political, economic, socio-cultural, technology) each (14.29%). Based on the analysis of environmental factors related to internal factors in the health facility amount of 33.33%. External environmental factors in health facilities that have been studied amounted to 66.66%. Based on the summary of research related to internal and external, it is known that industry environment factors and rivalry environment factors are still rarely studied. The general environmental factors of demography and epidemiology are still rare studies and have the opportunity to be researched and developed.

Keywords: strategic management, medical, strategic, tools, environment factors

Introduction

Strategic management is very important to decisions making and to determine the future of the hospital. Due to the carefully conducted strategic analysis, a hospital can define:

- Tasks that must be addressed as well as opportunities and threats that emerge in the surrounding environment
- Possibilities arising in the surrounding environment,
- The present and future position in the managed market of health certificates
- The projected strategy that must be implemented, answering the challenges and flowing the chances arising from its immediate and more distant environment ¹

Because of the introduction of (regulated) market competition and self-regulation, strategy in becoming and importance management field for health care sector ². Healthcare organizations today are facing a series of problems such as patient dissatisfaction, demanding user, lack of medical personnel and others, demand the need for a strategic management in health service ³. Changes in the external environment (i.e., demographic and epidemiological transitions, economic fluctuations, public and political expectations) and health care systems (i.e., health market, demands, costs, new technologies, regulations) have put pressure on hospital managers to implement strategic management programs responding to environmental challenges⁴,⁵. According to studies, most health care facilities develop strategic plans (71.4%). For 21.4% of the studied facilities, the strategic plan is known mainly to management. In contrast, 28.6% of entities do not have a strategic plan. Health facilities that have implemented of strategic management using methods SWOT analysis 64.2%, break-even point analysis 42.9%, PEST analysis 14.3%, with factors that influence strategies such as political and
legal, economic, sociocultural, technology, demographic and epidemiology. Previous research conducted in Indonesia comparing Muhammadiyah Hospital in East Java with Muhammadiyah Hospital in Central Java showed that hospitals in one organization may not necessarily have the same management standards in hospital management, so it cause the different speeds development.

**Literature Review**

**Strategic Management Models**

The business model is a template that depicts the way the firm conducts its business. It describes the system of interdependent activities that are performed by the firm and by its partners and the mechanisms that link these activities to each other. Strategic management in health facility research is very important for its future development and for maintaining competitiveness. According to Fred David’s strategic model, strategic management process is comprised of three stages that include strategy formulation, strategy implementation and strategy evaluation. It drives all the activities of an organization. Strategy formulation also familiar as strategic planning involves the steps: development of vision and mission statements, audit of internal and external environment, long term objectives, and generation, evaluation and selection of strategies respectively. The second stage of strategic management process is commonly known as strategy implementation. In this stage, business strategy is actually implemented. It involves the activities like establishing annual objectives, devising policies for each business function, and allocating resources etc. for achievement of organizational objectives. The third stage is the strategy evaluation (strategy evaluation) this stage is carried out by evaluating work and taking corrective action in each stage of the strategy. Organization should continuously update and its internal and external environments by knowledge management and competitive intelligence respectively. Any change in important internal and external factors or identification of new ones can lead to change in business strategy. Currently the process of making a management model is developing, observations of important information to make a business strategy model can using computer including to see environmental factor are most influential in determining strategy management. The process of developing information systems in making strategic management of the synergy Decision Support Systems (DSS) with Knowledge Management (KM) in a Management Information Systems (MIS). The important factors in Knowledge Management (KM) are environmental factors that influence management strategies to make organization competitive advantage.

**Tools of Strategic Management Formulation Research**

According to previous research in Lubin region, most health care facilities develop strategic plans (71.4%). For 21.4% of the studied facilities, the strategic plan is known mainly to management. In contrast, 28.6% of entities do not have a strategic plan. Health facilities that have implemented of strategic management using methods SWOT analysis 64.2%, break-even point analysis 42.9%, PEST analysis 14.3% and none of the surveyed health care facilities applies the balanced corecard. This may indicate a relatively low knowledge of this tool among health care managers. The most common tool used in strategic management is the analysis of strengths and weaknesses. External factors are related to opportunities and threats, while internal factors are related to strengths and weaknesses. Research related to SWOT analysis in health facilities that have been carried out include strategies in medical tourism, improved dengue mapping, information technology development in the health industry, translation evidence and guidelines into medical strategies for individual patients, development of targeted health promotion strategies, facility strategic management (buildings, infrastructure, organization and environment) public hospitals.

Hospitals are complex organizations that have many professionals and resources in a variety of medical therapy services, so we need tools to measure.
performance indicators systematically. For this reason, the Balanced Scorecard (BSC) tool is used to measure performance management or performance effectively and efficiently in hospitals. Balanced scorecard makes the strategic target of an enterprise into some balanced indexes of performance evaluation, and examines the state of the indexes in different time. In this way, a reliable performance evaluation system is built to achieve the strategic target. The performance evaluation of an enterprise is divided into four indexes: finance, customer’s satisfaction degree, internal process, innovation and improvement. The main advantage of the method consists in guiding managers, departments, human resources, technological and financial toward the strategy organization. Unfortunately BSC is mainly used in private companies, because high costs and lack of specialists pose a real obstacle in implementing this instrument. Balanced Scorecard (BSC) is used to achieve an operational strategic vision at all levels of the organization regarding issues related to performance, strategy, communication, resource allocation, decision-making and competitiveness. The research related to BSC analysis in health facilities that have been conducted include to measure performance against the national standards and guidelines in the Essential Package of Hospital Services, used to assess the quality of health services to strengthen health services in the development of a country.

Break-even analysis is the use of a simple mathematical formula to determine the sales level in which the business. Break-even analysis, sometimes called cost volume profit analysis, is an important analytical technique used to study relations among costs, revenues and profits. The research related to Break-even analysis in health facilities that have been conducted include immunization development programs for children to find out the relationship between fixed and variable costs to income received from immunizations. This analysis is also used to assess procurement of equipment such as MRI scans in health facilities, cost analysis to determine the most effective and efficient method for treating dementia patients, Analyze the risk of companies that can be reduced by health promotion programs.

Most of the studies use PEST analysis to analyze the general environment which represents political, economic, sociocultural, and technological factors. Describes a framework of macro-environmental factors used in the environmental scanning component of strategic management but the word PEST is no more than a convenient mnemonic. The underlying thinking of the PEST analysis is that the enterprise has to react to changes in its external environment. This reflects the idea that strategy must involve an analysis of the external environment in determining strategy. The research related to PEST analysis in health facilities includes analysis of environmental factors that affect mental health, use of PEST analysis to find out important factors that influence the pharmaceutical sector, PEST analysis to create a competitive advantage in the health industry. The used tools of strategic management is based on the purpose of the strategy because they have their respective functions and strengths.

Factors That Affect Strategic Management

Internal and external environment is one of the factors that influence the evaluation and performance of an organization. Internal and external environmental factors are factors that influence the strategy. Internal environmental factors include:

1. Resources (Finance, physic, technology, human resource, innovation dan reputation)

2. Value chain analysis (infrastructure, MSDM, technology development, procurement, Inbound logistics, operations, Outbound logistics, marketing and selling, dan service)

While external environmental factors allow:

1. General environment (politic, economy, socio
cultural, technology, demography, environment)

2. Industry environment (threat new entrants, bargaining power suppliers, bargaining power of buyers, threats of substitutes products)

3. Rivalry environment

Analysis of environmental factors, can be analyzed by PESTEL analysis, i.e. Politic (P), Economic (E), Social (S), Technological (T), Environmental (E), and Legal (L). PESTEL analysis can be combined with SWOT analysis to make better and prudent decisions and strategic solutions. External environmental factors have a significant effect on the company's value. Therefore external environmental factors (i.e. politic and legal, economy, socio cultural, technology, demography dan epidemiology) it is important to be analyzed and controlled for the achievement of successful strategy formulations for the company. Analysis of external environmental factors allows the organization to extract timely information about the environment, the business environment at the regional level and to develop the development programs of the organization in the short and long term. The choice of strategy is influenced by the business environment. Companies must be able to identify these factors, especially external factors because these factors are outside the company and difficult to be managed by the company. Then an analysis of environmental factors is used in determining strategies that will have a positive impact on the company. Analysis of environmental factors must also be integrated to determine the strategy will be developed by the company.

In previous studies, internal factors affecting health facilities include research with value chain management to compare the speed of development of Muhammadiyah Hospital in East Java and Central Java Indonesia. Resource analysis of hospital performance. External factors that have been studied in health facilities include political and legal, economic, socio-cultural, technological, demographic and epidemiological factors.

**Method**

This paper is a review and study of various research related to models of strategic, tools of strategic, and factors that influence both internal and external strategic, especially in the scope of health research. The articles collecting by the google database, google scholar and mendeley. A review was conducted on articles with topic tools of strategic and factor that affect strategic especially in the scope of health research. We identified approximately 51 articles that were published in the last decade. The review in this article is divided into several sections that are strategic management models, tools of strategic, environmental factors that affect strategic management as well as conclusions and possible research that can be developed.

**Results and Discussion**

In hospitals, as highly pluralistic contexts, organizational knowledge, legitimacy and social capital play an important strategic role. However, their accumulation involves a variety of internal and external stakeholders concerned with both internal conditions and the external environment. The strategy management process revealed many similarities in how this process occurs at both hospitals. The main similarities are: (a) only the partial adoption of the SP; (b) the relevance of political interactions (more than plans) in strategic decisions; and (c) the influence of the institutional environment in strategic decisions and actions. Only the partial hospital adoption of the Strategic planning (SP) this is an appropriate other research in Lubin region, most health care facilities develop strategic plans (71.4%). For 21.4% of the studied facilities, the strategic plan is known mainly to management. In contrast, 28.6% of entities do not have a strategic plan. Health facilities that have implemented of strategic management using methods SWOT analysis 64.2%, break-even point analysis 42.9%, PEST analysis 14.3%, with factors that influence strategies such as political and legal, economic, sociocultural, technology, demographic and epidemiology. Based on a summary of studies, using tools to determine the strategies in health facilities, as in the table 1:
Table 1. Summary of research using tools of strategic in health facilities.

Source^{4,14,29–33,37,39,51,16–21,26,27}

Based on table 1. It is known that SWOT analysis is the most popular strategy tool used in the health sector, while other formulation tools of strategic are still relatively unpopular. Based on previous research conducted on health facilitation research in the Lubin area, it is known that there are six environmental factors that influence the strategy including political and legal factors, economic factors, social culture, technology, demography and epidemiology. What is the reason why SWOT analysis is used the most while PEST analysis is the least used should be able to be addressed in further research. The results in table 1 also show that research related to PEST and BSC in the health sector is still very minimal and is a research opportunity that is still very likely to be developed.

Conclusion

For a company to have a competitive advantage and be able to compete for a long term, the company must have the tools of strategic. Various strategies that can be used such as SWOT analysis, Break-even analysis, PEST analysis and balanced scorecard (BSC) analysis. The used tools of strategic management is based on the purpose of the strategy because they have their respective functions and strengths. On formulating the strategy there are environmental factors that influence such as internal factors and external factors. Internal factors include resources (Finance, physic, technology, human resource, innovation dan reputation) and value chain analysis (infrastructure, MSDM, technology development, procurement, inbound logistics, operations, outbound logistics, marketing and selling, dan service). While external environmental factors include the general environment (politic, economy, socio cultural, technology, demography, environment), industry environment (threat new entrans, bargaining power suppliers, bargaining power of buyers, threats of substitutes producs), rivalry environment.

The research related to implementation tools of strategic in health facilities still rarely. Previous research conducted at health facilities in the Lubin area can be developed to see variations of tools of strategic applied in different regions or countries. Is this related to internal and external environmental factors in the region. What are the internal and external factors that most influence can be studied. Previous studies that no one has researched what sub factors most influence the socio-cultural, demographic and epidemiological factors. The use of BSC and PEST analysis tools are still rarely used in health facilities and have the opportunity to be researched and developed. Based on a summary of research related to internal and external factors that have been carried out in health facilities, it is known that industry environmental factors and rivalry environment are still rarely to be studied. The general environmental factors of demography and epidemiology are still rarely research that explores it in health facilities so it can be a future research opportunity.

Peutz Jeghers Syndrome in 47 Years Old Woman (Histopathological Review) : Case Report

Danu Yuliarto¹, Prasetyadi Mawardi², Ambar Mudigdo³

¹Recidency Program, ²Associate Professor in Department of Dermatology and Venereology, Faculty of Medicine, Sebelas Maret University/ Dr. Moewardi General Hospital, Surakarta, Indonesia, ³Professor in Department of Anatomical Pathology, Faculty of Medicine, Sebelas Maret University/ Dr. Moewardi General Hospital, Surakarta, Indonesia

Abstract

Background: Peutz-Jeghers syndrome (PJS) is an autosomal dominant inherited disorder, characterized by intestinal hamartoma polyps in association with distinct patterns of skin and mucosal macular melanin deposition. Patients with PJS have a 15-fold increased risk of developing bowel cancer compared to the general population.

Case: A 47-year-old woman complained of black patches appearing on the lower and upper lips. Several months ago, the patient said that black patches appeared on the gums and inner cheeks. Gastrointestinal complaints such as nausea or vomiting were previously denied. Dermatological examination in the oris et gingivae et buccalis region showed multiple well-defined hyperpigmented macules. Histopathological examination found an increase of melanocytes in the stratum basale with rows of melanocytes. Patient had an endoscopy in the gastrointestinal tract and histopathological examination of the colonic mucosa, no abnormalities were found and no signs of malignancy were found on histopathological examination.

Conclusion: Result of histopathological examination showed an increase in the number of melanocytes in the stratum basale with lined melanocytes. Based on histopathological examination in this patient more leads to the diagnosis of PJS

Key words: Peutz-jeghers Syndrome, Histopathology, Melanocytes

Introduction

Peutz-Jeghers Syndrome (PJS) is an autosomal dominant inherited disorder characterized by intestinal hamartoma polyps in association with a distinct pattern of association of skin and mucosal macular melanin deposition.¹⁻⁹ This syndrome was described in 1921 by Jan Peutz (1886-1957), a Dutch physician who noted the association between intestinal polyps and mucocutaneous macules in Dutch families. Harold Jeghers (1904-1990), an American physician, contributed with a definitive descriptive report of this syndrome, when he published “generalized intestinal polyposis and melanin spots of the oral mucosa, lips and fingers”, in 1949, with McKusick and Katz. The eponymous Peutz-Jeghers syndrome was introduced by the radiologist Andre J. Bruwer in 1954.¹⁻³⁻⁵

Forty-eight percent of patients with PJS develop cancer and die from cancer at 57 years old. Cancers that develop in the gastrointestinal tract of patients with PJS have a higher frequency than that occurring in the
general population. During the first 3 decades of life, anemia, anal bleeding, abdominal pain, obstruction or intussusception are common complications in patients with PJS. Nearly 50% of patients experience intussusception during their lifetime, most often in the small intestine. The median age at first diagnosis of cancer is 42.9 years, ± 10.2 years.

Peutz-Jeghers syndrome should be diagnosed in patients as early as possible. Genetic counseling should also be provided. Many of the gastrointestinal lesions begin to develop early in life, even if the syndrome does not become clinically apparent until the second and third decades of life. Appropriate screening for colon cancer and extra intestinal cancer must be carried out. This paper will report a case report with the results of anamnesis, physical examination, dermatological examination and histopathological picture of melanocytes lined up in the stratum basale. The purpose of this case report is to increase knowledge about diagnosis through histopathological examination of PJS.

Case

A 47-year-old woman from Sukoharjo came to the skin and genital polyclinic of the dr. Moewardi Regional General Hospital Surakarta on March 29th, 2016 with the main complaint of black spots appearing on her lips and gums.

The current history of the disease began about a year ago where the patient complained of black patches appearing on the lips. Initially, the complaint of spotting appeared only on the lower and upper lips, but several months ago the patient said black spots appeared on the gums and inner cheeks. There are no complaints of pain in the spot and never bleed.

This is the first time for the patient has experienced this type of complaint. No family member is sick like this. A history of taking drugs in the long term, a history of wounds, canker sores or previous skin diseases in the area was denied. There was no history of asthma, allergies to certain foods or drugs in the patient or family. Gastrointestinal complaints such as nausea or vomiting were not previously found.

Physical examination showed good general condition with vital signs still within normal limits. Dermatological examination of the oris et ginggiva et buccalis regions showed multiple well-defined hyperpigmented macules (Figure 1). This case was differentially diagnosed with PJS and Cronkhite-Canadian syndrome (CCS).

Subsequently, this patient underwent a skin biopsy in the oris region. After histopathological examination, the epidermis showed an increase in the number of melanocytes in the stratum basale with rows of melanocytes (Figure 2).

The patient is planned for consulted to the internal medicine department, then endoscopy is done by the internal medicine department. This patient received therapy in the form of cryotherapy for lesions on the lip mucosa from the skin.
Figure 1. A-D The oris *et* gingival region shows multiple hyperpigmented macules with well-defined borders. E-H The *region buccalis dextra et sinistra* showed multiple hyperpigmented macules with well-defined borders.

Figure 2. A-D Melanin cells at the base are lined up. Melanin in the papillary dermis.
Discussion

Peutz-Jeghers syndrome consists of two main components, hamartomatous polyposis of the gastrointestinal tract and mucocutaneous pigmentation. The incidence of PJS is reported to be 1 in 150,000 to 200,000 people.\textsuperscript{18} Initial manifestations of PJS are melanin spots, i.e. 1-5 mm hyperpigmented macules on the lips, buccal mucosa, periorbital area, nose, genitals and fingers, usually present in the first year of symptoms and represent mucocutaneous marker of this syndrome. This sign is most commonly seen on the mucous membranes of the lips and cheeks as well as the anal and intestinal mucosa, nose, periorbital area and hands and feet. In some observations there is pigmentation on the nails, however this finding is rare.\textsuperscript{16} This case was differentially diagnosed with CCS. Cronkhite-Canada syndrome was first described by Cronkhite and Canada in 1995; so far, about 400 cases mainly of European or Asian descent with a mean age of 59 years have been reported. Cronkhite-Canadian syndrome is also characterized by intestinal polyposis and lentigo-like macules, usually on the face, extremities and palms. Pigmentation tends to be more diffuse than in PJS. Symptoms of CCS may vary, but classic symptoms are characterized by the presence of diffuse gastrointestinal tract polyposis, dystrophic changes in the nails, alopecia, skin hyperpigmentation, diarrhea and weight loss. Other symptoms such as hypogeusia and xerostomia have also been described in the literature.\textsuperscript{21} On physical examination in this patient found black patches on the lips, patches on the upper and lower lips, black spots also appeared on the gums and inner cheeks, so in this case it is more suitable with a picture of PJS.

The results of microscopic examination of the skin of patients with PJS who were biopsied gave an abnormal picture of increased melanin deposition, there was basal hyperpigmentation in the pigmented macula. There is conflicting opinion as to whether an increased number of melanocytes, basal hyperpigmentation with or without increased melanocyte proliferation, that seen in CCS.\textsuperscript{16} In this patient’s biopsy, histopathological examination results in the epidermis showed an increase in the number of melanocytes in the stratum basale with rows of melanocytes. This is more likely with the histopathological picture in PJS, whereas in CCS when histopathological examination is carried out, hyperpigmentation results in the stratum basale without an increase in the number of melanocytes.

Autosomal dominant PJS is characterized by the association of gastrointestinal polyposis with the presence of pigmented macules, this syndrome has an increased risk of developing cancer at a relatively young age. There is genetic heterogeneity, although the majority of cases involve the serine/threonine kinase (STK11/LKB1) gene on chromosome 19p13.3. This gene encodes the protein LKB1 that regulates the p53 mutation pathway. Apoptosis in gene regions involved in substrate recognition is more often associated with malignancy than mutations in gene regions involved in ATP binding and catalysis. A case has been reported in association with primary melanoma of the rectum.\textsuperscript{16,19} In the majority of cases, multiple polyps develop in the small intestine which may become malignant in 2-3% of patients.\textsuperscript{20} According to Giardiello et al, endoscopic examination is a surveillance for cancer detection. The age range of finding colorectal cancer in PJS varies from 21-71 years, with an overall risk of 39%, the majority being in males. Hearle et al found that colorectal cancer was the most common cancer of the gastrointestinal tract. The risk of colorectal cancer is 3%, 5%, 15% and 39% at the age of 40, 50, 60 and 70 years. In this large series only one case of sigmoid cancer was detected during surveillance. Less common upper gastrointestinal cancer. Gastric cancer is much more common than oesophageal and the median age at diagnosis of cancer of the gastrointestinal tract is 30 years. Although very rare, upper gastrointestinal cancers have been reported during the first and second decades of life.\textsuperscript{12,22} Upper GI colonoscopy and endoscopy are sometimes performed as early as 8 years of age. It is possible that polyps are detected, this should be repeated every 3 years. If no significant polyps are found on initial endoscopy, routine surveillance is repeated at age 18 or earlier depending on symptoms, then repeated every three years. We
recommend that after the age of 50 years the frequency of examinations increases to every 1–2 years because of the increased risk of malignancy at this age.\textsuperscript{22} While the endoscopic appearance of CCS may vary, colonic polyps have been characterized by a “strawberry-like” appearance in one study.\textsuperscript{21} The etiology of CCS is not well understood but several studies have shown an association with elevated antinuclear antibody (ANA) and IgG4 levels, there is also an association between CCS and hypothyroidism and various autoimmune diseases such as rheumatoid systemic lupus, rheumatoid arthritis, and scleroderma, all of which lead to autoimmune etiology.\textsuperscript{16,19} In this patient, an endoscopy of the gastrointestinal tract and histopathological examination of the colonic mucosa was performed, from the two investigations, no abnormalities were found on gastrointestinal endoscopy and no signs of malignancy were found on histopathological examination of the colonic mucosa.

Although the mucocutaneous pigmentation seen in PJS may fade with age, it can be psychologically disturbing for the patient. The use of intense pulse light (IPL) with a 590nm cut-off filter was reported in one case where it led to cosmetic improvement of the lesions. Similar improvements also have been described with Q-switched ruby lasers and CO2-based lasers. In addition, in the study reported, cryotherapy was performed on 15 patients and gave satisfactory results. Cryotherapy has a mechanism of tissue destruction by rapid clotting. The lesion froze and produced necrotic tissue which then sloughed off spontaneously.\textsuperscript{22} In this patient’s case, cryotherapy was administered to the skin and genitals.

**Conclusion**

It has been reported a case of PJS in a 47-year-old woman with complaints of black spots appearing on the lips, the spots appearing only on the lower and upper lips, the complaints have been felt since one year ago, the spots do not increase. On dermatological examination in the oris et gingiva et buccalis region, multiple hyperpigmented macules were clearly demarcated. After histopathological examination, the epidermis showed an increase in the number of melanocytes in the stratum basale with rows of melanocytes, this picture supports the diagnosis of PJS. No abnormalities were found on gastrointestinal endoscopy examination from the internal medicine department. Furthermore, this patient received therapy in the form of cryotherapy on the skin and genitai.

Readiness to Change, Medication Adherence and Quality of Life among Alcoholic Patients at Selected Hospitals, Bangalore

Dayananda Bittenahalli Omkarappa¹, Rajratan Gupta², Reema Jacqueline Andrade³

¹Professor, HOD, Department of Psychiatric Nursing, Kempegowda College of Nursing, K.R. Road, V.V. Puram, Bangalore, ²Assistant Professor, Dept. of Psychiatric Nursing, Nursing College, All India Institute of Medical Sciences, Bhopal, ³Registered Nurse, Northern Devon District Hospital, Barnstaple, United Kingdom

Abstract

Background of the Study: Alcohol affects virtually every organ system, and alcoholics are at increased risk medical problems. Many factors contribute for poor response to treatment and outcome. The factors like poor adherence and motivational level by patients with alcohol use disorders (has often been raised in the literature. However, there has been a limited effort to measure the problem. Hence the investigator felt that there is need to assess the level of readiness to change, Medication adherence and Quality of life among alcoholics.

Methods: A descriptive Survey research design was adopted for the present study. 100 alcohol dependent individual were recruited by simple random sampling method. The Stage of Change Readiness and Treatment Eagerness Scale, Morisky Medication Adherence Scale and WHO quality of life-BREF were used to assess readiness to change, medication adherence and quality of life. The study was conducted at selected Hospitals, Bangalore.

Results: The result shows that majority (73%) of respondents are having low level of readiness to change, medication adherence (67%) and quality of life (56%). A moderate positive correlation was found between readiness to change and medication adherence ($r=0.67$), a negligible positive correlation found between readiness to change with quality of life ($r=0.032$) and a high positive correlation was found between quality of life with medication adherence ($r=0.71$).

Conclusion: The study concludes that alcohol dependent individual had low level of readiness to change, medication adherence and quality of life.

Key words: Readiness to change, medication adherence, quality of life and Alcoholics

Introduction

Alcoholism is a broad term for any drinking of alcohol that result in problems. Alcohol affects virtually every organ system, and alcoholics are at increased risk for cirrhosis, gastrointestinal bleeding, pancreatitis, cardiomyopathy, trauma, mental health disorders, and a wide variety of cancers. Patients with viral hepatitis who abuse alcohol significantly increase their risk for cirrhosis and ensuing hepatocellular carcinoma.

W.H.O ranked alcohol dependence as nine among ten medical disorders causing morbidity in the world. As many as 80% of men and 60% of women in

E-Mail: Rajratan.nursing@Aiimsbhopal.edu.in
developed countries drink at some time during their lives. In the United States, 138.3 million people age 12 and older, surveyed, report that they actively use alcohol, in addition, 40% of patients have experienced complications of alcohol misuse in the world.

In India 85% of men who are violent towards their wives were frequent or daily users of alcohol. 3 to 45% of household expenditure is spent on alcohols, use of alcohol increases and reduces the ability to pay for food and education. The National Household Drug Use Survey done in India found that alcohol (21.4%) was the primary substance used (apart from tobacco) followed by cannabis (3.0%) and opioids (0.7%). 17 to 26% of alcohol users qualified for ICD 10 diagnosis of dependence and low of 7% in the western state of Gujarat (officially under Prohibition) to 75% in the North-eastern state of Arunachal Pradesh.

The stigma associated with substance use, the guilt and shame resulting from inappropriate use and the lack of awareness about the part drugs play in the problems they face –all these lead to a denial of the problem of addiction. In an attempt to protect the dignity of the family, in most cases family members also deny the existence of any serious problem. Hence, Readiness to change (RTC) becomes one of the key issues in the treatment of alcohol dependent persons.

Motivation to change had a significant association with complications of alcohol use, medical comorbiditly, onset and severity of alcohol dependence, socioeconomic status, religion, and mode of referral. The higher RTC scores were associated with improved alcohol use outcomes and the strongest effects were for confidence. Even RTC score translates into short-term reductions in alcohol use and in turn alcohol consequences, and highlight important of motivation. Medication adherence is also one of factor which determines the treatment effectiveness along with motivational factor.

Nonadherence diminishes the effectiveness of treatment for all chronic diseases, including alcohol dependence. Rates of adherence to pharmacotherapies for alcohol dependence range widely, both within and among agents. The factors like use of external reinforcers, such as positive and negative contingencies, and involvement of family members or significant others; and specific prescribing and dosing practices that may improve adherence and there by improve the quality of life among alcohol dependent patients.

There is sound evidence that both higher levels of alcohol consumption and the severity of drug dependence correlate with poorer Quality of life (QoL). Assessment of QoL, medication adherence and motivational level in alcohol dependence is a valuable measure of clinical status and also helps to identify predictors of relapse. Early identification of factors influencing relapse helps in prevention of complications; hence the investigator felt there is need to “assess to readiness to change, medication adherence and quality of life among alcoholic patients”.

Materials and Methods

A cross sectional descriptive study was conducted on alcohol dependent patient who admitted at KIMS hospitals Bangalore, from December 2017 to July 2018. The simple random sampling technique was used to collect the data from 100 samples. The inclusion criteria include patients who are diagnosis with alcohol dependence syndrome aged between 25 to 50 years and Free from alcohol withdrawal symptoms. The exclusion Criteria includes Patient suffering from mental and behavioural disorders due to use of alcohol and individual with other sever life threatening illness. The study protocol was approved fromInstitutional human ethics committee and permission was taken from hospital authority. Informed consent was obtained from the patients and their care givers.

Assessment

Subjects were administered with socio-demographic data sheet, The Stage of Change Readiness and Treatment Eagerness Scale, Morisky Medication Adherence Scaleand WHO quality of life-BREF.

1. Socio-demographic data sheet: It includes questions on age, sex, religion, area of residence,
educational status, occupation, marital status and family income. Clinical parameters included duration of alcohol intake, no of previous hospitalization, duration of treatment and family history of alcoholism.

2. The Stage of Change Readiness and Treatment Eagerness Scale: There were 19 items for SOCRATES questionnaire. Each item has five options with relevant answers. The most relevant answer for each item was five and least relevant answer for each item was one. Thus for 19 items maximum score is 95 and minimum score is 19. The readiness to change was classified based on scores as low level for score up to 48, a score of 49-71 as medium level and a score higher than 71 as classified as high level of readiness to change.

3. Morisky Medication Adherence Scale (MMAS): is used to assess the drug non adherence and consists of eight items, that assess the medication-taking behaviour with a scoring scheme of “Yes”=1 or “No”=0 for the first seven items and a 5-point Likert response for the last item. The items are summed to give a range of scores from low adherence to high adherence though they are dichotomized in this study by considering scoring greater than 3 were low adherence, 1-2 considered as medium adherence and score of zero considered as high adherence.

4. WHOQOL-BREF: It contains 26 items; each item has five options with relevant answers. The most relevant answer for each item was five and least relevant answer for each item was one. Thus for 26 items maximum score is 130 and minimum score is 26. The quality of life was classified as low level for score up to 52, a score of 53-78 as medium level and a score higher than 78 as classified as high level of quality of life.

**Statistical Analysis**

Data were analysed using Statistical package for the Social Sciences Software Package (Version 23), and results were presented in table form. Descriptive statistics were used for study variable. Correlation coefficient was calculated to find out relationship between readiness to change, medication adherence and quality of life among alcoholic patients.

**Results**

In the present study, majority (42%) of the subjects were from 35-45 years age group, most (92%) of the respondents were male and majority (70%) of the respondents belongs to Hindu religion. Majority (60%) of the subjects from rural area, most (52%) of the samples were studied up to PUC and 40% of samples were having private job as occupation. Majority (96%) of the respondents were married and most (65%) of the respondent’s monthly family income ranges less than Rs 20,000. The mean duration of alcohol intake is 5±0.96 years, mean duration of treatment is 20±3.96 days and most (53%) of respondents admitted twice previously. Majority (56%) of the respondents had family history of alcohol consumption.

With regards to classification of respondents scores, majority (73%) of respondents are having low level of readiness to change, medication adherence (67%) and quality of life (56%). (Table 1)

A moderate positive correlation was found between readiness to change and medication adherence(r=0.67), indicating that as the readiness to change scores increased medication adherence scores also increased. A negligible positive correlation found between readiness to change with quality of life (r=0.032) and a high positive correlation was found between quality of life with medication adherence(r=0.71). (Table 2)

**Discussion**

Motivation and medication adherence are the key element in treatment and recovery that influences a patient’s progression through the stages of change—from considering change, to making the decision to change, to following the planned action into sustained recovery. The present study shows that majority of respondents were in low level of readiness to change, medication adherence and quality of life.

Our findings echo previous research evidence which shows that alcohol dependent patient shows
poor readiness for change their behaviour towards drinking.17-18 The studies have shown that effectiveness of treatment modality mainly dependent upon individual readiness to change.19 The study conducted by Bertholet N et al-2012 shows that among the 377 subjects reporting unhealthy alcohol use, 216 (58%) reported low level of readiness to change.20

Concern about poor adherence with medication by patients with alcohol use disorders (AUD) has often been raised in the literature. Nevertheless, there has been a limited effort to measure the problem, despite the recognition that it adversely affects treatment outcomes. The study conducted by KranzlerHR et al -2008 shows that less than 15% of patients treated with oral naltrexone for AUDs over a 6-month period were able to persist with refills for at least 80% of the time, while more than 85% were identified as non-persistent.21

The substance abuse treatment seeks to promote abstinence or at least significant reductions in substance use, its ultimate aim is to improve the patient’s quality of life. The present study shows that poor quality of life among alcoholics. This finding is supported by Pasareanu AR et al study shows that majority of patients had Low QoL at inpatient and need active intervention to improve their condition.22 The studies have shown that QoL measurements were useful for providing evidence of therapeutic benefit in the ADS field.23-24 The study also found that there is significant correlation between the readiness to change, medication adherence and quality of life. The study suggests that intervention should be aimed at improving the factors which helps in improving well-being of alcohol dependent patients.

Limitations: The study is limited to small sample size (100) and small number of subjects’ limits generalization of the study.

Conclusion

The study concludes that alcohol dependent individual had low level of readiness to change, medication adherence and quality of life. Health care members should focus on the factors which improves the quality of life of patients along with prevention of relapse.

Ethical Consideration: Ethical approval was obtained from the institutional ethical committee (KINEC: 13/16-17).

Analysis of Nurse Personal Factors of Triage Decision-Making in Emergency Installation at University of Muhammadiyah Malang Hospital

Ali Rahmanto¹, Loeki Enggar Fitri², Ika Setyo Rini³
¹Master of Nursing Student, Nursing Department, Faculty of Medicine, Universitas Brawijaya, ²Department of Parasitology, Faculty of Medicine, Universitas Brawijaya, ³Nursing Department, Faculty of Medicine, Universitas Brawijaya

Abstract

The high frequency of patient visits to the ER will disrupt the service process at the Emergency Department (IGD). One solution is the application of a triage system, which is the process of sorting patients according to their level of gravity. The accuracy of triage decisions has a significant impact on patient outcomes so that in this case nurses in the ER must have knowledge, understanding, and skills about triage. Analyze personal factors that influence emergency nurse decision-making. This study aimed to identify personal factors influencing triage decision-making among emergency nurses. Respondents were 30 male and female nurses who worked and were active up to now in the IGD Hospital of the University of Muhammadiyah Malang. Data on work experience, education, and training were taken from data on the characteristics of respondents. The knowledge questionnaire came from the Emergency nurses association/ENA while the skills questionnaire used the Triage Skill Questionnaire/TSQ. The Spearman correlation test shows that there is a significant relationship between skills and education with triage decision making (p=0.000; r=0.626 and p=0.039; r=0.378). Meanwhile, the variables of knowledge, work experience, and training do not correlate with triage decision making (p> 0.05) except that GELS training shows a significant relationship between GELS training and triage decision making (p=0.016; r=0.437). The results of linear regression analysis, skills, and education are factors that influence decision-making in conducting triage in the ER (45.4%). Skills and education are the factors that most influence triage decision-making.

Keywords: triage, decision making, emergency nursing.

Introduction

Emergency Room (IGD) is part of the service in a hospital that provides 24 hours of service every day. The prevalence of emergency patient visits to the ER is increasing, both in patients with stable and unstable conditions. The data on patient visits to the emergency room in Indonesia in 2007 were 4,402,205 patients (13.3%) of the total visits to the hospital¹. Data on patient visits to the ER in East Java province in 2014 were 8,201,606 cases². Data on patient visits to the ER at the University of Muhammadiyah Malang Hospital (UMM Hospital) in 2017 were as many as 25,715 cases³.

The high frequency of patient visits to the ER will disrupt the service process in the ER (National Center for Health Statistics, 2008). Besides, the density of services provided to patients with emergency conditions has an impact on decreasing the quality of service to patients⁴. In this regard, a patient management system or management is needed which will determine the assessment of medical or nursing actions called triage. Triage is a decision-making process in prioritizing the
needs and therapy given to patients in the ER based on the level of emergency. The existence of an optimal and systematic triage system can reduce the waiting time (length of stay) of patients in the emergency room and improve the quality of health services.

Triage is the initial activity performed by nurses when the patient comes to the ER. The accuracy of triage decisions has a significant impact on patient outcomes. There are still many nurses working in the IGD who lack knowledge and skills about triage. In general, two factors affect the accuracy of nurses’ decision-making in implementing triage. The first factor is an internal factor that describes the knowledge, work experience, and training of nurses, while the second factor is an external factor covering matters related to the work environment and workload. Ignoring internal and external factors can cause the implementation of triage to be inaccurate and result in permanent disability in patients. Another study states that the absence of guidelines and socialization regarding filling out the 5-level triage scale raises doubts for triage nurses to determine the patient’s triage scale, thus making the triage assessment undertriage and overtriage. The inaccuracy of filling in the triage scale is the first step in the occurrence of long waiting times and affects the satisfaction rate and patient safety.

In its application, triage guidelines are important for triage officers and medical personnel in determining the success of medical intervention and management in patients because they can be used as a reference in determining patient emergency measures. Failure to determine the right level of priority based on triage will result in delayed intervention in patients with critical conditions so that which will have an impact on the worsening of the condition which can lead to morbidity and mortality. The ability of health workers to carry out triage will affect the interventions that will be carried out on patients. Related to this, there are several factors behind this, including knowledge of triage and work experience. Besides, several other factors also influence, among others, the work environment and personal characteristics. This statement is also supported by research that triage decision making can be influenced by personal factors including experience, assessment skills, training that has been followed, strength in decision making, skills and teamwork, flexibility, knowledge, and the sharpness of the ability to identify problems.

Besides, other research states that to do the correct triage requires a high cognitive process as well as skills, expertise, competence, qualifications, and readiness in making triage decisions. Other results add that sufficient work experience, awareness of signs and symptoms of disease, adequate equipment and resources have a very important role in carrying out the correct triage. In other results, it is said that the accuracy of triage is determined by internal/intrinsic factors which include fear of making mistakes in dangerous situations, insight, clinical qualifications, and the ability of nurses as well as external factors such as work environment stress, high workload, and work environment density.

Based on a preliminary study conducted at UMM Hospital, the triage system used in the last 7 years has undergone 2 changes, namely in the first year at the opening of UMM Hospital using the Simple Triage And Rapid System (START) and in the 5th year using Australian Triage Scale (ATS) which has been modified according to the needs of the hospital and following the existing room in the ER at UMM Hospital. This triage system has only been implemented in UMM Hospital IGD for the last 3 months. ER UMM Hospital often experiences a lot of patient congestion, with the number of patient visits every day around 45-55 patients and the number of patient visits per week around 350-400 patients.

**Materials and Methods**

This research is a type of quantitative research using an analytic observational research design using a cross-sectional approach. The population in this study were all male and female nurses who worked and were active until now in the ER at UMM Hospital, amounting to 30 people. The sampling technique used in this study was the total sampling technique so that this study the samples were all nurses who worked actively, both men...
and women in the ER at UMM Hospital, totaling 30 emergency nurses.

The data used in this study are primary in the form of a questionnaire sheet. The questionnaire sheet consists of a questionnaire, namely a questionnaire that must be filled in by the nurse who conducts the triage, namely knowledge, and the questionnaire sheet which is observed by 2 enumerators who are Triage Course certified. Several statements based on indicators that have been compiled by researchers related to knowledge about triage, work experience, and the skills of nurses in conducting triage, and statements of decision making in the ER in conducting triage to patients who come to the IGD UMM hospital. The work experience, education, and training questionnaires were taken from the characteristic data of respondents, namely emergency room nurses. The knowledge questionnaire came from the Emergency nurses association / ENA. Then modified by researchers. Furthermore, the skills questionnaire uses the Triage Skill Questionnaire/TSQ (Fathoni et al., 2013) modified by researchers. The decision-Making Questionnaire (DMQ) was modified by (French et al., 1993). Both questionnaires were modified and translated into Indonesian. The reliability test was carried out on 10 emergency room nurse respondents at Lawang Medika Hospital on August 26, 2019, with the results of the instrument being reliable because the alpha value was> 0.6.

Analysis of data using univariate analysis includes data on the characteristics of respondents, namely age, gender, education, and length of work of nurses. Univariate analysis on the independent variables includes knowledge, work experience, skills, education, and training. Meanwhile, for bivariate analysis using the Spearman Rank correlation test. Linear regression was used for multivariate analysis.

Based on table 1, explains the characteristics of the respondents based on gender. From the picture above it is known that. The highest number of nurses in the Emergency Room at the General Hospital of the University of Muhammadiyah Malang were male (53.3%). Characteristics of respondents based on the level of education, it is known that the majority of nurses in the Emergency Room Hospital Muhammadiyah University of Malang have S1 education with a total of 20 nurses or 66.7%. Based on the length of work, IGD nurses worked at most for 1-1.5 years with 9 nurses (30%). Based on training experience, it is known that nurses in the Emergency Room at the General Hospital of the University of Muhammadiyah Malang have attended the most BLS training (23%), and others include Advanced Cardiac Life Support / ACLS (19%) and Basic Trauma Life Support / BTLS (13%), ALS (4%), General Emergency Life Support / GELS (4%), disaster management 13% and those who attended triage training (16%).

Based on table 2, it is found that there is no significant relationship between knowledge about triage, work experience, training which includes triage, BLS, ALS, BTLS, ACLS, and Disaster management with triage decision making. There is a relationship between skills, education, and GELS training and triage decision making.

</table>

Based on table 3 shows the results of the bivariate test, it is known that 3 variables have a relationship with the dependent variable, namely skills, education, and GELS training. Therefore, the three independent variables will be analyzed using linear regression with the backward method. However, after being entered using the backward method, the results were not significant, so in the second (final) step, it was eliminated from the regression model, leaving skills and education. So that skills and education are the most dominant personal factors in influencing triage decision making in emergency room nurses with a variation of 45.4%.

Discussion

The relationship between knowledge and triage decision making

Based on the results of the data obtained, there is no significant relationship between nurses’ knowledge of triage and decision making. Theoretically, with better knowledge, the better the decision-making should be. However, even though they have been given the same understanding of triage, many nurses still use visual triage according to the understanding of each nurse because it is faster according to the nurse and does not require a long time. Because each nurse had also equipped themselves before entering the ER at UMM Hospital, besides that the nurses felt comfortable with it because several times the triage system in the IGD of UMM Hospital had changed because of hospital needs or because the head of the installation had changed 3 times and triage, too, was revamped. Therefore, the nurse uses each assessment which is considered the same as the other triage, in essence, sorting out the patients.

Research by (Purwoko, 2015)\(^7\) on 50 emergency room nurse respondents was conducted to measure the correlation between knowledge and the accuracy of nurses’ decision-making in the implementation of triage. The results showed that there was a significant correlation between these 2 variables with a p-value of 0.000 and a correlation coefficient of 0.565. While research conducted by Khairina (2018)\(^8\) on factors related to nurse decision making in triage accuracy, it was found that the length of work was the most dominant factor with a p-value of 0.012 and an odds ratio value of 17.856.

A study presented and reported that nurses had insufficient knowledge about hospital triage, 39.94% of the responses to the knowledge level questions were correct in that study. They concluded their findings that in hospital emergency departments in Iran, nurses were
not equipped with triage knowledge. As well as nursing curricula for different nursing programs do not have sufficient triage process content to prepare nurses for these systems in the emergency department. It can be concluded that based on the results obtained, knowledge of triage among nurses is inadequate in Pakistan\textsuperscript{19}.

Another study mentioned 100 nurses in three teaching hospitals in Pakistan, 69\% of nurses were found to have poor knowledge of triage. The correct response to the entire questionnaire was 43.22\%. With these findings, it is considered important to establish a knowledge improvement program through training that will help to build and improve the knowledge of nurses working in the ER\textsuperscript{20}.

The relationship between work experience and triage decision making

The Emergency Nurses Association (ENA) in the United States suggests that qualifications are stated to place triage nurses and may need more consideration, one of which is clinical experience, requiring them to have at least 6 months of experience in emergency resuscitation. However, it is recommended that you have at least 2 years of work experience in the ER to improve competence and triage skills\textsuperscript{21}.

From this research, it is known that the nurses who work in the ER of UMM Hospital are very diverse, ranging from those who have worked for 5 to 6 years, and some who are new, namely 3 months. Even though before becoming IGD nurses, they had been briefed on the triage used in the ER, there are still many nurses who still use their respective understanding so that the triage assessment is following the understanding of each nurse. Nurses who have longer work experience are expected to be more skilled in conducting objective and subjective assessments, as well as in determining triage priorities for patients who enter the ER at UMM Hospital.

The results of this study are in line with the research of Considine et al. (2007)\textsuperscript{22} which states that there is no significant relationship between experience (length of work) and nurses’ decision-making in conducting triage. Experienced nurses as well as nurses with little or less clinical experience may have the same ability to perform triage.

The relationship skills with triage decision making

Based on the results of research on the skills of nurses in making triage decisions, significant results were obtained. From this research, it is known that nurses who work in the ER UMM Hospital are very skilled in terms of assessment and anamnesis, meaning that some respondents have good skills. So the relationship between nurse skills and triage decision making has a positive correlation, indicating that the higher the skills of nurses in conducting triage, the higher the level of success in making appropriate decisions on patients.

Several factors have been identified as having contributed to the skills of nurses in triage. Among them, Chung (2005)\textsuperscript{23} stated that training experience can improve nurses’ skills about triage to identify patient priority scales, diagnose patients, and provide nursing interventions in the ER. To become skilled in triage, ER nurses are required to participate in training programs for triage and other related topics and renew every one to three years. Correct clinical assessment of the patient’s condition requires thinking and insight, which is achieved based on knowledge and skills. The relationship between work experience and the achievement of work skills has been explained by the banner, it is explained that a nurse develops a process of skills and education through clinical experience, and after going through this their decision-making abilities will change and be correct.

Research conducted by Fathoni., Et al (2010)\textsuperscript{17} on the relationship between knowledge about triage, training, work experience, and triage skills in nurses in several hospitals in East Java showed that the level of skills of nurses was moderate, possibly due to emergency room nurses. have a lot of experience, and 82\% of them have worked in triage. Besides, it was also stated that the majority of IGD nurses collaborated with doctors in conducting the triage process, so that this collaboration
could help nurses to have triage skills in making the right decisions in several circumstances. The research also resulted that training experience and knowledge had a positive relationship with triage skills, which reflected that the higher the knowledge and training that nurses participated in, the more skills about triage would also develop.

**The relationship between education and triage decision making**

Based on the results of research on nurse education in triage decision making, significant results were obtained. From this research, it is known that nurses who work in the IGD of UMM Hospital have an average education level of D3 and Nurse, meaning that some respondents have a good education. The positive correlation in the results of this study shows that the higher the education possessed by nurses, the higher the score for triage decision making.

For a nurse who works in an emergency service unit is very important to follow training, especially related to applied triage. CENA in 2007 provided guidelines that were a core component in the choice of triage for nurses consisting of history, knowledge, and applied triage practices, for example, using triage that was appropriate to hospital conditions, communication skills, primary and secondary surveys, assessment, and related triage decision making, with the type of patient condition such as trauma patients, pediatric patients, obstetrics, and gynecology.

Nursing education and high competence will increase the knowledge and skills of nurses in conducting triage assessments quickly and accurately. nurses who have high education and have competencies related to triage can improve nurses in making triage decisions in the emergency room. This high education and competence of nurses is the main basis for nurses to be able to assess the appropriate triage category according to the patient’s condition to improve nurse performance and better outcomes.

The relationship between training and triage decision making

Based on the results of the data obtained, there is a significant relationship between GELS training for nurses on triage and decision making, however, in several other pieces of training, there are no significant results. After the GELS training was entered using the backward method, the results were not significant, so in the second (final) step it was eliminated from the regression model. Theoretically, the better the training, the better the decision-making. However, even though nurses have been given the same understanding of triage and each of them has attended outside training to support personal abilities, many nurses still use visual triage according to their understanding because it is faster according to the nurse and does not require a long time, besides The nurse felt comfortable with it because several times the triage system in the IGD of UMM Hospital had changed because of the needs of the hospital or because the head of the installation had changed 3 times and the triage was also changed. Therefore, the nurse uses each assessment which is considered the same as the other triage, in essence, sorting out the patients.

For a nurse who works in an emergency service unit is very important to take part in training, especially related to applied triage. CENA in 2007 provided guidelines that were a core component in the choice of triage for nurses consisting of the history, knowledge, and practice of applied triage, for example using triage that was appropriate to hospital conditions, communication skills, primary and secondary surveys, assessment and related triage decision making, with the type of patient condition such as trauma patients, pediatric patients, obstetrics, and gynecology.

**Personal factors influencing triage decision making**

The results of the multivariate analysis showed that the personal emergency nurse factors that most influenced triage decision-making were skills and education. These factors explain 45.4% of the variation in emergency nurse decision-making. Triage skills in emergency
nursing are defined as the ability of emergency nurses to use their decision-making skills to prioritize patients into appropriate categories in a fast time. Nurses’ skills in conducting triage include rapid assessment, patient categorization, and patient allocation\textsuperscript{17}. Yuliastuti, 2007\textsuperscript{26} states that the higher the skills possessed by the workforce, the more efficient the body, energy, and thoughts are in carrying out work.

Education is a process of awareness that occurs because of the interaction of various factors concerning humans, the environment, and their potential. Education in the field of nursing is a process of awareness and self-discovery as nursing personnel who have maturity in thinking, acting, and acting as professional nurses, so that they can answer various challenges in their personal and professional life. Higher education is related to triage decision-making (Kusnanto, 2003)\textsuperscript{27}.

**Conclusion**

There is a relationship between GELS skills, education and training, and triage decision-making. There is no relationship between the knowledge and work experience of nurses with triage decision-making. Skills and education are personal emergency nurse factors that significantly influence triage decision-making in the Emergency Room at the University of Muhammadiyah Malang Hospital.

Articaine: Opening up a New Vista for Pediatric Dentists

Ananthu H, Ashwin P Rao, Suprabha B S

1 Post Graduate Student, 2 Associate Professor, 3 Professor and Head, Department of Pediatric and Preventive Dentistry, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education (Mahe), Manipal

Abstract

Lidocaine has remained the gold standard local anaesthetic agent to perform dental procedures both in the adult as well as in the pediatric patients. However, the invent of articaine has offered the clinicians with a newer and more potent local anaesthetic agent, which causes minimal side effects. Articaine is 1.5 times more potent and 0.6 times less toxic than lidocaine. Also, adequate anaesthesia achieved through infiltration route of administration of the drug, almost eliminates the need for the painful and difficult inferior alveolar nerve block in children, thereby minimising the side effects. Thus, achieving adequate anaesthesia through the administration of a small volume of the drug has opened up a new vista for pediatric dentists in managing pain in children, although manufacturers do not recommend the usage of articaine in children less than 4 years of age due to paucity of evidence. So, this review article tries to throw light on the use of articaine in pediatric patients, citing evidence from literature and also tries to portray the recent advances in the research on articaine use in pediatric patients less than 4 years of age.

Key words: articaine, local anesthesia, pain, children

Introduction

Pain management plays a crucial role in the success of any dental treatment in a pediatric patient (1). Minimising the fear and anxiety, a proper management protocol employed, can help develop a positive attitude towards dental treatment in the patient. Though considered a painful and challenging procedure, the administration of local anaesthesia continues to be one of the most commonly used methods for managing pain in the pediatric age group (2). Maximum efficacy through minimum number of injections with negligible adverse events effected, should be the objective of the local anaesthetic agent used (3).

The discovery of the first amide local anaesthetic agent Lidocaine (Proprietary name: Xylocaine), also known as Lignocaine, in the 1940s, marked a revolution in the arena of pain management in dentistry as it offered better potency and triggered less allergic reactions when compared to the then commonly used local anaesthetic Novocain (Procaine) (4). Since its inception, Lidocaine has remained the “gold standard” local anaesthetic agent to perform dental procedures, all around the globe. However, the search for more effective local anaesthetic agents led to the discovery of newer local anaesthetic agents in the subsequent years. Articaine was one among the newer local anaesthetic drugs developed (5). It was originally developed and synthesised as ‘Carticaine HCl’ by H. Rusching et al in 1969 (6). It was introduced into clinical practice first

Article type: Review article

DOI Number: 10.37506/ijfmt.v15i4.16838
in 1976 in Germany and Switzerland followed by the other European countries and Canada \(^{(7)(8)}\). In the United States, the US Food and Drug Administration approved the use of articaine in April 2000 \(^{(9)}\). Gradually, articaine started to gain attention and clinicians began employing articaine in adult dentistry. However, the use of the drug in the pediatric age group has raised concern over times, though literature shows that the efficacy and safety of articaine is comparable to the other commercially available local anaesthetic including lignocaine \(^{(10,11)}\) or even superior \(^{(12,13)}\). A survey among pediatric dentists in India concluded that the majority of the respondents still preferred lidocaine with epinephrine as local anaesthetic for use in children \(^{(14)}\).

**Uniqueness of Articaine**

Articaine or Articaine HCl ("4-methyl-3-[2-(propylamino)-propionamido]-2-thiophene-carboxylic acid, methyl ester hydrochloride") is an amide type local anaesthetic. The molecular weight of articaine HCl is 320.84 and it contains a thiophene group instead of a benzene ring, a peculiar characteristic that differentiates it from the other local anaesthetic agents. The greater lipid solubility and potency offered by the thiophene ring helps in the entry of a greater amount of the administered anaesthetic solution into the neurons. It is also able to diffuse more easily through soft tissue surfaces and has a high degree of plasma protein binding of 95%, when compared with the other local anaesthetics. Though classified as an amide, owing to its linkage of intermediate chain, articaine also contains an ester side chain, which triggers the plasma esterases and the hepatic microsomal enzymes to bring about the biotransformation of articaine in plasma and liver respectively. This imparts articaine a half-life of 20 minutes and the primary metabolite obtained is articainic acid which is pharmacologically inactive. This accounts to the decreased systemic toxicity effected by articaine, thereby rendering itself as a safer alternative\(^{(15)}\). Articainic acid (64.2 ± 14.4%), articainic acid glucuronide (13.4 ± 5.0%) and the parent drug (1.45 ± 0.77%) are excreted via urine after the metabolism of articaine \(^{(16)}\).

4% solution with 1:100,000 or 1: 200,000 adrenals are the commonly manufactured forms of articaine and they are dispensed in 2.2ml and 1.7ml glass dental cartridges. The two articaine formulations have been used in both adults as well as in children.

**Safety of Articaine in Children**

Articaine is well tolerated and safe to use in children above 4 years of age. The potency of articaine is 1.5 times that of lidocaine, which enables the administration of a smaller volume of the drug. The reduced volume may help decrease the discomfort felt by the child during anaesthesia administration, especially in cases where an inadequate co-operation of the child is experienced. It is also 0.6 times less toxic as compared to lidocaine \(^{(17)}\). There is also a lesser need for supplemental injections in articaine. Articaine can be given via buccal infiltration to children requiring pulp therapy and extractions and can thereby be used to replace inferior alveolar nerve block (IANB). The high risk of inferior alveolar and lingual nerve damage can be avoided by replacing IANB. The extent of soft tissue analgesia experienced by the patient can be reduced and therefore the incidence of complications like lip biting can be minimized \(^{(18,19)}\). When buccal and palatal infiltration with other local anaesthetic agents was replaced by a single buccal infiltration using articaine, it yielded favourable results during the extraction of primary molars in the maxillary arch. Also, articaine delivered via intraligamentary injection can be used to replace IANB to extract primary molars \(^{(20)}\).

According to Lemay et al, the onset of anaesthesia by articaine was 168±131 sec (nerve block) and 85±60 sec (infiltration) in children; for adults it was 170±131 sec (nerve block) and 119±84 sec (infiltration) \(^{(21)}\). For maxillary infiltration, the duration of action on soft tissues ranges from 2.6 to 4.5 hours whereas for nerve block, it ranges from 4.3 to 5.3 hours \(^{(6,8)}\). The volume of distribution of articaine is inversely proportional to the patient’s age. For children between ages 4-12 years, the dosage of articaine ranges from 5-7 mg/kg body weight, however a lower limit of ≤5mg/kg was advocated in
children aged 4-12 years by authors who performed studies using articaine in conjunction with sedative agents. In any case, it should always be remembered that the concentration of articaine can be considered double as that of lidocaine, and thus will require half the safe number of cartridges.

**Comparison with Other Local Anesthetic Agents in Pediatric Dentistry**

Multiple investigators have reported their findings and conclusions on the use of articaine as a local anaesthetic agent in pediatric population.

Malamed in 2000 compared the pain control property of “4% Articaine HCl (with 1: 100,000 epinephrine)” with “2% Lidocaine HCl (with 1: 100,000 epinephrine)” in children under the age of 13 years, by employing the Visual Analogue Scale (VAS). He found Articaine to be comparable to Lidocaine and gave a green signal to its use in the branch of pediatric dentistry citing its safety and efficacy.

Ram and Amir in 2006 compared Articaine and Lidocaine during operative procedures in children aged 5-13 years. They stated that “Articaine 4% with 1:200 000 epinephrine is as effective as lidocaine 2% with 1:100 000 epinephrine”. However, articaine produced a longer lasting anaesthetic effect on the soft tissues as compared to lidocaine.

Yilmaz et al in 2011 compared Articaine 4% with (1:100000 epinephrine) and Prilocaine 3% (with felypressin) in 162 children belonging to the 6 to 8 age group, undergoing primary molar pulpotomy. Similar intensity of pain was reported during administration of both the anaesthetic solutions. However, coronal pulp amputation, prilocaine gave a pain score which was 1.5 times higher than that of articaine. The adverse events reported were also comparable.

In a review by Leith et al in 2012, it was also reported that 4% articaine showed better pain control than 2% lidocaine for both simple and complex dental procedures.

In 2012, Odabaş compared 4% articaine with 3% mepivacaine, to study the pain reaction and duration of soft tissue numbness during the administration of local anaesthesia in children. A “randomized, double-blind, split-mouth” design was adopted for the study which included a sample size of 50 children (25 girls and 25 boys) belonging to the 7- to 13-year-old age group, who required comparable operative treatment needs in symmetric primary teeth. The objective evaluation of the children was carried out by the modified behaviour rating scale and the subjective evaluation by using the Wong-Baker FACES pain rating scale which helped assess the post injection and post treatment experience. The duration of numbness felt was recorded by the parents by asking the children. Articaine (140.69±49.76 minutes) presented with a prolonged time period of soft tissue anaesthesia than mepivacaine (117.52±42.99 minutes). Neither did the efficacy of the anesthesia nor did the heart rate, blood pressure, or oxygen saturation show any significant differences during all evaluation spans for both anaesthetic solutions. The two anaesthetic solutions also showed similar post treatment experience. It was concluded that same efficacy and identical child behaviour was observed with 4% articaine and 3% mepivacaine, though articaine reported longer soft tissue numbness.

In 2012, Arrow compared “4% Articaine (with 1: 100,000 epinephrine)” administered via buccal infiltration to “2% Lignocaine (with 1: 80,000 epinephrine)” administered via buccal infiltration (BI) or inferior alveolar nerve block (IANB) during standard restorative procedures in the posterior teeth of the mandibular arch among school children. The study assessed pain response via the Faces Pain Scale – Revised (IASP) and found no statistical difference in pain response between both the solutions. The study declared that both Articaine and Lignocaine, were declared equally effective in pain management in children for routine restorative procedures.

In 2014, Thakare evaluated and compared 4% Articaine and 0.5% Bupivacaine through his randomized controlled crossover clinical trial, in patients aged 10-18.
years who had their premolars indicated for orthodontic extractions. The study showed that 4% Articaine presented with a quicker onset of action and lesser Visual Analog Scale scores as compared to Bupivacaine. However, Bupivacaine presented with a longer time period of analgesia and time to the first uptake of medication for rescue analgesia. Articaine was declared more potent and effective considering its quicker onset of action and low pain scale scores.

In 2015, Arali and Mytri P (27) studied the anaesthetic efficacy of “4% articaine (with 1: 100,000 epinephrine)” delivered via buccal infiltration and “2% lignocaine (with 1: 100,000 epinephrine)” delivered via inferior alveolar nerve block (IANB) by employing a “randomized, double-blind, cross over” study design in children aged 5-8 years, presenting with the clinical condition of irreversible pulpitis. The study also assessed the necessity for the administration of supplemental injections. The trial reported that the anaesthetic onset was quicker with 4% articaine than 2% lignocaine. A shorter span of anaesthesia was observed with articaine infiltration and with a lesser requirement for the administration of supplemental injections. The study concluded that 4% articaine can be given via buccal infiltration to children undergoing management for irreversible pulpitis.

A study by Zurfluh et al in 2015 (28) assessed whether an articaine solution could reduce the period of soft tissue anaesthesia and thereby reduce the risk of self-inflicted soft tissue lesions, while still providing an adequate anaesthesia. The study reported that owing to its high efficacy, tolerance, and reduced soft tissue anaesthesia, 4% articaine (with 1: 400,000 epinephrine) was considered safe for treatment in paediatric population.

In 2015, a study was performed by Mittal (29) in 112 children, to compare the anaesthetic efficacy of articaine with lidocaine during the extraction of primary molars in the maxillary arch and assess whether a buccal infiltration injection could achieve sufficient palatal anaesthesia as well. The study reported that buccal infiltration with articaine can be considered a potential substitute for lidocaine in achieving local anesthesia in children, though it did not succeed in achieving sufficient palatal anaesthesia.

In 2016, Chopra et al (30) compared the efficacy of buccal infiltration with articaine against inferior alveolar nerve block with lignocaine for primary molars in children aged 4-8 years, indicated for pulpectomy or pulpotomy. The efficacy of both the anaesthetic agents were assessed using the Pain Scores, the Facial Image score, Sound Eye Motor (SEM) scores and Heft- Parker Visual Analogue Score (HP-VAS). Buccal infiltration with articaine showed significant lower pain scores as compared to IANB (p<0.001). SEM scores at the time of pulp extirpation were also higher for IANB than infiltration (p<0.001).

Kolli et al in 2017 (31) stated that Articaine buccal infiltration can be used as an alternate to conventional local anaesthetic delivered via buccal and palatal infiltration, for extracting primary molars in the maxillary arch.

In 2018, Sharan et al (32) assessed the effectiveness of “2% lidocaine (with 1:80,000 epinephrine)” and “4% articaine (with 1:100,000 epinephrine)” to extract primary mandibular molars in children aged 6-10 years, by employing the intraligamentary injection technique. The study utilised the Sound eye motor scale to assess pain perception. The study showed 80% success rate in Articaine group and 30% success rate in lidocaine group. The study concluded that the intraligamentary injection technique using articaine might serve as an alternative to IANB during extraction of primary molars in the mandibular arch.

Rathi conducted a study in 2019 (33) among 100 children to compare the anaesthetic efficacy of articaine with that of lignocaine. It was concluded that a single buccal infiltration of 4% articaine with 1:100,000 epinephrine is more effective when compared to 2% lignocaine with 1:80,000 epinephrine for extracting primary molars in children aged 7 to 12 years.
Massignan in 2020\(^{(34)}\) stated that though articaine reported a higher pain incidence during the injection, no difference in efficacy was observed when the anaesthetic administration of articaine was compared to lidocaine in the extraction of primary molars. In the study, the efficacy and the adverse events of “4% articaine with epinephrine 1:100 000” was compared with that of “2% lidocaine with epinephrine 1:100 000” during the extraction of primary molars, by employing anaesthesia via buccal infiltration in forty-three children belonging to the 6-10 age group. 21 children received local buccal infiltration with 4% articaine whereas 22 children received lidocaine 2%. The pain experienced during injection of the anaesthetic solution and during extraction of the tooth was the major outcome assessed. The anaesthetic efficacy of both the solutions was observed to be identical though a higher pain incidence was reported by children belonging to the articaine group. Similar adverse effects were observed in both the groups which included post-operative pain, edema and nausea.

It can be summarised that there is evidence to conclude that 4% articaine is comparable to or more efficacious than the other local anaesthetic agents used in children. However, the parents should be cautioned about self-inflicted soft tissue injuries that may arise due to the prolonged numbness, commonly reported with articaine administration. However, the evidence suggests that articaine is safe in children, as the administration of the drug triggers few adverse events, which are commonly noticed with lidocaine as well.

**Evidence For Use in Children Below 4 Years of Age**

Some studies have specifically reported the use of articaine in paediatric dental patients less than 4 years of age with positive results, however the manufacturers still do not recommend it for children younger than 4 years.

Wright et al in 1989\(^{(22)}\) conducted a retrospective research which analysed the usage of articaine hydrochloride as an anaesthetic agent in children aged less than 4 years of age. Records of articaine administration on 211 patients, with additional administrations of the agent on 29 patients was retrieved from two pediatric dentistry offices by a record audit. Some cases even reported administration of higher doses of the drug than recommended for older children. The clinicians have not noted the occurrence of any systemic adverse reactions. The report provided initial evidence for the use of articaine in children under 4 years of age.

Jakobs et al in 1995\(^{(35)}\) studied the pharmacokinetics of articaine on 27 children, 3 to 12 years of age, who underwent dental procedures under intubation anesthesia. They determined the serum concentrations after local anesthesia with 2% and 4% articaine solutions in this age group of children. They concluded that articaine shows age-related differences in the pharmacokinetics and hence there is no need to fix a lower mg/kg dose limit while administration in children.

A study was conducted in young children below four years of age by Elheeny in 2020\(^{(36)}\) to assess the efficacy and safety of 4 % articaine as a local anesthetic agent by comparing it with 2 % lidocaine hydrochloride. The study had an equivalent randomized control trial design, with two parallel arms including 184 young children (92 per group) aged from 36 to 47 months, in whom, pulpotomy of mandibular primary molars was indicated after administering anesthesia by buccal infiltration injection. The results of the study indicated that during pulpotomy, children who received articaine showed less pain as compared to their counterparts in the lidocaine group and no statistically significant differences were observed between both the drugs, considering the post-operative complications. It was concluded that the findings supported the efficient and safe use of articaine hydrochloride 4% with epinephrine 1:100 000 as a local anaesthetic agent during dental procedures in children aged between 3 and 4 years.

The evidence supports the use of articaine in children less than 4 years of age. However, limited research demands clinical trials on a larger sample size to be performed before employing articaine as a local anaesthetic agent in children less than 4 years of age.
Conclusion

Articaine is a safe and effective local anesthetic drug which can be employed in pediatric patients to help achieve dental analgesia during invasive procedures. The evidence that articaine administered via infiltration technique can replace Inferior Alveolar Nerve Block makes it even more interesting. The ability of articaine to penetrate into deeper spaces by diffusing through bone and soft tissue should be understood by the clinicians as it helps to achieve excellent depth of anesthesia, while avoiding block and palatal anesthesia for dental treatment in children. However, advanced research and clinical trials is a necessity, as articaine is not recommended by manufacturers in children below 4 years of age.

Amniotic Band Syndrome with Unique Clinical Presentations: A Case Report

Donel Suhaimi1,2, Maya Savira3, ShintaPuja Tilusari4
1Associate Professor, Department of Obstetrics and Gynecology, Faculty of Medicine, University of Riau, Pekanbaru, Indonesia, 2Associate Professor, Department of Obstetrics and Gynecology, Arifin Achmad Hospital, Pekanbaru, Indonesia, 3Assistant Professor, Department of Microbiology, Faculty of Medicine, University of Riau, Pekanbaru, Indonesia, 4Resident, Department of Obstetrics and Gynecology, Faculty of Medicine, University of Riau, Pekanbaru, Indonesia, 4Resident, Obstetrics and Gynecology, Arifin Achmad Hospital, Pekanbaru, Indonesia

Abstract

Amniotic band syndrome is a rare congenital disorder which associated with physical abnormalities such as disruption, deformation, and malformations of organs. The most common abnormalities usually involve the limbs that could range from simple constriction rings to complete amputation. In this case report, we report an amniotic band syndrome with unique clinical presentations. The case was a newborn male baby who was normally delivered and presented with a ring-like constriction at over middle right lower limb and fusion (syndactyly) of left lower limb and right arm. In this report we also discuss different diagnostic modalities which could be used in diagnosing amniotic band syndrome, the risk factors, type of amniotic band syndrome, post-natal diagnose, as well as the therapy.

Keywords: Amniotic band syndrome, ABS, constriction rings, syndactyly, case report

Introduction

Amniotic band syndrome (ABS) is a group of congenital birth defects believed to be caused by entrapment of fetal parts (usually a limb or digits) in fibrous amniotic bands while in utero.1,2 ABS should be called a sequence rather than a syndrome because ABS is related in wide range of physical abnormalities, which are significantly disabling and disfiguring in nature.1-5

Most of infants with ABS have multiple deformity of the limbs and arms and could range from simple constriction rings to complete amputation. ABS has known as amnion rupture sequence, amniotic deformities/adhesions/mutilations (ADAM complex), amniotic band disruption complex, congenital constricting bands, terminal transverse defects, or Streeter anomaly.1,2 Various studies estimate the incidence of ABS to be between 1 in 1,200 to 1 in 15,000 living births.3-5,6 There is no known clear etiology of ABS.3-15 In this case report we report an ABS case with unique clinical presentations.

Case Report

A 22 years old female, 28-29-week gestation, presented to Arifin Achmad Hospital with first stage of labor and preterm premature rupture of membranes (PPROM) and oligohydramnios. The patient was referred from a clinic with placenta previa. The patient complained the rupture of membranes wet in the cloths about one day before admitted to the hospital; however, the patient felt this about a month already. The patient...
also had regular contraction followed by blood mucus.

At the hospital, the patient was thoroughly examined including general as well as obstetric and gynecologic examinations. Patient vital signs were stable and no associated comorbidities such as maternal trauma or drug intake. Physical examinations suggested minimal fluxus from ostium urethra externa, nitrazine test was difficult to interpret due to blood mucus. Ultrasonography showed oligohydramnios with maximum vertical pocket (MVP) of 0.75 cm.

Patient was managed conservatively and was planned for cerclage and amnioinfusion. However, the patient was in labor and delivered a single alive newborn male baby with 1.4 kg, APGAR score was 7/6 and amniotic fluid was clear. On gross examination, the baby had ring-like constriction at over middle right lower limb and fusion (syndactyly) of left lower limb and right arm (Figure 1A-C). The baby was admitted to Neonatology Unit as sepsis and asphyxia and was thoroughly evaluated. Karyotyping and histopathology examination were ordered and returned with normal results (Figure 1D).

![Figure 1](image)

**Figure 1.** Clinical manifestation of the ABS case and its karyotyping. (A) Constriction rings at over middle right lower limb. (B) Syndactyly of the right arm. (C) Syndactyly of left lower limb. (D) Karyotyping showing normal result.

**Discussion**

ABS is a rare disorder with the estimated incidence between 1 in 1,200 to 1 in 15,000 living births. ABS can be diagnosed prenatally by ultrasound and the most important ultrasound diagnostic features are visible amniotic bands, constriction rings, irregular amputations of fingers and/or toes with a terminal syndactyly, or deformation of major anatomic. In a rare case, a strand of amniotic fibrous tissue could be seen attached to tissues and restricting the free movement of fetus in-utero. In this case, patient ultrasound showed no significant deformity since it was difficult to figure the extremities. Some studies found mild defects during ultrasound.
examination; however, ABS is less likely to be diagnosed prenatally and most of defects were seen after birth.6,16-20

ABS etiopathogenesis is still unknown, but there are four main theories.12 In this case, karyotyping result was normal (46 XY), the possibility cause is oligohydramnios. One of the well-known theories is rupture of the amnion in early pregnancy, with formation of amniotic band and liquid loss, or multiple loose strands (amniotic bands), followed by extrusion of all or parts of the fetus into the chorionic cavity. Bands entrap the parts of the growing fetus or limbs or other body parts become entangled and are subject to compression.

The abnormalities such as constriction rings and in some severe cases leading to vascular disruption and could potentially result in amputation of the involved anatomic structures of the body parts. Adherence, even without constriction can have adverse mechanical effect that result in malformation or deformation. In this case, the baby was classified as group IV of ABS (isolated defect).13 Other theories suggest that the amniotic band or vascular disruption due to genetic mutation.8-10,13-17

In such condition, all patients should receive counseling about the fetal abnormalities detected. Consulting with subspecialists is ideally recommended. There is no standard guideline of management for pregnancy complication with fetal ABS. Recently, some treatments for prenatal with ABS have been tried such as fetoscopic laser cutting of amniotic bands before their compression on the fetus.19-20 However, the efficacy of the procedure is not well-documented.

Conclusion

ABS is a rare disorder caused by entrapment of fetal parts usually limbs or arms in fibrous amniotic bands while in utero leading to complex multisystem anomalies. The prenatal diagnosis is difficult although could be diagnosed by ultrasound which indirectly showing the ABS. The treatment and follow-up of ABS children require a team of specialists accordingly.

Abstract

The quality of human resources should be prepared since in early stage. Pregnancy is one of a significant period which can take advantage to by providing proper nutrition and adequate stimulation. For instance, sound and music, the most harmonious combination and easily accepted by the fetus (1). Experimental analytic type with post-test only control group design was employed on 30 pregnant Rattus norvegicus which were divided randomly into 3 groups, namely the control group, qari group, and qariah group. Each of the groups had stimulation starting 6th to 17th days of pregnancy for 60 minutes. At 18 days of pregnancy, the mother of Rattus Norvegicus was sacrificed and bring forth with Sectio Caesarea (SC). As a result, the number of astrocyte glia cells in the cerebrum was higher in the qariah recitation stimulation group (22.62 ± 3.75), compared with the group that was listened to qari recitation stimulation group (19.84 ± 2.48), while the control group (16.54 ± 2.78). A significant difference found in the number of astrocyte glia cells in the Cerebrum Rattus norvegicus newborn that were listened to the qari and qariah recitation stimulation group and the control group. The highest number of Glia cells is obtained from the stimulation of qariah recitation.

Keywords: Stimulation, Pregnancy, Recitation, Astrocyte glia cells, Cerebrum, Rattus norvegicus

Introduction

The quality of human resources should be prepared since the early stage. The important process to generate qualified human resources is by ensuring that every baby is born from a physically, mentally, and socially healthy mother. Providing proper nutrition and adequate stimulation during pregnancy is one of the ways to generate qualified human resources. For instance, stimulating by sound and music is proven to change the structure and function of the fetal brain in the uterus (1).

Glia is the most plenty of cells in the human brain which always increase following the development of the human brain. Glial cells provide lactate for energy sources in neurons and support energy for axons (2). Astrocytes have functions in the physical arrangement of the brain, correlate with neuron synapses, and the assistance of electrical impulses in the brain (16). Damaged or missing astrocytes can be used to function and structure the brain (15). Here, the process to ensure the quality of the fetus is by increasing glial cells with reducing apoptosis and increasing the glial cell ratio (1,3).
The ear starts growing at 18 weeks of age. Then, at 22 to 24 weeks, the fetus will begin to hear low-frequency sounds from outside the uterus \cite{4}. The stimulation of the Mozart instrument influenced the number of neuron cells more than to dangdut and gamelan songs \cite{1}. Mozart’s instrument played with a frequency of 75-10,000 Hz and an intensity of 70-130 dB which provides a lower apoptotic index than other music \cite{5}. A good response came up after playing music for the fetus in the uterus which showed that the heartbeat may often increase, causing it to move faster \cite{17}. Even though the fetus is inside the uterus, it has an environment with sound, vibration, and movement \cite{18}. The heart of the fetus can be seen from the changes in fetal heartbeat and its movements after giving sound stimulation. The escalation response from the fetal heartbeat occurs in ± 20 weeks pregnancy and mostly occurs in ± 26 weeks pregnancy \cite{19}.

The human voice is divided into two major groups, namely the type of voice in men and women. The voice type in men is divided into tenor, baritone, and bass, while in women it is a soprano, mezzo-soprano, and alto \cite{6}. The fundamental frequency (f0) difference between men and women is clear, the fundamental frequency of human voices for men and women is two normal distributed curves with a little overlapping \cite{9}. Qari is a person who recites the Qur’an by restricting to the correct rules. A qari is usually used for a male who recites the Qur’an, and qariah is used for a female who recites the Qur’an \cite{20}.

**Material and Methods**

This study conducted analytical experimental research with a post-test-only control group design by using the *Rattus norvegicus* as a model by giving stimulation as the pregnant mother. The research was carried out in January-March 2021 at the Pathology Laboratory and Experimental Animal Cages of the Faculty of Veterinary Medicine, Campus C Universitas Airlangga, Surabaya, Indonesia.

The population of this study was 2-3 months old white mice Wistar strain (*Rattus norvegicus*) with an initial weight of 120-160 grams, with 30 *Rattus norvegicus* according to the inclusion and drop-out criteria as the sample. They were divided into 3 groups random, namely, the control group, the qari group, and the qariah group. Each of the groups will be listened to recitation for 60 minutes, with an intensity of 65 dB. Here, the mice were inside a soundproof cage so that it is adjusted and arranged to focus on the recitation which will be played through the speakers that had been installed.

In the initial process of fertilization of *Rattus norvegicus* was injected with *Pregnant Mare Serum Gonadotrophin* (PMSG) 10 IU and 10 IU hCG injection. Then, the mating process was done 48 hours later, with 1 male mouse and 1 female mouse, Manomatting. After 17 hours, a copulatory plug will be evaluated as a marker of pregnancy day 0. The treatment was started on day 6th -17th of pregnancy. At the age of 18th days of pregnancy, the mother of *Rattus norvegicus* was sacrificed and the neonatal *Rattus norvegicus* was brought forth by *Sectio Caesarea*. Here, the researcher selected 2 each, starting from the heaviest and the lowest weights.

CUBASE 5 software was utilized to analyze the highest and lowest frequency of qari and qariah recitation to determine the sound intensity using a sound analyzer application and a sound meter application.
Figure 1. Analysis of qari recitation frequency with the farthest frequency, around 15.400 Hz

Figure 2. Analysis of qariah recitation frequency with the farthest frequency, around 13.000 Hz
To measure the number of Glia Astrocyte cells in the cerebrum newborn’s Rattus norvegicus between the treatment group and the control group, employed normality test used the Saphiro-Wilk test, followed by the homogeneity test using the Levene variety. The test to differ each group was by employing the Analysis of Variance (ANOVA) with the Least Significant Difference (LSD) further test. If the p-value <0.05 means that there is a significant difference. Then, computer software SPSS 21.0 was used as a tool to simplify the data processing. At last, the study ethics are considered during the research process to include a replacement, reduction, and refinement.

Results

The number of Astrocyte Glia Cells in the cerebrum was determined and calculated by Hematoxylin-Eosin staining technique with a magnification of 5 fields of view, at 400x magnification.

Table 1. Mean and Standard Deviation the Number of Astrocyte Glia Cells in the cerebrum and cerebellum of Rattus norvegicus offspring from mothers was listened to the recitation of surah Ar-Rahman by qari, qariah, and the control group.

*p < 0.05 = there are significant differences

Based on table 3, there was a difference number of astrocyte cells in the Cerebrum Rattus norvegicus newborn with a calculated F value of 6.504 and significance value of 0.005, it indicated that there was a significant difference between treatment groups on the number of astrocyte cells in the cerebrum of Rattus norvegicus.

Based on Figure 3, yellow arrow showed the difference number of Glia cells at Cerebrum Rattus norvegicus newborn in the control group (K1), Qari grup (K2) and Qariah grup (K3).

Discussions

In this study, the elements of dB intensity and frequency range are analyzed by utilizing the Sound Analyzer application so that the two groups get almost the same dB value, with qariah recitation with 65.2 dB and qari recitation with 65.3 dB. The sound frequency is processed by employing CUBASE 5 software with resulted in the qariah recitation obtained the highest frequency, around 13.000 Hz, and the lowest frequency of 167 Hz. For qari, the highest frequency is around 15.400 Hz and the lowest frequency is 20 Hz. The difference in frequency generated from the two sounds of qari and qariah can cause a difference in the signal that is picked up by the stereocilia inner hair cell in the cochlea and causes an influx of Ca2 + and stimulates the release of neurotransmitters in the ear nerves. Here, the neurotransmitters will release a potential action and transmitted by the vestibulocochlear nerve then reach the Cerebrum, so that the message captured by the brain is different.

There are many different types of sound based on various classification systems. In music theory, humans have different types of voices, both male and female. Types of voice in men are divided into tenor, baritone, and bass. Whereas women are divided into soprano, mezzo-soprano, and alto(6). Furthermore, men’s and women’s voices have a different frequency, it was found that there was a difference in fundamental frequency (f0) between men and women. The value of f0 women is higher than men. Because of that, the human voice f0 for men and women is two normally distributed curves with slight overlapping. Here, the average female voice is above 200 Hz, while the male voice is below 170 Hz(9).
Producing human voices require three elements, namely, resources, sound sources, and sound modifiers. The power source of the normal sound signal resulted from the compression motion of the lung muscles. A sound modifier is an articulator that changes the shape of the vocal tract so that the frequency characteristics of the acoustic cavity pass through what the sound passes so that the resulting frequency will be different. The accuracy results for the testing process on female voices obtained 100% accuracy results, while men obtained 95.47% accuracy results. The system’s ability to detect the female gender was better than male. From each group, there was a difference in the pitch value of each individual. This is influenced by the shape of the vocal cords, mostly, women’s voices have a higher pitch value than men’s.

Due to the mass and tension of the vocal cords, men have longer and heavier vocal cords than women. Men have a baseline frequency prevalent at 125 Hz, while women have an octave (twice) higher baseline frequency than men at around 250 Hz. The lowest frequency that can be achieved by a bass singer is around 64 Hz. The basic tone of men is lower than that of women, where the average basic tone of men and women is, 129Hz to 167Hz with a peak of 152Hz for men and 207Hz to 269 Hz, and a peak of 239Hz for women.

As a result, there was a significant difference in the average number of glial cells in the cerebrum of Rattus norvegicus newborn, between the control group and the group of exposure to the surah Ar-Rahman recitation by qariah. The highest mean number of glia astrocyte cells is in the group listened to the surah Ar-Rahman recitation by qariah. Here, it can be seen that there are differences in the mean number of astrocyte glial cells in the group listened to surah Ar-Rahman recitation by qari, qariah, and the control group. It occurs due to the difference in dB intensity and the range of the highest and lowest frequencies generated from the voices of reciter and qariah, where the voice of qariah produced the highest average number of glial cells compared to qari and control groups.

**Conclusion**

The number of glial astrocyte cells in the *Cerebrum Rattus norvegicus* newborn in qariah recitation group had the highest value compared to the qari and control groups. Moreover, there was a significant difference in the number of glial astrocyte cells.

Abstract

Background: Scabies is caused by parasite, called Sarcoptes scabiei, infestation into the skin. Scabies is generally found in children who live in crowded environments and poor hygiene.

Methods: This is a retrospective descriptive study with secondary data collection from medical record data in the Outpatient Installation of RSDM for the period January 2015-December 2019. The subjects were infants to children aged 14 years with a diagnosis of scabies. Data variables used included age, gender, family history of scabies, diagnosis, comorbidities, supporting examinations and, therapy in scabies patients.

Results: There were 88 pediatric patients with scabies. The most age group that experienced child scabies was 11-14 years (33%) with the most sex being male (55%). The largest source of scabies transmission was from the family (39%). The most common lesion morphology was papules and excoriations (49%). The lesion location was found mostly between the fingers (24%). Examination of skin scrapings using NaCl 0.9% was positive only in 5 patients (6%) with the most diagnosis was scabies (77%)

Conclusion: This study shows that most of pediatric patients with scabies in the 11-14 years range are dominated by males. The most common sources of infection were families with papule morphology and excoriation, whereas the most lesions were found between the fingers. Skin scrapings are only positive 6% of cases. The most commonly used topical therapies are 5% permethrin and 2% ointment mupirocin while the systemic therapies are cetirizine and cefadroxil.

Key words: Scabies, Sarcoptes scabiei, permethrine, cetirizine, cefadroxil

Introduction

Scabies is caused by parasite infestation (Sarcoptes scabiei) into the skin. Scabies is generally found in children who live in crowded environments and poor hygiene.¹ The prevalence of scabies is affecting 200 million population worldwide, 5-10% of children and 10.4% of adults with the same proportion in both sexes.² Pruksachatkunakorn et al reported that scabies is mostly found in 1-7 years old childrens (87.3%).² The prevalence of scabies in Indonesia based on data from the Ministry of Health of the Republic of Indonesia (Depkes RI) in 2008 was 5.6-12.95% and is the third most reported skin disease. Paramita et al reported that the prevalence of scabies was 282 cases with the highest age being 5-14 years old (63.8%).⁴

Cardinal sign of scabies can manifest as nocturnal pruritus. On physical examination, excoriations were seen in the interdigital area, wrist, volar, axilla, areola mammae, scrotum, penis, gluteus and in areas with...
thin skin. The diagnosis is confirmed by finding pathognomonic signs in the form of tunnels in the skin and identification of *Sarcoptes scabiei* mites, eggs or scabies on microscopic examination.\(^1\)

Scabies is also called a great imitator disease. Some of differential diagnosis of scabies include atopic dermatitis, dyshidrotic dermatitis, pyoderma, and prurigo.\(^1\) In atopic dermatitis, the appearance of polymorphic lesions found on face and extensor (infants and children) and flexor areas in adults. Scabies accompanied by atopic dermatitis will give symptoms of itching and skin lesions like papules, pustules or vesicles. Severe pruritus causes patient to scratch the skin excessively, causing erosion and excoriation that facilitating secondary infections like pyoderma.\(^5,6\) In dyshidrotic dermatitis, clinical features are found in the form of papules and vesicles which are mainly found on the lateral fingers.\(^7\) Another complication that can occur in children is crustous impetigo with a clinical picture of multiple vesicles which then break down into crusts (mainly found in the face and extremities).\(^8\)

Some of the therapeutic modalities that can be used in scabies are pyrethroid scabicide drug, namely 5% permethrin cream, 1% gamma hexachlorocyclohexane lotion, 10% crotamiton cream, 5-10% precipitum sulfur, 10% benzyl benzoate lotion and oral ivermectin. These scabiei drugs are neurotoxic to *Sarcoptes scabiei* neurons, causing late repolarization, paralysis and death of adult *Sarcoptes scabiei*.\(^1,9\)

**Materials and Methods**

This research is a retrospective descriptive study with secondary data collection from medical record data in the Outpatient Installation of RSDM in January 2015 until December 2019. The subjects were all infants to children aged 14 years with a diagnosis of scabies. Data variables used were age, gender, family history of scabies, diagnosis, comorbidities, supporting examinations and therapy. The inclusion criteria were children aged 0-14 years, no other skin disorders and no other systemic diseases. The exclusion criteria were patients over 14 years of age, having skin diseases other than scabies and atopic dermatitis.

**Study area and population**

In this research, there were 88 pediatric patients with scabies. The age group that experienced child scabies the most was 11-14 years as many as 29 patients (33%) and most of them is male with 48 patients (55%). The largest source of scabies transmission was from the family in 34 patients (39%), with the most common lesion morphology was papules and excoriations in 43 patients (49%), the lesions location were mostly between the fingers in 21 patients (24%). Skin scrapings using NaCl 0.9% was positive only in 5 patients (6%) with the most common diagnosis being scabies in 68 patients (77%) (Table 1).

Description: CTM: Chlorpeniramine maleate

There were 67 patients who did not return for control (76%). The duration of therapy in most cases was 8-14 days in 11 patients (13%), with improvement in clinical symptoms such as itching and skin lesions in 21 patients (24%), and recurrence was found in 3 patients (3%) (Table 3).

Discussion

Scabies is a parasitic infestation caused by Sarcoptes scabiei on the skin which often affects children. Scabies is a problem in developing countries due to poor hygiene, low socioeconomic conditions, and crowded environment. Dagne et al. reported that scabies commonly affects children aged 11-14 years of 46%, males more often than females. The higher prevalence of 10-14 years old children suffering from scabies is due to the more frequent close contact of children in that age range and most of them do not know how to maintain proper personal hygiene, especially in boys.

Several factors related to scabies transmission include close contact with the sufferer, especially among household members. Paramita et al. reported that the most common source of scabies transmission was through family members (51%). This study is in accordance with Paramita et al. with the most common source of scabies transmission between family members being 39%. Family members have sufficient time together which allows the scabies transmission through direct or indirect contact, such as using clothes, sheets, towels, and family tools together.

The morphology of scabies lesions are papules, pustules, erosions, and excoriations. The distribution of scabies lesions mostly on interdigital area of manus and pedis, volar, wrist, lateral palmar, elbow, axilla, scrotum, penis, glutea, and also in the areola mammae and labia in women. Paramita et al reported that most scabies morphology lesions are papules and pustules (35%) and was most commonly found between fingers (37%). This study reported different results with Paramita et al. that the most common morphology lesions are papules and excoriation by 49% and 24% between the fingers.

Simple investigations to diagnose scabies include skin scrapings taken from unexcoriated papules. Skin scrapings are placed on a slide and then examined under a microscope in dim light. Abdel-latif et al. reported that skin scrapings were positive in 10% of cases. This study reported 6% positive skin scrapings and is in accordance with Abdel-latif et al. Positive results on skin scrapings have low accuracy and are influenced by the low number of mites found due to errors during specimen collection and improper collection time (daytime).

The diagnosis of scabies can be made based on the discovery of 2 out of 4 cardinal symptoms, including nocturnal pruritus, infection attacking humans in groups, found cuniculus, mites, and egg. Paramita et al reported that the diagnosis of scabies was found in 73% of cases. This study reported the results consistent with Paramita et al. which the diagnosis of scabies without secondary infection was found in 77% of cases.

Permethrin cream 5% is the first line recommendation for scabies therapy because high effectiveness with low toxicity risk. Anderson et al. reported that 69% of scabies patients received 5% permethrin therapy. This study is in accordance with Anderson et al., that all pediatric scabies patients (100%) were treated with 5% permethrin cream. Permethrin is a synthetic pyrethroid which works by damaging the cell membrane of mites, disrupting the balance of the sodium channels which results in depolarization and paralysis of the respiratory tract in Sarcoptes scabiei.

Scabies is often accompanied by secondary infestations for example pyoderma which is most commonly caused by gram-positive coccus bacteria. Mupirocin is a broad-spectrum topical antibiotic that’s recommended especially for gram-positive bacterial. Vasani et al. reported that the topical antibiotic used in secondary infestation of scabies was mupirocin by 30%. This study is in accordance with Vasani et al. that the topical antibiotic used in secondary infestation of scabies was mupirocin by 18%. The action mechanism of mupirocin is to interfere with the synthesis of isoleucyl-tRNA synthetase, thereby inhibiting bacterial protein synthesis. Mupirocin has been shown to have excellent activity against Staphylococcus and most Streptococci but less effective against gram-negative bacterial infestations. Mupirocin has good skin penetration, can be absorbed through the circulation and metabolized into an inactive derivative, namely monic acid, and there is rarely a side effect of irritation on the skin.
Systemic therapy for secondary infestations of scabies that can be considered is the first generation cephalosporins (cefadroxil), macrolides (azithromycin) and clindamycin. This study is inconsistent with Mark et al. which reported that the most common systemic antibiotic used in cases of secondary infestation of scabies was cefadroxil by 5%. Cefadroxil is a broad-spectrum beta-lactam ring antibiotic used in both gram-positive and gram-negative bacteria. The beta-lactam ring binds to protein binding protein (PBP) to play a role in inhibiting the activity of cell wall synthesis. Cephalosporins are also thought to play a role in autolysis activation of bacterial cells which causes bacterial cells to become lysis.

Cetirizine is a second generation non-sedative antihistamine which is effective in reducing itching. Paramita et al. reported that the most used antihistamine in scabies was mephidrolin napadisylate at 64%. This study the antihistamine given was cetirizine (97%) which is not in accordance with Paramita et al. Cetirizine is a fast-onset antihistamine and selective antagonist against histamine 1 (H1) receptors on smooth muscle cells, vascular endothelial cells, and gastrointestinal tract. Cetirizine does not cross the blood brain barrier and provides less sedation than first generation sedative antihistamines. Cetirizine reduces pruritus by inhibits histamine production, neutrophil and eosinophil migration. Cetirizine is rapidly absorbed through the gastrointestinal tract and excreted through kidneys.

Scabies patients are advised to return for control within 7-14 days after receiving the first treatment. Paramita et al. reported that 61% did not return for control. This study’s results were consistent with Paramita et al. That 67% of patients did not return for control. It is probably because the patient feels that the disease already recovered or the existance of secondary infections causing patient to go to other medical personnel.

Scabies therapy using 5% permethrin can be repeated 7 days after receiving the first therapy with an average length of treatment for 14 days. Sungkar et al. reported that scabies therapy using 5% permethrin was administered for 21 days in 69 patients (74 %). This study reported results inconsistent with Sungkar et al. which scabies therapy using 5% permethrin was administered for 14 days in 86 patients (97%). Evaluation for 14 days is necessary because the larvae will become adult stage Sarcoptes scabiei within 10-14 days. Permethrin 5% cannot kill Sarcoptes scabiei eggs so that repeated therapy after 7 days is needed to kill Sarcoptes scabiei eggs that have hatched into adult mites.

Improvement of clinical symptoms in the form of reduced itching, skin rash and, the absence of new papules in scabies patients are indicators of successful therapy. Musthaq et al. reported that pruritus and skin rash decreased during the 14-day evaluation were found in 45% of cases. This study reported the results according to Mushtaq et al., that pruritus and skin rashes were reduced in 21 (24%) cases. The correct application of scabicide, for example 5% permethrin, is very important in the success of therapy.

Scabies recurs if the individual still shows clinical manifestations after 6 weeks of initial therapy. Sungkar et al. reported that scabies recurrence was 15.9% of cases. This study is not in accordance with Sungkar et al who reported that scabies recurrence was found in 3% of cases. Symptoms that persist for more than 6 weeks should be re-evaluated because the possibility of treatment failure leading to recurrence in cases of scabies.

**Conclusion**

In conclusion, there were 88 pediatric scabies patients in January 2014-December 2019. The age group experiencing child scabies the most is 11-14 years (33%), more males than females. The most common source of scabies transmission is the family (39%), with the morphology of papules and excoriations (49%), the lesions location was found mostly between fingers (24%). Only 6% positive skin scrapings were diagnosed with scabies in 77% of patients. Topical therapy using permethrin 5% was given to all scabies patients, the
most used topical antibiotic was mupirocin ointment 2% (18%). Systemic therapy was given in the form of antihistamines cetiricine (58%) and cefadroxil (5%).

Abstract

Background: This article aims to discuss and investigate forms of pedagogical knowledge of mathematics instructors and influence of their educational beliefs on their students during Coronavirus disease where progress in learning is typically influenced by self-confidence and anxiety.

Materials and Methods: A study survey was carried out to find out the extent of anxiety and self-efficiency students have before and during mathematics exams in distance learning.

Results: Out of 252 students, 88% are females and 12% are males, majority of students of the second level from different faculties filled the survey. The study reveals student’s responses to the levels of the variables where confident is of ‘always’ attitude with mean 2.3714 (SD=.37764). On the other side, anxiety is of ‘sometimes’ attitude with mean 1.8595(SD=0.4196). Those results are good and indicates that no big problems in mathematics either inside or outside university faced by sample we dealt with, this result refers to the simplicity and good characteristics of instructors of the university. Moreover, lots of programs that help in understanding basics and advanced mathematics.

Conclusion: Successful pedagogies instructors of mathematic used give the best explanation of results we have got in this study especially in distance learning. Detailed study plan that clarifies the course objectives, topics, evaluation method, books and resources must be given to students.

Key words: Mathematics learning, pedagogy, Self-confidence, Anxiety.

Introduction

Pedagogy is a Latin word that means the art, methods, strategies and procedures used in teaching. These methods or procedures include the targets of education which focus on creating an interactive environment between the teachers and their students. The procedures include many aims beside creating an interactive environment, exploring the ways that knowledge and skill grow and training instructors before starting teaching throughout educational programs by social and educational experts. In order to increase the efficiency of learning process, monitor learning and fulfill targets of learning process, experts and novices must collaborate and strike horizons of conversation.

Scientific theoretical frameworks the shape of learning process and instructional decisions, hence pedagogy depends essentially on the scientific theories of learning that are considered as basis of how learning works, theories are behavioral, cognitive and constructivist. Many of those theories imply the roles of both of the learner and teachers. In addition, professional educators are guided by these theories.
Behavioral theories are inadequate, unsupported but no alternative explanation instead them where they are recently having a widespread acceptance. Typically, behavioral education must be done within a reasonable framework rather than within scientific human theories. We must focus on reasonable justification perspectives on individual’s behaviors to enrich our reasoning and thinking of behavioral theories.

Decisions made by teachers are influenced by the strategies they acquired from their experience in teaching where they use many techniques such as activities, assignments, learning groups,…, etc. The importance of pedagogy comes from its ability to deal with events occur during teaching, thus without this terminology, teachers cannot explore, criticize, analyze and investigate the credence about the behavior of students, so the behaviorist pedagogical tactic focuses on teachers, so behaviorism is considered as a traditional teaching model.

It is primarily outcome-based, approaching defined and preordained subject matter and standardized basic skills that adult decision-makers (not learners) want teachers to transfer to learners, employing instructional models that include the use of conditioning through incentives, coercion, manipulation and other more forceful means used to achieve goals that were selected for the learner instead of by or with the learner. The theory of interaction describes learner’s behaviors during the learning process where those behaviors can be imitated or repeated for many purposes. However, behavioral theories have an uneasy relationship with theories of learning. Using pedagogy depends on basic skills, instructional models, conditioning via incentives, coercion, manipulation, ... etc.

Constructive theories are acquired via experiences and thinking where it is based on projects, inquiries and brain storms. Piaget initiated ‘schemas’ based on the fact that learners are ready to learn, whereas teacher construct activities that simplify thoughts and ideas for learners. For learners with little ages, learning must be done through physical activities, however older learners outline symbolic and abstract ideas.

Contradicting constructivism that Piaget put some of its basics, social constructivism pedagogy considers learning as an interactive participatory process between students and teachers like group works, in addition it is considered as a mixture of two priorities: teacher is guiding learning process and student is under his concentration. Typically, interactive activities between teachers and students are vital methods for creating such a common context of experience within the school/university especially when teachers and the students are not of the same background.

For effective pedagogies, clear outcomes must be taken in consideration as necessity either long-term goals or short-term goals where depending lecturer’s knowledge, beliefs, skills and behaviors is a priority.

Lots of learning strategies fit different situations instructors meet while teaching either online or in a class. Such strategies reinforce skills of instructors besides knowledge and behaviors of learners. In addition, they develop higher thinking proficiency, meta-cognition and improve dexterity of dialogue for both of instructors and learners. Embedding variety of ways of assessment helps in understanding what a learner needs exactly, but some instructors lack how to assess in a valid, reliable and efficient way. We carried out a survey on our students to assess what are problems they have in dealing with mathematics. We analyzed results statistically and described it. Next section shows what we got and what are strategies we will take in consideration to come over our student’s problems.

Our survey titled “Self-Confidence and Anxiety of mathematics in distance learning” is designed to measure the range of fear of mathematics especially before exams. The survey includes a sample of 252 students of Applied Science Private University in Amman, Jordan. The students a survey includes are from different faculties and different levels where the levels are first, second, third…and seventh year. Each participant filled an online questionnaire including demographic information, information concerning their
ways to deal with mathematics in and outside university and how they prepare to mathematics exams. [5] For the validity and reliability of the results we have got, inductive and statistical analysis are used. Moreover, we calculated correlation coefficients between many items and determined their type and the strength of them.

2. Sample description

A sample of 252 students of Applied Science Private University were recruited to the study titled “Self-Confidence and Anxiety of mathematics in Coronavirus disease”. Approximately 88% of them are females and the rest are males. We found that 90 students in their second year, that is 35.7% of the sample.

Study of items’ means

The following part of our study reveals student’s responses to the levels of the variables. Here, mean and standard deviation are calculated for each item, then they are ranked in descending order according to mean. Higher mean value indicates more agreement on that item.

A. Confident

<table>
<thead>
<tr>
<th>Rank</th>
<th>Item No.</th>
<th>Item</th>

<td>.60952</td>
<td>always</td>
</tr>
</tbody>
</table>
From table 2, item 3 “I think I can complete all mathematics assignments” and item 4” I think I’m a person who knows mathematics” have the highest mean value of 3(SD=0.000) with ‘always’ attitude.

In the second rank is item 7 “I hope that I know mathematics “ with mean 2.4167 (SD=.60952) with ‘always’ attitude. Item 8 “I feel confident when taking a mathematics test “ has the lowest mean with 1.9841 (SD=.64350) with ‘sometimes’ attitude. In general, confident is of ‘always’ attitude with mean 2.3714 (SD=.37764).

**B. anxiety**

</tbody>
</table>

From table 3, item 1 “I feel nervous when preparing for a math test “ has the highest mean of 2.2262(SD= 0.650) with attitude of ‘sometimes’. In the second rank is item 4 “ I am afraid I will not be able to get good grades in math subjects “ with mean 2.1667(SD=.6827) with attitude of ‘sometimes’. The minimum mean is for item 5 “ I feel nervous when listening to the math lecturer at the lecture “ with only mean 1.000(SD=.0000) with attitude of ‘never’. In general, anxiety is of ‘sometimes’ attitude with mean 1.8595(SD=0.4196).

Correlation analysis

Table (4): Pearson’s correlation coefficients

<table>
<thead>
<tr>
<th></th>
<th>Confident</th>
<th>Anxiety</th>
</tr>
</thead>
<tbody>

<td>1</td>
</tr>
<tr>
<td>Sig. (2-tailed)</td>
<td>0.000</td>
<td></td>
</tr>
</tbody>
</table>

From table 4, the relationship between confidence and anxiety is strongly negative.
3. Tests and Analysis of variance

Are there significant differences in the levels of the study constructs that can be attributed to gender, class? Independent samples t-test will be used to test for gender while, analysis of variance (ANOVA) will be used to test for other personal variables.

Table (5): Mean and standard deviation for males and females

</tbody>
</table>

Actually, from table 6, There are no significant differences between confident and anxiety that can be attributed to gender.

Recommendations

Provide a weekly summary containing a reminder of the assignments and tasks that are supposed to be achieved and delivered during the week, as well as lectures and topics that will be studied during it. Some applications and videos on a websites help students who feel shy or cannot ask freely during mathematics lectures to understand well because of their flexibility, availability and simplicity. Moreover, these application reinforce student’s self-confidence. Lots of cartoon films and games support axioms, theories and facts students learnt and contribute to the stability of information in their memory. Investing time has a vital in raising student’s awareness and responsibility and helps them to realize the need of every hour and minute, you can imagine the storm in his brain thinking what he must do to be better?
Typically, giving an immediate stimulating comment to the student’s performance has a great effect on the student’s self-confidence, provides students reassurance and creates a positive relationship between them and their instructors. [7] Comments might be written by massages, e-mails, audio, or through some applications. Definitely, rapid replies to students’ inquiries and questions makes them feel trusted, not tense and comfortable. If we overcome socially accepted dominant ideas thought “I’m not good at mathematics”, [9] we will enhance a student self-confidence and it will be a great job we ever done. Encourage each student especially those who feel that they can’t do mathematics well to get rid of their fears.

For exams, [8] it is good to persuade student to practice some previous exams at home before their exams. Practicing gives them the ability to prioritize questions from easiest to hard ones, they also get used to the atmosphere of the exams, hence mitigating their fears of exams, pacing and knowing how exam looks like. Connections between ideas, theorems and axioms of mathematics with objects students use in their daily lives easiest thoughts stocking in a mindset, we can use expressions like “All Students Take Calculus” to illustrate in which quadrant a trigonometric function has a positive sign by relating the first letter of each word with a first letter of a trigonometric function. We tried to easiest the irrational number $\pi = 3.1415926$ by letting a student counts words of “May I Have a Great Container of Coffee”. [10] This strategy leads us to emphasis on the importance of embedding games in teaching mathematics, the way that make mathematics fun and engage student’s attention, like using a box filled with letter noodles and asking each student to draw number of those noodles and calculate probabilities of getting a certain letter or number of ways of getting letters of a word a student guess. We may use a die while talking about axioms of probability.

Finally, trying to make distance learning during Coronavirus useful via letting students imagine the world after Coronavirus disappearance and how can this affect their future plans.

Effect of Aqueous and Alcoholic Extract of *Hydrastiscanadensis* Plant on Bacteria Isolated from Otitis Media

Eman Fadal Abbas Al-Lahibi¹, Hadeel MizherYounis Al-Hadeethy²

¹Research Scholar, Biology Department, Faculty of Science, University of Tikrit, Iraq, ²Professor, Basic Science Department, Faculty of Dentistry, University of Tikrit, Iraq

Abstract

The results of the current study showed that the effect of the alcoholic extract of the *Hydrastiscanadensis* plant was more effective than the aqueous extract on the bacteria isolated from otitis media at the same concentrations. As the alcoholic extract had the highest effect on *proteusmirabilis, Staphylococcus epidermidis, Escherichia coli, Pseudomonas aeruginosa* and *Klepsiella pneumoniae* with an inhibition diameter ranging (20, 18, 17, 16, 16, 15) mm respectively at a concentration of 200 mg/ml. The study also showed that the higher the concentration of the extract, the greater the inhibitory activity against the bacterial species, with significant differences in the probability level 0.05 of the two extracts on the bacterial species, except *Pseudomonas aeruginosa, Staphylococcus aureus* there was no significant difference in the effect.

Keywords - *Hydrastiscanadensis, alcoholic extract, aqueous, Bacteria, Otitis media.*

Introduction

Otitis media is one of the main reasons for visiting health centers all over the world, as it causes serious complications, including hearing loss(¹), meningitis and brain abscesses(²), if not treated properly. It is an inflammatory disease that affects the lining of the mucous membrane of the middle ear and the associated incision(³), which is either acute(⁴) or chronic(⁵). The causative agent may be bacterial, viral or fungal(⁶), but more causes of inflammatory middle ear common are infections with bacteria such as *Pseudomonas aeruginosa, Staphylococcus aureus, Prokusspp, Staphylococcus epidermidis, Escherichiacoli, Klepsiella pneumoniae*⁷. The increase in bacterial resistance to antibiotics in recent times has become one of the most serious threats facing the entire world, as some strains have acquired resistance to most antibiotics, which calls for seeking to find new antibacterial agents that cause disease to overcome bacterial resistance(⁸). Medicinal plants with antimicrobial properties are alternatives to the increasing problem of bacterial resistance to antibiotics⁹, including plant *HydrastisCanadensis*, which also known by other names including Goldenseal, Orange root, Yellow puccon, India eye, eye root, Ground raspberry(¹⁰). It is a small perennial herb found in the humid forests of Canada and the eastern United States and belongs to the Ranunculaceae family(¹¹), the effectiveness of alcoholic extract due to the alkaloids such as berberine, canadine, hydrstine, canadline and others, which have anti-bacterial, antifungal, protozoal and tuberculosis effectiveness as well(¹²). The efficacy of alkaloids against bacteria has been proven by many studies, where it was found that they have high inhibitory efficacy against both Gram positive and Gram negative bacteria(¹³). They also play an important role in treating a number of diseases such as asthma, analgesic and anti-cancer conditions(¹⁴). It's

mechanism of action is to inhibit bacterial cell division by interfering with DNA replication, targeting enzymes RNA polymerase, gyrase, topoisomerase IV and stopping bacterial replication\(^{15}\). Berberine has been found to be effective against Vibrio cholera, Staph. aureus, Klebsiellaspp, Shigella, Streptococcus pyogenes\(^{16}\).

**Materials and Methods**

The aqueous extract of the plant in this study were prepared by mixing 40 g of the plant model in 160 ml of sterile distilled water (4:1 weight/volume), then the plant model was placed with the Blander crushing device inside an ice bath, and the plant samples were stirred by the electro-magnetic stirrer for 60 minutes, in order to disintegrate and tear the cell wall of the samples, leave the mixture in the refrigerator for 24 hours for the purpose of soaking, filter the mixture through several layers of gauze, then filter again using a Buchner bowl funnel and using Whatman No.1 filter papers with vacuum. By means of a vacuum, to get rid of (the non-milled parts and the remnants of the fibers), after that the extracts were poured into sterile glass containers and placed in an electric oven at a temperature of 40 °C until all the water evaporated and to preserve the active substances and after drying the extracts, they were placed in airtight glass containers. Close, labeled, and refrigerated until use\(^{17}\). In the same way previously mentioned, the alcohol extract was prepared by adding ethyl alcohol at a concentration of 95% instead of distilled water.

The method of researchers Shinkafi and Dauda 2013 was adopted to test the effectiveness of both the aqueous and alcoholic extract of the Golden Seal against the bacterial species isolated from otitis media (Pseudomonas aeruginosa, Staphylococcus aureus, Staphylococcus epidermidis, Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis) after being diagnosed with biochemical tests and confirming the diagnosis with the VITEK2 system device. The plates containing Muller Hinton agar medium were prepared for the purpose of implanting a bacterial suspension on them after comparing them with a McFarland tube. The disc diffusion method was used in which disks of Whatman No.1 filter paper with a diameter of 6 mm were prepared and then sterilized with oven at 160 °C for two full hours. Then the tablets were saturated with concentrations (200, 100, 50, 25, 12.5, 6.25 mg/ml) aiming to test their effectiveness against bacterial isolates, and using sterile forceps, they were placed on the surface of the medium and then incubated at 37 °C for 24 hours to observe the effectiveness or not, and measure the inhibition diameters in mm compared to chloramphenicol antibiotics as positive control\(^{18}\).

**Results**

The results of the current study showed, that the effect of alcoholic extract of goldenseal plant was higher than that of aqueous extract as showed in table (1), the effect of the alcoholic extract had the largest effect on P. mirabilis with an inhibition diameter of 20 mm. The least effect was on bacteria. pneumonia, where the inhibition diameter was 15 mm, while the effect of the aqueous extract was almost non-existent at the same concentration of 200 mg/ml where the maximum effect of the aqueous extract was on isolates with an inhibition diameter of 7 mm for each of P. aeruginosa, Staphylococcus epidermis, k. pneumonia, in which there are statistically significant differences, at a probability level of 0.05.
Table (1): The inhibition diameters of both the alcoholic and aqueous extract of the *Hydrastis Canadensis* on bacteria isolated from otitis media.

**Discussion**

The study showed that the extract of the golden seal plant had inhibitory activity against the isolated bacterial species of otitis media, especially the alcoholic extract, which was more effective than its aqueous counterpart. This is due to the solubility of the active substances in alcohol more than water, and as the study showed that the lower the concentration of the extract, the less inhibitory activity against bacteria. Udvardy and his colleagues (2015), found that the medicinal effect of golden seal plant is mainly due to the alkaloids such as berberine - hydrastine - which are present mainly in the roots and other alkaloids. In another study, it was found that the extracts of this plant were effective against germs that cause periodontitis. Junio and his colleagues (2011) also found that extracts dissolved with ethanolic alcohol from the aerial parts of the plant and roots have efficacy against *Staph. aureus* by influencing flow inhibition of ethidium bromide. The aqueous and alcoholic extracts of herbs plants, especially the golden seal, are composed of complex active ingredients with bioactivity that can limit the increase in bacterial species gaining resistance. The mechanism by which bacteria are targeted by using plant extracts in general has not yet been clarified, but there is proposed mechanisms include influencing the genetic synthesis of the bacterial cell, especially DNA and RNA, disrupting the biological membranes of the microorganism, interfering with the nutritional pathways of the microorganism, stimulating clotting of cytoplasmic contents and influencing the phenomenon of quorum sensing (QS) which means cutting off the normal cellular communication of germs.
Conclusions

Golden seal (Hydrastis Canadensis) plant extract has inhibitory efficacy against bacteria isolated from otitis media and can be considered as antibacterial agents.

The Construction of Legal Protection For Aesthetic Patients

Endang Sri Sarastri
Faculty of Law, University of 17 Agustus 1945 Semarang, Indonesia

Abstract

Plastic surgery, primarily aesthetic plastic surgery, is increasingly becoming one of the beauty procedures that is increasingly considered commonplace to be carried out by people in various countries in the world. When viewed from the sociological aspect of this aesthetic operation, it is solely aimed at improving the quality of life and utilizing science and technology, both of which, when linked from a legal perspective in Indonesia, is in line with the formulation contained in Article 28 C paragraph (1) of The 1945 Constitution of the Republic of Indonesia as the state constitution of Indonesia. However, this aesthetic plastic surgery encountered various obstacles; this can be proven from the problems that occurred with Mrs. P and Dr. W, where this case is related to the actions of Doctor W, who performed reconstructive and aesthetic surgery on Mrs. P’s nose. For this case, Dr. W was threatened with unlawful acts for the medical actions he took. Therefore, this article will analyze the legal construction in Indonesia that regulates legal protection for plastic surgery patients. This article aims to find out and analyze how legal construction in Indonesia regulates aesthetic plastic surgery. This is indicated to provide an understanding and test whether the medical action of aesthetic plastic surgery can be said to be part of the scope of regulation regarding consumer protection which is accommodated in Law No. 8 of 1999 or not. This research uses normative legal research methods. That is research conducted by examining library materials. The data used is secondary data, which includes primary legal materials in statutory regulations, then also uses secondary legal materials that explain primary legal custody. Construction of Legal Protection for Aesthetic Plastic Surgery consists of laws and regulations relating to the health/medical field that apply in Indonesia and the laws that apply in Indonesia, namely Law no. 29 of 2004 concerning Medical Practice, Law No. 36 of 2009 concerning Health, Law Number 44 of 2009 concerning Hospitals, Law Number 36 of 2014 concerning Health Workers, and the Civil Code: Article 1313; 1319; 1320; 1330; 1333; 1337; 1338 and 1454, so that the provisions governing consumer protection are not included in the scope for medical treatment.

Kata Kunci: Construction, Legal protection, Aesthetic Patients

Introduction

Aesthetic plastic surgery is increasingly becoming one of the beauty procedures that is increasingly considered to be commonly carried out by people in various countries globally, including Indonesia. Such a statement is based on the fact that social media in Indonesia has recently reported many appearance enhancements carried out using aesthetic plastic surgery. The term plastic surgery in medicine is called “aesthetic plastic surgery” because, in the medical world, the field is included in the specialist in reconstructive and aesthetic plastic surgery. A doctor carries out aesthetic plastic surgery with particular expertise in Reconstructive Plastic Surgery Specialist and Aesthetics, commonly abbreviated as dr.SpBP-RE. In recent times, many social media have reported improving appearance using plastic surgery. Indeed, plastic surgery is increasingly becoming one of the most common cosmetic procedures to be performed. Actually, what is meant by social media in the medical world, is called “aesthetic plastic surgery” because, in the medical world, this field is included in the specialty of reconstructive and aesthetic plastic surgery. The doctor who performs the medical procedure is called the Reconstructive and Aesthetic Surgeon, abbreviated as dr.SpBP-RE.
The tendency to be beautiful is the natural desire of every woman. However, according to Hamid Reza Salehi, the significant doubts regarding the legality of aesthetic plastic surgery have been removed by considering the purpose of the medical procedure of this type of surgery and also contemporary theories in the authorization of surgery which aims to improve one’s appearance so that aesthetic plastic surgery is now legal under the law. However, the law in Islamic countries does not agree with this.

In Indonesia, from the sociological aspect, aesthetic operations to improve the quality of life and utilize science and technology are under Article 28 C paragraph (1) of the 1945 Constitution of the Republic of Indonesia based on Pancasila. Then from a philosophical point of view, the decision to perform aesthetic plastic surgery is a human right following Article 13 of the Republic of Indonesia Law No. 39 of 1999, based on considering how physical and psychological suffering that has been carried so far, it is regarded as the best treatment is aesthetic plastic surgery because it can increase self-confidence.

From the patient’s side, they assume that they are service consumers, so they want Laws of the Republic Indonesia no. 8 of 1999 concerning Consumer Protection, also applies to consumers of health services. So that they have the right to comfort, security and safety, this is reinforced by the issuance of the Decree of the Minister of Health of the Republic of Indonesia No: 756/Menkes/SK/VI/2004 concerning Preparations for Trade Liberalization and Services in the field of Health. However, medical procedures for aesthetic plastic surgery include surgery using invasive “anesthesia” where a person’s condition is “unpredictable,” while the Protection Act applies to goods and services. What is meant by goods here are inanimate objects or non-humans, and what is meant by services are services whose results can be predicted/predicted, while a person’s condition cannot be predicted.

Aesthetic plastic surgery was initially a taboo subject to be carried out, primarily if it was related to religious issues and also the legality of its implementation. But over time, many women tend to be beautiful (something that is a natural desire of every woman), especially if a woman who has problems on her face, such as burns, will need aesthetic plastic surgery to overcome these problems. So, Hamid Reza Salehi stated that the legality of implementing aesthetic plastic surgery in Indonesia has now undergone developments that have implications for aesthetic plastic surgery, which is now legal according to Indonesia’s legal construction in force.

In Indonesia, aesthetic plastic surgery, viewed from a sociological perspective, can be said to be a series of efforts to improve the community’s quality of life and utilize science and technology. The development of the quality of life and the use of information technology has a constitutional basis in Article 28 C paragraph (1) of the 1945 Constitution of the Republic of Indonesia which states, “Everyone has the right to develop themselves through the fulfillment of their basic needs, the right to education, and to benefit from science and technology, arts and culture to improve the quality of their lives and for the welfare of mankind.”

The implementation of aesthetic plastic surgery in practice does not always go according to the desired expectations. In practice, there are many cases of failure of aesthetic plastic surgery caused by several factors, which can be proven from the problems that occurred Mrs. P and dr. W in Bandung. This case is related to the actions of doctor W, who performed reconstructive and aesthetic surgery on Mrs. P’s nose. Although, for this case, dr. W was threatened with unlawful acts for the medical actions he took, fortunately in this case, and peace was carried out.

Based on the case above, the patients always assume that they are consumers of services, so they want the Law of the Republic of Indonesia no. 8 of 1999 concerning Consumer Protection and applies to consumers of health services. So that they have the right to comfort, security and safety, this is reinforced by the issuance of the Decree of the Minister of Health of the
Republic of Indonesia No: 756/Menkes/SK/VI/2004 concerning Preparations for Trade Liberalization and Services in the field of Health. However, medical procedures for aesthetic plastic surgery include surgery using invasive “anesthesia” where a person’s condition is “unpredictable,” while the Protection Act applies to goods and services. What is meant by goods here are inanimate objects or non-humans, and what is meant by services are services whose results can be predicted, while a person’s condition cannot be predicted.

Based on the problems that arise related to the implementation of aesthetic plastic surgery, the writing in this article will try to discuss and analyze the legal basis for the performance of aesthetic plastic surgery, especially the legality of the law regarding the protection of patients for all actions and practices of this aesthetic plastic surgery.

**Research Method**

This research uses normative legal research methods. That is research conducted by examining library materials. The data used is secondary data, which includes primary legal materials in the form of statutory regulations. Also, it uses secondary legal materials that explain primary legal prisoners, for example, research results and works from legal circles, as well as tertiary legal materials in the form of language dictionaries and legal dictionaries. Data collection is carried out using a literature study, namely collecting, reviewing, processing literature, legislation and articles, journals, and scientific works to support the theory. The data obtained were described, then analyzed qualitatively, namely by studying, analyzing, and interpreting the collected data. The results are described in the form of sentences.

**Observation and Results**

According to the author, in this case, what is meant by construction is an arrangement consisting of several elements into a single unit, which is the main force that can be used to build a particular thing. Thus the Construction of Legal Protection for Aesthetic Plastic Surgery Patients in this study consists of several legal elements, which are the main forces used to build legal protection for aesthetic plastic surgery patients. So that in this study, several aspects of legal protection are combined into a single unit to create a guideline that provides legal protection for aesthetic plastic surgery patients.

People, especially patients, are now increasingly aware of their rights and obligations as patients in health services. Often critically question the disease, examination, treatment, and medical action that will be carried out. Often they even seek a second opinion. In this case, the patient must be seen as a subject that significantly influences the final service outcome, not just an object. Patient rights must be fulfilled considering that patient satisfaction is one of the barometers of service quality, while patient dissatisfaction can be the basis of lawsuits.

According to the author, service quality assurance should be prioritized along with the development of medical technology and the patient’s way of thinking, especially aesthetic plastic surgery patients who demand results from a medical action. However, it must be realized that in the provision of services, health services have differences with other services, namely the existence of patient ignorance or patient ignorance, so that special skills are needed in handling medical actions. Then there is the supplier-induced demand. In this case, the aesthetic plastic surgery patient does not know what medical action is being taken and how to deal with it if things are not desirable so that the patient does not have bargaining power and choice. In addition, health care products are not a homogeneous concept, limitations on competence, uncertainty about illness due to the different conditions of each patient, and healthy conditions are human rights.

In this case, providers are dominant in meeting the needs of patients as recipients of health services. So, if the provider recommends health services or medical actions and the types of drugs to be consumed, for example: what kinds of medical activities taken and
what medications and how many doses to take and others, usually the patient will follow suit.

Thus, the Construction of Legal Protection for Aesthetic Plastic Surgery Patients, especially in Indonesia, consists of several pillars of legislation as guidelines for providing legal protection. The laws and regulations are:

1. **Civil Code.**

The term therapeutic agreement is not known in the Civil Code. Still, the elements in a therapeutic agreement can be categorized as an agreement as mentioned in Article 1313. An agreement is that one person binds himself to one or more other people. At the same time, Article 1319 of the Civil Code reads all agreements, both those that have a particular name, or those that are not known by a specific name, are subject to general rules regarding engagements in general.[17] In addition, in general, provisions regarding arrangements based on the principle of freedom of contract as regulated in Article 1338. This principle relates to the agreement’s content, namely the freedom to determine what is to be agreed upon and with whom the agreement will be carried out legally by the parties is a rule for those who make it.[18]

A valid agreement is an agreement that fulfills the conditions determined by law. According to Article 1320 of the Civil Code, if it is associated with aesthetic plastic surgery patients, the requirements for a valid agreement are:

a. In this case, there is an agreement (consensus) or will between the parties who agree, in this case, between the patient and dr. SpBP-RE. The agreement in question is an agreement between the patient and dr. SpBP-RE regarding the subject of the agreement.

b. The existence of the ability between the parties (capacity) to agree. People who carry out legal actions are adults, namely 21 (twenty-one) years old or before 21 (twenty-one) years of marriage. As stated in Article 1330 of the Civil Code, people who are incapable of making agreements are people who are not yet adults, people under guardianship, women who have husbands. They must be represented when carrying out legal actions. Most plastic surgery patients are more than 21 (twenty-one) years old because plastic surgery is usually done to increase self-confidence. Therefore it is generally done by people who have worked a lot who socialize with the community. If they have not reached the age of 21 (twenty-one) years, there must be a representative, while if a married woman and her husband are still present, it must be with the husband’s approval, meanwhile for dr. SpBP-RE is clearly more than 21 (twenty-one) years old. It is because to study to become dr. SpBP-RE takes a long time. Children start attending elementary school. Usually, they are more than 6 (six) years old, then the travel time from elementary school to dr. SpBP-RE takes 21 (twenty-one) years or more. Therefore for dr. SpBP-RE is of sufficient age.

c. The existence of a particular thing (object), which is the subject of the agreement, the object of the agreement, and the achievements must be fulfilled. An elucidation in Article 1333 of the Civil Code, what is meant by a particular thing is that the object of the agreement must be specific. Clarity of the principal agreement or entity of the agreement to enable the implementation of rights and obligations. In this case, it is aesthetic plastic surgery, not reconstructive surgery or other surgery. In this aesthetic plastic surgery, because it involves results, it includes the *resultaat verbintennis*. However, because this requires surgery using anesthesia, which is an invasive medical procedure, where the condition of different people/patients cannot be predicted, the agreement also includes *inspanning verbintennis*. [19]

d. The existence of a legal cause (causa) is the agreement’s content that describes the goals to be achieved by the parties agreeing, whether prohibited by law or not, contrary to public order and morality or not following the sound of Article 1337 of the Civil Code. For aesthetic plastic surgery, does it have a purpose as included in the prohibition stated in Article 69 paragraph (2) of the Republic of Indonesia Law Number 36 of 2009, concerning Health, which reads: reconstructive plastic
surgery must not conflict with the norms prevailing in society and not intended to change identity. Changing identity is prohibited because there is a possibility to commit a crime after it.

The first and second conditions are Article 1320 of the Civil Code, personal requirements regarding the subject of the agreement. If the agreement is not fulfilled, it can be cancelled. But if the judge does not ask for cancellation, this agreement remains binding even though it is threatened with the cancellation article, namely Article 1454 of the Civil Code. The third and fourth conditions of Article 1320 of the Civil Code are objective conditions, namely regarding the object of the agreement. If these conditions are not met, the agreement is void, that is, if one of the parties does not fulfill its obligations.[20]

In this study, in patients with aesthetic plastic surgery, the first requirement is the agreement or will of the parties, namely between the patient and dr. SpBP-RE. Initially, patients with aesthetic plastic surgery came to dr. SpBP-RE to ask for help in fulfilling their wishes, namely in the form of aesthetic plastic surgery, for example, “sharp nose (rhinoplasty).” Then dr. SpBP-RE conducts examinations and interviews, where the patient expresses her/his wishes or desires. Next dr. SpBP-RE explains everything related to the medical action carried out, from preparation, treatment during surgery and after surgery. Legally dr. SpBP-RE guarantees the patient’s authority. This is reflected in the talks/interviews and the approval that aesthetic plastic surgery patients will give. Aesthetic plastic surgery patients usually have no medical indications, so the patient concerned can think clearly. If you agree, then between dr. SpBP-RE and the patient agree to agree that the contents follow the parties’ wishes. Thus this has fulfilled the legal requirements of the agreement Article 1320 of the Civil Code.[21]

Furthermore, for the second condition, the therapeutic agreement has an exceptional nature, so that not all provisions of the Civil Code can be applied. Under Article 1 point (7), the Minister of Health of the Republic of Indonesia Number: 290/MENKES/PER/III/2008, concerning Approval of Medical Actions, it is explained that the patient concerned is an adult patient or not a child or had been married, is not physically disturbed, can communicate naturally, does not experience mental retardation and does not suffer from mental illness, can make independent decisions independently. Who came to dr. SpBP-RE is a competent patient. If the patient is not qualified, then dr. The SpBP-RE can refuse because the aesthetic plastic surgery patient described was a healthy patient with no medical indications, so that medical action could be postponed. According to Bayu Wijanarko, to anticipate this, unwritten legal provisions can be used, namely customary law, which states that someone is considered an adult if he/she is already working.

Based on the therapeutic agreement described above, the basis for medical liability is the default (Article 1234 of the Civil Code) and onrechtmatige daad as stated in Article 1365 of the Civil Code. There is a difference between the notion of default (broken promise) and onrechtmatige daad (acts against the law).

The definition of default in this study is dr. SpBP-RE did not carry out its obligations, not because of overmacht conditions. Dr.SpBP-RE who deviates in the form of breaking a promise or breach of commitment on the therapeutic agreement he made, will be subject to rules or must be held civilly responsible according to Article 1239 of the Civil Code, which essentially reads: Each engagement to do something, or not to do something, if the debtor does not fulfill his obligations, gets a settlement in the responsibility by providing costs, losses and interest. Aesthetic plastic surgery patients who feel aggrieved because they think dr. SpBP-RE does not perform its contractual obligations. It can file a claim on the grounds of default and demands material and immaterial compensation for the losses it suffers. It’s different when dr. SpBP-RE resulted in harm to the patient. It turned out to be an unlawful act as regulated in Articles 1370 and 1371 of the Civil Code, then dr.SpBP-RE is responsible for repaying the patient even though there is no contractual relationship.
According to civil law, a person can be considered to be in default if he does not do what he can do.

a) Too late to do what was promised to be done.

b) Carry out what was promised, but not as expected.

c) Do something that, according to the agreement, should not be done.

Meanwhile, the elements that can be used as the basis for filing a lawsuit against the law are as follows:

a) there is an unlawful act

b) there is a loss

c) there is a causal relationship between illegal actions and losses

d) there is an error

In the world of medicine, a doctor can be declared to have made a mistake and must pay compensation if there is a close relationship between the losses caused by the errors made by the doctor. In determining a doctor’s error, it must refer to professional standards. So that in the implementation of medical practice, acts against the law can be identified with the actions of doctors that are contrary to or not following professional standards that apply to professional development in the field of medicine.

Following Article 1 point (1) of this Law, what is meant by Medical Practice is a series of activities carried out by doctors and dentists for patients in carrying out health efforts. Then in Article 3, it is stated that the regulation of medical practice aims to provide protection to patients, maintain and improve the quality of medical services provided by doctors, also provide legal certainty to both doctors, patients, and the public. In this article, the purpose of the regulation of medical practice is apparent.

In receiving health services during the implementation of medical practice, the following articles relating to patient protection are:

a) Article 44 states that doctors and dentists carrying out medical practice must comply with medical and dental service standards.

b) Article 45 states that every medical or dental action performed by a doctor or dentist on a patient must obtain approval. The approval is given after the patient has received a complete explanation regarding matters such as the diagnosis and procedure for medical action, the purpose of the medical action taken, alternative actions. Risks and complications that may occur as well as the prognosis of the action taken. In addition, article 45 also states that consent can be given orally or in writing. Any high-risk activity must be approved in writing. As explained above, what is meant by high risk is surgery related to anesthesia because the patient’s physical condition is different and unpredictable. A Ministerial Regulation regulates provisions regarding the procedure for the approval of such medical/dental procedures.

Furthermore, according to Article 45 of the Republic of Indonesia Law Number 29 of 2004, concerning Medical Practice, Minister of Health Regulation Number 290/MenKes/Per/III/2008 and the 2008 KKI Medical Action Approval Manual, Informed Consent is approval for medical action given by the patient or the family after receiving a complete explanation of the medical action to be carried out. Meanwhile, other laws and regulations that are in line with informed consent are Article 37 of the Law of the Republic of Indonesia Number 44 of 2009, concerning Hospitals, which reads:

(1). Every medical action carried out in a hospital must obtain the consent of the patient or his family.

(2). The provisions regarding the approval of the medical action are carried out following the requirements of the legislation.

So basically, informed consent [22] explains until
the patient understands the medical action and the medical risks carried out on him. Informed Consent is more emphasized on the obligation to provide correct information. A new agreement is valid if it has been signed and agreed upon by both parties. The agreement can be cancelled if the information provided is incorrect.

Terms of valid informed consent:

2. Patient competence in giving consent.
3. Voluntary, and there is no element of compulsion.
4. The doctor explains in a language that is easy for the patient to understand.
5. The patient understands what the doctor is explaining.

Several rules must be considered in the preparation and provision of informed consent so that the law of this engagement is not legally flawed, including:

1. Not beguiling (fraud)
2. Not trying to force (force)
3. Do not create fear (fear)

From criminal law, absolute informed consent must be fulfilled not to be included in Article 351 of the Criminal Code concerning persecution. An invasive action (e.g., surgery, radiology) carried out by a medical service provider without permission from the patient. The medical service provider can be prosecuted for committing a criminal act of persecution. In Article 52, patients in receiving services in medical practice have the following rights:

- get a complete explanation of the medical action that will be carried out. In terms of aesthetic plastic surgery, the relation in this research is to explain the advantages and risks that arise as a result of the operation.
- ask another doctor’s opinion, in this case, regarding the surgery to be performed.
- get services according to medical needs, in this case. There is a possibility that the doctor will order other medical actions, which have absolutely nothing to do with the surgery to be performed by the patient, for example, rhinoplasty, the patient is asked for an x-ray, even though this is not something to do with rhinoplasty.
- refuse medical action, since aesthetic plastic surgery is performed on patients who usually do not have medical indications, then if there are things that are considered unsuitable for both the patient and dr. SpBP-RE, then one or both parties can refuse.
- get medical records, which is vital for further medical action if things are not desirable.

In Article 53, patients in receiving services in medical practice have obligations, among others:

- provide complete and honest information about their health problems. In this study, aesthetic plastic surgery patients came to dr.SpBP-RE to change specific body organs according to her wishes. What is expressed is that the desire is not the disease. However, the patient must inform the condition she has suffered (comorbid) so that medical action can be carried out with extra care.
- comply with applicable regulations in health care facilities. In this case, the patient must comply with the rules that apply in health care facilities or hospitals, namely during their stay in the hospital, both before and during post-operative care.
- comply with the doctor’s advice and instructions. These instructions are given by dr.SpBP-RE both before surgery, during surgery (if using local anesthetic), and after surgery or post-surgery. Especially in this study, according to the authors, are post-operatively, where the patient is not under intensive supervision by dr. SpBP-RE, because the patient has been discharged from the health care facility (hospital) where the aesthetic plastic surgery was performed.
- provide compensation for services received. In this case, both dr.SpBP-RE services and hospitalization costs as long as the patient stays at the health care facility where the person concerned is being treated.

This Law, apart from regulating the rights and obligations of patients, also protects users of doctor or dentist services to complain about losses due to negligence or errors on doctors or dentists in carrying out their profession to the Chairperson of the Indonesian Medical Disciplinary Board. This is regulated in Chapter VII, Article 66 number (1).

In this Law, some provisions protect patients. The article is Article 56:

(1). the patient has the right to refuse the doctor’s action after receiving and understanding the complete explanation of the information.

(2). this right does not apply if the patient suffers from an infectious disease, the patient is unconscious, or the patient is suffering from.

The Law of the Republic of Indonesia regarding Hospitals can be related to patient protection, namely in the following articles:

I. Article 29

Number (1) reads that every hospital has an obligation to:

a. provide correct information about hospital services to the community.

b. provide safe, quality, anti-discriminatory, and effective health services by prioritizing the interests of patients following hospital service standards.

c. provide emergency services to patients according to their service capabilities.

d. provide facilities and services for the poor and underprivileged.

e. carry out social functions, including service facilities for indigent patients, emergency services without asking for a down payment, free ambulances, social services in humanitarian missions.

f. maintain service quality standards in serving patients.

g. maintain medical records.

h. provide accurate, clear, honest information about the rights and obligations of patients.

i. respect and protect patient rights.

II. Article 32

Every patient has the right to:

a. obtain information about hospital rules and regulations.

b. obtain information on the patient’s rights and obligations.

c. obtain humane, fair, honest services without discrimination.

d. obtain quality health services following professional standards and standard operating procedures.

e. obtain effective and efficient services to avoid physical and material losses.

f. complain about the quality of service received.

g. choose a doctor and treatment class according to the wishes and hospital regulations.

h. ask for consultation with other doctors, both inside and outside the hospital.

i. get privacy about the confidentiality of his illness.

j. get complete information related to his health
Articles related to patient protection are:

I. Article 68:

This law relates to patient protection. It reads as follows:

(1). Every individual health service activity carried out by a health worker must obtain approval.

(2). The consent is given after getting a proper and sufficient explanation.

(3). The description shall at least include:
   a. service action procedures
   b. the purpose of the service action performed
   c. the alternative course of action
   d. possible risks and complications
   e. the prognosis for the action taken

(4). The consent is given orally or in writing.

(5). Every action of a health worker that contains a high risk must be provided with a written agreement signed by the person who has the right to consent.

(6). A Ministerial Regulation regulates the provisions of this procedure.

II. Article 77:

Every Health Service Recipient who is harmed due to the error or negligence of a Health Worker can request compensation following the provisions of the legislation. Legal protection for Health Service Recipients or other Patients in this Law is as stated in the criminal conditions on:

I. Article 84:

(1). Health workers who commit gross negligence resulting in serious injury to the Health Service Recipient shall be punished with imprisonment for a maximum of 3 (three) years.

(2). If his negligence causes death, the sentence is a
maximum of 5 (five) years.

II. Article 85:

(1). Health workers who practice not having a Registration Certificate are fined a maximum of one hundred million rupiahs.

(2). Foreign Health Workers without a Temporary Registration Certificate fined a maximum of one hundred million rupiahs.

III. Article 86:

(1). Health workers who do not have a Practice License are fined a maximum of one hundred million rupiahs.

(2). Foreign Health Workers without a Temporary Practice License are fined a maximum of one hundred million rupiahs.

The two objectives in this Law are:

1. Empower consumers in their relationship with business owners (public/private), goods, and services.

2. Develop an honest and responsible attitude of business owners.

Some parties argue that this Law is also a provision that regulates patient protection. They consider that the basis of the condition in Article 1 number (2) states: every person who uses goods and/or services available in the community, both for the benefit of themselves, their families, other people, and living creatures. The final consumer is the final consumer in the form of goods, such as medicines, food, tools, or other objects, including services provided by people, such as building construction services, Environmental Impact Analysis making services, doctor/dentist, insurance services, etc. From this understanding, patients can be categorized as consumers. It can be seen that patients are included as users of services available in the community.

In a therapeutic transaction, the engagement is *inspanning verbintenis*, meaning that it is not based on the result but is based on earnest effort. In this case, the doctor or hospital is not required to provide the patient’s desired outcome because, for the patient’s recovery, many things are influential and are factors beyond the reach of the doctor’s ability, namely: the patient’s physical condition, age, body resistance, drug quality, level of illness, patient compliance, health care facilities.

Furthermore, according to Article 1, number (3) of the Consumer Protection Act, a business actor is any individual or business entity, whether in the form of a legal entity or not a legal entity established and domiciled or conducting activities within the jurisdiction of the Republic of Indonesia that conducting business activities in various economic fields. Thus, doctors/health workers include business actors in the area of health services.

Several parties are still debating this explanation. To find out whether the profession of a doctor or health worker or health service facility is a business owner or not, several provisions of the applicable laws and regulations must be considered. Those provisions are:

“Health Worker” is any person who devotes himself to the health sector and has the knowledge and/or skills through education in the health sector which for certain types requires the authority to carry out health efforts.

“Patient” is any person who consults on his health problem to obtain the necessary health services, either directly or indirectly, from a doctor or dentist.

c. Law of the Republic of Indonesia Number 36 of 2014, concerning Health Worker.

States that a “Health Worker” is any person who devotes himself to the health sector and has the
knowledge and/or skills through education in the health sector, which for certain types requires the authority to carry out health efforts, and “Health Service Recipients” are anyone who conducts health consultations to obtain the necessary health services, either directly or indirectly, to health workers.

d. Law of the Republic of Indonesia Number 44 of 2009, concerning Hospital.

States that a “Hospital” is a health service institution that provides complete individual health services that provide outpatient, inpatient, and emergency services. Meanwhile, a “patient” is any person who consults on his health problems to obtain the necessary health services, either directly or indirectly, at the hospital.

The rights and obligations of health service providers for doctors/health workers/hospitals according to the Law of the Republic of Indonesia Number 36 of 2009, regarding health as explained earlier that their right is to obtain legal protection in carrying out their duties following their profession. At the same time, the obligation is to comply with professional standards and respect patients’ rights. Then for patients, their rights are: receive clear information, give consent, medical secrets, ask for opinions from other doctors, while their obligations are: following information and procedures instructions, having good intentions, paying agreed fees, and complying with applicable provisions in health care facilities.

Thus, in this study, the relationship between dr. SpBP-RE with Aesthetic Plastic Surgery Patients based on trust because it was the patient who came to dr. SpBP-RE, so that there is a therapeutic agreement that requires a result (resultaat verbintennis), but due to patient endurance (age, physical condition, level of medical action taken, patient compliance, quality of drugs, and available health care facilities), it is difficult to predict, doctors can only try to achieve the maximum possible results (inspanning verbintennis). Then, the relationship between Hospitals or Health Service Facilities with Aesthetic Plastic Surgery Patients follows the treatment agreement; namely, the Hospital provides treatment rooms, nurses, and dr.SpBP-RE personnel for medical action.

Furthermore, the relationship between dr. SpBP-RE with the Hospital is in providing health services. Hospitals need dr. SpBP-RE as its medical personnel, so that the Hospital is civilly responsible for all activities carried out by its health workers. This is under Article 1367 of the Civil Code, namely “That employers and those who appoint other people for their affairs are responsible for losses issued by their servants or subordinates in carrying out the work for which these people are used.” Therefore, if the patient is not satisfied because of what happened at the hospital, the patient can sue and sue and hold the hospital accountable, then the hospital chief will determine who is at fault.

e. Law of the Republic of Indonesia Number 8 of 1999 concerning Consumer Protection.

As has been explained above regarding what is called a consumer and what is called a business owner, according to the WTO (World Trade Organization) or GATS (General Agreement on Trade Services), the professions of doctors and dentists are as follows:

* Health Sector:
  - Hospital Services
  - Other Human Health Services
  - Other

* Business Services Sector:
  - Professional Services
  - Medical and Dental Services
  - Physiotherapist
  - Nurse and Midwife

The Black Law Dictionary also states that: Business (business activities in various economic fields) includes employment occupation, profession, or commercial activity engaged in/or gain or livelihood (all activities to
earn profit/livelihood).

In addition, the Decree of the Minister of Health of the Republic of Indonesia Number: 756/MENKES/SK/VI/2004 concerning Preparations for the Liberalization of Trade and Services in the Health Sector is a business. So that the position of health service providers and consumers of health services is the same: they both have rights and obligations.

Several parties, namely, have debated the things mentioned above:

1. Parties argue that the patient’s position is as a “customer of health services.” In contrast, doctors/health workers/health service facilities (hospitals) are “business actors in the field of health services,” as described above.

2. Parties who argue that the therapeutic relationship/agreement is an engagement relationship of a unique nature so that in the event of a dispute between the “provider/provider” of health services and the “recipient” of health services, each party is subject to the legal provisions governing it. Especially in the research, according to the author’s opinion, because this medical procedure has “targeted results” as stated before, the agreement includes resulataat verbintennis, while since everyone’s endurance is different, dr.SpBP-RE strives for the maximum possible results, where the agreement consists of inspanning verbintennis. Therefore, this engagement is subject to both, namely inspanning & resulataat verbintenis.

Apart from these differences of opinion, the author believes a conflict or dispute between dr. SpBP-RE/health service providers with their patients, conflict resolution, can be done in 2 (two) ways, namely: litigation method (through the judicial process) and non-litigation method (out of court). To file this lawsuit, the plaintiff must be able to prove 4 (four) criteria, namely:

- there is a duty of care, where the doctor, in this case, dr. SpBP-RE is obliged to provide the best possible care to patients as a medical contract. Dr. SpBP-RE promises to try to take the best possible medical action for the patient. Then the patient will comply with the instructions and treatment given by dr. SpBP-RE as well as possible.

- there is a breach of duty, where dr. SpBP-RE does not perform its proper obligations, while the form of the violation is an error/error in medical action such as misdiagnosis, interpretation of supporting examination results, medication errors. Meanwhile, a violation in the form of negligence is not doing things that should be done according to good medical practice standards.

- There is an injury to the patient in the form of physical, mental, to the heaviest, death.

- there is a direct causal relationship between the occurrence of violations in the form of errors/errors/omissions with physical disabilities suffered by the patient, even to death.

According to the author, since aesthetic plastic surgery patients are “healthy” or not sick patients, this medical action does not have to be done immediately. So to realize the medical activity, both parties need to think again. Dr.SpBP-RE must explain all the risks and complications that may occur, while if the patient disagrees, the operation can be cancelled.

**Conclusion**

Construction of Legal Protection for Aesthetic Plastic Surgery consists of laws and regulations relating to the health/medical field that apply in Indonesia and the laws that apply in Indonesia, namely:

1. Law Number 29 of 2004, concerning Medical Practice.

2. Law Number 36 of 2009, concerning Health.

3. Law Number 44 of 2009, concerning Hospital.

4. Law Number 36 of 2014, concerning Health Worker.

5. Civil Code: Article 1313; 1319; 1320; 1330; 1333; 1337; 1338; and 1454
To avoid things that are not desirable, make a special agreement that is complete and clear in detail, including mentioning the risks and complications that may occur. So that if one or both parties do not agree, it can be cancelled.

**Ethical Clearance : Not applicable**

**Source of Funding : Self**

**Conflict of Interest : Nil**

Prevalence and Determinants of Hypertension in Indonesia

Eny Dwimawati¹, Fitri Dian Nila Sari², Evamona Sinuraya³, Purwaningsih³

¹Researcher, Faculty of Health Sciences, Universitas Ibn Khaldun Bogor, Indonesia. ²Researcher, Nutrition Science Study Program, Nahdlatul Ulama University of North Sumatera, ³Researcher, Nursing Study Program, Akademi Keperawatan Kesdam I/Bukit Barisan Medan, Indonesia

Abstract

It is estimated that there are 15 million people with Hypertension in Indonesia, but only 4% are controlled. The prevalence of hypertension sufferers is relatively high, 7% to 22%. Prevention of Hypertension can be done by eliminating or minimizing risk factors, one of which causes it, such as reducing salt consumption, if not done, then there is a risk of Hypertension. This study aims to determine the risk factors with the behaviour of Hypertension in Puskesmas. This research is a quantitative study with a cross-sectional method. A sample of 225 respondents who visited/sought treatment at the health centre using Accidental Sampling technique. Data analysis was performed using the chi-square test. The results showed that the factors causing Hypertension were age, exercise habits, smoking habits, alcohol consumption, nutritional status, sodium intake and stress. To reduce people suffering from Hypertension, the Puskesmas should be able to provide information to the public about Hypertension and how to prevent it by doing health promotion or counselling either individually or in groups.

Keywords: Risk factors, Hypertension, prevalence and determinants

Introduction

Hypertension or better known as high blood pressure is a condition in which a person’s blood pressure is above the standard limit, where the systolic pressure is ≥ 140 mmHg. In comparison, the diastolic pressure is ≥ 90 mmHg, the causes of Hypertension are smoking, drinking alcohol, obesity, genetics, stress, excessive salt consumption, consumption of seafood, such as shrimp, fish, shellfish, and others. Symptoms that often appear in Hypertension are dizziness in circles, feeling heavy in the neck, tingling, palpitations, shortness of breath, headaches. Hypertension is not only at high risk of suffering from heart disease but also suffering from other conditions such as diseases of the nerves, kidneys, and blood vessels and the higher the blood pressure, the greater the risk.¹⁴.

Correspondence Author:
Eny Dwimawati,
Faculty of Health Sciences, Universitas Ibn Khaldun Bogor, Indonesiaeny@uika-bogor.ac.id

The increase in cases of Hypertension, especially in developing countries, is estimated to be around 80% in 2025 from a total of 639 million cases in 2019, estimated to be 1.15 billion cases in 2025. Predictions on the current number of hypertension sufferers and the recent population growth. In Indonesia, the number of hypertension sufferers is estimated at 15 million people, but only 4% are controlled. The prevalence of hypertension sufferers is relatively high, 7% to 22%. Based on the results of a survey of patients who ended up in 75% heart disease, 15% stroke, and 10% kidney failure. Research also shows the prevalence of Hypertension also increases with age. From various epidemiological studies conducted in Indonesia, it shows that 1.8% -28.6% of the population aged over 20 years are hypertensive sufferers⁵⁶.

Until now Hypertension is still a problem because there are still many hypertensive patients who have not received treatment or have been treated, but their blood pressure has not reached the target, as well as the
presence of comorbidities and complications that can increase morbidity and mortality.

Hypertension is the third leading cause of death after stroke and tuberculosis in Indonesia. Hypertension will be a severe problem because if it is not treated as early as possible, it will develop and cause dangerous complications such as heart disease, congestive heart failure, stroke, vision problems, and kidney disease.

Prevention is better than cure. Hypertension can be avoided by eliminating or minimizing the risk factors causing it. Risk factors that cannot be changed or eliminated are genetics, age, gender. In contrast, risk factors that can be changed are weight loss for those who are obese, controlling stress, reducing salt consumption, stop smoking, not drinking alcohol, doing regular exercise, limiting consumption of fat, reduce caffeine consumption.

Public knowledge and attitudes about hypertension prevention are deemed necessary because it will affect their behaviour, to prevent it is better than a cure. So you can avoid attacks of Hypertension by eliminating or minimizing the risk factors that cause it. We cannot control risk factors such as genetics, increasing age. But other risk factors can be reduced or even eliminated. If you are overweight to obesity, you can certainly try to reduce your weight to a healthy weight with diet and exercise. Smoking, drinking alcohol and caffeine habits can be reduced or even eliminated. Stress, which can cause blood pressure, can be managed in such a way that it is slightly reduced.

Material and Method

This study used a cross-sectional study and analyzed using chi-square, the population in this study were 225 people who visited the Puskesmas. The variables measured in this study were risk factors for Hypertension such as gender, age, exercise habits, smoking habits, alcohol consumption, BMI, sodium consumption and stress.

This study used a questionnaire which aims to act as a research tool to make it easier to conduct research and obtain accurate data from respondents so that it can describe the research variables which are risk factors for hypertension disease.

Discussion

Gender roles are part of social roles and are not only determined by the sex of the person concerned, but by the environment and other factors. In women, blood pressure generally increases after menopause. Postmenopausal women have a higher risk of hypertension than those who have not menopause. So far, it has been concluded that hormonal and biochemical changes after menopause are the main causes of changes in blood pressure. These hormonal changes make women experience increased sensitivity to salt and weight gain. Both of these have the potential to trigger higher blood pressure3,13.

Generally, people with Hypertension are people aged over 40 years, but at this time, it is possible to suffer from young people. Most of the primary Hypertension occurs at the age of 25-45 years, and only in 20% occurs under the age of 20 years and over 50 years. This is because people at a productive age rarely pay attention to health, such as eating patterns and unhealthy lifestyles such as smoking8,14.

There was a trend toward increasing prevalence with increasing age and usually at ≥ 40 years of age. This is due to the arterial pressure that increases with age, the occurrence of aortic regurgitation, and the presence of a degenerative process, which is more frequent in old
When there is an increase in age until they reach old age, there is also an increased risk of diseases including neurological/psychiatric disorders, heart and blood vessel disorders as well as the reduced function of the five senses and metabolic disorders in the body.\textsuperscript{15,16}.

Based on the results of the statistical test of exercise habits with Hypertension, the irregular exercise proved a significant relationship with Hypertension, with \( p = 0.000; \ OR = 56.3; \ 95\% \ CI = 10.67-230.53 \). This means that people who do not exercise regularly have a risk of developing Hypertension by 56.3 times compared to people who have regular exercise habits.

People who do not regularly exercise will have an increased risk of developing hypertension compared to those who regularly exercise. Exercise is widely associated with the management of Hypertension because regular and isotonic exercise can reduce peripheral resistance which will lower blood pressure. Exercise is also associated with a role for obesity in Hypertension. Lack of exercise will increase the likelihood of obesity, and if salt intake is also increased, it will facilitate hypertension\textsuperscript{17}.

Exercise can reduce blood pressure not only due to weight loss but also how it is generated. Blood pressure is determined by two things, namely the amount of blood pumped by the heart per second and the obstacles faced by the blood in doing its work through the arteries. Exercise can lead to the growth of new capillaries and new blood vessels. Thus things that inhibit blood flow can be avoided or reduced, which means lowering blood pressure. Although the ability of the heart to do its job is increased through exercise, the effect of this reduction in resistance results in a significant reduction in blood pressure\textsuperscript{17–19}.

Lack of physical activity increases the risk of suffering from Hypertension because it increases the risk of being overweight. Inactive people also tend to have a higher heart rate, so the heart muscle has to work harder with each contraction. The harder and often the heart muscle has to pump, and the more pressure is placed on the arteries\textsuperscript{18,19}.

Based on the results of statistical tests between smoking habits and blood pressure, it was found that there was a significant relationship between smoking habits and blood pressure \( p = 0.000 \). The relationship between smoking and Hypertension is not clear. According to literature, nicotine and carbon dioxide contained in cigarettes will damage the endothelial lining of arteries, reduce the elasticity of blood vessels, causing blood pressure to rise. This mechanism explains why respondents who smoke every day have a risk of suffering from hypertension\textsuperscript{12,20}.

Smoking behaviour is an act that has no positive value in all respects, especially in health. Smoking is the beginning that brings various types of deadly degenerative diseases, such as cancer and heart disease. The nicotine in tobacco is the cause of the increase in blood pressure immediately after the first inhale. Like other chemicals in cigarette smoke, nicotine is absorbed by the tiny blood vessels in the lungs and circulated into the bloodstream. In just a few seconds, the nicotine has reached the brain. The brain reacts to nicotine by signalling the adrenal glands to release epinephrine (adrenaline). This powerful hormone constricts blood vessels and forces the heart to work harder due to higher pressure. By smoking, a cigarette will have a big effect on increasing blood pressure. This is because cigarette smoke contains approximately 4000 chemicals, 200 of which are poisonous, and 43 other types can cause cancer in the body\textsuperscript{21–23}.

In the alcohol consumption variable, respondents who consumed alcohol and were exposed to Hypertension were 71.4\%, and those who did not consume alcohol were 26.5\%. The results of statistical tests stated that there was a significant relationship \( p = 0.048 \).

Some theories support this statement, among others, people who drink alcohol too often or who drink too much have a higher blood pressure than individuals who do not drink or drink little. Blood pressure due to alcohol is unclear. However, it is suspected that an increase in cortisol levels and an increase in red blood cell volume and blood viscosity play a role in raising blood pressure.
Several studies have shown a direct relationship between blood pressure and alcohol intake and among them report that the effect on blood pressure is only seen when consuming 2-3 glasses of standard size alcohol per day; 22,24,25.

Overweight (obesity) is a characteristic of the hypertensive population, and it is proven that this factor is closely related to the occurrence of Hypertension in the future. To find out if someone is overweight or not, it can be seen from the calculation Body Mass Index (BMI). The relationship between blood pressure and body weight was more significant for systolic pressure than for diastolic pressure; 2,26.

The results showed that there was a significant relationship between BMI and Hypertension (p<0.05). One of the controllable risk factors for Hypertension is obesity. The risk of Hypertension in someone who is obese is 2 to 6 times higher than someone with normal weight. Based on the results of the study, it is known that there are 76.9% of hypertensive respondents who have a BMI which shows more nutrition (obesity) and 6.1% who have a BMI which shows no more or normal nutrition. This study shows the relationship between body weight and Hypertension. If the body weight increases above the ideal body weight, the risk of Hypertension also increases.

When body weight decreases, total blood volume also decreases, the hormones associated with blood pressure change, and blood pressure decreases; 26. Weight loss will result in a decrease in blood pressure. An experiment shows that a 1% reduction in body weight will result in a decrease of 1 mmHg for systolic pressure and two mmHg for diastolic pressure; 2,26.

The results of the analysis showed that the incidence of Hypertension was more prevalent in respondents who had frequent sodium intake (51.7%) than respondents whose sodium intake was not frequent (17.4%). From the statistical test, it is known that there is a significant relationship between sodium intake and blood pressure with a value of p = 0.000. People who frequently consume foods high in sodium have a greater number of cases of Hypertension who do not frequently consume foods high in sodium.

Several studies have shown that an average decrease in sodium intake by ± 1.8 grams/day can reduce the systolic blood pressure of 4 mmHg and diastolic 2 mmHg in hypertensive patients. Another supporting theory is that a high-salt diet can pump harder to push the increased blood volume through narrower spaces which in turn causes blood pressure to rise; 27,28.

High sodium intake (≥ 2,300 mg), when supported by decreased renal adaptation, can cause sodium retention in the kidneys and also reduce potassium stored in the body. This results in a volume displacement of the extracellular fluid resulting in the release of factors associated with Na⁺ / K⁺. Excess sodium and potassium deficiency in cells result in contraction of blood vessel cells.

The existence of contraction of blood vessels increases peripheral vascular resistance which results in Hypertension. High sodium intake can cause an increase in plasma volume, cardiac output and blood pressure. Sodium causes the body to retain water at levels exceeding the body’s normal threshold, which can increase blood volume and high blood pressure. High sodium intake causes adipocyte cell hypertrophy due to lipogenic processes in white fat tissue. If it continues, it will cause narrowing of the blood vessels by fat and increase blood pressure. Besides, individuals who are overweight and obese are more likely to have salt sensitivity which affects blood pressure; 27,28.

The effect of stress is also still controversial, and the effect is thought to be through sympathetic nerve activity which can increase blood pressure as a physical reaction when someone experiences a threat (fight or flight response). One of the causes of increased blood pressure in hypertensive patients is stress. Stress is an unpleasant physical and psychological stress. Stress can stimulate the child’s kidney glands to release adrenaline and stimulate the heart to beat faster and stronger, so that blood pressure will increase. If it occurs for a long time, it will be dangerous for people who already
suffer from Hypertension, causing complications. These complications can attack various target organs of the body, namely the brain, eyes, heart, arteries, and kidneys. As a result of the complications of Hypertension, the patient’s quality of life is low and the worst possibility is the death of the patient due to complications of hypertension. 29–31.

Correlation between Gestational Weight Gain in the Second and Third Trimester and Preeclampsia Risk: A Study From Indonesia

Ernawati Ernawati\(^1,2\), Lilis Kurniawati\(^3\), Sri Umijati\(^4\)

\(^1\)Department of Obstetrics & Gynaecology, Faculty of Medicine, Universitas Airlangga/ Soetomo Teaching Hospital, Indonesia, \(^2\)Department of Obstetrics & Gynaecology, Airlangga University Academic Hospital, Indonesia, \(^3\)School of Midwifery, Faculty of Medicine, Universitas Airlangga, Indonesia, \(^4\)Department of Public Health Sciences and Preventive Medicine, Faculty of Medicine, Universitas Airlangga, Indonesia

Abstract

Introduction: Many studies have proposed that pre-pregnancy body mass index and higher gestational weight gain (GWG) during pregnancy are risk factors for preeclampsia incidence. However, most of those studies give attention to total GWG during pregnancy to the risk of preeclampsia, not in a specific trimester.

Aim: To examine whether abnormal gestational weight gain in the second and third trimester correlated with the incidence of preeclampsia.

Methods: This cross-sectional study was conducted in a public health centre, in Surabaya, Indonesia, between October 2018 and October 2019. The samples were 63 pregnant women in the second and third trimester. The variable observed was gestational weight gain (GWG) each week during the second and third trimester compared to their pre-pregnancy body mass index (BMI) using the Institute of Medicine (IOM) standards and preeclampsia incidence. Statistical analysis used was Fisher’s Exact Test and Chi-Square Test with a significance level of 5%.

Results: There were 11 and 52 samples in the second and third trimester, respectively. Abnormal weight gain was recorded in 54% of samples in the second trimester and 57% of the preeclampsia third-trimester samples. Moreover, preeclampsia was diagnosed in 83.3% and 60% samples with abnormal weight gain in the second trimester and third trimester. Statistical analysis showed abnormal weight gain in the second and third trimester related to preeclampsia with P-values 0.015 and 0.0001.

Conclusion: Abnormal gestational weight gain in the second and third trimester was correlated to preeclampsia.

Keywords: preeclampsia, abnormal, gestational weight gain

Introduction

Preeclampsia and other pregnancy hypertensive disorders are still significant problems in maternal health services. It can affect 10% of pregnancies and cause maternal morbidity and mortality in the world\(^1,2\). This condition also occurs in Indonesia; preeclampsia/eclampsia cases are still the most significant cause of maternal death and tend to increase from year to year. This can have long-term adverse effects on the health of the mother and the outcome of pregnancy\(^3\).
Many studies have shown that body mass index (BMI) before pregnancy, and a tremendous increase in GWG during pregnancy are risk factors for preeclampsia\(^4,5\). Excessive gestational weight gain (GWG) is associated with increased maternal and neonatal complications, including hypertensive disorders of pregnancy, fetal macrosomia, and increased cesarean delivery rate\(^6,7\).

However, most of the existing studies only looked at total GWG during pregnancy with preeclampsia risk. These results are broad bias because pregnant women with preeclampsia are more likely to develop oedema during pregnancy than normal pregnant women. Of course, this will have an impact on a very significant increase in GWG. Other studies suggest that the correct management of GWG that occurs in early pregnancy can reduce the risk of developing hypertension in pregnancy\(^6\).

Effective treatment remains a considerable challenge\(^8\). GWG management in the second and third trimester of pregnancy is a potential target for interventions to reduce preeclampsia risk. Alternatives that can be taken are to manage in the field of prevention\(^9,10\). Based on the above background, this study aims to determine whether abnormal pregnancy weight gain in the second and third trimesters is associated with preeclampsia incidence. This study’s results are expected to be a reference for improving the quality of maternal health services.

**Methods**

This observational analytical study was done using a cross-sectional approach on 63 pregnant women in the second and third trimester in a public health centre, Surabaya using medical records, the study was conducted between October 2018 and October 2019. The Human Research and Ethics Committee approved the trial for Basic Science and Clinical Research Dr Soetomo Academic Medical centre Hospital, Faculty of Medicine Universitas Airlangga Surabaya.

The sample consisted of all pregnant women in the 2nd and third trimesters who had antenatal care at Public Health Center Surabaya with several inclusion criteria, such as (1) 20 weeks gestational age or above; (2) had an antenatal care at least two times in the 2nd trimester; (3) had an antenatal care at least two times in the 3rd trimester; and (4) there is a record of prepregnancy body mass index (BMI). Multiple pregnancies were excluded from this study. Simple random sampling was applied to the sampling technique.

The variables measured were gestational weight gain in the 2nd and third trimester and the incidence of preeclampsia. The diagnosis of preeclampsia was following the 2014 ISSHP criteria that (1) the blood pressure is by 140/90 mmHg or more and (2) there are one or more organ disorders that previously did not exist but then appeared in or after 20 weeks of pregnancy\(^11\). The increase of body weight was assessed by calculating the average weight gain in one month reported in the medical record when the respondents performed an antenatal care (ANC) examination, then compared to the weight gain based on The Institute of Medicine (IOM) recommendation and prepregnancy BMI\(^9\). The recommended weight gain for pregnant women in the second and third trimester, which is underweight, normal, overweight, and obese BMI, was 0.44-0.58; 0.35-0.50; 0.23-0.3; and 0.17-0.27 kilograms per week.

Statistical analyses were carried out using the Fisher’s Exact Test and Chi-Square Test with a significance level of 5% of the SPSS program. Abnormal GWG was determined to be abnormal, increasing gestational weight gain outside of the IOM recommendation was deficient or excessive weight gain.

**Results**

Out of the 63 respondents, 17.5% were in the 2nd trimester and 82.5% in the 3rd trimester. Forty-five percent of respondents were diagnosed with preeclampsia in the 2nd trimester while 38.5% were diagnosed in the 3rd trimester.

**Characteristics of Respondents**

Characteristics of pregnant women in this study are presented in Table 1. Women aged over 35 years,
Nulliparous women and pre-pregnancy BMI >30 (obese) were more likely to develop HDP.

Discussion

This study proves that one of the risk factors for preeclampsia is maternal age, where at the age of more than 35 years, there have been changes in tissues and reproductive organs. Previous studies have shown that preeclampsia is more common in women of advanced maternal age. Furthermore, it is also an independent risk factor for adverse outcomes in first-time mothers with preeclampsia\(^1,5\). Sixty-nine percent of respondents who experienced obesity before pregnancy were known to have preeclampsia. Obesity is a risk factor that has been widely investigated for the occurrence of preeclampsia\(^12,13\). Systematically reviewed by Ren et al., it also mentioned that pregnant women who had an excessive BMI before pregnancy had a higher risk factor in getting preeclampsia, high BMI before pregnancy had twice the risk of preeclampsia\(^9\). Excess fat in obese pregnant women increases oxidative stress, stimulating an inflammatory response and accelerating endothelial vascular damage resulting in preeclampsia manifestations. In other words, high BMI before pregnancy can increase oxidative stress, which then will stimulate the inflammatory response and accelerate endothelial damage\(^1,14\).
A previous study recorded GWG could change throughout pregnancy and challenge separate weight gain due to oedema or weight gain due to rising adiposity. Oedema is the normal picture in normotensive pregnancies, but it is more often in preeclampsia, which might have an impact in higher weight gain during pregnancy and is noted as overestimation of excessive GWG on Preeclampsia. So it is hard to see whether increased oedema in patients with preeclampsia causes a higher weight gain or whether higher weight gain due to preeclampsia15. However, patients with gestational hypertension should have less chance to have oedema because there is no protein urine on gestational hypertension, so the weight gain is more likely adiposity16.

Another study on increasing weight gain in early pregnancy stated that oedema is rare to occur in early pregnancy, so excessive weight gain at this stage is correlated with oedema. Thus it suggests that GWG predicts the development of preeclampsia. However, research on weight gain in early pregnancy and the risk of preeclampsia is sparse. Only one study from Macdonald-Wallis C et al. examined weight gain during early pregnancy and proved that GWG in early pregnancy is a risk factor for preeclampsia and gestational hypertension6. They recorded that excessive weight gain during the first 18 weeks of pregnancy was associated with risks of developing preeclampsia and gestational hypertension. More study is needed to prove the relationship between weight gain in early pregnancy and preeclampsia risk10.

Our study proved that abnormal weight gain, excessive and deficient weight gain, increases risk factors for developing preeclampsia in the second or third trimester. Many studies, as discussed above, show that excessive weight gain correlates with preeclampsia. Endothelial activation is the impact of various stimuli are oxidative stress and inflammatory mediators. Elevated lipids, mostly fatty acids, may have a direct effect on endothelial function. These could have a beneficial or detrimental effect. Failure to push non-esterified fatty acids into insulin resistance will reduce endothelium-mediated vasodilatation12.

However, only a few studies discussed the effect of short weight gain on risk of preeclampsia occurrence. One of the old journals in 1976, Davies et al., stated that undernutrition was beginning to be considered more critical than over-nutrition; they published a study of 180 preeclampsia women in Jerusalem using dietary recall to get a diet assessment. The preeclampsia diagnosis included patients with hypertension and proteinuria or oedema. They compared 180 preeclampsia women with 360 concurrent normal women. Lower intake of energy, fats and protein was shown in preeclampsia women than in control women. However, further investigation indicated that it was due to illness, so proposed it would be secondary to the disease rather than causal17. Another study by Clausen et al., examined 3771 Norwegian women on dietary intake using food questionnaires in 17–19 weeks gestation. This study showed that higher energy intake in preeclampsia women and early-onset preeclampsia was the highest18.

Our study results proved that excessive weight gain would increase the risk of preeclampsia occurrence and deficient weight gain and increase preeclampsia risk. This is supported by Clausen and Davies studies. Even though it is challenging to conclude from these studies, increasing energy and carbohydrate intake observed in women who later develop preeclampsia may be due to population differences. Another study showed that low protein intake is correlated with the risk of preeclampsia19, but no studies indicated that lower protein intake increase risk to develop preeclampsia. Trials of protein supplementation recorded no preeclampsia incidence reduction20.

**Conclusion**

Gestational Weight Gain (GWG) is a critical indicator in monitoring pregnant women’s nutritional health. Deficiency or excessive increase can be abnormal and may cause some complications to arise in pregnancy. This study showed that abnormal gestational weight gain (GWG) in the second and third trimester was associated with preeclampsia. GWG management in the second
and third trimester of pregnancy is a potential target for interventions to reduce preeclampsia risk.

The Impact of Extra-Weighted Exercises in Improving Physical Abilities Towards Accurate Ace Shots in Volleyball Game

Ethar Hamdi Abdulrahman¹, Adnan Fad’us Omar²

¹PhD Student, The Ministry of Education – General Directorate of Anbar Education, Iraq, ²Professor, College of Sport and Physical Education Sciences, University Of Anbar, Iraq

Abstract

This study aimed to prepare special exercises to develop some of the physical and skill aspects of volleyball players, and to pay attention to the use of additional weights and thus stand on one of the main and important aspects and its money in the role of preparing players in accordance with the requirements of the game and to identify the effect of these exercises using different resistances in some physical abilities and my skills Serving and crushing volleyball players, and the research sample consisted of (12) players in the specialized training center for volleyball aged (15-17) years and in a deliberate manner for the academic year (2019-2020), and the researchers concluded that the training curriculum has a positive effect on developing physical abilities And skill, which indicates the impact of the training curriculum prepared by the researchers in developing these abilities. As the research objectives are achieved, the researchers recommended making use of the prepared training curriculum in building similar approaches to develop some physical and skillful abilities of volleyball players.

Keywords: Volleyball, physical abilities, Fitness, extra-weighted.

Introduction

Proper planning based on solid scientific foundations and principles in the field of training and the use of various tools and resistances leads to rapid development in various games and sporting events, whether individual or collective, so the specialists in the field of training have paid attention to the physical aspects and focus on special approaches that seek to develop them. Physical preparation is one of the most important pillars on which the trainer relies to reach the individual to the optimal performance of sports activity, as it aims to develop the capabilities and improve the level of his physical capabilities to meet the requirements of progress in the methods of practice for sporting activities until the individual reaches the level required to perform in competition to achieve the goal.

Fitness is one of the important and basic elements for volleyball players, as the better the player’s level of physical fitness, the greater his ability to improve his skill and planning level, and the poor physical fitness of volleyball players leads to a weakening of the skill performance of volleyball skills depending on physical fitness. As for how can a player implement offensive skills unless he has the strength in the legs to jump up¹.

Researchers reviewed the training curriculum developed by the school coaches. Notice that the coach does not pay much attention to the use of different resistances, thus this is reflected in some physical characteristics and abilities. The physical aspect of performance has a great influence in raising the level of the players’ skillful performance. This was shown in the intermediate test results for special physical and skill aspects. To address the problem. First preparing exercises using different external resistances for the players of the specialized volleyball training center. Second identify the effect of exercises using different resistances on some physical abilities and the accuracy
of the crushing skill performance of the Volleyball Training Center players.

The importance of this paper lies in preparing special exercises to develop some of the physical and skill aspects of the players of the Specialized Volleyball Training Center and paying attention to the use of additional weights. Thus standing on one of the basic and important aspects and its role in preparing the players in accordance with the requirements of the game, the player who is well-prepared physically and skillfully is in a good condition to perform and implement technical skills and economy in an effort, and then the achievement is towards the best.

**Areas of Research:**

1. The human field: the players of the Specialized Volleyball Training Center-aged (15-17) years in the district of Hit - Anbar province.

3. The place field: Hit middle school for boys.

**Methodology**

The researchers used the experimental method and the experimental design method for one group with two pre and post-tests.

**The Research Sample:**

The researchers selected the research sample from the players of the Specialized Volleyball Training Center at the ages of (15-17) years, according to the deliberate method for the academic year (2019-2020). The research sample included (12) players, and (Libero) players were excluded from the research sample, as the research sample became (10). Thus, the percentage of the sample represented (83.33%) of the research community.

**Devices:**

Electronic Stopwatch - Video Camera - Digital Electronic Calculator - Pulse Meter.

**Tools:**

Volleyball arena - ball holder - volleyballs - tape measure (30) m - extra weights - colored adhesive tape - various medical balls (2-3-4) kg - chalk - whistle - different height surfaces - different height barriers (30-40-50) cm.

**Means of gathering Information:**

Arab and foreign sources - tests and measurements - questionnaire and data collection form - exploratory experience - the Internet.

**Procedures:**

Determine the research variables (physical and skill)

Determining the research variables is one of the important and basic matters in the subject of the research, which is to be developed for the players of the specialized volleyball training center, as the physical and skill variables were determined by the researchers and their reliance on previous studies in this aspect. And on Tuesday, 6/8/2019, as well as their reliance on the research problem that was extracted as a result of the researchers observing the tracer (intermediate) tests performed by the trainers of the training center.

**Table (1) Shows the research variables that have been identified**

**Tests Used:**

After determining the research variables by the two researchers, the following tests were used:
A- the test of the force of characteristic velocity of the muscles of the arms. 

Title of the test: - Flexing and extending the arms continuously for a period of (10) seconds.

The purpose of the test: - To measure the velocity force of the muscles of the arms.

Used tools: - Electronic stopwatch.

Description of the performance: - The laboratory takes the front support position on the ground so that the body is in an upright position. At the start signal, the tester bends and extends the arms completely and continues to repeat the performance to the largest number of iterations without stopping for a period of (10) seconds.

The conditions: - Are not allowed to stop. To note the straightness of the laboratory body during performance. The necessity of touching the chest to the ground when performing. Notice the bending and extension of the arms completely.

Scoring method: The laboratory score is the number of correct repetitions during a period of (10) seconds, as shown in the following figure:

B- Second: Throwing a medical ball weighing (3 kg) with two hands.

The purpose of the test: to measure the explosive force of the muscles of the arms and shoulders.

Devices and tools: medicine ball weighing (2 kg), chair, trunk fixation belt, tape measure, flat space area, airtight.

Performance specifications: The laboratory sits on the chair and the medical ball is carried by hands over the head, with the torso adjacent to the edge of the chair.

The conditions: The tester is given three attempts to score the best. When the chair vibrates or moves during the performance, the result is not counted.

Scoring method: The distance between the front edge of the chair and the nearest point the ball places on the ground is calculated, as shown in Figure (2).

C- Third: Sargent’s vertical jump test of stability.

The aim of the test: to measure the muscular capacity of the two men.

Devices and tools used: a wall height (3.50 m), a tape measure, and a blackboard fixed to a wall of (0.5 m) width and length (1.50 m), on which lines are drawn in white and the distance from one line to another is (2 cm), and pieces of chalk and pieces of cloth are also used. To wipe the blackboard after reading every attempt made by the laboratory, the blackboard can also be used so that it is fixed on the wall and its lower edge is higher than the ground (1.50 m), and the board can be movable and fixed according to the length of the laboratory with the arm, and then the laboratory is jumped.

How to perform the test: The tester holds a piece of chalk and stands facing the blackboard. Knees and push the feet together to jump up with the arms swinging strongly forward and up.

Test conditions: The upward jump is done with the feet together from a steady position and not by taking a step. Measurements should be taken to the nearest centimeter. Do not extend the piece of chalk outside the fingers of the hand.

Scoring method: The recording is made by the number of centimeters reached by the laboratory from the standing position. The distance between the first mark and the second mark is calculated for the amount
of muscle capacity. See figure 3.

**Figure 3: Shown the explosive force test of the legs.**

- **Fourth:** the crushing multiplication test 1.

   The purpose of the test: to measure the accuracy of the crushing attack in the inner triangle of the opponent’s court.

   Tools: five volleyballs, dividing the playing field as shown in Figure (4). So that divides the pitch into two triangles (half of the pitch opposite) and then divides the inner triangle (grid point) into three regions each display area (3 m).

   Performance specifications: After preparation, the tester makes a crushing attack towards the inner triangle of the network side.

   The conditions: Each laboratory has five attempts. Good preparation must be done in each attempt.

   Scores are calculated according to where the ball fell as follows: (In the first region (3) degrees - In the second region (1) a degree - In the third region (5) degrees - Outside these areas the laboratory gets a (zero)).

   Scoring: The laboratory records the scores he obtained in the five attempts, meaning that the final score for this test is (25) marks.

**Exploratory Experience**

The two researchers conducted the pilot experiment on a sample of (4) players on Thursday, 5/9/2019 at 05:00 PM. And they were randomly selected by drawing lots from the research sample. The researchers were keen to fulfill the same conditions and circumstances in which the pre-tests are possible, and the aim of them was the following:

1. Verify suitability and ease of application of tests used for the sample.
2. Verify the safety of devices and tools used in the research.
3. Knowing the time required to carry out the tests and the suitability of the place.

**Pre-Examinations (Physical and Skill):**

The two researchers applied the pre-tests of the variables under study for the research sample on Saturday (14/9/2019) at 05:00 PM. The two researchers took care as much as possible to control the variables in terms of time, place, and auxiliary work team.

**Main Research Experience:**

Exercises have been used to develop the physical capabilities of the arms and legs. And the skills of serving and spiking. These exercises were aimed at:

1. Trying to develop physical capabilities.
2. Development of the skills side of the research sample.
3. Trying to reach the player to a high training state in terms of physical and skill.
4. Achieve the goals that have been set through the use of exercises.

Two researchers developed special exercises using extra weights to develop some physical aspects and skills of serving and spoiling with volleyball.

The exercises were applied on Thursday 19/9/2019.
until Thursday 15/11/2019 on the research sample (Specialized Volleyball Training Center players). The exercises were applied by the center’s coaches.

Researchers used the circular method in carrying out the exercises with the intensity of interval training. The researchers used the additional weights that were determined according to the relative weights of each player in the implementation of the selected exercises, and the use of the fixed ball carrier device. Exercises were carried out circularly in the form of the stations of each station in which a different exercise was carried out. The choice of exercises in the one training unit were exercises of close and equal time to carry out exercises in all stations at one time because of the presence of another player in the station. It also helps to control the time to move from one station to another. The difference is in the number of repetitions or the distance over which the selected exercise is carried out in one training unit. The components of the exercise load for the exercises used are stability in intensity, comfort, and change in exercise volume.

* The curriculum included (24) training units with (3) training units per week on Saturdays, Tuesdays, and Thursdays, and the application of the used curriculum took (8) weeks for special preparation.

* The two researchers used the calculation of the total intensity of the training units that were contained in the following equivalent exercises.

**Dimensional tests:**

The two researchers applied the dimensional tests for the research sample on Thursday (28-11-2019). The researchers took care as much as possible to control the variables.

**Statistical means:**

The statistical data were processed by using the (SPSS) program to process the results.

Table (2) shows the arithmetic mean, standard deviations, and the two calculated and tabular (T) values of the research variables.

Discussion

So, the table showed (the results of the search sample in the variables of physical abilities for the pre-tests, the arithmetic means were respectively (8.25, 4.44, 48.75, and 10.5) and standard deviations (1.28, 0.94, 9.69, and 5.92). Where the dimensional arithmetic mean (11.12, 5.26, 53.62, 17.37) and standard deviations (1.45, 0.82, 27.14, 2.38) and by extracting the value of (T) calculated of (9.48, 7.06, 9.56, 6.93), and It was greater than the tabular (T) value of (2.26) and at (9) temperature and with an error level (0.05). This indicates that there is a significant difference between the pre and post-tests.

There is an evolution in all physical abilities understudy in the post-tests when compared with the results of the pre-tests of the second experimental group. The researchers attribute the effectiveness of the exercises used in the program, which used times, to the development of the characteristic strength, speed, and muscle strength. The development of muscle strength as well as the raising of the degree of neuromuscular compatibility.

(Hussein and Ahmad) stated, “Weight training has a fast and effective effect on the growth of muscle strength on the one hand and the increase in muscle size on the other hand” 2. And (Hammad) states, “The use of weights aims to increase the intensity of exercise performance and thus decrease the volume and increase the positive comfort, but it remains incomplete. Also, one of its main goals is to develop the characteristic of strength distinguished by speed” 3. In the explosive force variable of arms and legs to the effectiveness of interval training using strength exercises represented in jumping and throwing exercises, using additional weights, and the use of medical balls in the throwing exercise, the effect on developing this trait. “Exercises in which resistance is used are an appropriate means for developing the components of explosive force. 4. As strength training increases the muscle’s ability to excite the largest possible number of fibers, as (Allawi and Abdel Fattah) mentioned that “the more muscle fibers participate, the more muscle fibers are involved in, the greater the strength that the muscle can produce” 5.

The development in the post-test was due to the effectiveness of exercises used with additional weights, according to the researchers. This led to the development of strength characteristic of speed for the muscles of the arms and legs. And speed is possible with accuracy in directing the ball to the opponent’s court, as (Wadih) states, “The development of special kinetic abilities or characteristics enables the athlete to perform the kinetic performance of the skill in the best possible way” 1, and that the volleyball player is constantly moving on the field, whether he is in Defensive or offensive condition. Thus, in addition to possessing the main physical qualities, he needs compatibility when performing skills. Thus, when performing the serving skill, he needs neuromuscular compatibility, as well as accuracy when hitting the ball, and this is in agreement with (Abdul Khaleq). Special mobility “2).

Conclusions

The training curriculum has a positive effect on developing physical and skill abilities, which indicates the effect of the training curriculum prepared by the researchers on developing these capabilities. Benefiting from the training curriculum prepared by the researchers in building similar curricula to develop some physical and skillful abilities of volleyball players. Generalizing the proposed training curriculum in training volleyball juniors. The need for coaches to pay attention to the tests adopted by the researcher to measure physical abilities and spiking skills.

Source of Funding: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: The scientific research ethics committee at Al-Anbar university has approved the research by letter No. 19 date 29-09-2019. All experiments were conducted at a specialized center at Hit city.

Abstract

Background: Laryngeal carcinoma is the most common malignancy of the upper respiratory tract, more than 98% are squamous cell carcinoma (SCC). New method is necessary for identifying and predicting nodal metastasis in laryngeal SCC. Overproliferating tumor cells will induce hypoxia and release HIF-1α, which in turn will upregulate CXCR4. CXCR4 then will induce MMP13, a protein that degrade extracellular matrix (ECM), thus promoting metastatic process.

Methods: A cross sectional study, using 30 samples of laryngeal SCC, divided into two groups: based on cervical lymph node status. All samples were stained immunohistochemically against HIF-1α, CXCR4 and MMP13 antibody. The expressions were evaluated using immunoreactive score (IRS).

Result: There were significant difference among HIF1α, CXCR4, and MMP13 in laryngeal SCC with positive nodal metastasis group compared to negative nodal metastasis group (p<0,05). There was no significant correlation between HIF-1α expression and CXCR4 expression (p = 0,403) (p>0,05). There were significant correlation between HIF-1α and MMP13 expression (r = 0,499), and between CXCR4 and MMP13 expression (r = 0,409). Conclusion: There were significant differences in HIF-1α, CXCR4 and MMP13 immunexpression in laryngeal SCC with cervical nodal metastasis compared to laryngeal SCC without cervical nodal metastasis. There was a positive correlation between HIF-1α and MMP13 expression, positive correlation between CXCR4 and MMP13 expression, but there was no correlation between HIF-1α and CXCR4 expression.

Keywords: Laryngeal carcinoma, lymph node metastasis, HIF-1α, CXCR4, MMP13

Background

Laryngeal carcinoma is the most common malignancy of the upper respiratory tract. Globocan estimates that there will be 177,422 new cases and 94,771 deaths due to laryngeal carcinoma worldwide in 2018.1 More than 98% of laryngeal malignancies are well differentiated SCC.2

Prognosis of laryngeal carcinoma depends greatly by tumor stadium. Laryngeal carcinoma confined to glottis has good 5 years survival rate (YSR), up to 85-95%, while presence of nodal metastasis will reduce 5 YSR significantly to 50%. The important significant single prognostic indicator of laryngeal carcinoma is the cervical nodal status.3,4

Identification of nodal metastasis in laryngeal carcinoma patients is not always easy. Probability of nodal metastasis without palpable nodal enlargement is about 13,7-37%, and better identification methods is indispensable.5
In SCC there will be changes in microenvironment of the tumor caused by proliferation of tumor cells. Up to certain tumor volume, blood and nutrients supply become inadequate and lead to tissue hypoxia. Hypoxia will induce HIF-1α, which is a major regulator of cellular response to changes in oxygen concentration supporting the adaptation of tumor cells to hypoxia in an oxygen-deficient tumor microenvironment. Overexpression of HIF-1α which in turn upregulates CXCR4.

Chemokine is a family of chemotactic that modulate cell movement and positioning, and act by coupling to G-protein coupled receptor. CXCR4 is a unique chemokine receptor because it has exclusive interaction with its ligand, CXCL12. The binding of CXCR4 and CXCL12 will initiates various downstream signaling pathways, resulting in various responses such as rising intracellular calcium, genetic transcription, cell proliferation, migration, adhesion, and invasion. CXCR4 is a critical tumor marker with a proven role in cancer progressivity and metastasis, but its role in laryngeal cancer is not yet well studied.

Infiltration of cancerous cell to the surrounding tissue is an important behavior in cancer progressivity. Proteolytic enzymes such as matrix metalloproteases (MMPs) contribute to tumor expansion by degrading extracellular matrix (ECM) components. Some studies showed expression of MMP in SCC. MMP13 has a vital role in MMP activation, and it’s also expressed in some head and neck SCC. Meanwhile, its role in nodal metastasis is not yet well known.

This study aims to analyse the expression of HIF-1α, CXCR4, and MMP13 in laryngeal SCC to unveil the roles of those markers in nodal metastasis process, which is expected to be an invaluable prognostic biomarker.

**Material and Methods**

This is an observational analytic study with cross-sectional approach. The population consists of all laryngeal SCC tissues with and without cervical nodal metastasis in paraffin blocks, archived in Anatomical Pathology Laboratory of Dr. Soetomo General Academic Hospital in Surabaya, during 2013 – 2016 period. The samples are 30 laryngeal SCC tissues in paraffin blocks from laryngectomy specimens, taken by random sampling methods.

In this study, immunoeexpressions of these three proteins were evaluated by immunohistochemistry examination. We used monoclonal antibody against HIF-1α (NB100-131, Novusbio) with 1:100 dilution, monoclonal antibody against CXCR4 (sc-53534, Santa Cruz Biotechnology, Inc., Texas, USA) with 1:50 dilution, and monoclonal antibody against MMP13 (sc-101564, Santa Cruz Biotechnology, Inc., Texas, USA) with 1:50 dilution. All antigen retrievals were done using decloaking chamber (heat-induced epitope retrieval) with DIVA solution in 110°C for 30 minutes.

HIF-1α was positive if expressed in nucleus or cytoplasm of tumor cells. CXCR4 was positive if expressed in the nucleus, cell membrane or cytoplasm. MMP13 was positive if expressed in cytoplasm of tumor cells.

HIF-1α, CXCR4, and MMP13 immunohistochemical staining were assessed using semiquantitative Immunoreactivity Score (IRS) refferancing to Remmele and Stegner. To determine the IRS, the percentage of positive tumor cells was classified into five grade (no positive cells = 0, <10% of positive cells = 1, 10-50% positive cells = 2, 51-80% positive cells = 3, and > 80% positive cells = 4). Then the grade of positive cells percentage is multiplied by the grade of staining intensity which is divided into 4 grades (no staining = 0, weak staining = 1, moderate staining = 2, and strong staining = 3). The final IRS score ranges from 0-12. The assessment was performed by two pathologists.

All datas were analyzed statistically using SPSS program. Analysis of expression differences of HIF-1α, CXCR4, and MMP13 was done with Mann-Whitney test. Analysis of correlation was done with Spearman correlation test. Statistical result is significant if p < 0.05.

**Result**

Mean age of all 30 patients was 55.9±8.36 years
The youngest was 49 years old and the oldest was 75. Patients were grouped into 4 groups with 10 years interval. As many as 53.33% patients were in the 51-60 years old group. Most patients were male. Out of 30 cases, there were only 2 female patients.

As many as 80% or 24 out of 30 cases of laryngeal SCC in this study were well differentiated. Four cases (12.33%) were moderately differentiated, and only 2 cases (6.67%) were poorly differentiated. Only 1 case (3.33%) was diagnosed in early stage (T1). Most cases, 43.33% or 13 cases of these cases were resected in stadium T3. There were 15 cases with cervical nodal metastasis; 8 cases (26.67%) in stadium N1 (metastasis to one ipsilateral lymph node with diameter ≤ 3 cm), and 7 cases with stadium N2.

Statistical analysis with Mann-Whitney showed that there was a significant difference among median scores of HIF1α, CXCR4 and MMP13 expression in laryngeal SCC without nodal metastasis group compared to laryngeal SCC with nodal metastasis group (p<0.05), as depicted in table 5.2.

In this study, Spearman correlation test showed no significant correlation between HIF-1α and CXCR4 expression, with p = 0.403 (p>0.05). Meanwhile, the test showed positive correlation between HIF-1α and MMP13, and between CXCR4 and MMP13 with rs = 0.499 and rs = 0.409 (p < 0.05), respectively.

Figure 1. HIF1α expression, stained positively in cytoplasm of tumor cells. A, with weak intensity. Internal positive control was inflammatory cells (arrow) (HE, 200x). B, with strong intensity (HE, 200x).
Discussion

In this study, statistical analysis showed that there was a significant difference in HIF-1α expression in laryngeal SCC with nodal metastasis compared to laryngeal SCC without nodal metastasis (p<0.05). HIF-1α was expressed stronger in metastasis group. This finding is in concordance with previous studies, such as studies by Wu et al and Popov et al who studied HIF-1α expression in laryngeal SCC\textsuperscript{13,14} and also in oral SCC\textsuperscript{15}. Zhou et al in a meta-analysis study showed that HIF-1α associated with not only lymph node metastasis, but also tumor size, tumor stage and overall survival\textsuperscript{16}.

Figure 2. CXCR4 expression, stained positively in cytoplasm and nucleus of tumor cells. A, with weak intensity (HE, 200x). B, with strong intensity (HE, 200x).

Figure 3. MMP13 expression, stained positively in cytoplasm of tumor cells. A, with weak intensity (HE, 200x). B, with moderate intensity (HE, 200x).

HIF-1 is an important factor regulating cell adaptation to oxygen deprivation. In a normoxic condition, the proline and lysine residues of HIF-1α subunits are hydroxylated by oxygen-dependent prolyl-4-hydroxylases (PHDs). Von Hippel-Lindau E3 ubiquitin ligase binds to hydroxylated HIF-1α and acts as a substrate recognition component of E3 ubiquitin ligase complex, which leads to proteasomal degradation of HIF protein. In solid tumors like laryngeal SCC, hypoxia is commonly found since there is a higher proliferation rate and intratumoral oxygen will be rapidly depleted. In hypoxic condition, the activity of PHDs and FIHs are suppressed, and HIF-1α translocates to the nucleus to bind with HIF-1β. The heterodimeric HIF-1α with HIF-
1β with the help of coactivators such as cyclic adenosine monophosphate response element-binding protein (CBP) and acetyltransferase (p300), then bind to the target gene hypoxia response element (HRE), resulting in their transcriptional upregulation. HIF-1α will then induce various pathways which influence survival, proliferation, apoptosis, intratumoral angiogenesis, and many other processes.6,17

Statistical analysis showed that there were significant differences of in CXCR4 expression in laryngeal SCC with nodal metastasis compared to laryngeal SCC without nodal metastasis (p<0,05). Previous studies on laryngeal and head and neck SCC were also found similar results.18-20 A study by Toyoma et al even proved that inactivation of CXCR4 will inhibit invasion and migration of tumor cells in SCC hypopharynx.21

Overexpression of CXCR4 is found in many malignancies. This is caused by CXCR4 upregulation by HIF-1α and HIF-2 secreted by malignant cells as a response to their increased oxygen demand.7 CXCR4 upregulation can also be caused by DNA demethylation of CXCR4 promotor, a particular process detected in various types of cancer.22 CXCR4-CXCL12 binding can increase MMP2 expression and inhibit tissue inhibitors of MMP. In addition, CXCL12 can promote the separation of tumor cells from tumor tissue and activated several cell adhesion molecules, and induce them to secrete more MMP and VEGF to dissolve ECM. These mechanisms contribute to tumor growth, angiogenesis, and metastasis.23 Biasci et al, proved that inhibition of CXCR4 combined with blockade of PD-1/PD-L1 T cell check points can induce T lymphocyte infiltration, resulting in an anti-cancer response.24 A study conducted by Tulotta et al showed that CXCR signaling supports the interaction between tumor cells and host neutrophils in developing tumor metastasis.25

This study also showed a significant difference in MMP13 expression in laryngeal SCC with nodal metastasis compared to laryngeal SCC without nodal metastasis (p<0,05). In this study, the median MMP13 expressions were stronger in laryngeal SCC with nodal metastasis group. Previous studies in laryngeal SCC.26,27 The study conducted by Huang showed that siMMP13 knockdown not only reduced the tumor invasion and migration, but also decreased the adhesion abilities of oral cancer cells. It is supported that MMP13 promotes invasion and metastasis in oral cancer cells.28

MMP13 has a wide range proteolytic capacity. It is produced and secreted from many cell types as a precursor form (pro MMP13), which can be activated by plasmin, MMP2, MMP3, and MMP14. MMP13 or collagenase-3 has the ability to degrade not only fibrillary collagen (type I, II, III, V, and XI), but also basal membrane, cartilage, collagen type IV, IX, X and XIX, gelatin, fibrillin-1, tenascin, aggrecan, perlecan, fibronectin, and osteonectin. MMP13 is expressed physiologically in conditions where rapid and effective remodelling of ECM are necessary, such as in fetal bone development and adult bone remodelling, and gingival and foetal skin wound healing. MMP13 is expressed pathologically in conditions involving overdegradation of ECM such as in rheumatoid arthitis, atherosclerosis, osteoarthritis and malignancy.29-31

In laryngeal SCC, tumor cells proliferate overwhelmingly. Tumor cells will secrete proteolytic enzymes and induce stromal cells, fibroblasts and inflammatory cells, in particular tumor associated macrophage (TAM), to produce MMP. MMP13 is a central key for other MMP cascade activation like MMP2, MMP3 and MMP9. All MMPs will then degrade ECM and basal membrane components together, facilitating tumor cells to invade stromal tissue and metastasize to lymph nodes and distant organs.32,33

Spearman correlation test showed no significant correlation between HIF-1α and CXCR4 expression, p = 0,403 (p>0,05). This finding is inconsistent with previous studies that showed a positive correlation between HIF-1α and CXCR4 expression in many types of malignancy, and also in laryngeal SCC.14,34

HIF-1α expression of laryngeal SCC tumor cells in this study tends to be low, while CXCR4 tends to be overexpressed. HIF-1α is known to be a major regulator
for CXCR4 upregulation, hence a low expression of HIF-1α should be followed by low expression of CXCR4. This contradictory finding could be caused by other molecular mechanisms which can also alter both protein levels, since molecules and biomarkers interactions in carcinogenesis are very complex and dynamic processes. As mentioned before, CXCR4 is not regulated solely by HIF-1α. Many malignancies had DNA demethylation of CXCR4 promoter, this will also upregulate CXCR4. Changes in multiple growth factors and transcription factors were also upregulate of CXCR4. A recent study from Izumi et al also found that CXCR4 could be secreted by stromal myofibroblasts, known as cancer-associated fibroblasts (CAFs). In this study, Spearman correlation test showed positive correlation between HIF-1α and MMP13 expression in laryngeal SCC, \( r_s = 0.499 \) (\( p < 0.05 \)). The stronger HIF-1α expression, the stronger MMP13 expression.

Hypoxia condition with high HIF-1α level will influence many mechanisms for tumor cells survival. HIF-1α regulates some proteins such as protein Twist, MMP-2, MMP-9, VEGF, and CXCR4/SDF-1. Matrix metalloproteinase like MMP-2, MMP-9 and MMP13 will degrade ECM surrounding tumor cells, eventually facilitate invasion of tumor cells through basal membrane into lymph and blood vessels to metastasize to lymph node and distant organs.

In this study, Spearman correlation test also found positive correlation between CXCR4 and MMP13 expression, \( r_s = 0.409 \) (\( p < 0.05 \)). The stronger CXCR4 expression, the stronger MMP13 expression. Previous studies also found similar results, not only in laryngeal SCC (Tan et al., 2008), but also in other malignancies such as basal cell carcinoma and colorectal cancer.

CXCR4 activation will induce various downstream signaling pathways, induce EMT (epithelial to mesenchymal transition), and promote metastasis. Activated CXCR4 will dissociate to α and βγ subunit. By β γ subunit will activate phospholipase C-β (PLC-β) and PI3K. PLC-β will then divide phosphatidylinositol into IP3 (inositol (1,4,5) triphosphate and diacylglycerol (DAG). IP3 will induce intracellular calcium release and then together with DAG will activate protein kinase C and MAPK/ERK pathway. MAPK/ERK then will relay the signal to induce MMP activity for ECM degradation by promoting transcription and translation of proMMP13 to MMP13.

Regulation of MMP13 expression by CXCR4 has been proven by Bu et al. They analyzed silencing effect of CXCR4 gene in some signaling pathways, and found a significant decrease in ERK phosphorylation level, mRNA and MMP13 protein level. This proved that CXCR4 could regulate MMP13 transcription level through ERK/NFκβ pathway.

### Conclusion

There were significant differences among HIF-1α, CXCR4, and MMP13 expression in laryngeal SCC with nodal metastasis compared to laryngeal SCC without nodal metastasis. All three were expressed stronger in laryngeal SCC with nodal metastasis group. There was a positive correlation between HIF-1α and MMP13 expression, positive correlation between CXCR4 and MMP13 expression, but there was no correlation between HIF-1α and CXCR4 expression.

Abstract

Stress is the mileage that life causes on the body. Every individual is facing one or another stressful events in life, in which students are also not an exception. Present study aimed to examine the effectiveness of Jacobson Progressive Muscle Relaxation (JPMR) Exercises to Reduce the Stress Level among B.Sc. Nursing Students at selected nursing institutes of Punjab and Haryana State. This was a pre-experimental one group pre-test and post-test study, in which 500 B.Sc. Nursing students were recruited by using non-probability convenient sampling technique. The study tools socio-demographic variables and Modified Perceived Stress Scale (MPSS) was used to gather the information’s. After pre-test the JPMR were introduced to each participant through video-assisted teaching and after 7th day of JPMR the post-test conducted. Analysis of study noted that majority of participants 51.2% have shown that they don’t have previous knowledge about JPMR, while highest number of participants 50% reported that they have once seen JPMR but not performed ever. The paired t test value of total academic score was 213.518 at calculated p value of <0.001 which concluded that the administered JPMR is effective to reduce the stress level among B.Sc. Nursing students.

Key words: Nursing students, Jacobson Progressive Muscle Relaxation, stress, video-assisted teaching

Introduction

The World Health Organization (WHO) has characterized youth as the movement from the presence of auxiliary sex attributes (pubescence) to sexual and regenerative development, the advancement of mental cycles and grown-up personality, and the changes from complete financial reliance to relative freedom. Stress is related with physical, mental and social encounters of life.¹

Stress is the mileage that life causes on the body. It happens when an individual experiences issues managing life circumstances, issues, and objectives.² Stress is an ordinary unavoidable truth. We can’t stay away from it. Stress results from any change we adjust to, running from the negative extraordinary of real physical risk to the thrill of becoming hopelessly enamoured or making some since quite a while ago wanted progress.³ Stress isn’t new understanding to us all, it’s viewed as present day society’s sickness, as the vast majority, regardless of how composed, will endure at any rate transient trouble while they arrange times of change, injury, difficulties and misfortune. Stress is something that we all experience every once in a while yet experience issues characterizing it.⁴

WHO report described that college students are facing stress which further leads to many other mental health disorders. Researcher have personal experience that during his professional journey, he come across
with many of nursing professional students who are facing many of stressful situations which are not just pressure of academic grades but there are many of such issues which creates pressure and stressful situations to nursing students. Being a healthcare professional and in that when we talk about nurses then we are speaking about center workforce of any healthcare setup. Getting an important and center member of healthcare team, nurse workload begins from their study onward, which further make their study structure different with other professional. Their extensive engagement in patient care made them to acquire theoretical, clinical (practical) and updated (research) knowledge of each and every side of human health which can be at institutionalized or in public health.5

In one investigation on nursing students at Greece pointed with to decide the commonness of sorrow and tension and the relationship between melancholy, nervousness and mental manifestations among nursing students.6 Stress for longer time prompts extreme emotional wellness issues in which the downturn is one of driving issue. One surveyed the downturn prevalence among undergrad clinical students at clinical school of Nepal and conveyed that the commonness of discouragement is high from the outset year students, so endeavors ought to be taken from starting. Since scholarly stress end up being one of the central point, measures to make the scholastic educational program more understudy inviting is proposed.7

Inevitably, when individual feel stressed, the muscles straighten out. At the point when muscles straighten out an excess of then individual can’t have open to feeling or to state get undesirable sentiments, for example.8 It alteration may be settle down by the help of some of muscle relaxation technique, hence among all the Jacobson Progressive Muscle Relaxation is widely used technique. Researcher gathered enough evidence that this technique is unique and helped to relax the muscle at comfortable level. As the use of such technique also promoted by WHO by stating utilizing of non-pharmacological therapies.9

Subhash M Khatri et al referenced in their randomized clinical trial with an intention to discover the viability of Jacobson’s relaxation technique in hypertension. The dissected information expressed that the normal decrease in circulatory strain was fundamentally more prominent in subjects treated with Jacobson’s relaxation technique alongside prescriptions when contrasted with just drugs. Investigators reasoned that Jacobson’s relaxation technique can be utilized as an adjunctive intercession in the treatment of hypertension.10 In a research by Wen-Chun Chen et al referenced their investigation to look at the adequacy of progressive muscle relaxation training on anxiety in patients with intense schizophrenia. They have found its effective to reduce anxiety level of schizophrenic patients.11

These evidences guided the researcher to assess the effectiveness of Jacobson Progressive Muscle Relaxation on stress of nursing students but reaching out to maximum students at different location was questionable, which was taken care seriously by researcher and adopted a video-assisted technique, so through video-assisted technique investigator can able to reach all participants.

**Study Objectives:**

1. To assess the pre-test stress level score among B.Sc. Nursing students.

2. To assess the post-test stress level score among B.Sc. nursing students.

4. To determine association of post-test stress level scores with selected demographic variables of B.Sc. Nursing students.

**Materials and Methods**

Researcher attempted a quantitative research approach with a pre-experimental research design to achieve the objectives and test the hypothesis of...
this research. Study participants were included B.Sc. Nursing students of selected nursing institutes of Punjab and Haryana institute. The samples were recruited by non-probability convenient sampling technique and total 500 samples recruited based on eligibility criteria.

**Inclusion criteria:**

The B.Sc. nursing students who are:

- Providing informed consent to participate in study.
- Any genders
- Any age
- Having any device to see video such as mobile, laptop, PC

**Exclusion Criteria:**

The B.Sc. nursing students who are:

- Physical handicapped.
- Having physical illness in which physical exercise is prohibited.
- Having vision related injury.
- Diagnosed with any mental health illness in last one year.

The data collected by validated tools. Data were collected in between December 2019 to January 2020 from all 500 participants. The tools were grouped in two sections, Section-I were leading to collect socio-demographic information’s whereas in section-II intended to measure stress level among B.Sc. Nursing students and it named as Modified Perceived Stress Scale (MPSS). Tool’s reliability assessed by split half method and found reliable with r=0.86. These tools were introduced first in from of collect pre-test data, then after researcher administered Jacobson Progressive Muscle Relaxation (JPMR) as a video to each participant, followed to it after 7 days the post-test data were collected. The gathered data were arranged in excel format as a master sheet. Researcher used 21 version of SPSS to analyse the data.

**Results and Discussion**

Relevant data were arranged and analysis completed. Table 1 reflecting the frequency and percentage distribution of B.Sc. nursing students.

P<0.05 level of significance  S- Significant
Table-2 presented the paired t test value and it divulged that not only total stress level but also each category of stress found strongly significant, as mentioned the calculated p value in each category is <0.001 which is much lesser than then the pre-determined level of significance p<0.05. These findings suggested that the provided JPMR is very effective method to reduce or manage the stress among B.Sc. Nursing students.

Discussion

Sneha Pitre et al has supported present research findings of frequency and distribution of socio-demographic variables. They have revealed that maximum number of their study participants 80% are belongs to age of 18 to 20 years and same percentage 80% of female gender were participated. A similar finding was suggested by a study by Wafaa Yousif Abdel Wahed and Safaa Khamis Hassan has stated their findings that majority of participants 66.1% were in age group of 20 to 22 years, highest number of participants 61.1% were female. Majority 92.3% were unmarried, more than half of participants 56.6% were residents of villages, majority of participants 27.1% were studied at first year followed by 26.7% in third year, 24% in second year and 22.2% were in final year of their study. But this differs in present study finding in case of socio-economic standards, which is in this study is high among maximum participants 40.3%. One study by Timothy Baghurst and Betty C. Kelley also stated that majority of participants were belongs to female 58.56% gender than male, the mean age of participants were 21.4 years.

Prameelarani Bommareddi et al has mentioned significant effectiveness of Jacobson progressive muscle relaxation exercise on anxiety and depression which was found effective at the p level of <0.001. G S Tak et al has mentioned in their study in which they attempted to see effectiveness of Jacobson progressive muscle relaxation exercise on anxiety and the findings suggested that the intervention is highly effective to reduce the anxiety level of participants at the level of <0.05. These findings are supporting our study findings. Archana Khanna et al has divulged in their study that out of three group intervention among stressed females, in which second group received Jacobson progressive muscle relaxation exercise has shown mean and standard deviation as 65.9±6.33, in compare with the pre-test which was 73.60±4.19.

Conclusion

B.Sc. nursing students found stressed at each level such as academic, personal or social which cumulatively stressed upon the fact that nursing students found stressed. Here, investigators would like to conclude the study based on study findings that administered Jacobson progressive muscle relaxation through video-assisted technique found effective to reduce the stress level of B.Sc. nursing students. Investigators recommended to institutes to offer such relaxation technique to nursing students with objective to keep them relax and focused.

Abstract

Background: Forensic Odontology is a rapidly evolving branch of dentistry which deals with the identification of an individual. In instances of deceased individual, establishing identity may still pose difficulties depending upon the time that has elapsed since death. The oral structures can reliably be used for establishing identity of the deceased as they are preserved for long after death. The mandibular foramen is amongst the core structures & has been used for age estimation with reliable degree of accuracy using radiographs which is a non-invasive and easily reproducible technique. Hence we decided to assess its importance in establishing gender. Methods: Digital Orthopantomograph (OPG) were used for the study as they are taken for all dental procedures and can be preserved as records and may facilitate comparison of ante-mortem and post-mortem records. Various dimensions from the mandibular foramen were recorded. Conclusion: We found statistically significant correlation of Anteroposterior and Posteroanterior dimensions in position of mandibular foramen to gender.

Keywords Mandibular Foramen, OPG, gender, dimensions, Superoinferior, AnteroPosterior.

Introduction

Identification of the individual followed by identification of gender is a very important and necessary tool in Forensic anthropology and every document in the field of forensic medicine begins with identification (either a live person or remains – dead body or skeletal remains).¹⁰ The Mandible is extensively used in Forensic odontological studies as it forms a strong and nonperishable source of facial skeleton. In living individuals, remodeling of the mandible takes place throughout life and these changes are observed on dried mandible as well as on its radiographic image. The body of the mandible and the mental and the mandibular foramina have been used as points of reference in various morphometric analyses of the mandible, by virtue of their stable relation with the basal bone. The mandibular foramen (MF) is an important landmark on the medial surface of ramus of the mandible which transmits the inferior alveolar nerves and vessels.¹¹ ¹³ Vast amount of data is available of the studies on either the mandibular basal bone or the other morphologic landmarks on the mandible but very few studies include the Mandibular Foramen as a landmark for evaluating age and fewer still for correlating Gender. Hence this study was designed to include the change in position of mandibular foramen and its morphology as the individual grows older and whether it can contribute to establishing Gender.
Materials & Method

This observational study consisted of 200 randomized digital OPG’s from a database in the extra oral radiographic machine in the Department of Oral Medicine and Maxillofacial Radiology. Thus, patients were not unnecessarily exposed to radiation and their identities remained confidential. The radiographs were selected based on the following criteria.

Inclusion criteria

- Subjects within the age group of 20 - 60 Yrs belonging to Nagpur Division population.
- Good quality (with respect to contrast) OPG’s with complete lower border of mandible.
- Individuals with all the teeth normally present for that particular age in right & left lower jaw.
- Devoid of any jaw lesions and traumatic injuries in the mandible.
- Images without radiographic exposure or processing artifacts.

Exclusion criteria

- Poor quality radiograph.
- Presence of processing artifacts.
- Presence of jaw fracture in mandible.
- Presence of any pathology, bony abnormalities / bifid mandibular canal, any systemic diseases affecting bone remodeling in the mandible.

All radiographs were taken with a digital machine, Orthophos XG X-ray system version 2.53 SIRONA Germany with the following parameters:

- Kilo voltage of 62-73 kVp
- Tube current 8-15 mA
- Time for 15 s.

Position of Mandibular foramen was identified (Fig-1) and measured in three directions superoinferiorly (SI) posteroanteriorly (PA) and anteroposteriorly (AP). Superoinferiorly it was measured as a line drawn from the deepest point of the mandibular notch to the mandibular foramen and was marked. Posteroanteriorly measurements were made by drawing a line from the posterior border of the ramus at the level of mandibular foramen to the actual mandibular foramen. Similarly measurements were made anteroposteriorly by drawing a straight (perpendicular) line from mandibular foramen to the anterior border of ramus (AP). The distances from the MF to various landmarks were recorded as an average of two measurements which were measured independently by two different people. The mean and standard deviation for each distance were calculated separately for right and left sides. Statistical analysis was performed that included mean values in males and females on the right and the left sides, Discriminate Function Test, $t$-test and p-value were calculated.

Results

The mean distance of the MF from anterior border of the mandibular ramus on the right side was $14.88\pm1.91\text{mm}$ and left side was $14.60\pm1.83\text{mm}$. The MF was located $14.90\pm1.90\text{mm}$ (Right side) and $14.62\pm1.83\text{mm}$ (Left Side) from the posterior border of Mandible. The distance of the MF from the mandibular notch was $22.70\pm1.57\text{mm}$ and $22.02\pm1.57\text{mm}$ on the right and left sides respectively. Table 1 shows the mean and std deviation of the distance of Mandibular Foramen from the anterior, posterior and superior borders of the Mandible respectively. The values of the Antero-posterior measurements on right and left sides was $14.18\pm1.60\text{mm}$ & $14.59\pm2.07\text{mm}$ in females and $15.17\pm1.70\text{mm} & 15.02\pm1.95\text{mm}$ in males, Postero-anterior dimensions recorded were $14.20\pm1.60\text{mm}$ & $14.61\pm2.07\text{mm}$ in females and $15.04\pm1.95\text{mm}$ & $15.19\pm1.7\text{mm}$ in males and Supero-inferior dimensions were $22.20\pm1.60\text{mm}$ & $22.88\pm1.59\text{mm}$ in males as compared to females $21.84\pm1.52 \& 22.51\pm1.53\text{mm}$. Table 2 shows Gender wise comparison of parameters left and right side which is statistically significant for Anteroposterior and Postero-anterior dimensions. The Anteroposterior and
Postero-anterior dimensions are higher in males than in females and are greater on right side than on left side. Table 3 shows Discriminant Function Analysis, i.e., Tests of Equality of Group Means which demonstrates that the change in Anteroposterior and Posteroanterior dimensions to be statistically significant.

Discussion

The mandibular foramen is located on the medial surface of the ramus approximately midway between the mandibular notch and the angle of the jaw and also midway between the internal oblique line and the posterior border of the ramus. Its relation to the occlusal plane varies by approximately 10.00 to 11.00 mm above the occlusal surface of the mandibular first molar and can vary depending upon the reference tooth that is used for measurement. The mental and mandibular foramina have been used as points of reference in various morphometric analyses of the mandible, by virtue of their stable relation with the basal bone.\(^\text{13, 9}\) It has been established that the mandibular foramen undergoes a shift in position from its location at birth into adulthood. This shift in its position is in a vertical plane and this study aimed to assess if there was a change in location with respect to gender of an individual and whether this information may have Forensic implication. In our study, the results showed that differences between gender for mandibular foramen at AP and PA was highly significant, which is similar to the study by Rashid et al 2011\(^\text{11}\), Samanta PP2013\(^\text{13}\) and Linganna CS2015 \(^\text{8}\). In our study the mandibular foramen shows a shift with age which is similar to the study by Lim MY et al\(^\text{7}\). The observation found in our study was a posterior shift because we studied adult population whereas in the study by Lim MY et al 2015\(^\text{7}\), the population studied were children. When compared between genders the mean values superoinferiorly were higher in males than females which is similar to the study conducted by Shendakar AT etal, 2010\(^\text{14}\). A similar finding was also reported by Direk F et al2018\(^\text{4}\) who used Multi detector computed tomography to assess mandible and suggested that the ramus dimensions are higher in males. The Posteroanterior and Anteroposterior dimensions were higher for males in our study; this can be attributed to the stronger masticatory muscles in males imparting greater stability to the ramus of the mandible. Sairam V et al2016\(^\text{12}\), Lasemi Eet al2019\(^\text{6}\), Bhardwaj D et al, 2014\(^\text{2}\) and Jalili MR, 2012\(^\text{5}\) studied mandibles through OPG and concluded that Superoinferior dimensions were higher in males. This difference was statistically significant between sexes, thus indicating a strong sexual dimorphism.

The difference in dimensions measured for the right and left sides showed values that were almost similar, with a non-significant difference and this applies for both the male and the female groups which is in accordance with study by C. Lavanya Varma et al\(^\text{2011}\)\(^\text{3}\) and Ashkenazi, 2011\(^\text{1}\). Thus the various parameters of the ramus of the mandible can be used for personal identification and also to identify gender, as they serve as stable landmarks and show gradual and steady modifications with age. These dimensional changes are greater in males than in females.

A Study to Assess the Effect of Food Consumption Pattern on Health Status among Nursing Students at Dinsha Patel College of Nursing, Nadiad

Dhara Vyas¹, Fiza Sherasiya², Ami Patel²

¹Associate Professor cum Head of Department Child Health Nursing, ²Clinical Instructor, Dinsha Patel College of Nursing, Nadiad, Gujarat, India

Abstract

College students are at risk for making poor dietary choices that can cause significant health problems. A descriptive study was conducted to assess the effect of food consumption pattern on health status among nursing students at Dinsha Patel College of Nursing, Nadiad. A sample of 101 students was selected by systematic random sampling technique. Five point Likert Scale was used to assess the food consumption pattern. The data was analyzed by using the descriptive and inferential statistics. The result of present study reveals 50(49%) students have more than 11 g/dl hemoglobin level, 56(55%) students are underweight, 73(72 %) students believes that they are taking balance diet. There is a statistically significant association with the perception regarding balanced diet and food consumption pattern and no significant association with other socio demographic variables such as age, sex, education, BMI, Hemoglobin level, religion, eating habits, residential status. The result shows 37(36.6%) students had unhealthy, 44(43.5%) students had average healthy, 19(18.8%) students had healthy diet pattern The study concluded that there is a need for health education programs that promote healthy food consumption pattern for nursing students.

Key Words: Food Consumption Pattern, Health Status, BMI, Hemoglobin level

Introduction

College students are at risk for making deprived dietary choices that can cause significant health problems. Majority of undergraduate students consume at college dining facilities with imperfect healthy food options. Moreover, if students do not accomplish sufficient nutrition daily, a decrease in educational or physical performance can result.¹⁻³

Despite the well-built emphasis on meeting dietary requirements every day to attain optimal health, many college students tend to care less about or neglect their nutritional requirements. Many factors come in to play as they transition to university life. Many of them leave the parental home, adapt to social and environmental changes, admit new financial responsibilities, build different social networks, and experience different time availability. Yet, meeting nutritional requirements leftovers important in achieving one’s health. It is very favorable for college students to formulize high-quality eating habits that lead them to obtaining health and finest function.⁶

Objectives of the study were

1. To describe the socio demographic profile of Nursing students at Dinsha Patel College of Nursing, Nadiad.

2. To assess the Food Consumption Pattern of Nursing students at Dinsha Patel College of Nursing, Nadiad.

3. To assess the health status of Nursing student in terms of BMI and Hemoglobin level

4. To find out the association between the Food Consumption Pattern and selected demographic variables of Nursing students at Dinsha Patel College of
Nursing, Nadiad.

**Research Methodology**

**Research Approach:** Descriptive survey approach

**Research Design:** Cross sectional study

**Sampling method:** Systematic random sampling technique

**Study population:** G.N.M., B.Sc (N), P.B.B.Sc (N), M.Sc Nursing students

**Study Setting:** Dinsha Patel College of Nursing, Nadiad.

**Sample Size:** 101

**DESCRIPTION OF TOOL:**

Tool consists of two parts.

**Part-I:** It includes socio demographic variable such as Age, Sex, Education, Height, Weight, BMI, Hemoglobin, taking balance diet, Religion, Family Income, Address, Residential Status, Permanent residence, Eating habits, Reason for skipping meals, Skipped meal substitute, Fasting

**Part-II:** Consists of Five point Likert Scale, it consists 30 items which food items. Total score is 150. The score more than 100 is considers as a healthy food consumption pattern and less than 90 is consider unhealthy food consumption pattern.

**Result**

**ASSOCIATION BETWEEN THE FOOD CONSUMPTION PATTERN AND SELECTED DEMOGRAPHIC VARIABLES**

Table shows that there is a statistically association between food consumption pattern and selected demographic variables among nursing students. The data shows that the chi-square value computed between the perception regarding balanced diet and food consumption pattern among nursing students which was found to be statistically significant (p=0.002). In statistical data of Age group Degree of Freedom was (df= 1), Calculated Value Chi square ($x^2 = 9.56$), Tabulated value at 0.002 level of significance was 9.56. So, The calculated value is more than tabulated value which shows association between food consumption pattern among nursing students and perception regarding balanced diet and there is no significant association between food consumption pattern among nursing students with other socio demographic variables such as age, sex, education, religion, income, residential status, permanent residents, eating habits, reason for skipping meals, skipped meal substitute, fasting.

**Conclusion**

The health status of student indicated majority of students were undernourished and having hemoglobin level more than 11 g/dl. 37% students had unhealthy, 44% students had average, 19% students had healthy diet pattern. There is a statistically significant association with balanced diet and no significant association with other socio demographic variables such as age, sex, education, religion, income, residential status, permanent residents, eating habits, reason for skipping meals, skipped meal substitute, fasting.

The Undernutrition Prevalence of Under-Two-Years Infant in Indonesia: Do breastfeeding Practices Ecologically Matter?

Fandaruzzahra Putri Perdani1, Agung Dwi Laksono2, Djazuly Chalidyanto2, Fandaruzzahra Putri Perdani3
1 Post Graduate Student of Department of Health Policy and Administration, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, 2 Researcher, Ministry of Health of the Republic of Indonesia, Jakarta, Indonesia, 3 Lecturer of Department of Health Policy and Administration, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

Undernutrition due to inappropriate feeding practices for children increases morbidity. Breastfeeding is considered the most important in a baby’s growth and development. Breastfeeding started within one hour of birth and was maintained exclusively for the first six months until one year of age or more to obtain optimal benefits. The study aims to determine the ecological relationship between undernutrition in 2-year-old infant and breastfeeding practice in Indonesia. This study is based on environmental analysis using a report of the 2018 Indonesia Basic Health Survey. The dependent variable was the prevalence of undernutrition in 2-year-old infant. Besides, the independent variables were four optimum breastfeeding practices. The analysis used bivariate analysis with scatter plot in statistic application. The study results show . The higher the proportion of early initiation of breastfeeding in a province, the lower the levels of undernutrition in children aged two years in that province. The higher the ratio of starting to breastfeed less than one hour in an area, the lower the undernutrition levels in children aged two years in that area. On the other side, the higher the proportion of the mother giving all colostrum in a province, the lower the undernutrition levels in children aged two years in Indonesia in that province. The higher the proportion of still being breastfed 0-23 months in a region, the lower the undernutrition levels in children aged two years in that region. The study concluded that optimal breastfeeding practices negatively affect the levels of undernutrition in children aged two years.

Keywords: Undernutrition, breastfeeding, early initiation of breastfeeding, exclusive breastfeeding

Background

Malnutrition during the developmental period can increase the risk of morbidity and mortality. On the other side, the first 1000 days are critical for growth and development throughout the child’s life. Meanwhile, undernutrition due to inappropriate feeding practices for newborns and children can increase morbidity1.

Moreover, children with malnutrition are the trigger of the death of 10.5 million children each year worldwide. Malnutrition is associated with the end of 35% of children. The percentage of stunting is 32% of children less than five years old in developing countries, and 10% of them suffer from malnutrition. Suboptimal breastfeeding, especially non-exclusive breastfeeding in the first six months, causes 1.4 million deaths and causes a 10% disease burden in children aged <5 years2. Based on the Indonesian Demographic and Health Survey, the infant and under-five children’s mortality rate in Indonesia in Infant Mortality Rate is 35 babies per 1000 births; if the breakdown, 157,000 babies die per year 430 babies per day. Meanwhile, every year, the under-five children mortality rate is 46 out of 10003.

We considered breastfeeding to be one of the most critical factors for a baby’s growth and development. Breastfeeding offers tremendous health benefits for both the child and the mother. The American Academy of Pediatrics recommends exclusive six months of breastfeeding, followed by introducing supplementary...
foods for up to 1 year of age or more as long as the mother and baby want it\textsuperscript{4}. One of the programs for accelerating infant mortality reduction in the Early Initiation of Breastfeeding and exclusive breastfeeding\textsuperscript{5,6}. Breastfeeding must be started within one hour of the baby’s birth and must be maintained exclusively for the first six months of the baby’s life to obtain optimal benefits. Exclusive breastfeeding means that a newborn is mother fed the baby only breast milk, and no other fluids (even water) or solids are given, except for oral rehydration salts, vitamins, mineral supplements, or medicines\textsuperscript{2,7}. The World Health Organization (WHO) recommends that capable mothers practice and maintain exclusive breastfeeding for the first six months of their baby’s life\textsuperscript{8}.

Inadequate breastfeeding practices can interfere with the health and development of children and mothers\textsuperscript{9,10}. Breastfed babies have fewer cases of diarrhea, respiratory infections, ear infections, and other acute illnesses. While these benefits are more excellent in developing countries, they are also crucial in industrialized countries. Inadequate breastfeeding practice caused nearly half of diarrhea episodes and one-third of respiratory infections. During the first six months of life in America, breastfeeding saves almost 1,000 lives and the US $ 13 billion in excess health care costs associated with not breastfeeding\textsuperscript{4}. More prolonged breastfeeding was associated with a 13% reduction in the chance of being overweight and obesity prevalence and a 35% reduction in the incidence of type 2 diabetes. We can prevent an estimated 20,000 maternal deaths from breast cancer each year by increasing breastfeeding rates\textsuperscript{10}.

According to the recommendations, the fulfill optimal exclusive breastfeeding, including breastfeeding until the age of more than two years, start breastfeeding in the first 1 hour, the length of Early Initiation of Breastfeeding and the provision of colostrum are all factors for the success of breastfeeding. This study aims to determine the ecological relationship between undernutrition in two-year-old infant and breastfeeding behavior in Indonesia. This research, hopefully, can be implemented as a consideration for policymakers in promoting the importance of exclusive breastfeeding according to the recommendations.

**Methods**

The thesis was planned by the author using an ecological research approach. Ecological experiments compare populations rather than entities. The data studied is composite data at a given community or level, particularly the provincial level. Aggregate quantities, environmental measurements, or global measurements may all be used as ecological research variables\textsuperscript{11,12}.

The study used secondary data from the 2018 Indonesia Basic Health Survey national report. The Ministry of Health of the Republic of Indonesia published the survey report openly, and we can access it on the ministry’s website\textsuperscript{13}. There are data from 34 provinces throughout Indonesia. The survey carried out measurements on 33,376 children aged two years spread across 34 provinces from Sumatra to Papua. The dependent variable measured was “prevalence of malnutrition and deficiency status.” The nutritional status used is the number of malnutrition and deficiency status in children aged two years. The independent variables measured were the fulfillment of exclusive breastfeeding according to recommendations, namely breastfeeding until the age of more than two years, the time to start breastfeeding in the first 1 hour, the duration of Early Breastfeeding Initiation, and colostrum administration.

The study carries out bivariate analysis using a scatter plot. The review uses the linear fit line to determine the relationship between undernutrition in two-year-old infant and the independent variable. The entire analysis process utilizes SPSS 21 software.

**Result and Discussion**

The study found that the four factors of breastfeeding behavior negatively relationship with the undernutrition prevalence of two-year-old infants based on the scatter plot. The higher the proportion of early breastfeeding initiation in a province, the lower the undernutrition levels in children aged two years in that province.
The higher the proportion of starting to breastfeed less than one hour in an area, the lower the undernutrition levels in children aged two years in that area. Meanwhile, the higher the proportion of the mother giving all colostrum in a province, the lower the undernutrition levels in children aged two years in Indonesia in that province. Moreover, the higher the proportion of still being breastfed 0-23 months in a region, the lower the undernutrition levels in children aged two years.
These results are consistent with all measured factors for optimal breastfeeding behavior. Breastfeeding helps protect babies from acute and chronic illnesses. Babies who are not breastfed have 6-10 times the risk of dying than babies who are breastfed\textsuperscript{14}. Babies who are given foods other than breast milk are at risk of developing diarrhea and pneumonia\textsuperscript{5}. Diarrhea is common in infants given artificial food even with high hygiene levels, such as in Belarus and Scotland\textsuperscript{15}. Growth and development from birth to the first two years are critical for optimizing growth and development. Nutritional deficiencies at 0-2 years can lead to stunting, so this is a crucial period for implementing strategies to reduce the risk of undernutrition\textsuperscript{15}. 

Figure 3. The scatter plot diagram of the undernutrition prevalence of two-year-old infants and the behavior of the mother giving all colostrum in Indonesia in 2018

Figure 4. The scatter plot diagram of the undernutrition prevalence of two-year-old infants and the proportion still being breastfed 0-23 months in Indonesia in 2018
Based on data analysis, East Nusa Tenggara has the highest percentage of infants aged two years undernutrition of the total population (24.5%) but has breastfeeding behavior above the national average except for the early initiation of breastfeeding variable. Meanwhile, West Java is a province with the lowest percentage of two-year-old babies with malnutrition and malnutrition of the region's total population (10.6%) having breastfeeding behavior above the national average. Gorontalo, Maluku, and North Maluku are provinces with a higher prevalence of undernutrition infants than the national average (16.6%). As well as lower breastfeeding behavior than the national average, including early initiation of breastfeeding (54.8%), percentage breastfed <1 hour (29.0%), giving colostrum entirely (83.5%) and the proportion was still breastfed 0-23 months (76.50%). The highest percentage of early breastfeeding initiation was in Jakarta (74.1%), and the lowest was in West Papua (34.3%)

Based on the scatter plot diagram, the higher the early initiation of breastfeeding practice, the lower the number of undernutrition in a province. According to WHO, early initiation of breastfeeding (EIBF) defines as an initiation of breastfeeding in the first 1 hour after delivery. Early initiation of breastfeeding has the benefit of preventing infection, lowering the risk of diarrhea, and increasing survival rates in children\(^2\). In mothers who underwent EIBF, neonatal mortality decreased by 33%. Although WHO has recommended every mother to perform EIBF, the practice of EIBF is still low, especially in developing countries\(^{16}\). The study found that the average EIBF practice in 34 provinces was 54.8%. The results are consistent with research on EIBF practices in Ethiopia, where EIBF practices in the districts of Amibara, Dale Woreda, Gurage zone, and Debre Birhan are 39.6%, 83.7%, 47.3%, and 62.9%, respectively\(^{17}\).

Meanwhile, the lowest percentage of breastfed <1 hour was West Nusa Tenggara (38.5%) and the highest was the rate of breastfeeding in the first hour in North Sumatra (17.4%). The practice of breastfeeding in the first 1 hour is essential for the initiation and continuation of breastfeeding and to increase the emotional bond between mother and baby\(^2\). In initiating early breastfeeding, the mother’s skin-to-baby skin contact begins immediately after delivery or at least 1.5 hours and should last as long as possible or at least 1 hour without interruption\(^{18}\). Early connection is essential for mother and baby. Early contact stimulates the flow of oxytocin, helps release oxytocin, reduces the risk of bleeding, and facilitates emotional bonding between mother and baby. The neonatal mortality rate increased by 33% in infants whose EBF was longer than 1 hour. The Zimbabwean study showed a risk of sepsis in the first one week of infants who delayed breastfeeding\(^{17}\).

Giving colostrum entirely mostly done in Yogyakarta province (97.7%), while the lowest was in Papua province (68.8%). Colostrum is the first milk that is very important for newborns to prevent infection. Mother breast produced colostrum in small amounts, namely 40-50 ml in the first days, and all babies are needed. Colostrum is rich in white blood cells and antibodies, especially sIgA, and contains high amounts of protein, minerals, and water-soluble vitamins (A, E, and K) than breast milk\(^{18}\). Colostrum can prevent infectious diseases from bacteria, viruses, fungi, and protozoa. The study found that colostrum administration can reduce the risk of malnutrition and malnutrition in children aged two years. Based on other tasks, children who do not get colostrum can be at risk of infection, stunting, and undernutrition\(^{19}\).

For more than two years, the duration of breastfeeding was mainly in the province of Central Java (86.7%), while the lowest was in Gorontalo province (60.2%). Breastfeeding should be continued until two years of age or older, upon request, as often as possible for as long as the child requests. Breast milk meets half or more of the energy needs of children aged 6-12 months and one-third of energy and high-quality nutrition for children aged 12-24 months\(^{14}\). Breast milk provides a critical energy and nutrition source when a child is sick and reduces the risk of mortality in malnourished children. Breastfeeding also reduces acute and chronic illnesses\(^{20}\). In children who have received complimentary foods
where breastfeeding is reduced, breastfeeding is given actively to meet breast milk needs in children\textsuperscript{19}.

The nutrients can explain the nutrition and development of children in breast milk. Breast milk ensures optimal bone development, thereby preventing stunting. Oleic acid in breast milk can increase the absorption of fat and calcium. Meanwhile, breast milk consumption can improve the quality of nutrients and micronutrients in children, but not the energy needs of children\textsuperscript{21}. Apart from breastfeeding, several other factors influence the nutritional status of children. The success of breastfeeding optimal is affected by a pregnancy, namely the provision of good nutrition during pregnancy, preparation for breastfeeding, and the support of health workers and families to accompany during the optimal breastfeeding process\textsuperscript{16}.

**Conclusion**

The study concluded that optimal breastfeeding practices negatively relationship the undernutrition levels of children aged two years. The research shows the higher the optimal breastfeeding practices, the lower the undernutrition levels of children aged two-years-old.

Abstract

In this study, series of hybrid emulsion copolymers with different composition ratios of acrylic acid, methyl-acrylic acid with butyle-acrylate, methyl-metha-acrylate, polyvinyl alcohol were generated. The preparation was performed in a batch reactor on an industrial scale to obtain the resulting resin. While applying various processes of emulsion polymerization, batch polymerization was chosen to find optimum conditions by investigating the parameters of the monomer percentages, initiators, temperature and time. Dodecyl Benzene Sulphonic acid SDBA as emulsifier, as well as sodium dodecyl sulfonic acid SDBAS as co-emulsifier as redox couple initiator have been chosen as the best and most effective initiators to hybrid acrylic resin processing. Water-dispersed acrylic resin was developed as a hydrophilic monomer, utilizing acrylic acid. To avoid gelatin and agglomeration, the reaction temperature of the acrylic resin preparation was taken for 4 hours at 70°C. To understand the effect of silane coupling agent on the properties of hybrid emulsion copolymers, in the presence of trimetyl-chloro saline. FTIR spectroscopy, ¹H NMR spectra, thermal analysis as well as mechanical tests were widely studied confirmation of the hybrid acrylic resins. The various physic-chemical properties of hybrid emulsion acrylic copolymers including density, viscosity, chemical resistance and volatile matter were studied. The results show that hybrid emulsion acrylic copolymers are readily soluble in aprotic polar solvents such as (Toluene, Acetone, Benzene, xylene, DMF, DMSO, Methanol, and ethanol) without being in need for heating. The emulsion copolymers obtained had a great solid content as well as have been used as binder in emulsion paints. These polymers have very useful properties such as high anticorrosive and chemical resistance, the experimental results reveal.

Key Words: hybrid acrylic copolymers, Binder, Surface coating, Batch polymerization

Introduction

Drying Test: Ethanol was used to clean aluminium plates to ensure no pollutants are present to impact the test. A hand coating with a particularly defined thickness has been used to spray the resin uniformly on the test plate surface. Density Test

Viscosity Test: Brook field rotary Viscometer Ku-2 model RVDV-II+P8500 was used to measure the viscosity at 25°C, and using a variousspindle with velocities

Volatile Matter Test: In previously weighted watch glass as well as heated floor (2h) at (135-140) °C, three specimens were put in the oven within min after the
preparation of methacrylic emulsion copolymers. The non-volatile matter was determined from the original and final watch glass weights variation. The average value of three results has been stated as the non-volatile percentage matter.

**Corrosion Resistance Test:** A salt spray test (ASTMD1654) was conducted to study the corrosion resistance of acrylic emulsion copolymers over the coatings. A 5% NaCl salt water solution was used as a corrosive environment; a 144-hour test was conducted. Coated panels were regularly inspected for blistering or sign of corrosion after (24 hours = one day, 72 hours = 3 days, 144 hours = 6 days) (12).

**Abrasion Resistance Test:** The test has been conducted to assess a resistance for coating films for abrasion affected via an abrasive fall from a specified height through a guide tube onto a coated metal (ASTMD968). It has been used as an abrasive factor for silica sand. This was sprayed on the coated metal when some scratches were found. The volume of sand that changes to some degree the thickness of a film determines the resistance to abrasion. In terms of “l per micrometre,” abrasion is given.

**Results and Discussions**

**Synthesis and Characterization of (PFA1):**
These polymer were synthesized by the emulsion polymerization for MAA by Styrene in the presence of Dodecyl Benzene Sulphonic acid SDBA as an emulsifier, sodium dodecyl sulfonic acid SDBAS as co-emulsifier and trimethylchlorosilane (TMCS). At (70°C) for (4 hours).

**Characterization of (PFA1) FTIR Spectra:**

![Figure 1: FTIR for PFA1](image)

**Synthesis and Characterization of (PFA2):**
This polymer has been synthesized by a emulsion polymerization for MAA with Epoxy in the presence of Dodecyl Benzene Sulphonic acid SDBA as an emulsifier, sodium dodecyl sulfonic acid SDBAS as co-emulsifier and trimethylchlorosilane (TMCS). At (70°C) for (4 hours).

**Characterization of (PFA2) FTIR Spectra:**

![Figure 2: FTIR for PFA2](image)

**Synthesis and Characterization of (PFA3):**
This polymer has been synthesized by a emulsion polymerization of MAA with BA and P.V.A in the presence of Dodecyl Benzene Sulphonic acid SDBA as an emulsifier, sodium dodecyl sulfonic acid SDBAS as co-emulsifier and trimethyl-chlorosilane (TMCS). At (70°C) for (4 hours).

**Characterization of (PFA3) FTIR Spectra:**

![Figure 3: FTIR for PFA3](image)

**Synthesis and Characterization for (PFA4):**
This polymer has been synthesized by a emulsion polymerization for AA with BA and MMA, and styrene in the presence of Dodecyl Benzene Sulphonic acid SDBA as an emulsifier, sodium dodecyl sulfonic acid SDBAS as co-emulsifier and trimethyl chlorosilane
Characterization of (PFA4) FTIR Spectra: The FTIR spectra of (PFA3) indicated absorption bond for (OH carboxylic) in (3400 cm\(^{-1}\)), (C=O ester) in (1770 cm\(^{-1}\)), (CH\(_3\)) for (1350, 1420 cm\(^{-1}\)), (C=O carboxylic) in (1725 cm\(^{-1}\)), (C=O ester) in (1110 cm\(^{-1}\)), (C-H aromatic) in (3010 cm\(^{-1}\)), aromatic (C=C) in (1650 cm\(^{-1}\)), (C-H) aliphatic in (2900 cm\(^{-1}\)).

Synthesis and Characterization of (PFA5): This polymer has been synthesized by emulsion polymerization for AA with BA and MMA, and Epoxy in the presence of Dodecyl Benzene Sulphonic acid SDBA as an emulsifier, sodium dodecyl sulfonyl acid SDBAS as co-emulsifier and trimethyl chlorosilane (TMCS). At (70\(^{\circ}\)C) for (4 hours).

Characterization of (PFA5) FTIR Spectra: The FTIR spectra of (PFA6) indicated absorption bond for (OH carboxylic) in (3400 cm\(^{-1}\)), (C=O) carboxylic in (1650 cm\(^{-1}\)), (C=O) ester in (1730 cm\(^{-1}\)), (C-H) aliphatic in (1370, 1420 cm\(^{-1}\)), (C=O) ester in (1200 cm\(^{-1}\)), (C=O epoxy for 1200 cm\(^{-1}\)).

Density Test: A substance density and the volumetric mass density are its mass per unit volume. The results were observed for the emulsion copolymers prepared at the density of emulsion acrylic copolymers increase when the ratio of butyle-acrylic increases. The density of emulsion acrylic copolymers increases, when the no. of monomer increasing, and the density of emulsion acrylic copolymers with epoxy increases more than styrene.

Viscosity Test: A fluid’s viscosity is a measure of its resistance to slow but steady deformation caused by shear stress or tensile stress. For fluids, this equates for an indirect “thickness” concept. The viscosity of the solution is so vital to characterization polymers area measure of molecular weight of polymer as the viscosity of the solution is a measure of the size. The factors affecting viscosity: Pressure: Pressure viscosity little importance, but viscosity effect appears when the pressure increases (68 bar). Temperature: When temperatures decrease viscosity because at high temperature of liquid increase distances between molecules less friction and therefore less viscous. The ecology of different types of the formulated binders shows a reduction through viscosity as the shear rate increased. Appropriately, it has been found that all the designed binders are thinning polymers (a thixotropic material) that become more fluid with an increased period of application or increased shear average raised.

Drying Test: Denser layers (120\(\mu\)m) are in need of more time to dry in comparison for thinner layers (30\(\mu\)m). A thicker films mechanism for drying necessities a great deal to form cross-link between chains. The thicker films emulsion copolymers drying time can radically increase with the increasing of styrene (11).

**Volatility Matter Test:** There is a difference in the value of the volatility between each emulsion copolymers prepared. The (PFA1) shows least value of volatility, because this monomer is hydrophilic, while (PFA2) shows the high value of volatility due to length chain of copolymer containing in its structure on hydrophobic monomers therefore the volatility increased.

**Testing Chemical Resistance:** In two media, distilled water, HCl, H2SO4 as well as NaOH solution, the resistance of emulsion acrylic copolymers was calculated, describing that after 18 hours of immersion in distilled water there was no impact on emulsion copolymers film, which was ample time to analyse the water resistance. While the emulsion copolymer film was submerged in the powerful alkaline solution as well as acid solution (3N NaOH) (3N HCl) as well as (3N H2SO4), the film was blanched for 8 hours after immersion, blistered for 16 hours after immersion as well as extracted for 24 hours after immersion.

(+) chemical resistant for polymer (no soluble) (-) chemical resistant for polymer (soluble)

Emulsion-methacrylic polymers demonstrated high solubility in various solvent forms. The sample solubility, determined by a solubility (0.01 g) of every sample formulated resin as well as melted by (2ml) of a solvent, including (DMF, acetone,) (Polaraprotic) non-polar solvents like (Benzene, CHCl3) as well as other solvents like (HCl, H2SO4). With the distance among the resin’s molecular series, solvent molecules raise. The gaps between long chains with a resin pendant side group are occupied with solvent molecules as they fill the space made accessible through the motion of a series. When moves put two series next to each other, hence, attractive forces for short-range are formed resulting in restricted chain movement and therefore the creation of the vicious system$^{(12,13)}$.

**Corrosion Test:** Salt spray tests are perhaps the most common and most controversial tests pertaining to corrosion resistance. It is well known that salts like sodium chloride could cause rapid corrosion for ferrous substrates, so it is beneficial to have knowledge about the actions of a specific system in both intact as well as deteriorated coating films to protect those substrates from corrosion. Even so, they are well known, as well as in the absence of long-term corrosion data, despite the issue of reproducibility, they are very useful guides to perform. They are also unlikely to have been discarded. Some workers consider them impractical due to the degree of acceleration of the corrosion process they accomplish as well as the uncertainty in the extent of the damage sustained in some for the tests. It should be said that the incorporation for (tri chloro-methyl saline) in the backbone for acrylic polymers has helped develop a coating with improved resistance to moisture including salt spray. With the rise in monomers, the resistant characteristics in formulated polymers rise, showing that the coating consistency raises and is less corroded, so it provides the binder so much strength to withstand weather conditions like moisture and thus enhances the binder’s durability to protect the surface from corrosion damage to hybrid polymers.

**Thermo Gravimetric Analysis (TGA) Study:** The thermal properties of 2 specimens among these emulsion acrylic copolymers were gated in the vest by means of thermogravimetric analysis (TGA) in an Argon at a heating rate of 10°C / min. Outcomes like Ti, Top, Tf, T50 percent, percent residue at 700°C, as well as char yields at 600°C Treatment. Temperatures of 50 percent weight loss (PFA1, PFA2, PFA3, PFA4, PFA6) as a typical predictor for polymer thermal stability were all 700°C, char yields (PFA1), 55 percent (PFA2), 57 percent (PFA3), 52 percent (PFA4) 45 percent and (PFA6) 42 percent at 600°C in Argon atmosphere, where it means that they could meet the temperature-resistant specifications that can be applied to surface coating. The weight residue (PFA1) is 68% (PFA2), 56% (PFA3), 58% as well as 61% (PFA4) at 700°C.

**Differential Scanning Calorimeter Analysis (DSC) Study:** Is fully dissolved and afterward the sample’s rate of absorption to the sun, as well as the degree for crystallization (Tc) of the mix (250 °C), was set via the curve. The outcomes of (PFA2) polymer showed the glass transition (Tg) value of the mix (120 °C), suggesting a rise in temperature flow and then raising the specimen absorption rate to temperature until it reaches the melting point (Tm) at (490 °C). The crystallization rate (Tc) for the mix (350 °C) was calculated in the curve. The outcomes of (PFA3) polymer the glass transition (Tg) value for a mix (65 °C), indicating an increase in the temperature flow as well...
as then a raise in the absorption rate of a specimen at the melting point (Tm) at (480 °C) when completely melted and afterward the absorption rate of a specimen at the heat and by the curve was set the crystallization rate (TC) of a mix (20° C). The outcomes of (PFA4) polymer the glass transition (Tg) value of the mix (110 °C), suggesting a rise in the temperature flow and afterward the absorption rate of a specimen at the temperature until it reaches the melting point(Tm)at(460 ° C) and then the absorption rate of a specimen at the heat as well as the mix (370) forming a curve (Tc).

Conclusions

From the results, we can infer that all acrylic copolymers formulated for the emulsion had non-Newtonian pseudo-plastic form. High shear rate, high viscosity as well as high compliance were provided by the methacrylic acid. For the composition, the polymer having (MAA) monomer was of high thermal stability. Analysis of salt spray indicates enhanced corrosion resistance for hybrid binders with increased resin content. Due to the chemical reaction through the reactive groups incorporated for polymer as well as its main chain, the physical properties are subject to adjustment of thermal treatment temperature. The higher the temperature of thermal treatment, therefore better physical characteristics are reached for copolymers. A hybrid in acrylic through polymerization for emulsion, resulting in lower VOC compared to traditional systems. It shows that in a hybrid system, by adding two elements, we can boost the system’s properties as well as rise good properties as the quality of one element rises the other characteristics are not impacted. Thus these resins could be used in coatings at which good requires corrosion-resistant paints. Corrosion resistance, resistance to abrasion as well as resistance for different chemicals.

Evaluation of Primigravida Women’s Childbirth Self-efficacy at Al-Elwea Maternity Hospital in Baghdad City

Fatima Fadel Benyian¹, Rabea Mohsen Ali²

¹Assistant Instructor, ²Professor, University of Baghdad, College of Nursing, Maternal and Neonate Nursing Department, Baghdad, Iraq

Abstract

Pregnant women who believe themselves have capabilities to cope with childbirth, they feel able to control labor stress. On the other hand, if they believe themselves uncappable to cope with labor, they cannot control labor stress and may choose cesarean delivery.

Objectives: To evaluate women’s self-efficacy of childbirth and find out the association between women’s self-efficacy and study variables.

Methods: Descriptive study of non-probability (purposive sample) was used to collect the data from (100) women. A pilot-test was conducted to determine the reliability of the questionnaire. Data were analyzed through the use of SPSS.

Results: The higher percentage of women’s age was (20-29) years graduated from secondary school. About one-third of them in gestational age 32 weeks. More than two-thirds of them are preferred cesarean birth. They have a low childbirth self-efficacy. There are significant differences between women’s age, education, occupation, delivery preference, and childbirth self-efficacy.

Conclusion: This study finds that primigravida women have low childbirth self-efficacy, and there are significant differences between women’s self-efficacy with the demographic and reproductive variables.

Recommendations: Primigravida women need prenatal education and encouragement regarding labor to increase their believe of own capability to control and cope with labor stress.

Keywords: Primigravida, Childbirth, Self-efficacy, Women

Introduction

Self-efficacy is essential factor that required to successfully perform a certain behavior in a specific situation, also it is important for change behavior and self-control [1].

Self-efficacy believes to control labor stressors has a significant role in anxiety arousal.

Pregnant women who have high level of childbirth self-efficacy is associated with lower levels of labor pain, anxiety, require less obstetric intervention and analgesia compared to low levels of childbirth self-efficacy [2][3].

Self-efficacy has four sources, first mastery experiences (performance accomplishments); second vicarious experiences (modeling); third verbal (social) persuasion; and fourth physiological and affective states [4].

Email: fatmaf@conursing.uobaghdad.edu.iq
Pregnant women’s self-efficacy can affect prenatal well-being such as to mood changes, anxiety, and childbirth fear. Fear of childbirth also associated with anxiety and depression\(^5\).

Vicarious experience is observing others perform a certain behavior in specific situation that an individual wants to perform. It does not always have a positive effect on self-efficacy, an individual must find a role-model to develops self-efficacy beliefs individuals, through observation and interpretation of others’ performance. Observation of successful performance may increase self-efficacy, while observation of failed performance may decrease self-efficacy\(^7\).

Pregnant women’s perception of pain during labor can vary according to their expectations and prenatal preparation; labor length; position of fetus; fear, anxiety; body image; self-efficacy; and support. Women who believe that they can control their situation (have self-efficacy) than are those who do not feel in control\(^8\).

**Materials and Methods**

Descriptive analytic study design was used to evaluate women’s childbirth Self-efficacy. The study was performed from October 2020 to February 2021. Non probability (purposive sample) used to collect the data from (100) women. Inclusion criteria (First pregnancy, Singleton pregnancy, Gestational age of (28 to 32) weeks, has no medical and obstetrical problem, Literacy, Accept participation in study). A pilot study conducted in order to determine the reliability of the questionnaire in a sample of (10) women (r1= 0.88). Content validity was determined through a panel of (21) experts their experience mean and SD 25.8 (11.1). The data was collected after obtaining the agreement from women to participate in this study. Data are analyzed through the use of SPSS version 26.

Table (5) results shows that there are no significant differences between women’s pregnancy planning, gestational age and childbirth Self-efficacy. There are significant differences between duration of marriage before pregnancy, delivery preference and childbirth Self-efficacy.

**Discussion**

The findings of the present study are consistent with Matinnia et al., who found that the mean age (25) years in the study sample which ranged from (18-34) years, most of them had planned pregnancies and more than two-thirds (62.6%) requested cesarean birth without any medical indication [8].

Kabukçu et al., found the majority of nulliparous women (94%) had a planned or a desired pregnancy, and more than half (56%) of nulliparous women preferred cesarean delivery [9].

The results of the study are inconsistent with Serçekuş et al., who mentioned the mean age and SD (27.7 ± 4.5) years of pregnant women which ranged from (25-63) years, and their mean gestational age and SD (26.9th week ± 0.8). The highest percentage of them
(86.8%) were university graduates and the majority of them (81.2%) were employed [10].

Zhang et al., who found that the mean age and SD (29.33 ± 3.09) years in the study sample (n=1211) which ranged from (21-36) years, and their mean gestational age and SD (23.35 \text{th} week ± 3.22) ranged from (13.6-27.5) weeks. The majority of them (80%) were had completed Diploma level or postgraduate education and more than two third (67%) employed [11].

The differences in the above studies could be due to this study conducted among different sample in the different setting.

The current study show that the highest percentage of study sample have low childbirth self-efficacy, with mean score (1.49) and relative sufficiency (29.8%).

Toohill et al. reported a significant higher percentage of women in the intervention group scoring higher on the CBSEI (76.3%) [12]. While Gao et al., (2015) found that average total score of childbirth self-efficacy among the pregnant women was 219.69 (SD¼50.56, range51-320). They found women have high level of outcome expectancy Mean (SD) \( \frac{1}{4}112.60 \) (\( \frac{1}{4}16.95 \)) range (20–160) and efficacy expectancy Mean (SD) \( \frac{1}{4}107.00 \) (\( \frac{1}{4}27.02 \)) range16–160 [13].

The present study found there are significant differences between women’s age, education, occupation, delivery preference and childbirth self-efficacy.

Lower efficacy expectancy was associated with higher FOC while preference for a caesarean section was not. Improvement of self-efficacy could be a part of care for women with FOC during pregnancy; however, it would not be enough for fearful women who wish to have a caesarean section [14].

The results of the study are inconsistent with Schwartz et al., (2015) who found no relationship between age, education, or of having a history of abortion and self-efficacy for first stage of labor in nulliparous or multiparous women [15].

Fadhil, stated that women’s perception of childbirth pain may be influenced by several factors such as culture, childbirth knowledge, fear of childbirth. Utilization of childbirth emotional support, holding hands can make a difference to childbirth coping [16].

**Conclusion**

This study concluded that the majority of study sample have low childbirth self-efficacy. more than two-thirds of them were preferred cesarean delivery. There are significant statistically differences between women’s age, education, occupation, gestational age, delivery preference with childbirth fear.

**Recommendation**

Physicians and nurse-midwives should provide education and support to pregnant women, especially for primigravida women during prenatal and antenatal period to increase their childbirth self-efficacy. Study factors that affecting childbirth self-efficacy.

**Funding:** this research was funded by Author. Moreover,

**Conflict of Interest:** None declared.

**Ethical Approval:** was taken from committee in College of Nursing/ University of Baghdad.

**Acknowledgments:** we would like to thank all the pregnant women who participated in this study.

Neoplasia of the Nictitating Membrane in A Domestic Short-Haired Cat based on Cytology of Fine Needle Aspiration

Fatimah Alaydrus¹, Lita Rakhma Yustinasari², Juliano Mwenda Ntoruru³

¹Veterinary Practitioner, Maha Pet Care Clinic, Jln. Phh Mustofa Surapati Core F-20, Bandung, Indonesia,
²Lecturer, Department of Veterinary Anatomy, Faculty of Veterinary Medicine, Universitas Airlangga, Indonesia,
³Research Assistant, Meru University of Science and Technology, Kenya

Abstract

A 3-year-old male domestic short-haired cat was presented with the complaint of a dark red mass of the nictitating membrane of the right eye covered most of the cornea, mucopurulent eye secret, lost appetite, medium dehydration, and cough. Physical examination was performed and showed high temperature (38.6°C). Ultrasonographic examination was not performed due to tool limitations. Cytology of fine-needle aspiration masses suggested an ophthalmic neoplasm with the characteristic of neutrophils infiltration, multinucleated giant cells, and cells having granular cytoplasm. Enucleation bulbi was performed subsequently to exenteration the eye and the contents of the orbit.

Keywords: cat, cytology, neoplasia, nictitating membrane

Introduction

Tumors are the frequent cause of death in cats (32%); which 0.34% of those affect the ophthalmic area.¹ Most cases of the feline ophthalmic disease were neoplastic. The neoplasms were organized according to location (orbit, conjunctiva, eyelids, nictitating membrane, globe). Neoplasia of the nictitating membrane (NM) is relatively uncommon in veterinary species, especially cats.³ However, the following neoplasms have been reported such as adenocarcinomas, adenomas, carcinomas, ependymomas, fibrosarcomas, histiocytic sarcoma, mast cell tumors, melanocytomas, melanomas, osteosarcomas, papillomas, and squamous cell carcinomas.⁴ ⁵ When considering cases with neoplasia, an evaluation of how the health and longevity of the eye and patient is essential to determine biologic behavior. Inflammation and secondary glaucoma may arise from neoplasms, which are considered vision-threatening and may cause loss of the eye.⁶ The most common cause of enucleation in cats is the ophthalmic neoplasm.²

Case History

A 3-year-old (3.6 kg) male, domestic short-haired cat was referred to the Maha Pet Care Clinic, Bandung, Indonesia with the complaint of irregular roughed masses affecting the bulbar and nictitating membrane of the right eye. The cat’s eye was injured in a fight, but the cat disappeared and returned two weeks later in a very bad condition. The nictitating membrane was severely hyperemic and covered most of the cornea (Figure 1) with inflammation on the eyelid, so we could not evaluate the internal ocular structures. The cat appeared to be in pain. On physical examination findings were normal. The cat had no history of other medical problems, and its vaccination status was current.

Ultrasonographic examination was not performed due to tool limitations. Fine-needle aspiration of the nictitating membrane’s masses suggested an ophthalmic neoplasm. Cytological evaluation was of an unencapsulated, well-demarcated, multilobular neoplastic mass composed of basal cells seated within a moderately dense fibrovascular stroma (Figure 2). Based on the cellular morphology, the neoplasm was diagnosed as a presumptive basal cell tumor. Due to the lack of natural borders and the size of the tissue fragments, it was difficult to determine whether the neoplasm represented
a benign process or a malignant process. There was no evidence of sebaceous or squamous differentiation in the examined sections. Considering the extensive nature of the lesion, the cat’s pain, and the owner’s financial constraints, we recommended enucleation bulbi to remove the eye and the contents of the orbit.

**Treatment**

Pre-anesthetic drugs included atropine sulfate (0.08 ml/kg) and acepromazine (0.02 ml/kg) given intramuscularly. Anesthesia was induced with intramuscular ketamine (0.05 ml/kg).

The exenteration was performed by enucleation bulbi approach. Scalpel blade No. 22 was used to incise the skin from the eyelid edge in an elliptical fashion to allow for smooth skin apposition at closure. The orbital contents were removed which were kept as close to the bones of the orbit as possible. The medial and lateral orbital ligaments were transected, and the nictitating membrane was completely removed. The dissection was continued around the eye and mass until the optic nerve was encountered. The nerve was then transected, and the tissue was completely removed. The subcutaneous tissue was closed with vicril 2.0 in a simple continuous suture, and the skin was closed in a simple interrupted suture(Figure 2).

The surgery was successful and the cat recovered from anesthesia. It was released to the owner following day. For pain management, the cat was given tramadol (0.1 ml/kg intramuscularly) for three days. A two-week postoperative reevaluation was scheduled and the cat was in a good condition.

**Discussion**

Following 2 weeks history of eye enlargement and ocular discharge from the right eye, an ophthalmic examination was performed on both eyes. Severe mucoid discharge was detected on right eye, inflammation of the nictitating membrane was covered almost entire the right eye. Pupillary light reflexes both direct and indirect were present. Incisional biopsy sections were of an infiltration of neutrophils, multinucleated giant cell, granular cytoplasm, different cells sized, irregular outlines of nucleus, and no mitotic cells was found. Based on the cellular morphology, the neoplasm was diagnosed. Due to the lack of natural borders and the size of the tissue fragments, it was difficult to determine whether the neoplasm represented a benign process or a malignant process. The nictitating membrane is composed of numerous tissue types including conjunctival epithelium, vascular substantia propria, lymphoid tissue, supporting hyaline cartilage, and associated glandular tissue which contributes to lacrimation. Once nictitating membra removed, the eye become dry and possibility of corneal ulcers. In this case, neoplasm is located in the nictitating membrane, metastasis/recurrence to the eyeball will sooner or later occur. Based on the case, we did not have any choice except surgical enucleation bulbi and the cat will loss of the right eye. The cause of the neoplasm remains unknown.

**Conflict of Interest:** There is no conflict of interest among the authors.

**Source of Funding:** This study was self-funded.

**Ethical Clearance:** Compliance with ethical standards.

Nursing Intervention Program for Enhancing Coping Patterns among Nursing Students

Fatma Adel Ahmed Ahmed¹, Sorayia Ramadan Abd El-fattah², Galila Shawky El-Ganzory², Hanaa Ezz El-din Prince³

¹Research Scholar, ²Professor, ³Lecture, Psychiatric-Mental Health Nursing, Faculty of Nursing, Ain-Shams University

Abstract

Background: Nursing students face many sources of stress during undergraduate nursing education and training as, fear of the unknown, lack of professional nursing skills. Aim: to enhance coping patterns among nursing students. Design: a quasi-experimental design was utilized to conduct this study. Setting: The study was carried out at a faculty of nursing Ain-shams University. Subjects: A convenient sample was selected for this study was performed on 80 nursing student. Tools: 1) Self-administered questionnaire sheet. 2) student clinical stressors Scale. 3)Coping patterns Scale. Results: The present study revealed that there were highly statistically significant differences were found between pre-post program implementation after five months regarding student clinical stressors and coping strategies among nursing students. Also, there were statistically significant correlations between total clinical stressors and coping patterns at a pre - post-program after five months. Conclusion: nursing students had high levels of clinical stressors, which decreased after the implementation of the management program with a highly statistically significant difference (P≤ 0.001). Recommendations: Designing systematically continuous Special remedial programs need to be constructed for students with high clinical and academic stressors and low coping patterns to provide proper information and psychological support that help them improve their academic performance which in turn increase their coping patterns and reduce the sense of stress.

Keywords: Clinical Stressors, Coping Patterns, Nursing Students, Management program.

Introduction

A nursing student is a student in a post-secondary educational program that leads to certification and licensing to practice nursing. The title ‘nursing student’ usually applies to students enrolled in a registered nurse or practical nurse program. A nursing student can be enrolled in a program that leads to a diploma, an associate degree or a Bachelor of Science in nursing (1).

Nursing is regarded as a demanding and stressful profession. Nursing students and nursing educators need to understand the concept of coping, the application of the coping concept in pre-registration nursing may provide fresh insights into nursing recruitment, retention and ultimately patient/client outcomes (1)(2). Coping has been highlighted as an important theoretical and practical construct. It has the potential to enable individuals to cope better and experience less stress thus contributing to a healthy and stable workforce (2).

There are many ways of coping with stress. Their effectiveness depends on the type of stressor, the particular individual, and the circumstances, for example, if we consider the way students deal with stresses such as exams, we will see a range of different coping responses (3). Higher education students cope in different ways with varying levels of success (4)(5).

The main sources of stress are academic and time concerns, fear of failure, classroom interactions, and...
economic issues. Apart from this, the parental system also affects a lot of these students. The parents have unlimited expectation from their children and therefore they impose their desires on them. The impact of these influences results in many students reporting emotional problems, anxiety, stress, and other neurotic problems😃😕.

Considerable stress is involved in nursing education. It is found that higher levels of stress and higher levels of physiological and psychological symptoms were found among nursing students than students in other health-related disciplines. Nursing Students experience increased tension before their clinical rotation and written examination especially their final examination📮.

An understanding of the stress experienced by students enables nurse educators to assist students in their stress and to provide a supportive learning environment for them, and there should be a collaborative effort among academic staff members to reduce the unnecessary stressors, this may create a positive attitude among nursing students and enrich emotions📝.

A nursing intervention program for enhancing coping patterns among nursing students include health education, stress management, decreasing maladaptive responses to the identified stressor, enhancing adaptation toward stressors, improving psychological wellbeing, communication skills, psychosocial skills, assertive techniques, relaxation techniques, problem-solving, crisis intervention, environmental change, social support, stigma reduction, role modelling, counselling, motivation, providing emotional support, lifestyle changes and the teaching of coping skills. managing stress effectively and using healthy coping strategies is an important skill required for students who enrol in nursing, for optimum performance in their future life📝.

Significance of the study:

Nursing students often work with vulnerable patients who. are in need of strong support to advocate and assist them to manage their health, and these students must be prepared and ready to assume their role with confidence and competence to free any stress.

Stress is a condition faced by students when they are unable to bear the burdens involved in higher nursing education. Students who learn and use effective coping patterns to deal with stress will most likely develop a positive self-concept. Students who become overwhelmed with stress may feel hopeless and powerless, leading to a feeling of low self-confidence and self-esteem. Thus, the present study will be made for enhancing coping patterns among nursing students.

Aim of the Study

This study aims to enhance coping patterns among nursing students.

The aim will be achieved through:

1-Assessing the practical stressors and coping patterns among nursing students.

2-Designing nursing intervention program for nursing students based on assessment.

3-Implementing nursing intervention program for enhancing coping patterns among nursing students.

4-Evaluating the effect of a nursing intervention program for enhancing coping patterns among nursing students.

Hypothesis:

Improving nursing students coping patterns will decrease practical stressors after the implementation of a nursing intervention program.

Subjects and Methods

- Research design: A quasi-experimental research design was used for the current study.

- Sampling: The sample size included all available nursing students in the faculty of nursing from fourth grade were around 80 students.
Tools of data collection

1- Self-administered questionnaire sheet (Appendix I):

It was developed by the researcher based on a comprehensive reviewing of the literature. It was reviewed and accepted by supervisions to collect data concerning nursing students perception and expectations about the nursing profession. The questionnaire was in the form of multiple-choice questions (MCQ). The nursing students were requested to circle the statement of choice in each question. The questionnaire consisted of two parts:

- Demographic data of the nursing students such as age, sex, academic year, place of residence and monthly income.

- The nursing students’ perception and expectations about the nursing profession such as what are the reasons for joining the college, what do you think of the nature of the college, what is the community’s view of the profession in your opinion, is nursing in Egypt similar to that of developed countries and the role of media for nursing.

2- Scale to assess student clinical stressors (SCSS):

This scale was developed by (El-Sebaie, 1991). It is intended to measure the stress experienced by undergraduate nursing students during clinical practice. This scale includes 34 statements on a 4-point scale: Unstressful, mild stressful, moderate stressful and severely stressful. the scale assesses three subscales as follows:

- Clinical setting.
- Work with different types of patients.
- Evaluation process.

3- Coping strategies scale:

This scale was developed by Ibrahim (1994). It consists of 69 statements measuring coping strategies on a 3-point scale: never, sometimes, and always. The sheet is divided into two main categories:

- **Problem-focused coping:** this part deals with 24 problem-oriented coping behaviours. These behaviours are primarily aimed at using cognitive skills in handling stressful situations through problem-solving techniques. They are classified into four subscales which refer to:
  - Seeking out information (3 statements)
  - Positive reinterpretation (6 statements)
  - Exert of restraint (5 statements)
  - Active coping (10 statements)

- **Emotional-focused coping:** this part deals with 45 emotional-focused coping behaviours. These behaviours are primarily adopted to manage the emotions accompanying a stressful situation. They are classified into seven subscales which refer to:
  - Helplessness (10 statements)
  - Mental disengagement (7 statements)
  - Wishful thinking (8 statements)
  - Turning to religion (3 statements)
  - Emotional discharge (13 statements)
  - Acceptance (3 statements)
  - Denial (1 statement).

**Results**

Table (1) shows that more than two-thirds of nursing students (67.5%) were in the age group 18->20, with Mean±SD: 1.49±0.50. Two-third of nursing students (60.0%) were Sufficient monthly income. More than half of the nursing students (55.0%) were males. More than two-thirds of nursing students (68.8%) were lived in the urban area and more than two-thirds of them (71.3%) were lived with their family.

Discussion

The current study was conducted on eighty students of the College of Nursing (N= 80), which revealed that most students were in age 19-21 years. This may be due to admission requirements, this result consistent with the study conducted by (13), who assessed socio-demographic and academic profile of nursing students of a public university, stated that the possibility of students aged 19 years feeling insecure regarding the requirements of professional education and of the profession they have chosen.

Concerning sex, the current study revealed that more than half of the students were male. This may be because males are the prominent gender in the nursing practice because of the phenomenon of the general trend of students towards the field of nursing as a work for him a good future. This finding is inconsistent with (3). Who assessed stress levels and coping patterns of nursing students in an international program practicum, showed that the majority of respondents were female.

About residence, the current study revealed that the majority of students were living in urban areas. This may be due to increased urban people aware of the nursing profession, in particular women in urban areas are independent but seek employment to make money but in rural areas rural cultures have been prevented from working as nurses because of rural culture, this justification consistent with the study conducted by (4), who assessed recruit nursing students and stated that students from rural backgrounds are more challenged in adapting to the large urban academic environment, often far from family and community supports.

Concerning monthly income, more than half of the students studied have sufficient monthly income to meet all the requirements of the study, this due to the financial burden and associated additional costs, such as study
costs and the continuing increase in the prices of books. Besides, The students who try to solve the financial burden of the study fees through the working night and have their academic performance affected by the lack of time available for study. This result is also congruent with (5) who discussed The key sources of stress emanated from clinical, academic and financial issues.

About the reasons for joining the college, we find that the most selected answer was a work with a good future. This explains the turnout of male nursing colleges more than females and in recent years it is consistent with (6) who described the many benefits of the nursing profession.

In relation to the effect of the nursing intervention program on total clinical stressors score, the results indicated that about a third of the study were under high clinical stress due to the stresses they were exposed to during practical training. This finding may be due to the most studied students’ fear of the new, unknown clinical environment, the conflict between ideal and real clinical practice, lack of knowledge of clinical history, lack of professional nursing skills, diagnosis and treatment of unknown patients, and the physical. Psychosocial care for patients, fear of making mistakes, giving medicines to children, and the death of the patient. Other sources of reported stress include negative interaction with coaches, monitoring and delaying teachers, bad relationships with medical staff and even talking to doctors.

A significant decrease in the percentage of stress among students was observed after applying the nursing intervention program. These results may be due to the students’ awareness created through the nursing intervention program to enhance coping patterns among nursing students, and it may also be because the nursing intervention program sessions provide the nursing students with specific information about clinical stressors such as the sources of clinical stressors, the effect and methods of prevention, and thus their knowledge increases after undergoing the program, and this means increasing students’ awareness through the Nursing Intervention Program to enhance the coping patterns among nursing students.

These results matched with (14) in the study entitled “Effects of an Online Mindfulness Program on Depression, Anxiety, Stress, and Coping among Undergraduate Second-Year Nursing Students” which revealed that there was highly statistical significant improvement between pre-post program about clinical stressors.

Furthermore, this results matched with (10), in the study entitled “Decreasing stress and supporting emotional well-being among senior nursing students: A pilot test of an evidence-based intervention” who stated that Overall feedback was positive, with participants describing how skill modules helped them establish relationships and manage stress in clinical, academic, and personal settings. Significant reductions in stress and improvements in well-being were also reported.

Also these results agreed with (15), in the study entitled” The effects of group mindfulness-based cognitive therapy in nursing students” who mentioned that stress scores decreased significantly in the experimental group.

On the other hand, these results were contraindicated with (16), in the study entitled” The effect of a peer mentoring strategy on student nurse stress reduction in clinical practice “ who found that knowledge of students in the preprogram equal the post and not changed after implementation of the program these may be due to awareness of students about hazards of substance abuse before program implementation. These findings may be due to, the difference of cultures and the range of education from country to country effects on student responsiveness to programs.

In relation to the effect of the nursing intervention program on total coping patterns score, the findings of the present study revealed that, there were highly statistical significant improvement between pre-post intervention program. This results could have been due to, the program sessions contribute to the improvement of coping related to clinical stressors by provides nursing
students with special information about coping patterns such as identify the concept of coping, the resources for effective coping and altering the mistaken beliefs and replacing them with right beliefs.

This finding were consistent with (17) which conducted study about “Effect of Nursing Intervention on Students’ Stressors related to their Training in Pediatric Critical Care Settings”. The study concluded that, the application of nursing intervention reduce the students’ stressors related to their training in pediatric critical care settings. The study recommended orientation program, identifying students’ needs in the pediatric critical care settings and developing effective nursing interventions to reduce their stress.

In the same line, this results came in agreement with the study of(18), in the study entitled; The effect of a stress and anxiety coping program on objective structured clinical examination performance among nursing students in shiraz, Iran, that found that there were The anxiety coping program improved the examination results of nursing students in the final exam compared to the midterm results.

Furthermore, these results were in harmony with the study conducted by(19), who noted that, there were highly statistical significance improvement pre –post intervention in the study entitled “The effects of group mindfulness-based cognitive therapy in nursing students: A quasi-experimental study”.

On the other hand, these result was contradicted with study conducted by (8) in the study entitled as “Stress and anxiety among nursing students: A review of intervention strategies in literature between 2009 and 2015” they clarified that, there were no statistical difference improvement pre-post intervention. The review concluded further methodologically sound, adequately powered studies, especially randomized controlled trials, are needed to determine which interventions are effective to address the issue of excessive stress and anxiety among undergraduate nursing students.

In correlation to the effect of the nursing intervention program on total clinical stressors score and total coping patterns score. The current study revealed that there was a highly statistical correlation between coping patterns and clinical stressors, these results may be due to, the more information about different coping patterns can cause the better attitudes and beliefs toward clinical stressors, also could attribute these findings to, the booklet which had an excellent source of information and references to the students which helped to increase their knowledge and improve their coping and.

This could be due to using different methods of educational guidelines program as face to face interaction, laptop, discussion and demonstration supported by using real objects, posters, models and handouts which are effective approaches for conveying information.

Additionally, the educational program can increase students level of information through the use of basic principles which are acceptance, understanding, empathy and communication which are helping students to make decisions for themselves according to their information and problems.

These results matched (20) in the study entitled “Stressors and coping of nursing students in clinical placement: A qualitative study contextualizing their resilience and burnout” who mentioned that there was a highly statistical correlation between coping and stressors.

**Conclusion**

Based on the results of the current study; it can be concluded that:

nursing students had high levels of clinical stressors, which decreased after implementation of the nursing intervention program with a highly statistically significant difference (P≤ 0.001). Also, there were statistically significant positive correlations between the total score of student clinical stressors and total score of coping patterns during the pre-post implementation of the nursing intervention program after five months (P≤ 0.001).
Recommendation

In the light of these findings, it was recommended that:

- Replication of the current study on a larger sample is recommended to achieve generalization of the results and wider utilization of the designed program.

- Designing systematically continuous Special remedial programs need to be constructed for students with high clinical and academic stressors and low coping patterns to provide proper information and psychological support that help them improve their academic performance which in turn increase their coping patterns and reduce the sense of stress.

- Implement psychosocial counselling sessions for social workers, instructors who work in the faulty of nursing to teaching them the physiological and psychological changes of students to help their students how to face their problems and provide a chance for students to express themselves and develop their ability to coping effectively.

- Workshops organization at the beginning of each semester for university students, especially those in the first year. In these workshops, they will learn how to deal with those clinical and academic stress, how to manage it and learn some effective time management.

- Training courses and workshops should be organized to improve self-esteem for nursing students and increase their awareness and appreciation of their profession, thus relieving stress towards their perception of careers.

- Communication channels to express students’ reactions should be more positive to increase the assessment of nursing students for themselves and their profession, thus relieving stress within them.

- Further researches about provide attention to clinical and academic stressors and coping patterns among students and identify the factors that affect them and work to address them. Also their instructors, nurses and parents should be offered methodological guidance to work on this throughout the educational process.

Ethical Clearance: The study was approved from ethical and research committee faculty of nursing Ain Shams University, Egypt.

Abstract

SARS CoV-2 infection causes various clinical manifestations ranging from mild to severe. Acute Respiratory Distress Syndrome (ARDS) is a severe complication of COVID-19 caused by activation of the kallikrein-kinin system which produces bradykinin which is a potent proinflammatory mediator. This research is an in silico study which aims to determine the potential of active medicinal plant compounds in inhibiting the kallikrein-kinin system. Molecular docking in this study using Autodock 4.2 with Lamarckian GA criteria. Human plasma kallikrein (PDB ID: 5TJX) was docked with 70 compounds and one native ligand and analyzed using Autodock 4.2. The smallest binding energy obtained from docking 5TJX with several compounds in sequence, namely, xanthohumol, nafamostat, demethoxycurcumin, epicatechingallate, beta mangostin, alpha mangostin (-9.52, -9.35, -9.33, -9.28, -9.19, -9.06 kcal/mol). Therefore, the compound shows the best potential as a plasma kallikrein inhibitor. However, further research is still needed to determine the potential of drugs and medicinal plant active compounds for medical treatment.

Keyword: COVID-19, ARDS, Kallikrein, Medicinal Plant, Docking, Health Risk

Introduction

SARS Cov-2 infection causes various clinical manifestations, from asymptomatic, mild, or moderate symptoms, to severe cases requiring intensive care 1. In severe cases, one of the serious complications that often occurs is Acute Respiratory Distress Syndrome (ARDS). Several studies from Wuhan, China reported the incidence of ARDS in COVID-19 patients of 14-29%, and among critically ill patients around 67%. ARDS is caused by extensive endothelial-barrier damage and an uncontrolled ‘cytokine storm’. Increased levels of cytokines in SARS Cov-2 infection result in endothelial dysfunction, deregulation of coagulation, and increased microvascular permeability, leading to tissue edema and shock that can develop into acute lung injury (ALI) and ARDS 2.

The Kallikrein-kinin system mechanism can also contribute to lung injury and angioedema which can lead to ARDS. Kallikrein is a serine-protease enzyme that converts kininogens into kinin plasma protein.
Dysregulation of the Kallikrein-kinin system in COVID-19 patients potentially affected by decreased ACE2 expression due to SARS Cov-2 infection. SARS Cov-2 also expresses cysteine proteases which can activate the kinin pathway by interacting with kininogens. Activation of the Kallikrein-kinin system causes the release of bradykinin. Bradykinin-receptor B2 (BKB2R) contributes to the pro-inflammatory pathway by activating nitric oxide (NO) and prostaglandins (PGs) thereby increasing vascular permeability. Bradykinin can contribute to lung injury and inflammation in patients with COVID-19.

The development of natural compounds that may have similar therapeutic potential with smaller adverse effects is considered to be used as therapeutic alternatives or as complementary therapies to current ALI therapies. Natural compounds can also form the basis of new drugs for the treatment of diseases. In recent decades, various natural compounds extracted from plants have been reported to have anti-inflammatory activity. Several polyphenolic compounds have shown important in vivo and in vitro anti-inflammatory activity, such as flavonoids, lignans, phloroglucinols, quinones, stilbenes, phenylpropanoids, and diarylheptanoids. Also, terpenoid compounds have shown anti-inflammatory effects.

Kallikrein-kinin system inhibitor is one of the ways to minimize widespread inflammation due to SARS Cov-2 infection, so it is supposed to reduce the incidence of ALI and ARDS in critically ill COVID-19 patients. Currently, there has not been much research on natural compounds that have the potential to inhibit the Kallikrein-kinin system. In this study, the authors conducted a molecular docking study using human plasma kallikrein (PDB ID: 5TJX) as a protein target and several natural compounds which aimed to determine the potential of these active compounds in inhibiting the formation of bradykinin.

**Material and Methods**

**Protein Receptors Preparation**

The 3D structure of human plasma kallikrein (PDB ID: 5TJX) was downloaded from the Protein Data Bank (https://www.rcsb.org/) in .pdb format. The active site of the protein was determined using Discovery studio 2016. Protein optimization by removing water, adding polar hydrogen, and adding charge using Autodock 4.2. The structure of the protein was saved in .pdb format for further analysis.

**Ligand Preparation and Drug Likeness Activity**

The 3D structure of each natural compound was downloaded from PubChem (https://pubchem.ncbi.nlm.nih.gov/) in .sdf format and being optimized using Avogadro 1.2 and converted format into .pdbqt by using Open Babel 2.4. The natural compound with anti-inflammatory effect was obtained from Dr. Duke’s Phytochemical and Ethnobotanical Databases (https://phytochem.nal.usda.gov/phytochem/search).

The drug-likeness analysis was conducted to know the molecules with good permeation and oral absorption have molecular weight <500 Da, C logP<5, H-bond donor <5, H-acceptor <10, violation <2, this was calculated using the SWISSADME (http://www.swissadme.ch/).

**Molecular Docking**

The device used in this study is a laptop with an Intel Core i5-7200U CPU @ 2.50-2.71GHz, 8GB RAM. Operating System using Windows 10 pro ver 1903, 64-bit OS. Firstly molecular docking was performed with the native ligand of the protein to validate the reliability of the molecular docking process with root mean square deviation (RMSD) value <2 Å. The grid coordinate (X,Y,Z) -11.377, -2,117, -16,39 with dimensions of the Grid Box 36x36x36. Throughout the docking process, the macromolecule was kept rigid and the ligand was flexible. The molecular docking was performed using Autodock 4.2 by adjusting the Genetic algorithm (GA) parameter, using 10 runs of the Lamarckian GA criteria. Human plasma kallikrein (PDB ID: 5TJX) was docked with 70 compounds and one native ligand and analyzed using Autodock 4.2.
Result and Discussion

In the 5TJX protein, there is only one native ligand, namely GBT with active sites LEU418, HIS434, HIS472, GLN473, SER478, GLU479, GLY480, TYR555, ARG560, MET561, ASP572, ALA573, CYS574, LYS575, GLY597, SER578, THY599, CYS602. Several drug candidate compounds have been selected according to the Lipinski Rule of Five (Table 1) then sorted according to their binding energy. The smallest binding energy obtained from docking 5TJX with 70 compounds in sequence, namely, xanthohumol, nafamostat, demethoxycurcumin, epicatechingallate, beta mangostin, alpha mangostin, avoralstat, camostat (-9.52, -9.35, -9.33, -9.28, -9.19, -9.06, -8.41, -8.23 kcal/mol).

Kallikrein is a serine protease enzyme that converts kininogens into kinin plasma protein. Activation of kallikrein causes the release of bradykinin which contributes to the pro-inflammatory pathway. The kallikrein-kinin system can be a factor that plays a role in the formation of lung injury and angioedema in COVID-19 patients. This study used human plasma kallikrein (PDB ID 5TJX) as a potential protein target for the prevention of ARDS in critically ill COVID-19 patients. The ligands that will be tested are berotralstat, avoralstat, nafamostatmesylate, camostatmesylate, and several natural compounds that have anti-inflammatory effects to assess potency as a plasma kallikrein inhibitor.

In this molecular docking study, we used berotralstat, avoralstat, nafamostat, and camostat as standard drugs for comparison. Berotralstat is a specific plasma kallikrein inhibitor therapy given orally once-
daily dose. Berotralstat has completed its phase III study as long-term prophylaxis for Hereditary Angioedema due to deficiency of C1-inhibitor (C1-INH-HAE). Berotralstat was reported to reduce attacks of C1-INH-HAE angioedema in a phase III trial. Avoralstat is a potent plasma kallikrein inhibitor. Oral avoralstat therapy has been tested in phase III trials to shorten angioedema episodes and improve the quality of life of patients with C1-INH-HAE compared to placebo therapy.

Nafamostat mesylate and camostat mesylate are synthetic serine protease inhibitors. Nafamostat inhibits several enzyme systems, namely the coagulation and fibrinolytic systems (thrombin, Xa, and XIIa), the kallikrein-kinin system, the complement system, pancreatic proteases, and protease-activated receptor (PARs) activation. In COVID-19, Nafamostat may prevent disease progression by controlling the immune system such as the complement cascade, preventing disseminated intravascular coagulation (DIC), and preventing viral invasion by inhibiting viral fusion in cell membranes. Camostat inhibits cholecystokinin, proinflammatory cytokines, and serine proteases. Camostat is used for the treatment of chronic pancreatitis, drug-induced lung injury, and has the potential as COVID-19 therapy by preventing the entry of the virus into lung cells.

The results of docking between human plasma kallikrein (PDB ID: 5TJX) and ligands using Autodock 4.2 showed binding energy ranges of -9.35 and -3.59. The natural compound that has the smallest binding energy is xanthohumol with -9.52. Nafamostat, Avoralstat, Camostat, and Berotralstat have binding energies of -9.35, -8.41, -8.23, and -3.59 respectively. Xanthohumol is a prenylflavonoid found in the hop plant (Humulus lupulus L.) which is used in brewing and medicine. In the previous study, Xanthohumol could downregulate inflammatory mediators by inhibiting transactivation of NF-κB in LPS-activated macrophages and inhibiting STAT-1α and IRF-1 activation in IFN-activated macrophages. Xanthohumol could effectively inhibit LPS-induced oxidative stress and inflammatory damage of lungs, which may be associated with upregulation of the Nrf2 pathway depending on AMPK activation and GSK3β inhibition.

Demethoxycurcumin has a binding energy of -9.33. Demethoxycurcumin can be found in turmeric (Curcuma longa) and ginger (Curcuma xanthorriza). This compound has anti-inflammatory, antioxidant, and antiproliferative effects. Demethoxycurcumin significantly reduces inflammation due to increased expression of IL-1β, IL-6, NF-κB, TNF-α, iNOS, and COX-2. Epicatechingallate exhibits binding energy of -9.28. Epicatechingallate is mostly found in the tea plant (Camellia sinensis). Epicatechingallate has been studied to have anti-inflammatory effects, which reduce the expression of TNF-α, IL-1β thereby attenuating the expression of iNOS and COX-2. Beta mangostin has a binding energy of -9.19. Beta mangostin can be isolated from hexane and chloroform extracts of mangosteen stem bark (Garcinia mangostana). Beta mangostin has anti-inflammatory effects by inhibiting the production of nitric oxide (NO). Based on the binding energy from the docking result, xanthohumol, demethoxycurcumin, epicatechingallate, beta mangostin, and alpha mangostin, are natural compounds that are recommended as potential inhibitors of plasma kallikrein for further in vitro and in vivo studies.

Conclusion

COVID-19 has become a global health problem due to the high spread and until now there has been no adequate therapy for ARDS complications which are triggered by activation of the kallikrein-kinin system which produces potent pro-inflammatory mediators. Therefore we recommend xanthohumol, nafamostat, demethoxycurcumin, epicatechin gallate, beta mangostin, and alpha mangostin which show the best potency as plasma kallikrein inhibitors. However, further research is still needed to determine the potential of drugs and medicinal plant active compounds for medical treatment.

Background: Guillain-Barre syndrome is an acquired inflammatory polynuropathy characterized by rapidly progressive symmetrical flaccid limb weakness and a reflexia.

Design. A quasi-experimental design was used to guide this study. The study included a sample of 30 nurses who work at pediatric intensive care and neurology unit in Assuit University Children Hospital.

Data were collected using a questionnaire and an observation checklist, used in pre-post testing to measure the effectiveness of the training program among nurses.

Results: The study revealed deficiency in pre-intervention nurses’ knowledge and practices. Statistically significant improvements on knowledge and practices were demonstrated at the post-intervention time for the studied nurses. Statistically significant relations were shown between knowledge and practices among studied nurses.

Conclusion: Implementation of the training program significantly improved nurses’ knowledge and practice. More experienced and aged nurses had better knowledge.

Keywords: Guillain Barre Syndrome, Nurses’ Knowledge and Practices

Introduction

Guillain Barre Syndrome (GBS) is classically defined as an acute acquired sensitive-motor polyradiculo neuropathy post infectious, immunologically mediated, usually of demyelinating nature. It is the leading cause of acute flaccid paralysis in developed countries, in which polio has been eradicated (¹).

Guillain Barre Syndrome is a relatively rare disorder, with an incidence ranging between 0.5 to 1.5 cases per 100,000 individuals in the population of 0-17 months. It is a well-recognized disease worldwide and it is the most frequent cause of acute flaccid paralysis in countries where polio vaccination has allowed polio eradication. GBS affects patients of all ages. The incidence of GBS in children is 0.8 cases per 100,000. It affects both sexes in a ratio M/F 1.5-1 (¹).

Nursing care is essential in all phases of disease because children with GBS are immobilized and have respiratory depression. The emphasis care is on close observation to assess the extent of paralysis and

Pediatric Nursing Department, Faculty of Nursing, Helwan University, Egypt,
Email: dr-hudashawky@yahoo.com
on prevention of complication including autonomic dysfunction as hypertension, orthostatic intolerance, respiratory dysfunction, pain management and life-threatening dysrhythmias (2).

Increasing nurses’ awareness of Guillain Barre syndrome and the related childcare management strategies for all phases of the illness; to enhance care provided to child, provide a more informed and higher level of care for children and their families impacted by this unique and challenging illness (3). This study aims to evaluate the effectiveness of training program regarding Guillain Barre Syndrome maneuver on nurses’ knowledge and practices through.

**Significance of the Study**

The GBS is a significant cause of long-term disability for at least 1,000 children per year in the United Stat and is considered a medical emergency. It is affecting approximately 100,000 children per year. The incidence of non-polio acute flaccid paralysis in Egypt from 2014 to 2015 was 1534 children and the incidence of using plasma pharesis as a first line for treatment was 60 % of total number of previous cases. So, the expected cases for Egypt are 2/100,000 among children < 15 years of age (4).

Children who are suffering from GBS require special care from nurses to ensure maximum performance. so, during the researchers’ work at neurology and pediatric intensive care unit in Assiut University Children Hospital, it was observed that nurses were lacking the necessary basic knowledge and practices related to caring of children with GBS. So, this study was designed in a trial to improve nurses’ knowledge and practices concerning the care offered to children with GBS.

**Materials and Methods**

**Research design**

A quasi-experimental research design was used to guide this study.

**Setting**

The study was conducted at neurology department and pediatric intensive care unit in Assiut University children Hospital.

**Sampling:**

A convenience sample of 30 nurses (3 baccalaureate and 27 practical nurse) working at the pervious selected setting in Assiut University Children Hospital.

The first tools utilized to collect data is a structured questionnaire interview sheet which includes the personal and sociodemographic characteristics (age, qualification, job position, duration of nursing total and current job experience, and previous attendance of training courses). The nurses’ knowledge form about GBS includes 28 items about definitions of GBS, types, incidence, causes, complications, management and prevention of GBS. These items were scored as 2 grades for each complete answer, (1) for incomplete, and (0) for wrong one. The total score of knowledge is 115. The cut-off-point of knowledge is satisfactory for > 60% and unsatisfactory for < 60%.

The second tool is observation checklist which was developed by Kumar (5) that evaluates nurses’ practices given to child with GBS. It includes 55 items about practices related to vital signs, 8 items related to blood sample, 6 items related assist during lumber puncture, 10 items related to intravenous fluid, and 21 items related to suctioning. These items were scored as (1) for those be done correctly and (0) for these not done. The practice was considered competent if the percent score was 60% or more and incompetent if less than 60%.

**The training program**

Handout about the training program content was developed by the researchers based on the knowledge and practices needs in a form of printed (Arabic booklet). It was also supplemented with information based on review of relevant literature (nursing textbook, journals, internet resources, etc.) about care provided to children in with GBS. Then the program was reviewed by a panel of experts before its implementation.
The program included two parts:

**Theoretical part:** It includes two lectures, one session for each. The first lecture included definition of GBS, types of meningitis, dangers type, causes and incidence. The second lecture included sign and symptoms of GBS, complications of each one, treatment and prevention.

Practical part: This part covered the nursing procedures offered for children with GBS such as vital signs, intravenous fluid, blood sample, lumber puncture and suctioning. One session of each procedure and each group has 1-2 nurses. The time required for the program implementation was 7 months with approximately 280 hours divided in 80 hours theoretical and 200 hours practical.

**Data collection**

An official letter was obtained from the Dean of the Faculty of Nursing to the Heads of the Neurology Unit, as well as the Head of Pediatric Intensive Care, soliciting the necessary approvals to conduct the research.

An Arabic translation of all study tools was done and preparation of the program lectures in form of Arabic module.

**Validity**

The validity of the study tool was assessed to check its content coverage, and clarity of the questions by a jury panel of professors from five expert pediatric field and its result was 96%.

**Reliability**

Reliability was estimated by Cronbach’s Alpha test for study \( r = 0. 68 \).

**Ethical consideration:**

The written consent was taken from all nurses participate in the study.

**Results**

Level of knowledge in pre, post and follow-up tests

Figure 1. Level of nurses’ knowledge over time
Table (1) shows that less than a half (46.7%) age 24-28-years with mean age (27.19±8.77). The majority (70%) had 5-10-years of experience mean duration of 9.88 and 60% of them had Supportive Strategies courses related to emergency need.

None of nurses had complete answers before program implementation about GBS is, among children. GBS is caused by many factors such as children at risk of GBS are and the most dangerous type of GBS. This percentage increased to 100% at post I and decreased to (60%, 70%, 50%, 43.4%, 20.0% & 36.7%) respectively at post II.

It was found that none of the nurses knew the sign and symptoms and treatment before the program implementation. On the other hand, all nurses mentioned that sign and symptoms and treatment, with statistically difference significant post-intervention (p <0.000*).

Moreover, when asked about the Supporting family of children with GBS, it was found that none of them had complete answers before program implementation, while 73.3% of nurses mention them completely at post I and 57.6% at post II (follow-up).

Table (3) indicates increases in the practice scores in all areas at the post-intervention. However, this increase reached statistical significance for nurses’ basic practice about vital sign, lumber puncture, intravenous fluid, blood sample and suctioning (p< 0.00*). However, the practice scores slightly declined after three months at follow-up. Nevertheless, the scores were still higher than the baseline scores.

Table (4) indicates statistically significant improvement in total knowledge over time (I) (96.8 and 216.67, respectively) compared to preprogram (10.43 and 45.58, respectively) (p=0.000).

Figure 1 showed in this figure the majority of nurses (90%) were poor knowledge before program implementation, while after program their knowledge was satisfactory and only 10% were poor.
Figure 2 displayed that only 10% of nurses had adequate level of practice before program implementation, while after program the majority (96.7%) had adequate level of practice.

**Discussion**

Concerning the nurses’ knowledge of GBS before the program implementation, it was found that none of them know the common types, causes, the sign and symptoms, and its treatment. On the other hand, all nurses at the post answered correctly the questions related to the sign and symptoms and treatment of GBS with statistically significant difference. While the percentage of the correct answered was increased to 100% at post I and slightly decreased at post II. These findings agree with that of Kudhaer and Mua’ala (7) who revealed that the majority of nurses had poor knowledge in relation to general information (only answer 5 items correctly out of 20 items) and nursing care (only answer 3 items correctly out of 12 items) of children with Guillain-Barre Syndrome.

The present study showed a comparison between mean score of nurses’ performance of GBS care throughout intervention program phases (pre, post and follow-up). The indicated increases in the practice scores in all practice areas at the post-program phase. However, this increase reached statistical significance for nurses’ basic practice about vital sign, lumber puncture, intravenous fluid, blood sample and suctioning. However, the practice scores have demonstrated some declines after three months at follow up testing. Nevertheless, the scores were still higher than the pre-program baseline scores.

As regards the nurses’ knowledge, the majority have poor knowledge before program implementation, while after program the majority were satisfactory level of knowledge. This result agrees with that of Kudhaer and Mua’ala who stated that, in general, nurses’ knowledge was poor before program (7).

Regarding nurses’ practices, they have improved over time. This study finding contradicts another study finding by Mohamed which revealed that more than three quarters of them (76.0%) had competent practices (8).

The current study indicated statistically significant improvement in total knowledge and practice over time. This finding was inconsistency with another study finding conducted by Abdelmonem et al. (9) who stated that nurses had unsatisfactory knowledge pre teaching program compared to post teaching program. The majority of nurses’ practice have been inadequate pre teaching program compared with post teaching program.

**Conclusions**

It was concluded that the implementation of the training program significantly improved nurses’ knowledge and practices. Program attendance was the only independent predictor of nurses’ knowledge and practices scores.

**Recommendations**

Continuous evaluation for nurses caring of children with GBS is crucial, as they may lose knowledge and skills in the course of time.

Providing educational guidelines, posters, pamphlets and manuals about GBS should be available at each nursing station in wards and encourage nurses to get use of them.

Encourage the nurses to participate in training courses and congresses held by specialists in GBS to update their knowledge.

**Conflict of Interest**: The researchers confirm that there is no any conflict of interest.

**Source of Funding**: This study is self-funded.

**Ethical Clearance**: The researchers obtained the ethical approval from the Bilad Alrafiadain University College

Molecular Detection of Helicobacter Pylori in Sheep at AL-Muthana Province of Iraq

Ftima Atiya Kareem¹, Nabeel M.H. Al-Maaly²
¹Scholar Researcher, ²Assistant Professor Internal and Preventive Medicine, College of Veterinary Medicine, Baghdad University, Iraq

Abstract

Helicobacter pylori (H. Pylori) was discovered in 1982. Over 50% of the world population is infected by this bacterium. H. Pylori is the main cause of gastritis, peptic ulcers, and gastric cancer in human. Foods with animal origins play a substantial role in the transmission of H. Pylori. The present investigation was carried out to study the molecular detection of H.pylori in stomach gastric tissue of the sheep. Collecting of the samples occur randomly from various area of Al-Muthana province slaughter house(AL-Muthana, AL-Khudur, AL-Rumethah) from October 2019 to February 2020. One hundred and fifty (n 75 male, n 75 female) abomasums samples were collected and dissection in aseptic manner then stored in deep freeze (Liquid nitrogen -196) until processing and analyzed for the presence of 16s RNA and VACA genotypes. This study showed that the Prevalence of H. Pylori in the gastric samples of sheep at slaughterhouses (Al-Muthana, Al-Khur, Al-Rumethah) were (9 positives) 18%, and (7) 14%, (15) 30% respectively. The most commonly detected genotypes in the gastric samples of slaughterhouses were 16s RNA (20.67%) in ewes(25.33%). AL-Rumetha was the most commonly detected H. Pylori (30%). Results showed that gastric tissue of sheep can act as a reservoir to H. Pylori and disseminate the pathogen in feces and milk then transmitted to human during uses of unpasteurized milk, or meat. samples could be the potential sources of virulent strains of H. Pylori. Application of sanitary measures in the storage, transportation and sale of meat is essential for reducing the levels of H. Pylori cross contamination.

Keywords: Molecular detection, helicobacter pylori, H. Pylori, sheep

Introduction

H. Pylori is a bacterium that infects the mucus lining of the stomach and Duodenum. Helicobacter bacteria are the only known microorganisms that can thrive in the highly acidic environment of the stomach with a diameter 2 to 4 μm in length and 0.5 to 1 μm in width. H pylori is gram negative, S-shaped or curved, microaerophilic, none sporulating, spiral coccoid flagellated bacterium. It consist from two to six flagella that give it the motility to withstand rhythmic gastric contractions and penetrate the gastric mucosa. Hp-pathogenesis is not yet clear. Hp is genetically heterogeneous and all strains may not play the same role in the development of malignancy. Specific allele polymorphism exists in domains of this gene: signal region (s1a, s1b, s1c and s2), the intermediate (i1, i2 and i3) and mid region (m1a, m1b and m2). Waist named due to its ability to cause “vacuole”-like membrane vesicles in the cytoplasmatic gastric cells, but the mechanisms in H. Pylori pathogenesis remain unclear. In addition to the induction of vacuolation, Vac A exert severity of other effects on target cells, including disruption of mitochondrial functions, stimulation of apoptosis and blocked of T-cell proliferation. Vac A is also important for colonization of H. Pylori in gastric mucosa, another virulence factor is cytotoxin-associated gene A (cagA), which is a gene of pathogenicity island of H. Pylori and can be a predictive marker for the bacterium pathogenicity. H. Pylori strains can be divided into two groups: cag positive and cag negative.
negative. According to previous studies, *cag* positive strains are more prevalent in patients with more severe clinical symptoms\(^\text{(4)}\).

Different modes of transmission have been suggested that gastric tissue of several animals, taking part in the human food chain, such as sheep 16 % and this suggest them as reservoirs\(^\text{(13)}\). Sheep may are natural host for *H. Pylori*\(^\text{(3)}\), *H. pylori has ability* to survive in complex foodstuffs such as milk, butter, cheese 30%\(^\text{(10)}\), feces of animals (sheep, cow, buffalo) play main shedding site, which agrees with the findings that *H. Pylori* colonizes the abomasum of animals and crosses the intestine. In accordance with previous studies, *H. Pylori* in milk might be attributed to contamination from feces or from the surrounding environment\(^\text{(5)}\).

**Materials and Method**

**Gastric Sample Collection**

Collection of samples from sheep gastric tissue of stomachs, including the antrum area from abomasum.

**Experimental animals**

Samples were collected from 150 sheep (75 male & 75 female) with different ages at a slaughterhouse. Dissection of samples occur in laboratory of Microbiology College of veterinary medicine and done under aseptic conditions. Tissue collection took place in the AL- Muthana province, Iraq. All animals prepared for consumption in this slaughterhouse are from AL-Muthana, the collection take place from different area of provence (rural, and city center) and many slaughter houses of (AL-Muthana, AL- Khudur, AL- Rumetha). After dissection the samples stored in deep freeze (-20) until processed.

**DNA Extraction and Genomic Characterization Of Helicobacter by Polymerase Chain Reaction**

Extraction of genomic DNA was from sheep stomachs antrum area of abomasums that preserved in deep freeze (-20), and using the G-DEX™ Ilc Genomic DNA Extraction Kit for Cell/Tissue (korea), according to the manufacturer’s instructions. To determine the presence of *Helicobacter pylori* 16S rRNA two 22-base oligonucleotide primers (Hp1 and Hp2) that amplified 1200 bp were used as described elsewhere. In addition, a set of primers specific for the *H. Pylori vacA* gene

(VAG-F: 59-CAA TCT GTC CAA TCA AGC GAG-39; and

VAG-R: 59 GCG TCA AAA TTC CAA GG-39) with a reported sensitivity of 98.4%\(^\text{(3)}\) was used to amplify a 570-645 bp product for *m1 & m2* from the middle region of the *vacA* gene. Furthermore, primers specific for *Helicobacter* genus–specific 16S rRNA described by Fox *et al.* were also used for polymerase chainreaction (PCR) amplification of DNA extracted from tissue samples. The primer pairs (C97, 59 GCT ATGACG GGT ATC C-39 (276–291 forward); ; and C05, 58-ACT TCA CCC CAG TCG CTG-38 (1478–1495 reverse)\(^\text{(6)}\).

After amplification, the reaction products were separated by electrophoresis through 1% agarose gels containing ethidium bromide ((5μl of a 10mg/ml stock solution per 100 ml of agarose gel) and the PCR products were visualized by ultraviolet fluorescence. All reactions were performed in duplicate.

**Sequence analysis**

The sequence of the nucleotide of Helicobacter pylori 16S Rrna gene was known in 6 samples, as 25 microliters of each sample of the PCR product with the Primers of the nucleotide of Helicobacter pylori 16S Rrna gene were sent to Macrogen in the Korea and after obtaining the results , all the results were compared directly with the nucleotide of the nucleotide of Helicobacter pylori 16S Rrna gene Available in the internet (http: NCBI Reference Sequence) by computer program (BioEdit Pro. version: 7.0.0)

**Statistical Analysis**

program was used to detect the effect of difference factors in study parameters. Chi-square test was used to significant compare between percentage in this study(19).

Results

Genomic Characterization of Helicobacter Organisms

The result show 31 of the 150 gastric tissue samples positive for the 16S rRNA also amplified specific vacA that 25 of 150 gastric tissue is positive. Statistically significant differences (p<0.01) were observed in the prevalence of H. Pylori in sheep gastric samples collected from different provinces (data shown in table 1), while table 2 observed that female had more tendency (25.33%) to harbor H. Pylori in it gastric mucosa than male (16%) also in this study the result shown this bacteria compare between rural and city of AL-Muthana provinces that AL-Rumetha with percentage 15%, AL-Khudur 7%, AL-Muthana slaughter house 9% data shown in table 3.

Sequence analysis

The results were registered in NCBI under accession numbers (LC589440, LC589441, LC589442). Which is available on the website (https://www.ncbi.nlm.nih.gov/nuccore/LC589441).

H- pylori 16S Rrna gene. The results of the analysis of the H- pylori 16S Rrna gene sequence were summarized in Table (4) and showed that there were 14 mutation in 6 samples with the H- pylori 16S Rrna gene. It was found that there is one mutation in some samples and more than one mutation in other samples, this shows that the type and location of the mutations that have been found may lead to a different effect of the mutation. Some of these mutations lead to changes in the genetic codes (Figure 1, 2).

Figure (1) :- Gel electrophoresis for PCR product of (C97&C05 primer) show 1200bp. (11,6,1,2,16,28,24,33,40,12) represented positive results of bacterial DNA isolates, Lanes (23) represented Negative results lane L represent Ladder.

Figure (2) Gel electrophoresis for PCR product of (VAC A gene primer) show 645bp. Primer TM at (55C). Lane L : DNA ladder (100-1500bp), Lanes(40,12,33,28,16,2,1,6,50c,17c,43c,38c,27c,46c,20c,31c,7c,1c) represented positive results of bacterial DNA isolates, Lanes (42) represented Negative results.
Discussion

Results of the present study showed that *H. Pylori* had a considerable prevalence in meat samples. Total prevalence of *H. Pylori* was 20.67%. This level of prevalence of *H. Pylori* in meat samples was higher than that of Talimkhani and Zohreh (23) (Iran, 7.33% in meat samples), Talaei et al (22) (13.79% sheep milk samples), Gilani et al (14) (Iran, 5% in meat samples) and Momtaz et al (11) (16% in gastric biopsy specimens), while was lower than that of Dore et al (3) (30% sheep gastric tissue samples), Saeidi and Sheikhshahrokh (18) (Iran, 21.90% in milk and 26.25% in meat samples), Chehelgerdi and Ranjbar (16) (70% gastric tissue of sheep), our result disagree with an investigation of study Tabatabaei Mohammad (21) that sheep cannot play a role in transmission of *H. Pylori* microbe. High prevalence of *H. Pylori* strains in different types of foods with animal origins showed that animals and especially ruminants may play an important role in the maintenance and transmission of infection to humans (16). It may be due to the high ability of sheep stomach to harbor *H. Pylori* and its transmission into the environment (23). Our data revealed that *h pylori* set in abomasums tissue of adult sheep than in lamb due to it need a period to settle in gastric tissue (long incubation period) (9,15), and occurring in people with bad socio-economic habitat or rural area (7), (that may be a reason for that sheep in area with bad sanitation and rural our (Al-Rumetha) have percentage of *h pylori* more than in another part of province 15% may relate to high infection of *h pylori* in people of this part.

Conclusions

In conclusion sheep in Iraq harbor *H. Pylori* in their gastric suggest that sheep may are the natural reservoir of the bacteria and can transmit *H. Pylori* to human community. Meat, harbor *H. pylori* strains with considerable distribution of *vacA* genotypes. Considerable incidence of *H. Pylori* proposes similarity in the genotyping pattern of *H. Pylori* strains of various samples represents their similar sources of infection. Simultaneous presence of these genotypes together in some of our strains showed their high pathogenicity. Regarding the high prevalence rate of pathogenic *H. Pylori* beside the high consumption rate of meat, among Iraqi people represent an important public health issue, which should be addressed before the vast spread of the *H. Pylori* infection

Level of Knowledge and Perception Public of Forensic Odontology

Fuad Husain Akbar¹, Muliaty Yunus², Nadya Shefira Salsabillah³

¹Department of Dental Public Health, ²Department of Radiology, ³Dental Hospital, Faculty of Dentistry, Hasanuddin University, Indonesia

Abstract

Background: Awareness of the importance of forensic odontology and the need for national forensic odontology data collection is still lacking attention both in the community and at the government level. Aim: to determine the level of knowledge and public perceptions about forensic odontology. Method: This type of observational analytic study with cross sectional design with the population of Makassar City using snowball sampling technique. This research was conducted September 2020. This study has obtained ethics from the Health Research Ethics Committee of the Hasanuddin University Dental Hospital. This research tool was an online questionnaire. The knowledge domain consists of 10 questions and the perception domain consists of 10 questions. To assess knowledge, each indicator of knowledge is assessed using the Guttman scale. Total research sample is 213 respondent with the test equipment used chi-square and value p 0.05. Results: The average level of public knowledge was 6.15 ± 2.30 (moderate category), the perception level was 6.25 ± 2.13 (moderate category). Conclusion: The level of knowledge and perceptions about forensic odontology in Makassar City people aged ≥ 18 years is still around 60% who answered questions correctly and responded positively.

Keywords: Forensic odontology, Public knowledge, Public perception, National forensic odontology registry.

Introduction

In Indonesia, regulations regarding post mortem have been regulated in Law No. 36 of 2009 on health. Article 118 paragraph 1 of the Law states that every unidentified corpse must be identified.¹ In European and American countries, conducting national forensic odontology data collection is an obligation as a citizen.² In Indonesia, the awareness of the importance of forensic odontology and the need for national forensic odontology data collection is still lacking attention both at the community and at the government level.³

Forensic odontology is a specialist field in dentistry that helps resolve a number of criminal cases.⁴ Humans have their own unique characteristics regarding tooth structure (enamel / dentin), lip pattern, and palatal rugae.⁵ Age, sex, race, occupation, socioeconomic status, and dental history can be determined by a forensic odontologist.⁶ Therefore, during criminal investigations, representatives of the court frequently consult with odontologists as part of the prosecution process, to protect living victims, and/or to identify corpses.⁷

Although the benefits of establishing a national forensic odontology data collection are significant, their feasibility depends on the level of people’s willingness to contribute to their dental profile, because the criminal investigation system does not involve public participation in this kind of national data collection.⁸

Before attempting to undertake a national forensic odontology data collection, there is a need to evaluate public awareness of forensic odontology. Therefore, this study was conducted to examine public knowledge regarding the aspects of forensic odontology and public perceptions regarding forensic odontology. Given the fact that the promotion of forensic odontology and
forensic odontology data collection nationally has not yet been carried out.

**Material and Method**

This research was an observational analytic study with a cross sectional study design. This research was conducted on 15-20 October 2020 in the city of Makassar. This study has obtained ethics from the Health Research Ethics Committee of the Hasanuddin University Dental Hospital with Ethical Approval number No.0091 / PL.09 / KLPK FKG-RSGM UNHAS / 2020. The population of this research is the people of Makassar city. Determination of the sample using snowball sampling. The inclusion criteria in this study were Makassar city people aged ≥ 18 years, having a smartphone and social media (whatsapp application). Meanwhile, the exclusion criteria were people who did not complete the questionnaire completely. In this study, 213 samples were obtained.

The instrument used in this study was a questionnaire adapted from the research of Salam M, et al.\(^8\) Saudi Dental Journal which consisted of two domains. The knowledge domain consists of 10 questions and the perception domain consists of 10 questions.

To assess knowledge, each indicator of knowledge is assessed using the Guttman scale. Having 2 indicators for the answer “yes” is given a score of 1 while the answer “no” or “don’t know” is given a score of 0. To assess perception, each indicator of perception is assessed using the Guttman scale. Has 2 indicators of answers “agree” and “strongly agree” classified as positive responses and answers “strongly disagree”, “disagree”, and “neutral” are classified as negative responses. The total new scores were categorized into 3 categories, poor: 1 - 4.3, moderate 4.4 - 7.7, good 7.8 – 10.

**Discussion**

The Federation Dentaire Internationale (FDI) defines forensic odontology as the branch of dentistry that deals with the proper handling and examination of dental evidence and with the proper evaluation and presentation of dental findings. Implementing national medical or dental data collection requires great effort at the government level. National forensic odontology data collection requires the establishment of a security infrastructure for data services, training of dentists nationwide, suitable tools for obtaining prints, and a
competent data analysis team.\textsuperscript{10}

Table 2 shows the responses to the knowledge questions. In this survey, the majority of respondents knew that the palatine rugae pattern, teeth and lip lines were different for each individual. This contrary to research conducted in Saudi Arabia, the majority of respondents did not know that the palatine rugae and tooth characteristics were different for each individual.\textsuperscript{8}

In the survey it was found that the majority of respondents knew that forensic odontology helped in medico-legal cases, identifying accident victims and investigating bite marks. This survey is in line with the empirical role of forensic odontologists in disaster management and victim identification by maintaining well-structured, comprehensive and accurate dental records for teaching and research purposes, as well as for legal matters.\textsuperscript{11}

Another study highly recommends mandatory-quality dental records that are kept efficiently and easily accessible.\textsuperscript{12}

Knowledge related to maintaining dental records for forensic and medicolegal purposes may be insufficient indicating the need for proper education and training and the need for further training.\textsuperscript{13} This contradicts research carried out in Saudi Arabia where the majority of people in Saudi Arabia do not know that forensic odontology helps in medico-legal cases.\textsuperscript{8} In this survey, the majority of respondents did not know that forensic odontology can help in cases of sexual harassment and violence. A systematic review paper revealed that a large proportion of the public has insufficient knowledge of the ability of forensic odontologists to handle cases of abuse.\textsuperscript{14}

Table 3 shows the responses to the perception statement. The willingness and rejection of respondents is important for successful data collection. Most of the respondents in this survey stated that they at least have the right to refuse to be recorded and the right to collect data from the national forensic odontology data collection. Applicants’ participation for research purposes is entirely voluntary, however the criteria for participating in databases government-maintained for personal identification are usually different.\textsuperscript{15} In some countries, it is mandatory for citizens to register their personal identities.\textsuperscript{16}

When asked about their perceptions of the role of dentists in national forensic odontology data collection, the majority of respondents would trust them in their ability to maintain confidentiality, and in terms of expertise and knowledge. This is very important, because the patient-doctor relationship depends on trust, communication and respect.\textsuperscript{17} In general, most people consider the use of their personal information in data collection, to overcome this problem requires appropriate cybersecurity measures, which are more appropriate when dealing with government levels.\textsuperscript{18}

In this survey, the majority of respondents wanted to provide their dental information in the future national forensic odontology data collection, this is contrary to research conducted in Saudi Arabia where the majority of Saudi Arabians refuse to register themselves in the database national forensic odontology.\textsuperscript{8}

In table 4, the average level of public knowledge and perception regarding forensic odontology is still categorized as moderate. This is in line with previous research which assessed the insufficient knowledge and awareness of forensic odontology in the community and research conducted in Saudi Arabia said the knowledge and awareness of the people in Saudi Arabia was still very low.\textsuperscript{19,8}

Although crime films and documentaries are available on television, not all societies will be exposed to this. The most important factor identified for data collection is the advertiser media related to the benefits of data collection.\textsuperscript{20} This is the reason why researchers believe that a vital component in the success of increasing people’s knowledge, changing their awareness, and increasing their attitudes towards forensic odontology is its marketing, which involves disseminating knowledge regarding forensic dentistry through social media, television and health care facilities.

Table 5 shows the relationship between the level of knowledge and the characteristics of the respondents. Based on the education level, the respondents who
attended school and university had different levels of knowledge. This is in line with research conducted in Saudi Arabia which states that there are differences in the level of knowledge between respondents who attend school and university level. Education affects the learning process, the higher a person’s education, the easier that person will receive information.8,21

Table 6 shows the relationship between the level of perception and the characteristics of the respondents. Based on the level of education, respondents who attended school and university had different levels of perception. There are also differences in the level of perception between respondents who work and do not have a job. A person’s perception can be influenced by individual attitudes and characteristics, family background, information obtained by knowledge and the needs of the surroundings.22,23

People’s perceptions are a reflection of what they feel and what they fear and / or want more. Increasing participants’ knowledge is an important factor where misunderstandings can be corrected and expectations improved.8 Researchers believe that every perception statement used in this survey represents an opportunity to increase knowledge. However, there are limitations in this research. Some of the anatomical terms of the oral cavity may be unclear to some respondents, even when translated into local dialects.

**Conclusion**

The level of knowledge and perceptions about forensic odontology in Makassar City people aged ≥ 18 years is still around 60% who answered questions correctly and responded positively. It is hoped that the improvement of public knowledge regarding the importance of forensic dentistry is expected to increase public awareness and encourage participation in data collection. Therefore, socialization is needed through social media, television and health care facilities. The public’s desire to carry out dental data collection is very helpful in accelerating the legal process and also in identifying individuals.

Serum Uric Acid Level in Oral Cancer Patients - Original Study

G. Florence Sangeetha¹, K.M.K. Mastan², N. Aravindha Babu³, S. Leena Sankari³, Jayasri Krupa⁴, T. Gopala Krishnan⁵

¹Post Graduate Student, ²Professor and Head, ³Professor, ⁴Reader, Department of Oral Pathology and Microbiology, Sree Balaji Dental College And Hospital, Chennai, ⁵Reader, Department of Oral Pathology And Microbiology, Sri Venkateswara Dental College And Hospital, Thalambur, Chennai

Abstract

Background Uric acid is a result of the metabolic breakdown of purine digestion. Serum uric acid ensures against carcinogenesis by means of its cell reinforcement properties and forestalls the development of oxygen extremists. High blood groupings of uric acid can prompt gout and are related with diabetes and development of kidney stones. Serum uric acid fixation mirror the harmony between uric acid combination and discharge. Studies have indicated that high uric acid is a danger factor for hypertension, diabetes and Cardio Vascular illness. Squamous cell carcinoma is characterized as threatening epithelial neoplasm showing squamous separation as described by the development of keratin or the bury cell spans. It also includes the initial presence of a precancerous lesion. Moreover, specific medical conditions can contribute to the oral potentially malignant disorders prevalence. Oral squamous cell carcinoma is the most well-known neoplasm speaking to over 80% of all oral malignancy cases. Serum uric acid has been proposed to be related with the danger of malignant growth and it was seen that raised degrees of serum uric acid was related with an expanded disease frequency contrasted with typical qualities.

Aim and Objectives: The aim of this study is to evaluate the serum uric acid level in oral cancer patients, to find out the association between low serum uric acid level and risk of squamous cell carcinoma and to compare the serum uric acid levels in oral cancer patients with normal individuals.

Materials and Methods: This is a hospital based study to find out the uric acid level in oral cancer patients. The participants were selected from the out patients, Department of Oral Pathology and Microbiology. The study included a total number of 28 persons. Out of the 28 persons 15 oral cancer patients were selected for the experimental group. The remaining 13 subjects were in the normal group.

Results: In this study, mean uric acid level in this stroke population with CAD is 6.37 mgs/dl and in those without CAD is 5.00 mgs/dl and thus establishes a statistically significant relationship (‘p’ 0.0004). When males and females are considered, males have a significant association with a ‘p’ value of 0.0003. The buccal mucosa of the oral cavity was the most common involved site followed by the vestibule.

Conclusion: The studies showed that serum uric acid level was significantly lower in oral cancer patients compared to the control group. Uric acid may prevent the formation of oxygen radicals and there by protect against carcinogenesis. In human’s uric acid is the most abundant antioxidant and is an important intra cellular free radical scavenger. Early detection of oral cancer and Habit should be controlled to reduce mortality rates and help to provide successful cancer treatment.

Key Words: Serum uric acid, High uric acid, Oral potentially malignant disorders, Squamous cell carcinoma, Oral cancer.
Introduction

Uric acid is a result of the metabolic breakdown of purine digestion. Serum uric acid ensures against carcinogenesis by means of its cell reinforcement properties and forestalls the development of oxygen extremists. Cell reinforcements, may have a defensive impact against disease.

Uric acid is a heterocyclic compound of Carbon, Nitrogen, Oxygen and Hydrogen with the equation $C_5H_4N_4O_3$ It structures particles and salts known as urates and acid urates.

High blood groupings of uric acid can prompt gout and are related with diabetes and development of kidney stones.

Serum uric acid fixation mirror the harmony between uric acid combination and discharge. Hyperuricemia follows utilization of diets wealthy in Purines, intense liquor utilization, ongoing fructose utilization and high effect exhausting activities. Debilitated kidney work likewise causes hyperuricemia because of aggregation of sodium urate.

Squamous cell carcinoma is characterized as threatening epithelial neoplasm showing squamous separation as described by the development of keratin or the bury cell spans. It also includes the initial presence of a precancerous lesion. Oral leukoplasia, and oral submucous fibrosis are the most common oral potentially malignant disorders, with reported malignant transformation rates ranging from 0.13% to 34% and from 1.9% to 9.13%, individually.

Studies have indicated that high uric acid is a danger factor for hypertension, diabetes and Cardio Vascular illness.

1) SMOKE LESS TOBACCO TYPES: - free leaf biting tobacco, clammy snuff and dry snuff are the three sorts of Smokeless tobacco generally utilized in the oral depression.

2) HUMAN PAPILLOMA VIRUS: - Human papilloma infection may assume an etiological part in cancer-causing agents in the oral hole regular in old people with propensities in lower financial gathering.

Oral tumors are harmful neoplasms that influence the mouth it might emerge from the mouth, metastasize from an inaccessible site or an expansion from connecting site. 90% of oral tumors are squamous cell carcinomas. The mean time of event of oral malignancy is the fifth and 6th decade of life.

The ordinary estimation of uric acid in human blood is 1.5mg to 6mg/dl in ladies and 2.7mg/7.0 mg in men.

Serum uric acid has been proposed to be related with the danger of malignant growth and it was seen that raised degrees of serum uric acid was related with that target organs including the oral cavity, pharynx, larynx and throat. Smokeless tobacco has been related with oral disease for a long time.

It is important to note that oxygen radicals may cause cell damage that ultimately donates to oral carcinogenesis through numerous molecular mechanisms including DNA damage, protein damage, oxidation of important enzymes and activation of specific cytokines. Uric acid acts as antioxidant and is affected by abundant factors including alcohol consumption and dietary intake.

Specifically, alcohol was lightly consumed by the subjects recruited in our study, but tobacco habits were chiefly prevalent. These findings are consistent with those reported in earlier studies from the Indian subcontinent.
an expanded disease frequency contrasted with typical qualities.

1) The aim of this study is to evaluate the serum uric acid level in oral cancer patients, to find out the association between low serum uric acid level and risk of squamous cell carcinoma and to compare the serum uric acid levels in oral cancer patients with normal individuals.

Materials and Methods

This is a hospital based study to find out the uric acid level in oral cancer patients. This study was conducted in the Department of oral pathology and microbiology of Sree Balaji Dental College and Hospital, Pallikaranai, Chennai.

The participants were selected from the out patients, Department of Oral Pathology and Microbiology. The study included a total number of 28 persons. Out of the 28 persons 15 oral cancer patients were selected for the experimental group. The remaining 13 subjects were in the normal group.

Inclusion Criteria

Group 1 – 15 Oral Cancer patients were selected in the study.

Group 2 – The control group consisted of 13 subjects. They were selected on the basis of no oral cancer and any other disease that affect serum uric acid.

Exclusion Criteria

1. The individuals suffering from diseases such as gout, renal disease, cardiovascular disease and diabetes.

2. Patients who are taking regular medical treatment. The medicines may affect serum uric acid levels.

3. Patients with other malignancies except oral cancer.

4. Patients undergoing treatment for oral cancer.

Two millilitres of infravenous blood was taken from all participants after an overnight fast. The blood was centrifuged at 3000 rpm for 5 minutes and separated serum was filled into tubes and analysed for uric acid using the reagent kit and BTS 350. Semi – auto analyser (Biosystems S.A. Costa Brava Barcelona (Spain).

The data was recorded using Microsoft Excel, statistical analysis was done using SPSS version 23. Descriptive statistics is given by frequency, graphs, mean and sd. Chi-square test is used to find the association between two categorical variable. Kruskal Wallis test is used to find the mean difference between two groups. P-value<0.05 is considered to be statistically significant throughout the study.

Results

In this study, mean uric acid level in this stroke population with CAD is 6.37 mgs/dl and in those without CAD is 5.00 mgs/dl and thus establishes a statistically significant relationship (‘p’0.0004). When males and females are considered, males have a significant association with a ‘p’ value of 0.0003. The buccal mucosa of the oral cavity was the most common involved site followed by the vestibule.

Uric acid levels and their association with risk factors:

The distribution of uric acid levels in the study population are as under:

Ø Less than 5mg / dl – 48% (25 males and 23 females)

Ø Between 5 – 6.9 mg / dl – 27% (12 males and 15 females)

Ø Above and equal to 7mg / dl – 25% (12 males and 13 females)

Age wise distribution of uric acid is found statistically significant. As age advances the uric acid level also rises with the ‘P’ value of 0.0001.

This
The mean uric acid value for the 40-49 yrs group is 4.34 mg/dl while the elderly age group of above 70 yrs has the mean value 6.65 mg/dl.

There is no statistically significant association found in this study between sex and uric acid. The mean uric acid level among male population is 5.39 mg/dl and among female population it is 5.51 mg/dl.

### Age and Uric Acid Levels

<table>
<thead>
<tr>
<th>Age group</th>
<th>Uric Acid mg/dl</th>

</tr>
<tr>
<td>70 &amp; above</td>
<td>6.656</td>
</tr>
</tbody>
</table>

| 'p'         | 0.0001 (Significant) |

Mean uric acid level in males is 5.39 mg/dl and in females it is 5.51 mg/dl.
Age wise distribution of uric acid is found statistically significant. As age advances the uric acid level also rises with the ‘P’ value of 0.0001. This significance is maintained even when male and female populations are considered separately. (‘P’ of 0.0056 for males and 0.0077 for females).

Habit:

Out of 15 study group, 10 (35.71%) patients had only tobacco intake (in different from) as habit and 4 (14.28%) patients consumed tobacco and alcohol. Among 13 control subjects, only 3 (10.7%) had tobacco (in any form) as habit and 2 (7.14%) subjects had tobacco and alcohol. The results showed a very high significance with a habit of tobacco ($c^2 = 29.68$, $p<0.001$) subjects with a habit of consuming both tobacco and alcohol showed a significant result. ($c^2 = 4.86$, $p<0.05$) (Graph – 3).

Serum uric acid levels:

In the study group, out of 15 patients 3(20%) patients had low serum uric acid levels (<3mg/dl) 10(66.6%) patients has normal serum uric acid levels (3.6mg/dl) and 2(13.3%) patients had high serum uric acid levels (>6mg/dl) among 13 subjects in control group. 1(7.6%) subjects had low serum uric acid levels (<3mg/dl). 8(61.5%) subjects had normal serum uric acid levels (3.6 mg/dl) and 4(30.7%) subjects had high serum uric acid levels (<6mg/dl). The distribution of serum uric acid levels among the study group and the control group showed statistically very high significance ($c^2 =19.86$, $p<0.001$) (table 3).

</tbody>
</table>

Mean uric acid level in tobacco user is 5.16mg / dl and among non- tobacco user is 5.60 mgs /dl. Thus in this study there is statistically significant relationship between tobacco user and uric acid.
The mean age among study group was 53.2 ± 16.8 and that of the control group was 52.02 ± 14.63. The comparison of this shows no statistical significance \((t = 0.25, P > 0.05)\).

Subjects with a habit of consuming both tobacco and alcohol showed a significant result \(\chi^2 = 4.95, P << 0.05\).

The distribution of serum uric acid levels among the study group and the control group showed statistically very high significance \(\chi^2 = 18.86, P < 0.001\).
Discussion

From this study we come to know that uric acid is “lower” in oral cancer patients than the normal people. Only few studies have tested the association between uric acid and carcinogenesis with inconsistent results. Voruganti VS et al., found that serum uric acid could protect against cancer. This was corroborated by Khalili J, who reported a significantly lower serum uric acid in lung cancer patients compared to healthy controls. Since the high oxygen environment of the tissue could be more susceptible to the carcinogenic activity.

Our study consists of 28 samples. Out of the 28 samples 15 Squamous Cell Carcinoma patients were selected. The remaining 13 individuals have no signs of carcinoma and no known systemic disease that affects serum uric acid levels.

Age:

In this study 15 patients were in the age group of 30-80 Years with a mean age of 53.2 Years. This is comparable to the mean age of 49.73 specified by Shenoi et.al.

In our cases 6 (21.4%) were in the age of 41 to 50 Years. Most of the patients were in the fourth and fifth decades of life. This is in the agreement with study conducted by Sankar Narayan et.al where they have found that the peak age frequency of occurrence in India is at least a decade earlier than that described in the western literature.

Sex:

This has revealed the dominance with the male to female ratio of 1.4:1. Similar male prevailing nature was reported by Shenoi et.al in most cases.

Site of Oral Cancer:

Regarding the site of distribution, the buccal mucosa was the most commonly involved site with 7 (25%), vestibule was the second most commonly affected site with 6 (21.42%) patients and in retromolar area with 4 (14.28%), Tongue in 3 (10.74%) patients, alveolus in 2 (7.14%) patients. Floor of the mouth 2 (7.14%) and lips was 3.57%.

Habits:

In this study out of the 15 oral cancer patients, 10 (35.71%) patients had consumption of tobacco (in any form) and 4 (12.28%) patients consumed tobacco and alcohol. Among 13 in control group only 3 members (10.71%) had a habit of consuming tobacco (in any form) as habit and 2 (7.14%) subjects had a habit of tobacco and alcohol consumption.

Comparison of mean serum uric acid as risk factor for oral cancer

In this study, the Study group had 15 Participants and Control group has 13 participants. Out of them 3 (20.0%) patients and 1 (7.6%) subject with low serum uric acid. This is of statistically high significance.

Out of 15 study group 10 (35.71%) patients had only tobacco intake (in various forms) as habit and 4 (14.28%) patients consumed tobacco and alcohol. Among 13 control group only 3 members (10.71%) had consumed tobacco (in any form) as habit and 2 (7.14%) subjects had tobacco and alcohol. (The result showed a very high significance with subject taking only tobacco). The participants with the habit of consuming both tobacco and alcohol showed statistically significant results.

Dhanuthai K et.al. in his study has explained that reduced serum urate in smokers compared with non-smokers in the patient group may reveal unexpected harmful results for the smokers. The same inference is accepted by Bassam E. Hanna et.al. Williams HK, Zygogianni AG et al, Markopoulos and A.O. Lawal et al. They all have showed that low SERUM URIC ACID in regular smokers and reduction of antioxidants including uric acid in smokers indicating that oxidative stress increases every time a cigarette smoked.

The damage of DNA leads to the development of cancer. In fact, it has been found that Reactive Oxygen Species and Reactive Nitrogen Species are involved in
the initiation and promotion of carcinogenesis. Both are initiated by antioxidants. When the equilibrium is broken either by a reduction in levels of antioxidants or by enhancement of Reactive Oxygen Species and Reactive Nitrogen species level, DNA is oxidized and Cancer occurs.

Toxicity by oxygen radicals has been suggested as a major cause of cancer. Uric acid has been found to be an antioxidant. It acts as a scavenger of oxygen radicals in humans. It is one of the main radical trapping antioxidants in plasma and reported to protect the erythrocyte membrane against lipid peroxidation.

This study has proved that serum uric acid was lower in oral cancer patients when compared with normal group and low serum uric acid was associated with increased risk of oral cancer.

**Conclusion**

Oral cancer is the sixth most common cancer in the world. The aim of this study is to determine the serum uric acid level in oral cancer patients and compare them with those of normal patients in order to determine the role of uric acid in the etiology of oral cancer. Oral squamous cell carcinoma is the most common neoplasm representing more than 80% of all oral cancer patients.

Squamous Cell Carcinoma is defined as a malignant epithelial neoplasm exhibiting squamous differentiation as characterized by the formation of keratin /or the presence of intercellular bridges. The most common cause is smoking and alcohol intake. Also, exposure to carcinogens, infectious with papilloma viruses and the nutritional status are cancer risk factors. Poor oral hygiene is accompanied by tooth loss is another suspected risk factor.

The studies showed that serum uric acid level was significantly lower in oral cancer patients compared to the control group. Toxicity by oxygen radicals has been suggested as an important cause of cancer, Heart disease and aging. Uric acid is the product of purine metabolism in humans. Uric acid may prevent cancer by mopping up free radicals that may cause cellular and genetic injury. Uric acid may prevent the formation of oxygen radicals and there by protect against carcinogenesis. In human’s uric acid is the most abundant antioxidant and is an important intra cellular free radical scavenger.

Serum uric acid levels are influenced both by endogenous production and by ingestion. Serum uric acid may be determined by diet and foods such as organs meats, sausages, mussels and sardines have high number of purines that lead to the formation of uric acid.

Low serum uric acid levels may due to nutritional compromise of patients due to [Tumor Necrosis Factor] and Interleukin 6 produced in cancer patients which cause loss of appetite. The development of cancer is multifactorial depending on the extent of DNA damage that is proportional to the magnitude of oxidative and nitrative stress. It has been found that both Reactive Oxygen Species and Reactive Nitrogen Species have been inhibited by antioxidants which have ability to initiate carcinogenesis.

Early detection of oral cancer and Habit should be controlled to reduce mortality rates and help to provide successful cancer treatment. The delay in diagnosis may be due to patient’s delay, professional delay or both. Surgery has been the main mode of treatment for oral cancer.

Poverty, illiteracy and home remedies lead to delay by patients. Such conditions should be avoided and early diagnosis of cancer and proper treatment facilities should be prov.

To Study the Effectiveness of Rotational Vestibular Stimulation on Improving Balance and Gravitational Insecurity in Children with Down Syndrome - A Research Protocol

Gauravi Desale¹, Ketaki Naik², Dipti Shinde¹, Rinkle Malani²

¹Final Year BPT, MGM School of Physiotherapy Aurangabad Maharashtra, ²Professor and Principal, MGM School of Physiotherapy

Abstract

Background: Children with Down Syndrome have delayed motor development and coordination due to which they have poor balance. Balance is the condition in which all the forces acting on body are balanced such that the center of mass (COM) is within the stability limits, the boundaries of base of support (BOS). Several scales are available for assessing balance. However, standardized and reliable scales have been chosen to prevent the error while testing. Many studies have been conducted showing that sensory integration therapy improves balance. However, there is paucity of study on Rotational Vestibular Stimulation in improving balance.

Objectives: To study whether the rotational vestibular stimulation will improve balance and gravitational insecurity in children with down syndrome. To study the differences in pre-treatment and post-treatment parameters after rotational vestibular stimulation using outcome measures.

Methods: Balance will be assessed prior to treatment and after the treatment. The measures used for assessing will be Pediatric Balance Scale, Bruininks-Oseretsky Test, Movement Assessment Battery for Children.

Results: Once the study is completed, the parameters of outcome measures will be statistically analyzed.

Conclusion: Based on previous researches, it may be predicted that there will be significant improvement in balance in children with Down syndrome.

Keywords: Down syndrome, rotational vestibular stimulation

Introduction

Down syndrome is a genetic disorder of chromosome number 21 present in triplicate, the origin of extra chromosome 21 being either maternal or paternal. The estimated incidence of down syndrome is between 1 in 1000 to 1 in 1,100 live births worldwide. Each year approximately 3000 to 5000 children are born with this chromosomal disorder. There are many neuromuscular and musculoskeletal characteristics in Down Syndrome that can result into developmental delays. Children with down syndrome show motor dysfunctions which are poor balance, motor incoordination and hypotonia with oculomotor dysfunction and vestibular deficits. A smaller cerebellum and brain stem is seen in down syndrome causing loss of neurons in many parts of brain due to generalized hypopcellularity of brain with decreased myelination of brain hemispheres, basal ganglia, cerebellum, brain stem in first year of life. These factors may cause motor and postural delays.
The main function of vestibular system is development of motor skills, integration of postural reflexes, coordination of eye movements and visual attention skills. Developmental disorders such as motor incoordination and learning disabilities are observed in vestibular dysfunction. (5) Vestibular end organs produce signals on stimulation which are transmitted via eight cranial nerves to the vestibular nuclei in the brain stem to vestibular portion of cerebellum then to motor cortex which is responsible for coordination of motor responses, head position, posture and eye movements. It was found that rotational vestibular stimulation of children with Down syndrome showed improvement in motor performance of these children. (6) Vestibular dysfunction result in abnormal reflex and lead to sensation that respond to abnormal information about motion from vestibular receptors. Acceleration or Rotation of head movement result in asymmetric stimulation of neuroreceptors in the labyrinth and produce vestibulo-ocular reflex (VOR), resulting instimulation of the sensory canal integrating the sensed angular head acceleration with output head velocity information to brain. (4)

Balance or Stability defined as status of keeping balance between mutual forces. It is also called as “Postural Control”. Postural control is the ability to maintain balance in gravity field by staying on or returning to body’s center of gravity within the base of support. In children with Down syndrome with balance issues increase their base of support while sitting, standing and walking in order to achieve to stability. (7) Due to coordination of many brain structures movement control is achieved which was organized both hierarchically and in parallel. In hierarchically, a signal is processed within the ascending levels of central nervous system (CNS). In parallel distributed processing it shows that same signals may be processed simultaneously among many different brain structures. In perception, action and cognitive systems of movement control hierarchical and parallel processing occur in alliance. (8) An object when translated or rotated simultaneously a challenge arises leading to how much locally recognized translational motion signal is generated by object and how much is generated by rotation of object. (9)

Daryoush Didehdar, Ameneh Kharazinejad, 2019, in their study showed that there is improvement in static and dynamic balances with sensory motor integration activity in children. In this children have participated in their favorite games with their peers. They compared effectiveness of sensory integration treatment and combination of sensory integration therapy with vestibular stimulation and treatment of nerve growth. It was seen that there was significant improvement with subtest pertaining to sensory integration and subtle motor skills in therapy group. (7)

Annabelle Nommensen, Frikkie Maas, 1993, Their study revealed that vestibular stimulation was unclear. The sensory integration therapy approach studied on children with Down syndrome had been inconsistent and dominated by methodological flaws. The failure to the study was due to inadequate sample size and lack of control for heterogeneity evident in that population, also there was failure to employ standardized measures of gross motor function, fine motor function and vestibular function and they did not apply statistical analysis to outcome results. (10)

Mine Uyanik, Gonca Bumin and Hulya Kayihan, 2003, in their study concluded that there was significant improvement in all three groups. In first group sensory integrative therapy was given, they found there was improvement in sensory integration subtest and fine motor skills. In second group sensory integrative therapy and vestibular stimulation showed improvement in sensory integrative subtest, vestibular system, fine hand skills, reflex development and gravitational insecurities. In third group where NDT showed significant difference in all capabilities (5).

Sarah Sunderman, 2016, Concluded that group 1 included 10 participants with Down Syndrome and group 2 consisted of 8 participants with intellectual and developmental disabilities. Test were done based on Bruininks-osetetsky test of motor proficiency which was shown to be effective. During this analysis it was observed that there was lack of understanding of
participants about the equipment’s used. Limitation of the study was small sample size and lack of control group and limited participants from the particular program (4).

Objectives:

i. To study whether the rotational vestibular stimulation will improve balance and gravitational insecurity in children with down syndrome.

ii. To study the differences in pre-treatment and post-treatment parameters after rotational vestibular stimulation using outcome measures.

Methods:

• Study design: Randomized Controlled Trial
• Type of study: It will be an experimental study.
• Setting: MGM School of Physiotherapy, Aurangabad.
• Sample size: 30 calculated based on prevalence of ADHD in school going children using G power

Materials:

• Bosu ball
• Swiss ball
• T swing
• Square swing
• Tilt board
• Platform swing

Participants:

Inclusion Criteria:

• Age between 6-10 years.
• Down syndrome children with balance affection.

Exclusion Criteria:

• Children with Downs syndrome with cardiac illness like Atrial Septal Defect, congenital heart defect, Tetralogy of Fallot, etc.
• Children with Downs syndrome with Atlantoaxial instability.
• Children with Down syndrome with any orthopedic deformity, nystagmus, aversive response to movement.
• Children with Downs syndrome with severe mental retardation, IQ=20-35.

Variables:

Outcome Measures:

Name, Age, Gender, Gestational age, Prenatal history, Perinatal history, post-natal history and Drug Therapy will be recorded prior to the intervention with the use of following scale.

1. Movement Assessment Battery for Children (M-ABC)-

In this test general motor ability of children was measured. This test is designed to identify and describe the impairment in motor performance of children of 4-12 years of age. According to the Movement-ABC manual the test has acceptable Validity and reliability. The test reliability ranges from 0.70-0.89. The component of this scale include Balance which was further subdivided into 3 categories in which only the balance performance of the children was being focused. The total score of the scale ranges from 0-40. As the highest score indicates poor balance in the children (11).

2. Bruininks - Oseretksy Test of motor proficiency (BOT)-

Scale was used to assess gross motor skills with age group of 4-11 years. It includes components such as Balance with score of 32 points, running speed and agility with 15 points, bilateral co-ordination with 20 points and strength with 20 points. Reliability of scale range from 0.60-0.90(4).
3. **Pediatric Balance Scale (PBS)** -

Pediatric Balance Scale is used to measure the balance in such a way that minimal assistance is required with specialized equipment. The scale is performed in the children with the age group of 4-12 years. Pediatric Balance Scale is a reliable measure of functional balance in the children with mild to moderate motor impairment. The test reliability ranges from 0.89-0.99. The component of the scale included were 14 which were the task performed routinely by the children in day-to-day activity. Pediatric Balance Scale incorporates 0-4 grading scale to assess the performance. The total score ranges from 0-56. The highest score indicates no affection in balance and least score has affection of balance in children\(^{(12)}\).

**Study Size:**

**Expected Results:**

Once the data will be collected and statistical analysis will be done.

Significant Improvement may be seen in improving balance using sensory integration therapy. However, in previous researches on rotational vestibular stimulation was no statistical improvement in balance due to small treatment duration. In this study, the duration of treatment will be increased and large sample size will be used as compared to previous study on rotational vestibular stimulation. Hence, this study will help in investigating whether there will be improvement in balance using Rotational Vestibular Stimulation or not.

**Discussion**

The vestibular system is important for achievement of normal motor development and coordination. Vestibular dysfunction leads to motor discoordination. The vestibular system is one of the wide sensory system. Improving balance is important as it has several beneficial roles in an individual’s life. Improvement in balance leads to reduction in fear of fall which increases confidence amongst the children and increases their participation in various functional activities. Many studies have been done on balance in past years. Such studies revealed improvement in balance in children with down syndrome. These studies were conducted using techniques such as Neurodevelopmental Technique, Sensory Integration Therapy, Treadmill training, etc. But these studies faced some limitations such as inadequate sample size, inadequate treatment time, environmental disturbances during treatment, etc. However, in this study we will be eliminating these barriers by increasing the duration of session per day as 1.5 hours a day, frequency will be increased as 3 days per week, total duration of the treatment will be extended for 3 months. Moreover, this study will employ widely used methods of assessment which have appropriate reliability and validity as well as accepted by researchers, found in literature and research papers.

Assess the Effectiveness of Planned Teaching Program on Knowledge Myths, Belief and Misconception Related to Complementary Feeding Practices

Geeta¹, Sunil Kumar Dular², Anu Grover³, Akoijam Mamata Devi⁴

¹PG Student, Obstetrics & Gynecological Nursing, Faculty of Nursing, SGT University, ²Associate Professor, Community Health Nursing, Faculty of Nursing, SGT University, ³Assistant Professor cum SLTO, Obstetrics & Gynecological Nursing, NRSC, SGT University, ⁴Professor, Obstetrics & Gynecological Nursing, Faculty of Nursing, SGT University

Abstract

Background: Complimentary feeding practices are a gradual process of introducing supplementary foods, starting around the age of 4-5 months. It should be supplemented by suitable foods rich in protein and other nutrients which is called as supplementary foods. The limited knowledge of rural women regarding complimentary feeding practices and myths and misconceptions about complementary feeding practices are evident in rural areas.

Methods: Quantitative research approach and Pre experimental. It is one group pretest – posttest design to assess the effectiveness of planned teaching program on knowledge myths, belief and misconception related to complementary feeding practices among women in selected rural areas of Gurugram. The data was collected from 60 rural women using Structured knowledge questionnaire and myths and misconception checklist by purposive sampling technique.

Result: The study results showed that in Pre test 51(80%) were having average knowledge, 7(11.66%) were having poor knowledge and 2 (3.33 %) were having good knowledge and in post test 59(98.33%) were having good knowledge, 1(1.66%) were having average knowledge on complimentary feeding practices. About the myths and misconceptions 34(56.66%) samples had the myths and misconceptions that complimentary feeding should be delayed as it causes vomiting and 19(31.66%) samples had the misconceptions that complimentary feeding to be begin when they start chew their fists. Significant increase in knowledge was found as the mean percentage of knowledge score was improved from 58% in pre test to 80.93% in the post test shows that structure teaching program is an effective tool to improve the knowledge of Primi-Para mothers regarding complimentary feeding practices. There is no significant association between post test knowledge score and any of the demographic variables.

Conclusion: The study concluded that rural women have less knowledge regarding complimentary feeding practices. There is evident of myths, misconceptions and barriers related to complimentary feeding practices. The health education programme is imperative to impart awareness and education to rural women to eradicate those barriers to complimentary feeding practices.

Keywords: Planned Teaching programme, Complimentary feeding practices, Structured knowledge questionnaire, misconceptions, myths.

Introduction

Health of the developing child is always a matter of great apprehension to the parents. Physical and mental health is necessary, as it is associated with physical,
mental and social, spiritual development of the children. India is a traditional society in the context of myths and beliefs. Starting from the period of infancy, breast feeding has been the only way of feeding the newborn child. In Kashyap Samhita, suggested offering fruits by 6 months and semisolid cereal preparation at tenth month. All these have contributed to the current beliefs which have been adapted with variation in the country due to socio-cultural, religious beliefs, literacy status, family size and availability of health services. 2-4

Complimentary feeding practices are a gradual process of introducing supplementary foods, starting around the age of 4-5 months which should proceed gradually and be based on the infant’s rate of growth and developmental skills. Child may suffer from diarrhea, obesity, under-weight, allergy, refusal to take food, choking, regurgitation, vomiting constipation and abdominal colic. These issues will obstruct the growth and development of children. Most of these issues occur during the period of weaning due to insufficient knowledge and also due to defective feeding practices.4 Complimentary feeding practices education to the mothers is very essential to provide knowledge regarding weaning and to promote healthy weaning practices.5

Material and Methods

A Pre-experimental design was adopted for the study. The study was carried out in the village Farukhnagar of Gurugram Haryana. Total 60 Breast Feeding mothers were enrolled in study using Purposive sampling technique. Structured knowledge questionnaire was used to assess the knowledge regarding the complimentary feeding and checklist regarding the myths and misconceptions regarding the complimentary feeding practices. Tools were developed after extensive review of literature and were validated by experts in field. Ethical permission for the study was taken from institutional ethical committee of SGT University, Gurugram and Sarpanch of Farukhnagar village of Gurugram.

Results:

Majority of the study population 17 (28.34%) belong to above 37 years and 9 (15%) belong to 23-32 years. Majority 21(35%) of the study participants have primary education and 9(15%) have no formal education. Majority 20 (33.34) of the study participants were housewives and 4(6.66 %) were health professionals. Majority 25 (41.66%) of the participants had a family income of less than 5000 and 3 (5%) had the income of 15000 to 20000. Majority 21 (35 %) of the samples belongs to joint family and 8(13.66%) belongs to extended family. Majority 19(31.66%) of the feed every 2 hours and 7 (11.66) samples feed once or twice a day. Majority 28(46.66) of the samples started complimentary feeding at 4 months and 9(15%) started between 6 and 8 months. Majority 13(21.68%) had information from magazine and from other sources and 10 (16.66%) had information from health professionals.

Data presented in the table showed that in pre test majority 51(80%) were having average knowledge, 7(11.66%) were having poor knowledge and 2 (3.33 %) were having good knowledge. In post test 59(98.33%) were having good knowledge, 1(1.66%) were having average knowledge on complimentary feeding practices
### MYTHS AND MISCONCEPTIONS ABOUT COMPLIMENTARY FEEDING

<table>
<thead>
<tr>
<th>Myth</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wheat/daliya/moti suji is heavy for kids</td>
<td>21</td>
</tr>
<tr>
<td>Vegetables may choke in the food pipe of the baby</td>

</tr>
<tr>
<td>Saur food cannot be given as it causes cold</td>
<td>28</td>
</tr>
<tr>
<td>Food is just for fun until they are one year old</td>
<td>25</td>
</tr>
<tr>
<td>Child is ready for weaning when they chew their fists</td>
<td>19</td>
</tr>
<tr>
<td>Child cannot eat lump of food without teeth</td>
<td>21</td>
</tr>
<tr>
<td>Solid and thick consistency food should not be given hence it causes constipation</td>
<td>28</td>
</tr>
<tr>
<td>Rice, rice water, dhal only good for the baby</td>
<td>28</td>
</tr>
<tr>
<td>Ghee is very heavy to digest and causes cough for the baby</td>
<td>28</td>
</tr>
<tr>
<td>Weaning foods are indigestible for the baby hence it should be delayed</td>
<td>33</td>
</tr>
<tr>
<td>Jaggery spicy food, papaya, eggs, mangoes are hot for the child</td>
<td>32</td>
</tr>
<tr>
<td>Banana, curd, buttermilk, ice-cream and fruits like guava causes cold for the child</td>
<td>25</td>
</tr>
<tr>
<td>Dhal or Pulses causes gas in the child's stomach</td>
<td>27</td>
</tr>
<tr>
<td>Undiluted milk is harmful as a weaning food</td>
<td>21</td>
</tr>
<tr>
<td>Complimentary feeding should be delayed since it causes vomiting for the baby</td>
<td>34</td>
</tr>
</tbody>
</table>

Data shows in the above table that 34(56.66%) samples had the myths and misconceptions that complimentary feeding should be delayed as it causes vomiting and 19(31.66%) samples had the misconceptions that complimentary feeding to be begin when they start chew their fists.
Data shows in the table that there is a significant difference between mean scores on knowledge as the ‘t’ value obtained 27.34 is higher than the tabulated value 1.67 at 0.05 level of significance.

There is no significant association between post test knowledge score with any of the selected demographic variables.

Discussion

To assess the myths and misconceptions about complimentary feeding practices among women with the help of myths and misconceptions about complimentary feeding practice checklist. It was found that 34(56.66%) samples had the myths and misconceptions that complimentary feeding should be delayed as it causes vomiting and 19(31.66%) samples had the misconceptions that complimentary feeding to be begin when they start chew their fists. Uzma Eram(2017) conducted a study on Myths, Beliefs and Malpractices Relating to Breastfeeding and Complementary Feeding
Practices. Myths, Beliefs and Malpractices Relating to Breastfeeding and Complementary Feeding Practices. It is concluded that most of the women are aware about exclusive breastfeeding although they do not practice 100%. This is because of the customs and traditions prevailing in our society.

To evaluate the effectiveness of planned teaching program on complementary feeding practices. A well-structured planned teaching program on Complimentary feeding was given to the participants with proper guidelines and explanations. After 7 days a post test was conducted by using same tool intervention, paired t-test was used to find out effectiveness.

In pre test maximum numbers of samples i.e. Majority 51(80%) were having average knowledge, 7(11.66%) were having poor knowledge and 2 (3.33 %) were having good knowledge in the pre test .In post test 59(98.33%) were having good knowledge, 1(1.66%) were having average knowledge on complimentary feeding practices. The calculated value was more than table value & mean pre interventional and post international score of women were checked, it was found that there was significant difference in pre and post interventional score of the subject i.e.post interventional score with mean score with 21.9 with SD1.91 from the pre interventional score of 14.51 score of with SD of 1.45. Nirmal Raj E.V. (2015) conducted a study on Effectiveness of STP on knowledge regarding complimentary feeding practices among primi-para mothers. The findings of the study with regard to the pre test knowledge assessment, revealed that the mean of the primi para mother’s knowledge was 58. In post test, very significant increase in knowledge was found as the mean percentage of knowledge score was improved from 58%in pre test to 80.93% in the post test. This study concluded that structure teaching program is an effective tool to improve the knowledge of Primi-Para mothers regarding complimentary feeding practices.

To find the association between knowledge and demographic variable chi square was used and result showed that the obtained P value is more than 0.05 and none of the variables has association with the post test knowledge score. Hence there is no significant association between post test knowledge score and any of the demographic variables.

**Conclusion**

The present study assessed the effectiveness of planned teaching program on knowledge myths, belief and misconception related to complementary feeding practices among women in selected rural areas of Gurugram, NCR. After the assessment it was found that myths and misconceptions about complimentary feeding is prevalent among women in rural areas. After the assessment it was found that there is optimal knowledge of women of complimentary feeding practices. There has been sharp increase in the knowledge of women on complimentary feeding practices after planned teaching programme. The study concluded that planned teaching programme could be significant in improving the knowledge of women regarding complimentary feeding practices and it would be beneficial in the rural settings.

Effect of an Educational Program for Patients Post Coronary Artery Bypass Surgery on the Compliance with Symptoms Management Strategies

Gehan Karawan Sayed Sallam¹, Kamelia Fouad Abdalla², Sara Fathi Mahmoud³
¹PhD Candidate, ²Professor, ³Assistant Professor, Medical Surgical Nursing, Faculty of Nursing-Ain Shams University

Abstract

Background: Patients undergoing CABG often experience a varied series of discomfort symptoms post hospital discharge include; shortness of breath, chest pain or angina pain, incisional pain, atrial fibrillation, fatigue, leg swelling, sleep quality, loss of appetite, anxiety and depression. Specific educational program regarding symptoms management strategies (SMS) are used to improve patient outcome, therefore patients’ compliance with this program is very essential to relief, manage it.

Aim: to evaluate the effect of an educational program for patients post CABS on the compliance with (SMS).

Design: a quasi-experimental design.

Setting: conducted at outpatient clinics in Cardio Thoracic Academy at Ain Shams Hospital.

Subject: a purposive sample of (150) patients post CABG were recruited.

Tools: demographic, medical data, Cardiac Symptoms Survey (CSS) and compliance scale are used.

Results: The subjects were complaint towards (SMS) pre-program (12.7%) changed to (83.3%) post program. As evidence, 53.3% of the subjects who had severe level of perception of symptoms pre, changed to 5.3% post. Moreover, (62.7%, 59.4% respectively) of the subjects who had severe level of frequency, severity of symptoms pre changed to (4 %, 2.7% respectively) post. In addition, (57.3% respectively) of the subjects who had severe level of interference with physical activity, enjoyment of life pre, changed to (4%,4% respectively) post.

Conclusion: Educational program showed positive effect on the subjects experienced discomfort symptoms post CABG and their compliance towards the management strategies.

Key words: Experienced discomfort symptoms post CABG, Symptoms management strategies, compliance, educational program

Introduction

Coronary heart disease (CHD) is a main cause of morbidity and mortality throughout the world. World Health Organization (WHO) expects 11.1 million deaths will occur from CHD in 2020. CABG has been the mainstay of treatment for revascularization in CHD patients, since 1960, in providing symptomatic relief and increasing life expectancy (14).

The main goal of (CBG) is releasing of angina, improved life expectancy. Although modern advances have enhanced the success rate of CABG they are not adequate to eliminate altogether the physical, psychological and social problems that patients tackled in the period following discharge. Patients post CABG conveyed that they experienced postoperative discomfort symptoms such as sleep disturbances, fatigue, swelling, shortness of breath, fatigue, loss of appetite, chest pain, gastrointestinal disturbance, weight loss, anxiety related to the treatment and their capability to adhere to the recommended physical activity, swelling of leg incisions, weakness, dizziness and depression (4).

The most important component of nursing care following CABS is concentrated on teaching patients to distinguish, manage postoperative symptoms. Nurses involved in postoperative teaching in acute care, home settings should deliver symptoms management strategies.
to patients and their families. Patients often learn through vicarious experience or modeling from others with similar experiences. SMS that other post-CABS patients have used successfully may improve a patient’s preparedness to try a strategy. SMS teaching could be enhanced with more explicit knowledge of strategies essentially used by patients (12).

Compliance is the process whereby the patient follows the prearranged, dispensed regimen as reinforced by the prescriber and dispenser. Compliance with treatment is a sign of a positive behaviour in which the patient is motivated appropriately to adhere to the prescribed treatment as a result of a perceived self-benefit and constructive consequence. Many studies suggested that patients who adhere to their treatments have better outcomes; they get long life, enjoy a higher quality of life (9).

The occurrence rate of CAD is growing all over the world including Egypt. According to ministry of health in Egypt, 2014 stated that CAD deaths reached 107,232 (23.14%) of all deaths. Age adjusted death rate is 186.36/100,000 population; this ranks Egypt #23 in the world. CAD deaths were 78,897 (21.73%) of all deaths, which make CAD the first killer in Egypt (7).

**Method of Study**

A quasi-experimental design was followed. The study was conducted among 150 post CABG patients for first time, discharged within 7 days after surgery and coming to follow up in outpatient clinics in Cardio Thoracic Academy at Ain Shams Hospital. Tools & data collection it was developed by the researcher based on the recent and related literatures it was written in Arabic to suit the level of education for subjectsthe data were collected through the following tools. **Tool I**, constructed multiple-choice questions to assess patient’s demographic characteristics which had two parts. Part A, concerned with socio-demographic variables. Part B included patients’ medical data. **Tool II**, It was used to assess patients’ level of the discomforts symptoms experienced by patients post CABS. It was adopted from (10). It consisted of 10 symptoms which included the following; (angina, shortness of breath, incision pain, a fluttering or racing heartbeat, fatigue, leg swelling sleep disturbance, loss of appetite, anxiety, and depression). Each of these ten symptoms was measured in regards to three an individual’s dimensions which included (perception evaluation and response to symptoms). Then each one of 10 symptoms was each rated on four different response scales (frequency, severity, interference with physical activity, and with enjoyment of life). **Tool III** It was used to assess extent to which patients’ behaviors comply with symptoms management strategies based on (11) and modified by researcher. Patient’s response were assessed through three numerical rating scale ranged from (1 = none or rarely, 2= sometimes and 3 = always). It was consisted of (10) common symptoms and management strategies items for each one of the symptoms it included 74 items.

The content validity was obtained from 7 experts in medical surgical nursing from different academic categories at the faculty of nursing, Ain Shams University. The expertise opinion’s elicited regarding the tools for clarity, consistency, accuracy relevance, comprehensiveness, simplicity and applicability and minor modification was done. **Testing reliability**, the test for this tools was carried out by Cronbach alpha test.

**Pilot Study**

A pilot study carried out for 10% of the subjects who the criteria. Based on the finding of pilot study the essential modification was done to the tool.

**D. Field Work:**

**Assessment Phase**

The aim of study explained to medical team of outpatient clinic. Interviewed subject who meet the inclusion. The required data were collected over 12 month. Six month spent for data collection and other six month spent for follow up the baseline patients’ data were assessed from the studied subjects that include demographic, medical data, cardiac survey and compliance of the first month of follow up visit in the
outpatient clinic.

Planning Phase

The educational program prepared and designed for the studied patients according to patient assessment needs and their level of understanding. The researcher assessed the compliance with SMS for the studied patients.

Educational booklet contain four main parts as following:

Part 1: consisted of anatomy & physiology of the heart, definition, indications, preoperative preparation prior to CABG and emergency instruction post CABG.

Part 2: included patient compliance with symptoms management strategies, experienced discomfort symptoms, importance of patients compliance.

Part 3: contained instruction regarding symptoms management strategies and how to deal with it post CABG for the common experienced symptoms e.g SMS for shortness of breath, chest pain /angina pain, incisional pain, a fluttering or racing heartbeat, fatigue, sleeping disturbance, leg swelling, poor appetite, anxiety, and depression.

Part 4: instructions for medication, movement, return to work, activity, follow up schedule, healthy diet. Each participant obtained a hard copy an education booklet.

Implementation Phase

The educational program covered the 4 parts of the booklet content by holding 3 main sessions each session aimed to teach two strategies to be taught to the patients. It was held on patient waiting area or any other empty room according to the situation of the clinic, it was around 60 minutes, the educational session conducted either during waiting time or after the patients appointment with physician the session were conducted on the morning time, afternoon. The assigned number of patients to educational session coordinated by researcher, clinic nurses and head nurse of outpatient clinic, maximum capacity per session was 10 patients, the educational program repeated from the researcher 8 times for 8 groups of patients to cover the total number of assigned patients in the study group.

Total hours for sessions for studied patients 3 hours one hour/session in each appointment and completed in the next appointment this phase took almost 3 months, the educational program as follows:

- **First session**: covered the first two parts of the booklet the researcher introduce the educational program to the patient and their families and discussed, (anatomy, physiology of heart, definition of CABG, compliance, discomfort symptoms)

- **Second session**: covered the third part of the booklet the patients trained about symptoms management strategies (chest pain /angina pain and shortness of breath), (incision pain, fluttering heart beat) (fatigue, leg swelling)

- **Third session**: covered the rest of the third, fourth part of the booklet (sleep disturbance, loss of appetite) (anxiety, depression) instructions for medication, movement, return to work, activity, follow up schedule, healthy diet.

Evaluation Phase

Effect of an educational program for patients post CABG on the compliance with symptoms management strategies evaluated the researcher by comparing the change in the studied patients experienced discomfort symptoms and their compliance to symptoms management strategies pre, 6 months post program implementation by using tools 2 and 3 in studied patients this phase took around 3 months.

**Results**

Table (1) revealed that mean age of the patients were $48.6 \pm 9.8$, 58% with age from 50-60 years old, regarding gender 58% of them were female and only 18% of them had university education, concerning social status, 82% of the studied patients were married. In addition, 63.3% of the patients had work, 59.3% of them from urban area and 68% of them had not enough income.

Table (2): Comparison between the studied patient regarding to total level of the experienced discomfort symptoms post CABG according to three dimensions pre- and post-educational program (n=150).

Table (4) presented that, there was highly statistically significant relation between the studied patients’ compliance total level toward management strategies for the experience discomfort symptoms post CABG post the educational program and their demographic characteristics as age, level of education, marital status and monthly income at (P= < 0.01). While, there was no statistically significant relation with their gender, working status and place of residence at (P= > 0.05).

Discussion

Part I: Patient’s demographic and medical data:

The current study demonstrated that mean age of patients was 48.6 ± 9.8, 58% with age from 50-60 years old, regarding gender more than half were females and only less than one fifth of them had university education, concerning social status, more than three quarters of patients were married. These results explained as increasing at age and female’s gender had high risk for cardiac disease than young people and male gender. These results were in cohort with the study performed by (5), about Association of microvesicles with graft patency in patients undergoing CABG, at Italy with sample size 60 patients and found the mean age of them was 64±8 and the majority of them were males. In addition, less than two thirds of the studied patients had work, more than half of them from urban area and more than two thirds of them had not enough income. These results attributed to setting of the selected study was university hospital which it wavers part of the cost of the surgery. These results were in cohort with the study conducted by (3), entitled Quality of Life among Post CABG Patients, at India with sample size 101 patients and found that more than half of patients were employee and had low income.
II–Patients’ cardiac symptoms survey:

Regarding to the patient total level of experienced discomfort post CABG pre- and post-educational program, there was highly significant difference where (p=<0.01). As evidence, less than two thirds of the patients who had sever level of the total experienced discomfort symptom preprogram, where changed to the few of them post program. These results may be due the designed educational program developed by the researcher based on need of the studied patient, it showed highly effective intervention for releasing experience discomfort symptom post CABG. These results were in agreement with the study conducted by (1)-about effects of implementing clinical pathway on pain and anxiety for patients undergoing cardiac surgery, at Egypt with sample size 50 patients and found that the intervention group had significantly lower level of anxiety and pain than the control group before and after surgery at p value <0.01**.

Part III: Compliance with symptoms management strategies (SMS)

According to the patient total compliance towards SMS, there was highly significant difference pre and post where (p=<0.01). As indicated, less than one fifth of the studied patients were complaint towards SMS preprogram, where changed to more than half of patients post program. These results explained as intervention program included valuable knowledge about importance of patient compliance to the health team instructions. These results were in cohort with the study performed by (6)-entitled Effects of tele monitoring on patient compliance with self-management recommendations and outcomes of the innovative tele monitoring enhanced care program for chronic heart failure: randomized controlled trial, at Australia with sample size 104 patients and found significant improvement at participant compliance with weight monitoring, although the withdrawal rate was high.

Also, this study finding supported with the study conducted by (8)-about the effects of a comprehensive rehabilitation and intensive education program on anxiety, depression, quality of life, and major adverse cardiac and cerebrovascular events in unprotected left main coronary artery disease patients who underwent CABG who detected that intensive education program had high significant improvement on patients’ compliance with guidelines of health team.

Part IV: Relations & correlations:

The study finding revealed that, there was highly statistically significant relation between the studied patients total’ compliance towards SMS pre-post educational program and their demographic characteristics as age, level of education, marital status and monthly income at (P= < 0.01). While, there was no statistically significant relation with their gender, working status and place of residence at (P= > 0.05). These results were in agreement with the study performed by (2)-about Frequency and predictors of non-adherence to lifestyle modifications and medications after CABG: A cross-sectional study, with sample size was 265 patients and stated that unemployment and expensive were the predictors to non-compliance to medication. Meanwhile, these result was inconsistent with the study performed by (13)-about Factors Affecting Compliance with Therapeutic Regimen for Patients with CABG Suggested Nursing Guidelines, at Egypt with sample size was 72 patients and reported that patient related factor had no significant relation with their compliance score at p value >0.05.

Conclusion

Educational program had highly statically significant positive effect on the studied patients experienced discomfort symptoms post CABG and their compliance towards the management strategies.

Conflict of Interest: Not present any conflict

Funding: Self-funding, without any external source.

Ethical Clearance: Ethical clearance obtained from ethical committee of faculty of nursing and Cardio Thoracic Academy at Ain Shams Hospital before conducting the study work.

1Master of Public Health Student, 2Associate Professor in Department of Public Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, KhonKaen University, Thailand, 3Kuchinarai District Public Health Office, Kalasin Province, Thailand, 4Lecturer of Department of Public Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, KhonKaen University, Thailand

Abstract

This is a cross-sectional study aimed to identify administrative factors and key success factors affecting the surveillance, prevention, and control of COVID-19 among the health personnel at sub-district health promoting hospitals in KhonKaen Province. The sample size was 138 health workers working in Sub-district health promoting hospital KhonKaen Province, Thailand. Respondents were selected by applying systematic sampling method. A total of 905 people were selected from the study population for the quantitative study and 12 key informants were selected for the qualitative study. The qualitative study was carried out by using in-depth interview guidelines. The questionnaire was evaluated by 3 experts yielding an IOC value of more than 0.50 in all questions. The Cronbach’s alpha coefficient of the questionnaire was 0.92. Data was collected between 21st December 2020 to 9th January 2021. Data analysis was performed by descriptive statistics and inferential statistics as a significant level at 0.05.

The results of the study showed that key success in all levels of agencies involved were with a work plan to support the performance, the performance link between the hospital and link to a major hospital, and the administrative factors of time, money, and management affecting and could jointly predict the surveillance, prevention and control of COVID-19 (R² = 0.727, p-value < 0.001). In conclusion, five factors are identified to affect surveillance, control and prevention of COVID-19 among the public health officials. Therefore, there should be a plan to support the performance in assigning responsibilities, promoting participation in policy making, planning of time, budget management and regular and proper co-ordination for internal and external organizations.

Keywords: administrative factors, key success factors, control coronavirus disease 2019 (COVID-19)

Introduction

The outbreak of Coronavirus Disease 2019 (COVID-19) since December 2019, and consequent widespread, on March 11, 2020, the World Health Organization (WHO) declared the novel coronavirus outbreak as a pandemic after the virus spread to 213 countries and territories. The report of COVID-19 as of June 30, 2020, it is found more than 10,629,405 were confirmed cases, more than 514,901 deaths, 5,833,268 were cured, 4,821,236 were undergoing treatment, it was spread in Thailand since the beginning of January 2020[1].

Corresponding author:
Surachai Phimha
Address: Lecturer, Department of Public Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, KhonKaen University, Thailand. E-mail: suraphi@kku.ac.th
In Health District 7, on September 17, 2020, 13 confirmed cases of COVID-19 were detected, 13 cumulative cases of infectious disease, one death and treatment, and 12 cases were missing[2].

As per the report of 1 May 2020, 6 confirmed cases of coronavirus 2019(COVID-19) and 613 surveillance physicians (PUI) were eligible for investigation in KhonKaenProvince[3]. The implementation of surveillance, control, and prevention of infectious diseases among public health workers in sub-district health promoting hospitalsto achieve this objective requires several factors. For the smooth work plan and its proper execution in terms of applying knowledge to control the disease in effective way, the administrative factors should play very immense role[4]. Ability to supervise and monitor the project are additional factors of health workers in the operational management[5].

From the problems, the researcher gets interested in studying administrative and key success factors that effect on surveillance and prevention of COVID-19 of public health officers in sub-district health promoting hospitals KhonKaenProvince. for the reliability of the study results we had applied a guideline about planning, developing and supporting, along with promoting surveillance, control, and prevention of COVID-19 infectious disease among public health workers in sub-district health promoting hospitals to be more effective sustainably.

Research Objectives

Objective of this study was to identify the administrative and key success factors that affect surveillance and prevention of COVID-19 of public health officers in sub-district health promoting hospital, KhonKaenProvince, Thailand.

Research Methodology

This is a cross-sectional descriptive study to collect quantitative and qualitative data. Population and sample size

Sample group of this study is public health professionals, who are working in sub-district health promoting hospital KhonKaenProvince, Thailand. There is a procedure for calculating the sample size. When the population is known and for the multiple regression analysis, sample size is calculated by using the formula for calculating the sample size of Cohen (1988)[6].

\[ N = \frac{\lambda(1-R^2_{AB})}{R^2_{AB}} + w \]  
\[ \lambda = \frac{\lambda_L - \lambda_U}{1/\lambda_L - 1/\lambda_U} \] 

According to the sample size calculation, it is found that “n” is equal to 138 respondents, who will be responding the questionnaire.

In-depth interview random sampling

A group of people who provided information on in-depth interview to verify quantitative data that obtained from public health workers who can provide information on the fast-moving surveillance practice of the sub-district health promoting hospital, KhonKaen Province (Key Informants 12 persons).

The research tools

Tools used for the data collection in this study is a questionnaire to confirm the quantitative data. It consists of two types of tools:

Set one is a questionnaire that consists of five parts: Part one is a question of personal characteristics which consists of gender, age, marital status, education level, position, income, length of time in disease control work including training on disease control. Part two is of 30 administrative factors which consist of budgets, personnel, materials, equipment, time management, and technology. Part three is 30 key success factors that consist of executives at all levels who support and follow up, support agencies at all levels have a support program, taking action in an area where ready and voluntary participation, making understanding and encouraging cooperation, developing the image of the service facility and connect with sub-district health
promotion hospital and community hospitals. Part four is 30 questions about prevention, control, along with prevention of COVID-19 which consists of screening and monitoring for patients at checkpoints, nursing homes, and communities, infection prevention, contact tracing and containment, and risk communication. Implementing social and legal measures. Coordination and management of information. Use rating scale five levels in part two, three and four[7].

The scoring criteria for comments are as follows: The highest level is five points. The high level is four points. The intermediate level is three points. Low level is two points. The lowest level is one point. Part 5 is three open-ended questions about problems, obstacles and suggestions about surveillance and prevention of COVID-19 of public health officers in sub-district health promoting hospital, KhonKaen Province.

Set two is an In-Depth Interview guideline that the information was found from the quantitative research data. The least average questions are used for in-depth interviews to confirm the data, support and explain the quantitative data. The researcher defined the issue in three parts: Part one is an in-depth interview guide about administrative factors. Part two is an in-depth interview guide about key success factors. Part three is an in-depth interview guide about surveillance, control and prevention of COVID-19.

Quality testing of the tools

Quality testing of the tools about content validity. The researcher led questionnaires and in-depth interviews offered three experts to check the correctness and validity. Then, questions were processed to find the Item Objective Congruence(IOC)[8].It was found that all items had IOC greater than 0.50. Checking the reliability of the tools [9] after improving them, try out was done with public health officials in sub-district health promoting hospital, Roi Et Province, Thailand that has similar area in operational service, and management characteristics. In this study, 30 people were given the reliability from Cronbach’s alpha coefficient of the whole questionnaire equal to 0.92, Administrative factors are 0.76, key success factors are 0.92, and surveillance, control, and prevention of COVID-19 infectious disease (COVID-19) are 0.94.

Data Analysis

Descriptive statistics used to analyze the data are percentage, mean, median, standard deviation. Inferential statistics used to analyze the data are Correlation Coefficient of Pearson, regression analysis and stepwise multiple regression analysis. In-depth interviews to verify quantitative data by Content analysis.

Research results

1. Personal characteristics

Personal characteristics of public health workers performing the work of surveillance, control and prevention of COVID-19 in the sub-district health promoting hospital, KhonKaen Province found that the majority of the sample was female, totaling 86(62.3%), most of them aged between 31-40 years, totaling 51(37.0%), average age is 39.72 years (S.D.=10.08 years, Min = 23 years old, Max = 59 years old). Mostly, the marital status amounted to 90 people (65.2%). Most of them are graduated with a bachelor’s degree or equivalent, 106 people (76.8%). There are 51 public health technical officer (37.0%) with an average income of 29,154.31 Baht (S.D.= 12,972.48 Baht). They have a duration of working about the surveillance and preventive work was 10 years or more, 62 people (44.9%) with a median of 10 years (Min = 1 year, Max = 39 years). Most of them have received training in an epidemiological course, a total of 111 respondents (80.4%).

2. Administrative and key success factors affecting to surveillance and control and prevention of COVID-19

The analysis results showed that independent variable that affects the surveillance, control and prevention of COVID-19 among public health professionals working in sub-district health promoting hospital, KhonKaen Province as follow: Key success Factors: supporting organizations at all levels have a support plan (p-value = 0.013), and connecting between
sub-district health promoting hospital and community hospitals (p-value < 0.001). Management factors: Time (p-value = 0.003), Budget (p-value < 0.001), and Management (p-value = 0.043). Therefore, five independent variables can forecast about surveillance, control and prevention of COVID-19 of Public Health Workers in sub-district health promoting hospital as 72.7 percentage (Table 1). Multiple Linear Regression equation which is a prediction equation is as follow:

\[
Y = 1.230 + (0.223)(\text{Key success factors: Supporting organizations at all levels have a support plan})
\]

\[
+ (0.250)(\text{Key success factors: Connecting between sub-district health promoting hospital and with Community Hospitals})
\]

\[
+ (0.242)(\text{Management factors: Time})
\]

\[
- (0.139)(\text{Management factors: Budget})
\]

\[
+ (0.160)(\text{Management factors: Management})
\]

**Conclusion and Discussion**

The results of the study showed that key success factors about supporting organizations at all levels have a support plan, connecting working between sub-district health promoting hospital and community hospitals, Management factors in Time, Budget, and Management can forecast about surveillance, control and prevention of COVID-19 of Public Health Workers working in sub-district health promoting hospitals, KhonKaen Province as 72.7 percentage.

Key success factors about supporting organizations at all levels have a support plan, connecting working between sub-district health promoting hospital and community hospitals. They are an essential part of the overall service coverage and efficiency. Supporting organizations at all levels have a support plan and make a surveillance action plan about control and prevent disease both short-term, medium-term, and long-term. This study’s results are consistent with the results of the study found that supporting organizations at all levels have a support plan effect on surveillance, control and prevention of infectious diseases of public health officials \[10-11\]. In addition, key success factors about connecting working between sub-district health promoting hospital and community hospitals affect on surveillance, control and prevention of public health officials \[12-13\]. However, the situation in COVID-19 working is different from other infectious disease therefore, the result of this study inconsistent with the results of the study found that supporting organizations at all levels have a support plan no effect on surveillance, control and prevention of infectious diseases of public health officials \[14-15\].

Management factors: Time, budget and management will be accomplished must take the time appropriately, organize work planning each day, each week, order of work by importance. As well as support the creation of a more efficient management process. Management is an essential process for resource management. Management to achieve the organization’s objectives goals base on effectively: planning, budgeting and organizing. This study’s results are consistent with the results of the study found that management factors; time, budget, and management affect on surveillance, control and prevention of infectious diseases of public health officials \[11,16\]. It also found that time management factors, budget management factors, and management factors affect the working of public health officials \[17-20\]. The management factors were applied by different directors and area problem thus the result of this study is inconsistent with the results of the study found that management factors; time, and budget no affect on surveillance, control and prevention of infectious diseases of public health officials \[21-22\].

Results of in-depth interviews represent the surveillance, control and prevention of COVID-19 of public health workers in sub-district health promoting hospital is interviewee about suggestions founded that the lowest mean is entry and exit to follow about the risk groups in areas where some people don’t have smartphones to report working data. Equipment isn’t enough, such as protective clothing. Therefore, the
management organization should provide sufficient supplies to support the work. In case of necessity, a raincoat can be used instead of protective clothing to prevent direct contact with secretions.

In conclusion, key success factors about supporting organizations at all levels have a support plan, connecting working between sub-district health promoting hospital and community hospitals, Management factors in Time, Budget, and Management affect on surveillance, control and prevention of COVID-19 of public health officials. Therefore, there should be a plan to support the performance in assigning responsibilities, promoting participation in policy making, planning time, budget, management and connecting working for internal and external organizations.

Suggested for next research

There should be a study of factors affecting the participation in the surveillance and control of the COVID-19 of public health workers in the district health promotion hospital.

Acknowledgements: The researcher would like to thank for all faculty members of the Faculty of Public Health, KhonKaen University. Thanks to KhonKaen Provincial Public Health Office, all district public health. Director of sub-district health promoting hospital, KhonKaenProvince who allowed the researcher to collect data in the area.

Ethical Clearance: The researcher collected research data after being certified by the Human Research Ethics Committee of KhonKaen University on December 14, 2020 number HE 632257. Data collection was done between December 21, 2020 to January 9, 2020.

Conflict of Interest: No conflicts of interest to declare.

Total Quality Management (TQM) and Sports (Development, Concepts and Definitions)

Ghazwan Aziz Mohsen1, Bashar Banwan Hasan1, Haidar Mahmood Allawi1
1Ph.D. Faculty of Physical Education and Sports Science, Wasit University, Iraq

Abstract

Sports entrepreneurship among countries is to achieve a good sporting performance in sportive competitions. At the present time, sports are considered as one of the essential parts in our life, which are sought out by the governments, due to the main role that sports take at the national and international levels in the political, economic, cultural and social levels.

The sports level has been improving over the past several decades, this improving coinciding with the changes of the sport concept that is generally recognised as system of activities which are based in physical athleticism or physical dexterity. The concept of the athlete has changed into a wide concept that is become a unit of feeling, excited, affected and tired.

Sports has got the attention of persons who interested in scientific, medical, social, political and economic matters, which made sports have different specializations such as administration and management.

Key Wards: Total Quality, Concept of Administrative, (TQM) and Sports.

Introduction

The development of administrative thought study is important as it helps to explain the past, practice and the different thinking styles that prevailed in it. Hence, this is due to the positive in understanding the present, and the changes that are happening such as: problems and challenges.

So, the prediction, the requirements and challenges of the future may be effect on the development of administrative thought that leads to decrease the deviations as well as to reduce the problems that may be effect on the productivity of the organization.

The development of sports management thought is related to the development of administrative thought at the level of the state as a whole and in all the various parts; It could even be said that sport in its various fields reflects the extent to which administrative thought has evolved, but in the Arabic countries such as Iraq, these countries interested in sports. So, the management is considered as a secondary element. The development of administrative thought has shown in sports a little while ago, especially in Arab world, which may be due to those who chronicling the management thought. Recent legislations and laws also made sport in the Arab world an area full of innovators and volunteers in form, and the issue is obligatory.

Management is considered as one of the practices that is as old as human, because the management is a part of knowledge. So, it is appeared in this century. As a result of the efforts of some intellectuals and scholars such as Taylor, Henri Fayol, Charles and Charles Babbage who try to put the scientific bases of administrative management; whose studies has stated that there is a scientific management that is used to achieve the aims, which every organization aims to.

The administration is also part of the world civilizations that have flourished; it is not possible to talk about administrative thought without referring to the
administrative capacity of ancient civilizations, because modern administrative thought did not appear except by being affected by what preceded it.

Researchers in the heritage of Sumerian civilization found written documents, indicating that the Sumerians exercised a color of administrative control, as the priests of their temples had a tight tax system, which they collected and managed large quantities of worldly goods, the Sumerian priests followed the writing system by recording all the data on all the transactions of the various priests responsible for the vast wealth of the religious establishment. Thus, the creation of Sumerian writing was for administrative control, not for religious rituals, i.e. it is found for administrative needs.

So, Management was the practice of man in the past, as they used to do planning; i.e., setting plans and making special decisions in the event of war, except that it did not appear as a science until the end of the last century, when man was interested in it as a thought and as a social philosophy of life We cannot talk about management as a science without getting to know management in ancient civilizations.

Based on all of the above, in this study we are going to talk about overall quality, as well as the development of administrative thought in general, and then the development of this thought in the field of sports.

Section One (Total Quality)

1. The Concept of TQ

Total quality means “a method that aims to cooperate and participate from all employees of the sports authority, with the aim of improving services and activities, thereby achieving the satisfaction of the beneficiaries of the activities, and achieving the objectives of the authority itself” 1.

To achieve the overall quality of the sports body, a number of components must be met:

1. Correct performance: it is intended to implement the work procedures correctly, from the first practice, and in time to complete it.

2. The use of information systems to solve problems: it means implementing the work procedures correctly, from the first practice, and in time to complete it.

3. Focusing on both processes and results: i.e. attention to the way of work, the way it is implemented, and the scrutiny of its continued development, i.e. attention to the administrative processes in the authority besides its results.

4. Human resources development: it means working to improve the performance of the individuals working in the sports body, through attention to training, to keep pace with changes and development in the field of career specialization, and to improve the conditions surrounding the work 2.

2. The Concept of Administrative

The word administrative comes from Latin, which made up of two syllables (ad=to), (ministrate =save) that means to save or to present a service 3.

The word management comes from the English verb “manage”, which also comes from the Italian maneggiare (to handle, especially tools or a horse), which derives from the two Latin words manus (hand) and agere (to act) 4.

Management (or managing) is the administration of an organization, whether it is a business, a not-for-profit organization, or government body 5.

The concepts that have been outlined for us have been made possible by many researchers in this field, Henri Fayol (1841-1925) stated: “to manage is to forecast and to plan, to organise, to command, to co-ordinate and to control” 6.

In another way of thinking, Mary Parker Follett (1868–1933), allegedly defined management as “the art of getting things done through people”. She described management as philosophy 7.
Jamal al-Din Laweisat defines it as: “is the coordination of different resources through planning, guidance and control processes, in order to reach established objectives”.

According to Amar Buhash, administrative is “the executive body charged with enforcing state laws and providing the necessary services to citizens, within the framework of the established laws and the objectives set by the political, economic and social leadership”.

Hassan Shelton and Hassan Mouawad also defined it as “the process of carrying out the work by others by planning, organizing, directing and controlling their efforts”.

Al-Hawari defined it as: “That member responsible for achieving the results for which any institution or body existed”.

To achieve results, management must essentially commit to:
1. Choose the best elements to achieve the planned results.
2. Use those elements, the best possible use.
3. Continuity in balancing short-term and long-term requirements.

3. Administrative and Other Sciences:

Science is an integrated structure, consisting of overlapping parts that are affected by each other, and affect each other; for example, psychology uses medical sciences, and the close relationship that exists between the humanities and each other, is evidence of influence and influence; The science of administration, history, economics, and law, they have close ties, as well as sport is associated with a lot of medical, psychological and social sciences.

4. The Administrative Level

After the industrial revolution, enterprises expanded and enterprises developed significantly, which increased the number of administrators, and this was a reason for their ranking at top to bottom levels; these levels are:

1. Top-Level Management

Top-Level Management is at the top of the organizational pyramid, with the organization’s policy being developed at its level; It has a group of administrators who develop the organization’s policy and general plans, in order to achieve the goal to be reached.

Top-Level Management is the mind of the organization: The mental management skills are the basis before human and technical skills, which is the ones that formulate policies, rules and laws, with objectives, setting plans, supervising them and following up on their implementation.

2. Middle Level Management

Middle manager is a link between the senior management and the lower (junior) levels of the organization. Due to involvement into day-to-day running of a business, middle managers have the opportunity to report valuable information and suggestions from the inside of an organization. Moreover, the middle manager is a channel of communication within the organization, as they pass on major decisions of executives and the main goals of an organization to lower levels of employees. This contributes to better coordination between workers and makes a company more united.

3. Supervision Management

The supervisory Management represents the various members of the organization, who hold the executive functions, and who oversee the performance, i.e. deal with the executor.

Section Two (The Development of Total Quality Management (TQM) and Sports)

1. The History of Sportive Thought

The development of sportive management thought is no different from that of administrative thought in general, except in the field of sports here, as it is full of
various activities and different levels of administrative work. The development of sports management thought is closely linked to the development of administrative thought at the state level as a whole and in its various sectors, but in developing countries, interest in management in the field of sports is lacking.

The administration is a secondary element, and attention to it has only emerged a short time ago, and this is due to historians of sports administrative thought, although the lack of law and the multiplicity of legislation and the change of senior administrations have made sport in the Arab world an area full of innovators and enthusiasts of volunteerism, which has led to their lack of interest in developing sports administrative thought and recording its history. Therefore, the management scientists, with great regret, did not give great importance to management in the field of sports, in order to apply their principles and theories, so they left for personal experience and the desire to achieve special benefit and political affiliations.

The department in the field of sport has also existed for a long time, as this is evident in the holding of the Old and Modern Olympic Games, as it is clear that they were sporadic efforts by individuals and groups, coordinating the administration among themselves to achieve the goal of organizing and establishing the modern Olympic Games, which began in 1896 and have continued to date once every four years; the presence of organizers, promoters, administrators and trainers is evidence of the concept of sports management. The Department is a guaranteed activity with key components, carried out by individuals who are able to use the available resources to guide staff towards specific objectives. Therefore, more analysis and characterization of the components of management are needed. From that characterization, the definition of sports management would be acceptable. Accordingly, sports management is defined as: “a process of planning, leadership and control, the efforts of the members of the sports organization, and the use of all resources to achieve the specified objectives”. (Badawi (Op. Cit.), p. 17)

Sports management was also defined as “skills associated with planning, organization, guidance, follow-up, budgets, leadership and evaluation within a body that provides a sports service, physical or recreational activities. Since the lack of expertise of sports bodies, the organization of the management of a tournament, a competition, a stadium, or a team started the sports management program, Ohio University began master’s studies in sports management in 1966, it was the first study in America, and then many other universities began to organize studies in this field”.

But the current situation is quite different: work in sports management requires the study of theories, arts, work and management, sports planning, potential in the sports sectors, administrative communication and laws, regulations and administration in the sports field, administrative leadership in the field of sports, organizational behaviour and supervision, guidance, follow-up and sports marketing.

2. The Concept of Sportive Management

With the diversity of sources of management knowledge between experience and study of public administration science, it has become difficult to define a specific definition of sports management since scientists differed in the definition of management, because of their differing views of definition. However, we mention some of the definitions of sports management developed by sports management students.

In this sense, the Department is a guaranteed activity with key components, carried out by individuals who are able to use the available resources to guide staff towards specific objectives. Therefore, more analysis and characterization of the components of management are needed. From that characterization, the definition of sports management would be acceptable. Accordingly, sports management is defined as: “a process of planning, leadership and control, the efforts of the members of the sports organization, and the use of all resources to achieve the specified objectives”. (Badawi (Op. Cit.), p. 17)

Sports management was also defined as “skills associated with planning, organization, guidance, follow-up, budgets, leadership and evaluation within a body that provides a sports service, physical or recreational activities. Since the lack of expertise of sports bodies, the organization of the management of a tournament, a competition, a stadium, or a team started the sports management program, Ohio University began master’s studies in sports management in 1966, it was the first study in America, and then many other universities began to organize studies in this field”.

Accordingly, the administrator is the person who directs the efforts of others with him/her to achieve the agreed objectives, using administrative processes and management skills, with optimal recruitment of capabilities and capabilities: planning, implementing,
following up and evaluating all sports activities.

3. The Importance of Administrative in Sports

The sports field of work absorbs large numbers of graduates of sports education to work in the management of sports bodies and institutions.

Although the talent for leadership is one of the requirements of administrative work in the field of sports, as in the management of the best areas. However: refinement, qualification, training, and study are important as a place to refine this talent, which can be said to be: the study of sports management is necessary to achieve success in administrative work, whatever the field in which it occurred 19.

All physical and sports activities are a collective effort; management is essential for the development of community spirit, advance planning of any programme, participation, coordination and cooperation in action, which requires accurate knowledge of the potential of management. Therefore, sports management is one of the most important components of modern scientific sports development; it helps to increase sports achievement and its development in quantity and quality.

The characteristics of effective scientific sports management are as the following 20:

1. Inclusion: that means the need for management to cover all aspects and areas of work in the sports body, within the limits of its competences.

2. Integration: that means intended to take over each department or part of the sports body for specialized functions, taking into account that all departments or parts of the administrative process of the sports body as a whole are completed, taking into account coordination to achieve the desired results.

3. Futurism: that means the sports management must work not only for the present, but also for the future through goals, aspirations and aspirations in a time to come, and in the course of its work to do so, it must look to the past and learn lessons from it. Here, the importance of predicting the future is evident as a fundamental duty of sports management.

4. Open-mindedness: It means that the sports management of the authority is characterized by openness to the environment in which it operates, so that it is affected and affected.

Conclusion

The development of sports management thought is related to the development of administrative thought at the level of the state as a whole and in all the various parts; It could even be said that sport in its various fields reflects the extent to which administrative thought has evolved, but in the Arabic countries such as Iraq, these countries interested in sports.

So, the management is considered as a secondary element. The development of administrative thought has shown in sports a little while ago, especially in Arab world, which may be due to those who chronicling the management thought. Recent legislations and laws also made sport in the Arab world an area full of innovators and volunteers in form, and the issue is obligatory.

On the basis of all of the above, sports management uses the elements and theories of management, and benefits from the development of administrative thought, in order to achieve the best social, educational, cultural, economic, and educational aims of the society, as well as the sports field, which is a catalyst in the success of other organizations: economic, industrial, commercial, government, political and educational institutions.

Association between Metacognition and Obesity in Male Individuals of South Indian Population

Gokul.K1, A.Sangeetha2, Kumaresan M3, Samuel Sundar Doss4, Hemachandrika C5

1II MBBS Student, Department of Physiology, Saveetha Medical College, Chennai, Tamilnadu, India, 2Assistant Professor, Department of Physiology, 3Assistant Professor, Department of Anatomy, 4Tutor, Department of Physiology, 5Professor, Department of Physiology, Saveetha medical College and hospital, Chennai, Tamilnadu India

Abstract

Introduction: Metamemory is the introspective knowledge of one’s brain memory capability and process involved in memory self-monitoring. This self-awareness of memory has important implications for how people learn and use memories. Aim: The aim is to assess the metamemory in male obese individuals. Materials and Method: A study was conducted among 165 male obese category at random south Indian population. The participants were asked to complete a self-reported questionnaire on Metamemory. The Multifactorial Memory Questionnaire (MMQ), developed to assess separate dimensions of memory ratings that are applicable to clinical assessment and intervention, includes scales of Contentment (i.e., affect regarding one’s memory), Ability (i.e., self-appraisal of one’s memory capabilities), and Strategy (i.e., reported frequency of memory strategy use). Result: Association between corresponding subscale scores and obesity indicates a weak correlation between BMI, satisfaction (r = -.11) and strategy (r = -.11). In addition, the MMQ subscales and the total score showed good internal consistency (αs = 0.81-0.84). Conclusion: The results would conclude that overweight and obese male individuals had poor metamemory scores. The study would also help the overweight and obese individuals to identify any early stage of cognitive impairment and create an awareness to delay or prevent any further metacognitive dysfunction.

Keywords: Metamemory, obese, dementia, physical activity, Cognitive performance, Cingulate gyrus

Introduction

Metamemory refers to knowledge and monitoring of one’s own memory. Metamemory monitoring can be done prospectively with respect to subsequent memory retrieval or retrospectively with respect to previous memory retrieval. [1]. This self-awareness of memory has important implications for how people learn and use memories. For example, when a person asserts that he or she is good at remembering faces, but poor at remembering names, that person is making a statement concerning metamemory knowledge. Metamemory awareness refers to our feelings or experiences of our own memory. For example, if a person feels certain that he or she will remember later something just learned now, that person is having a metamemory experience [2-5]. Metamemory is a subarea of Meta cognitions. Accordingly refers to people’s self-monitoring and self-control of their own memory process and strategies that can aid memory. Due to a sedentary lifestyle, more and more people are becoming obese nowadays. In addition to health-related problems, obesity can also impair cognition and motor performance [6].

Obesity is related to several diseases (e.g., diabetes, stroke, and high blood pressure; [7] and it leads to early death [8] and cognitive decline[9]. What are the cognitive causes to enforce, maintain and to eliminate obesity are at a center of an extensive research effort [10,11]. It is increasingly evident that obesity negatively impacts human health and the prevalence of obesity is increasing world-wide [10]. Both overall obesity (body mass index (BMI) >30 kg/m²) and fat distribution (waist-hip-ratio (WHR) >1.0 in men and >0.85 in women indicative of abdominal fat accumulation) have been linked to cardiometabolic diseases and death in observational studies [12-15]. Compared to BMI, central adiposity has a stronger association with the risk of developing cognitive impairment and dementia in women [16]. Therefore it is important to evaluate the state of metamemory in obese female individuals. The state of metamemory in overweight or obese person will surely result in better understanding of the cognitive condition by the physicians. Therefore, the purpose of this study is to investigate and understand the relation between the decrease or increase in metamemory in obese individuals.

**Materials and Method**

**Ethical Consideration:**

The study proposal was approved by the board of the Saveetha medical college and hospitals (IRB No. SMC/IEC/2020/03/029). The purpose and objective of the study was clearly explained to the participants through an information sheet. It was emphasized that their participation was optional and the confidentiality of data was assured. The participants were requested to sign a consent form attached with the questionnaire, to ensure their willingness to participate in the study.

**Study setting and design:**

This was a cross-sectional, descriptive correlational study. This standard questionnaire was done by 165 male obese individuals who volunteered to participate in this study. A convenience sample of participants from 19 to 55 years old female individuals was recruited from Medicine OP, Saveetha Hospitals. The questionnaire was administered through face-to-face contact by the investigator with potential participants. Potential participants who expressed interest in the study were screened for eligibility based on the inclusion/exclusion criteria. Inclusion criteria were as follows: ages from 19 to 55; BMI ranges between 30 to 40; ability to read, speak, and understand english. Participants with comorbidities like diabetes mellitus, hypertension and hyperlipidemia were excluded. Individuals with cognitive impairment (Alzheimer’s disease) were also excluded. After the inclusion/exclusion criteria were applied, 165 participants have received paper copies of the study’s survey instrument. The questionnaire included about age, height and weight, hence BMI calculated BMI = Weight/Height in meter². The participant’s BMI ranges are between 30 and 40. Individuals falling under obese I & II category were included.

**Procedure:**

**Perceived memory:**

The multifactorial memory questionnaire is a standard metamemory questionnaire (MMQ) which helps to assess a Metamemory of a person. It consists of three scales measuring separate aspects of metamemory. Items are rated on a 5-point Likert scale (0 = strongly agree, 1 = agree, 2 = undecided, 3 = disagree, 4 = strongly disagree) based on the test’s takers experiences. The three MMQ scales and their respective metamemory domains include: MMQ-Satisfaction (formerly called MMQ-Contentment). This scale measures satisfaction, concern, and overall appraisal of one’s own memory. Each of 18 statements is rated based on degree of agreement. The score range is 0 to 72, with higher scores indicating a higher degree of satisfaction. MMQ-Ability. This scale measures self- perception of everyday memory ability. Respondents rate how often they experienced each of 20 common memory mistakes over the previous two weeks. The score range is 0 to 80, with higher scores indicating better self-reported memory ability. MMQ-Strategy. This scale measures the use of practical memory strategies and aids in day-to-day life. Respondents rate how often they used each of 19 memory strategies.
over the previous two weeks. The score range is 0 to 76, with higher scores indicating greater use of memory strategies. Based on questionnaire data total score ranges are measured. Using a method formula; Prorated Score = Number of possible items X (Obtained score/ Number of completed items).

Data Analysis

Statistical analysis was done using SPSS Version 25.0. Descriptive variables were reported (Mean with standard deviation, Percentage) for all demographic variables. Pearson’s correlation analysis was used to assess correlations between BMI and the survey scores (Satisfaction, ability and strategy) and Cronbach’s alpha was calculated to measure internal consistency among the individual scores (17). The significance level was set at 0.05.

Results

Among the 165 participants, the mean and SD for age, height & weight were calculated (Table 1). Mean and SD for BMI and MMQ Subscale scores (Satisfaction, ability and strategy) are given in Table 2. Age and BMI were correlated with MMQ subcomponents (Table 3). The internal consistency of subscale scores are measured by cronbach’s alpha to check the reliability. There was a weak negative relationship between age and MMQ subscales (Satisfaction, ability and strategy). This relationship suggests that in obese male individuals, increasing age is associated with decreased satisfaction and strategy. Based on the MMQ subcomponent scores the study participants were found to have more worries about their memory (MMQ-contentment), reported significantly more instances of forgetfulness (MMQ-ability), and use less memory aid strategies in their day-to-day activities (MMQ-strategy) (Table 2 & 3). BMI had a weak negative correlation with MMQ-contentment ($r = -.11$) or MMQ-ability ($r = -.19$) or MMQ-strategy ($r = .11$). In our evaluation with a sample of 165 middle-aged and older obese male individuals analyses using Cronbach’s alpha indicated good internal consistency for the Satisfaction ($\alpha = .84$), Ability ($\alpha = .81$), and Strategy ($\alpha = .83$) scales (Table 3).

**Discussion**

In the present study, Obesity in male individual adults showed a negative correlation on all the metacognitive components. When the BMI values were correlated with metamemory components it showed a weak negative correlation. Simply, the study has indicated that male with overweight and obese reported more worries about their memory, more forgetfulness, and more use of strategies to ameliorate memory difficulties. Based on BMI data, individuals who are overweight or obese, fall in the lowest quartile of global cognition, verbal fluency, delayed recall, immediate logical memory, and intelligence (18). Other than BMI, other adiposity measures are also related to cognitive performance and brain changes. Visceral adiposity is inversely correlated with verbal memory and attention. High visceral adiposity is associated with smaller hippocampus and larger ventricular volume (19). There is also a negative correlation between waist-to-hip ratio and hippocampal volume and a positive correlation between waist-to-hip ratio and white matter hyperintensities (20).

Global loss and regional alterations in gray matter volume occur in obese male subjects, suggesting that male subjects with a high BMI are at bigger risk for future declines in cognitive skills or other brain functions (21). Statistical parametric mapping has revealed a significant negative correlation between BMI and metabolic activity in prefrontal cortex (Brodmann areas 8, 9, 10, 11, 44) and cingulate gyrus (Brodmann area 32) but not in other regions (22-24). These results further indicate the urgency of creating awareness on obesity in the society. A host of previous literature has suggested that exercise can improve both obesity-related cognitive and motor declines. As more and more people develop obesity in young age, introducing exercise intervention early would result in the greatest benefits towards good health (6).

**Conclusion**

Obesity has become a worrying health and social issue. The current study also has shown that obese and overweight individuals had poor metamemory scores. Obesity affects cognition mainly through altering the brain structures and functions and motor performance. The study would help the obese individuals to identify any early stage of cognitive impairment and create an awareness to delay or prevent any further metacognitive dysfunction. Regular physical activity and exercise benefits both cognition and motor behaviours.

**Limitations:**

The small sample size from a single area of the country also limits generalizability. The current study had taken individuals who were obese for past 2 years. BMI measurements were independent of the quantity of total body fat and a number of potential confounders, including age and household income. The study did not differentiate metamemory values between overweight and obesity. Physical activity was not measured. Future research is needed to investigate relationships between these metacognition variables, objective neuropsychological tests, and functional MRI imaging.

Abstract

Background: Poisoning is the major health problem in developing countries like India. Rodenticides are the substances used to kill rats. Rodenticides are one of the commonest substances used for poisoning in India one of the reasons is that it is easily available and cheaper than other pesticides. They differ from chemical composition and toxicity profile. Prognosis mainly depends on chemical content of poison.

Methods: A retrospective descriptive 6-year review of data from 597 rodenticide poisoning autopsies performed by the Department of Forensic Medicine at Vijayanagar Institute of Medical Sciences (VIMS), Ballari, Karnataka, India between January 1, 2015, and December 31, 2020, was carried out. Data were obtained from judicial requisitions, autopsy reports, toxicology, and histology results. Different variables like the gender, age-wise distribution of cases, marital status, profession, antemortem laboratory investigations, and manner of death were analysed. The data were analysed using Statistical Package for Social Sciences (SPSS) version 27.0.

Results: Out of 597 autopsy cases, majority of the cases 492 (82%) were male, 105 (18%) were female. Most common age group was 51 to 60 years (45.23%) cases, followed by 41 to 50 years (26.19%) cases. Most victims were married 469 (79%) and by profession were farmers 292 (48.91%) cases. Majority of the cases were mostly reported in the night 454 (76.04%). Antemortem laboratory investigations data like prothrombin time (PT), activated partial thromboplastin time (APTT), aspartate aminotransferase (AST), alanine aminotransferase (ALT), total bilirubin were elevated in majority of the cases. Manner of death was suicidal 497 (83%) cases.

Conclusions: Rodenticide poisoning is quite common and treatable, most of the time it is suicidal in nature. Public should be educated regarding consequences of poisoning. Family support and proper counselling for high-risk groups may decrease these incidences.

Key words: Rodenticides, Agriculturist, Suicide, Epidemiological Profile, Coagulation markers.

Introduction

Rodenticides, commonly referred to as “rat poisons,” are chemical agents aimed at eliminating small rodents [1-5]. The common targets for their use are household rodents i.e., rats/mice, squirrels, gophers, etc. Controlling rodents is imperative as they are vectors for spread of disease, destroy crops/grains, and multiply...
India being a primarily agrarian country, rodenticides are widely used and freely available. They are available in various formulations as powders, pastes, pellets, cereal baits, or blocks[7].

Rodenticides are classified based on their toxicity as:[1]

- **Highly toxic**: Median lethal dose (LD 50) ranging from 0 to 50 mg/kg body weight.e.g., Strychnine, Thallium, Elemental phosphorous, Metal phosphides, Sodium monofluoroacetate, Arsenic, Alpha-naphthyl thiourea.

- **Moderately toxic**: LD 50 ranging from 50 to 500 mg/kg.e.g., Cholecalciferol, Warfarin.

- **Less toxic**: LD 50 ≥ 500 mg/kg.e.g., Superwarfarins— brodifacoum, bromadiolone, chlorophacinone, difenacoum, and diphacinone, Bromethalin, Red squill.

Poisoning due to rodenticides is relatively rare compared to organophosphorus compounds but rodenticide poisoning is an important health problem with a high case fatality rate especially with metal phosphides[8]. In India it is a major health problem due to its easy availability, over the counter or on e-commerce websites, and a lack of antidotes for rodenticides[1-8]. Improving public awareness regarding their lethality and strict monitoring of sales and usage of rodenticides could help to avoid indiscriminate use and poisoning[9-11]. The knowledge on the epidemiology and clinical manifestations of rodenticide poisoning is essential not only to the clinical practitioners but also to the forensic pathologist because of their predominant haemorrhagic manifestations which can sometimes mimic injuries caused by blunt force trauma[11-16]. The present study was undertaken with objectives of studying the epidemiological Profile of rodenticide poisoning which could help the health and various other agencies take some precautionary measures against rodenticide poison sale and consumption.

**Methods**

A retrospective descriptive 6-year review of data from 597 rodenticide poisoning autopsies performed by the Department of Forensic Medicine at Vijayanagar Institute of Medical Sciences (VIMS), Ballari, Karnataka, India between January 1, 2015, and December 31, 2020, was carried out. Data were obtained from judicial requisitions, autopsy reports, toxicology, and histology results. Judicial requisitions contained the identity of the victims and a brief description of the circumstances of death. All autopsy cases were subjected to comprehensive toxicology testing for pesticides, drugs, and alcohol. Specimens including blood, urine, and stomach contents were collected from each victim at autopsy. Rodenticide poisoning was confirmed in these cases by analysing the substance using thin-layer chromatography and gas chromatography–mass spectrometry at the Regional forensic science laboratory (RFSL). Antemortem laboratory investigations data like prothrombin time (PT), activated partial thromboplastin time (APTT), aspartate aminotransferase (AST), alanine aminotransferase (ALT), total bilirubin was collected from the hospital records. Different variables like the gender, age-wise distribution of cases, marital status, profession, antemortem laboratory investigations and manner of death were analysed. The data were analysed using Statistical Package for Social Sciences (SPSS) version 27.0. This study was approved by the ethics committee of Vijayanagar Institute of Medical Sciences (VIMS), Ballari, Karnataka, India.

**Results**

A total of 597 medico-legal autopsies of rodenticide poisoning cases were conducted between 1st January 2015 and 31st December 2020. Majority of the victims 492 (82 %) were males (Fig. 1). The age of the victims ranged from 11 to 82 years, with a peak incidence in the fifth decade of life 152 (25.46%) while not a single case occurred in the first decade (Fig. 2). Majority of the victims were married 469 (79%) cases (Fig. 3). When we investigate the occupation of the victims 292 (48.91%) cases were agriculturist closely followed by unemployed 163 (27.30%) cases (Fig. 4). Most of the incident of rodenticide poisoning happening at night 454 (76.04%) cases. (Fig. 5). When laboratory investigations were...
analysed, prothrombin time (PT), activated partial thromboplastin time (APTT), were elevated in 498 cases whereas aspartate aminotransferase (AST), alanine aminotransferase (ALT) and total bilirubin were raised in 350 cases (Fig.6). Manner of death in 497 (83%) cases were suicidal closely followed by 100 (17%) cases of accidental poisoning there was case of homicidal poisoning.

Discussion

In the present study males 492 (82%) outnumbered females. Our study correlates with other study in which incidence was high among males [16]. But our study does not correlate with a study done by Suneetha, et al 2016 [17] where they reported female preponderance. Most of the cases 152 (25.46%) were in the age group of 51-60 years however only 123 (23.95%) cases in this study were 11 to 30 years old, contradicting other studies where majority of the cases where below 25 years old [7], those studies attributed those findings to increased peer pressure, competitiveness, stress, and heavy expectations from family and loved ones. According to the American Association of Poison Control Centre’s (AAPCC) 2009 annual report, about 70% of the rodenticide exposures occurred in children younger than 6 years [3], whereas no children were exposed to rodenticides in the present study. Most of the rodenticide poisoning cases 469 (79%) were married which was comparable to other studies [7]. This finding can be due to abuse, marriage related issues, dowry related issues, extramarital affairs, divorce, impotence or infertility illness, unemployment, or other family problems. Rodenticide poisoning was commonly seen among farmers 292 (48.91%) cases, closely followed by unemployed 163 (27.30%) as these groups are more vulnerable groups and easily exposed to the poisoning agents. Similar findings were reported by Suneetha et al and Morrissey et al [17,18]. Most cases of rodenticide poisoning were reported at night 454 (76.04%). But according to other studies the popular time for ingestion of poison was the daytime (6 am to 6 pm) [19-21]. In our study altered laboratory findings such as an increase in APTT and PT can be attributed to inhibition of vitamin K (1)-2,3 epoxide reductase and thus the synthesis of vitamin K and subsequently clotting factors II, VII, IX and X. These findings correlate with many other studies [10-15]. Similarly, increased AST and ALT levels are due to hepatic accumulation of these compounds. Furthermore, the intent for poisoning in the greatest number of the patients in this study was suicidal 497 (83%) cases, followed by accidental poisoning 100 (17%) cases, which was comparable to other studies [22,23,24,25]. Three was no homicidal poisoning reported in this study. However, a study done in France showed 70% cases were accidental in nature [26].

Conclusion

Epidemiological profile of rodenticide poisoning cases was discussed in our study. As majority of the cases of rodenticide poisoning were suicidal community awareness programs, and campaigns, poison control centres and suicide help lines, targeted towards the youth, especially women, can help significantly reduce the incidence of poisoning. Moreover, rodenticides should be clearly labelled, locked, and safely stored at homes to prevent accidental poisoning among children and dissuade suicidal poisoning among adults. Finally, legislation and guidelines restricting sales of pesticides to those without farmlands should be strictly implemented to prevent non-farmers from having access to these chemicals.

Socialization Program for Prevention and Early Detection of Congenital Hearing Loss in the Families of Deaf Schoolchildren

Gwenny Ichsan Prabowo¹, Citrawati Dyah Kencono Wungu¹, Retno Handajani², Nyilo Purnami³, Fis Citra Ariyanto⁴,⁵

¹Associate Professor, ²Professor, Department of Physiology and Medical Biochemistry, ³Associate Professor, Department of Otorhinolaryngology Head and Neck Surgery, Faculty of Medicine, Universitas Airlangga – Dr. Soetomo General Academic Hospital, Surabaya, Indonesia, ⁴Staff, Hearing Vision Ltd – Darmo General Hospital, Surabaya, Indonesia, ⁵Postgraduate, Faculty of Nursing, Universitas Jember, Jember, Indonesia

Abstract

Objective: socializing hearing loss examination and early detection to patients and their families in deaf type B schools. Methods: A community service program in the form of socialization was performed to the family of patients with hearing loss in deaf school type B, Surabaya, Indonesia. Pretest and posttest were conducted to determine the initial understanding and post socialization knowledge of these people. We also asked the participants to fill on a questionnaire regarding the possible causes of the hearing loss (family history, drug use, history of disease, and history of head trauma). Results: Based on the summary of pretest and posttest from the participants, an increase in participants’ knowledge of hearing lost was found. This activity was attended by 90 family members of 37 patients with hearing loss. Pre and post test results. The results of the questionnaire showed that 94.59% of the patients came from Javanese ethnicity. As many as 21.62% of patients had a family history of hearing loss, and even 2 patients had a father, mother, and sibling with hearing loss. A total of 18.92% had a history of using ototoxic drugs, 16.22% had a history of maternal Rubella infection during pregnancy, and 2.7% had a history of head trauma. Conclusion: Socialization program was effective to increase knowledge of congenital hearing loss for family of deaf schoolchildren. The result of the questionnaire showed that deaf schoolchildren had several risk factors for the occurrence of hearing loss. Similar program can be performed in communities in other areas to increase prevention and early detection of hearing loss in Indonesia.

Keywords: Socialization, hearing loss, deaf schoolchildren

Introduction

Hearing loss is a commonly found sensory disorder, around 1/1000 births. Hearing loss can be caused by genetic factors, environmental factors and the interaction of these two factors. Genetic factors play a role in about 50% to 75% of the cause of hearing loss(⁵, ²). Hearing loss can occur by sensorineural disturbances (damage to the inner ear, for example: damage to cranial nerves VIII, brain stem or cortex cerebri) or by disturbances in the conductive system (for example: outer ear anomalies or middle ear)(⁶). Hearing loss greatly affects the development of language skills as it can interfere with development in children’s social life and education. Hearing loss related to genetic factors (congenital hearing loss) can be found in two forms: syndromic disorders and non-syndromic disorders. About 70% of congenital hearing loss is in the form of non-syndromic disorder⁷,⁸.

Factors that contribute to hearing loss can come from: genetic, environmental or the interaction between the two factors. There are two forms of hearing loss that are influenced by genetic factors: syndromic and non-syndromic hearing loss. According to Guy Van Camp et al., 50% of hearing loss is hereditary and about 70% of congenital hearing loss is in the form of non-syndromic hearing loss (most often due to sensorineural disorders). Congenital hearing loss is very complex, as it is influenced by various genes and can be either autosomal recessive, autosomal dominant, X-linked or mutations in mitochondrial genes. Eighty percent of congenital hearing loss is autosomal recessive and is often seen prelingual\(^5,\)\(^6\) Environmental factors that contribute to hearing loss are: prenatal and postnatal (eg asphyxia, prematurity), exposure to infection (eg rubella virus, cytomegalovirus) and the use of cytotoxic drugs\(^6\).

An understanding of the mechanisms associated with the onset of congenital hearing loss plays an important role in early detection and its therapeutic aspects. Genetic analysis of congenital hearing loss is an important means of tracking hereditary diseases in the patients as early as possible so that they can be treated immediately, besides tracking the presence of hearing loss in family members of sufferers and can be used as a premarital screening\(^7\). Considering the lack of knowledge of the public about risk factors of hearing loss and the low awareness of the community to get early detection, we conducted socialization on the family of deaf schoolchildren for early awareness and detection of hearing loss to increase knowledge and reduce the incidence of congenital hearing loss in Indonesia, especially in people with family history of hearing loss.

**Methods**

This socialization program targeted 90 family members of deaf schoolchildren in deafschool type B, Surabaya. The program consisted of socialization of congenital hearing loss, risk factors and early detection of hearing loss in children, screening of hearing loss in infants, and managements of children with hearing loss. Socialization was conducted by expert otolaryngologists. Pretest and posttest before and after socialization were performed to determine the increase of knowledge of the participants. Both pretest and posttest had similar questions, thus a paired t-test was performed and the results were analyzed by SPSS version 23. Representatives of each deafchild family member were asked to fill on questionnaire consisted of the child’s information: age, sex, family history, race, use of ototoxic drugs, history of disease, and history of head trauma. The questionnaire used to assess the participant’s knowledge was first performed validity and reliability beforehand. The validity value of the questionnaire was 0.76-0.92 and declared reliable with a value of \(\alpha = 0.83\).

**Results**

At this program, from the results of the pretest assessment, the total average score was 62 of 100 (61.89 ± SD 14.37), with results: 50% had poor knowledge (<50 score), 32% had moderate knowledge (50-70 score) and 18% had good knowledge (>70 score). In the results of the posttest assessment, the total average score was: 87 (87.11 ± SD 7.68), with results: 90% had good knowledge and only 10% had moderate knowledge, and no participant had poor knowledge (Table 1). From the results of the evaluation of the pre-test and post-test results, it can be said that this program at deafschool type B could significantly increase participants’ knowledge about the prevention and early detection of congenital hearing loss (\(p < 0.001\)). During the discussion, participants actively asked questions and gave responses to the problems raised.

In this program, representatives of family members of 37 deaf schoolchildren with hearing loss were asked to fill out a questionnaire about the child with hearing loss. The results of the questionnaire is displayed on Table 3. The result had almost the same distribution between children aged <10 years and ≥10 years and between female and male. The patient tribe is dominated by Javanese (94.59%). A total of 21.62% of patients had a family history of hearing loss, with 50% of them having sibling with hearing loss, and 25% of them had a
family history of complex hearing loss (father, mother, and sibling). A total of 18.92% of patients had a history of use of ototoxic drugs, with 85.71% being the drug ibuprofen. As many as 16.22% of patients had a history of maternal infection during pregnancy in the form of Rubella infection. Only 2.7% had a history of head trauma.

Discussion

There are 360 million persons in the world with disabling hearing loss, in which 32 (9%) millions of these are children. The prevalence of hearing loss in children is greatest in South Asia, Asia Pacific and Sub-Saharan Africa\(^{(8)}\). The prevalence is also high in developing and underdeveloped countries. Hearing loss can occur at various ages. It becomes a public health problem because the population in both developed and developing countries is around 6-8%\(^{(1)}\). The results of the 2013 Basic Health Research showed that the prevalence of hearing loss in children aged 5-14 years was 0.8%. From these data, it is known that the prevalence of respondents with hearing loss in women tends to be slightly higher than that of men (2.8-2.4%), however the research does not differentiate by age. This result is somewhat different from our data which shows that girls with hearing loss have a higher prevalence than boys\(^{(9)}\).

In this study, 21.62% of schoolchildren deaf students had a family history of hearing loss, there were even 2 children with multiple family history of hearing loss, in which all of the main family members were affected. Hearing loss can be caused by genetic factors, environmental factors and the interaction of these two factors. Genetic factors play a role in about 50-75% of the cause of hearing loss\(^{(1, 10)}\). Hearing loss related to genetic factors (congenital hearing loss) can be found in two forms: syndromic disorders and non-syndromic disorders. About 70% of congenital hearing loss is in the form of nonsyndromic disorder\(^{(11)}\). Previous research conducted by Purnami et al showed the prevalence of mutations in the gap junction protein beta-2 (GJB2) gene was 13.64% in schoolchildren deaf schoolchildren in Surabaya, Indonesia\(^{(12)}\).

In this study, 18.92% of children had a history of using ototoxic drugs, namely Ibuprofen and Streptomycin. A systematic review conducted by Kyle et al showed a significant increase in the risk of hearing loss in patients taking Ibuprofen (RR = 1.13; CI = 1.06-1.19), even though Ibuprofen is an over-the-counter medicine that is often given to children\(^{(13)}\). Ibuprofen is a non-steroidal anti-inflammatory drug (NSAID) for the treatment of inflammation, mild-to-moderate pain and fever in children, and is the only NSAID approved for use in children aged ≥3 months\(^{(14)}\). The use of streptomycin is also often associated with hearing loss. Streptomycin is an aminoglycosides class of antibiotics which can cause cochlear or vestibular damage\(^{(15)}\).

In this study, 16.22% of children had a history of pregnant women with Rubella. Rubella is a viral infection that can cause Congenital Rubella syndrome (CRS). CRS is a syndrome consisting of several congenital disorders such as deafness, cataracts and heart defects. Deafness is the most common manifestation in CRS cases and 70-90% suffer from sensorineural type deafness. The mechanism of hearing loss due to the rubella virus can be caused by hypoxia, which occurs when the endothelial damage in the cochlea is followed by cell death in the organs of the Corti and the stria vascularis\(^{(16)}\). Apart from Rubella, other infections in pregnant women such as mumps, measles, meningitis, and cytomegalovirus can also cause congenital deafness\(^{(8)}\).

The World Health Organization (WHO) estimates that around 60% of childhood hearing loss could be avoided through prevention measures\(^{(8)}\). This program has benefits for the community to reduce the incidence of congenital hearing loss in Indonesia, especially for families with risk factors. Screening and detection of risk factors in children with congenital hearing loss also helps better management of congenital hearing loss patients in the community.

Conclusion

Socialization program could increase public awareness about hearing loss, especially for family who had children with hearing loss. Most deaf schoolchildren involved in this program had risk factors for hearing loss that could be prevented for the other family members. In general, there was an increase in the knowledge of the participants about hearing loss. Additional support from the community is needed and similar programs need to be carried out in other places, especially in families who had members with hearing loss to increase public
Awareness and reduce the incidence of hearing loss, especially congenital hearing loss in Indonesia.

Measurement of Some non-routine Markers in Patients with Chronic Kidney Disease

Haider Ali Laibi¹, Abdulkareem M. Jawad²

¹Research Scholar, ²Assistant Professor, Medical and Health Technical College, Southern Technical University, Iraq

Abstract

Chronic kidney disease has an indirect effect on global disorder and death by raising the risks of morbidity and mortality. This study included (60) patient diagnosed chronic renal failure; it also included (25) healthy subjects as control. In study population age ranged from (14-65) years old who visited Al-Basrah Teaching Hospital in Basrah throughout the period from October 2020 to February 2021. Enzyme-Linked Immunosorbent Assay (ELISA) was used to measure human serum soluble alpha klotho proteins, irisin and cystatin C. The results showed that there is a high significant difference (P value < 0.01) in the levels between CKD patients and control for the following: Soluble-a-klotho protein; Irisin (ng/ml); Cystatin-C (ng/ml). There was also a high significant decrease in the levels of irisin (ng/ml) among different stages of chronic kidney. The same table revealed a high significant increase (P value <0.01) in the levels of Cystatin-C (ng/ml) and Soluble-a-klotho protein (ng/ml) among different stages of chronic kidney and respectively. The study concluded that there is a remarkable decrease in the level of serum soluble alpha klotho proteins and irisin and increase in serum cystatin C in patients with chronic kidney disease; and these differences are positively correlated with the glomerular filtration rate.

Keywords: CKD, soluble alpha klotho proteins, irisin, cystatin C

Introduction

Chronic kidney disease has an indirect effect on global disorder and death by raising the risks related with at least five other main killers: cardiovascular diseases (CVD), diabetes mellitus (DM), hypertension, human immunodeficiency virus (HIV) and malaria. For instance, the Global Burden of Disease (GBD) has been estimated to cause 1.2 million deaths a year, of them 19 million disability-adjusted life-years (DALYs) and nearly the same million years of life died from cardiovascular diseases were straightly resulted from reduced glomerular filtration rates. It has also been estimated that, in 2015, 1.2 million people died from kidney failure, an elevate of 32% since 2005. In 2010, an estimated 2.3–7.1 million people with end-stage kidney disease died without access to chronic dialysis. Additionally, each year, around 1.7 million people are thought to die from acute kidney injury. Finally, therefore, an estimated 5–10 million people die yearly from kidney disease. According to some epidemiological data, the common shortage of knowledge and the frequently poor experience to laboratory facilities, such numbers may be underestimate the real deaths resulted from kidney disease.

Patients of chronic kidney disease (CKD) clients may complain from cardiovascular or cerebrovascular disorder, and their deaths may be imputed to either consequences. Changed kidney function is often found in clients with hypertensive and ischemic heart disease, both of which are correlated with elevated cardiovascular
disorder and death. About 30 percent of clients with diabetes have diabetic nephropathy, with elevated risk found in some ethnic groups. (3).

Traditionally, renal function has been evaluated having levels of plasma and/or serum creatinine or urea. Unluckily, both markers are not reliable and less sensitive in intensive care clients. Cystatin C reveals few non-GFR determinants when comparing to creatinine and is more sensitive and specific to find out early reduces of GFR. At recent, new functional assays are investigated, called the furosemide stress test (FST) and renal functional reserve (RFR). An elevate in urine output to >100 ml/h is indicator of a GFR >20 ml/min and mainly certainly excludes progression to AKI stage III and need for RRT (4).

Materials and Methods

This study included (60) patient diagnosed chronic renal failure; it also included (25) healthy subjects as control. In study population age ranged from (14-65 years) old. Who visited Al-Basrah Teaching Hospital in Basrah. All patients in this research were examined by specialist physicians in Al-Basrah Teaching Hospital throughout the period from October 2020 to February 2021. Several patients have been excluded from the study because of acute and chronic diseases. All patients affected by hormonal disturbances were excluded from the study. Enzyme-Linked Immunosorbent Assay (ELISA) was used to measure human serum soluble alpha klotho proteins, irisin and cystatin C.

Table (1) is about differences in the measurement of non-routine markers between control group and CRF group. This table shows that there is a high significant difference (P value < 0.01) in the levels between CKD patients and control for the following : Soluble-a-klotho protein (T test = 8.03 ; P value = 0.000) ; Irisin (ng/ml) (T test = 9.39 ; P value = 0.000); Cystatin-C (ng/ml) (T test = 3.96 ; P value = 0.000) .

Table (2) is about ANOVA table for Differences in the measurement of non-routine markers among different stages of chronic kidney disease . This table shows that there is a high significant decrease (P value <0.01) in the levels of irisin (ng/ml) among different stages of chronic kidney (F test = 17.74 ; P value = 0.000) . The same table revealed a high significant increase (P value <0.01) in the levels of Cystatin-C (ng/ml) and Soluble-a-klotho protein (ng/ml) among different stages of chronic kidney (F test = 35.2 ; P value = 0.000) and (F test = 3.53 ; P value = 0.02) respectively .

Discussion

Klotho protein in mammals is present in 2 different isoforms: a membrane-bound protein and as a soluble form . Full-length Klotho is a single-pass transmembrane protein that functions as an obligatory co-receptor for fibroblast growth factor-23 (FGF-23) which promotes phosphate excretion and inhibition of calcitriol synthesis (5) .

The serum levels of soluble Klotho may be determined by age, and renal function . Although a decrease in urinary Klotho levels in a relatively small number of CKD patients was reported previously , Some studies clearly demonstrated for the first time that not only the serum Klotho concentration, but also the amount of 24 hr urinary excreted Klotho correlated with the eGFR among the patients with various degrees of CKD. Besides the finding that the serum Klotho concentration was negatively correlated with age, which is consistent with previous findings, it was also confirmed that there was a similar trend between the amount of urinary excreted Klotho and the patient age. However, the clinical significance of age on the serum and urinary Klotho levels among the overall patients with CKD should be interpreted carefully, since our
results demonstrated that the eGFR, but not age, was one of the pivotal predictive variables for the amount of urinary excreted Klotho in various CKD patients, while only the serum calcitriol was identified as a predictor of the serum soluble Klotho levels (6).

The kidneys, parathyroid gland, and choroid plexus of the brain have been identified as the sites where the Klotho is predominantly expressed. This concept is strongly supported by the recent demonstration of the Klotho expression in human vascular tissues, including vascular smooth muscle cells, which is reduced during the course of CKD and can be restored by exogenous calcitriol. In an animal model of chronic kidney disease, in wildtype mice, Hu et al. showed very low renal, plasma and urinary levels of Klotho. Klotho is also one of the novel components in this complex systems biology between the kidney, skeleton and cardiovascular system. In chronic kidney disease, the expression of membrane-bound Klotho, an obligatory co-receptor for fibroblast growth factor-23 (FGF-23) signaling, is reduced and this limits FGF-23-stimulated signal transduction (5).

Cystatin C plays role in many biological processes, such as degradation of cellular proteins, regulation of enzymes and many pathologic processes. It is present in all body fluids and is important in arterial wall remodeling and atherogenesis. Cystatin C is synthesized by all nucleated cells of body and the rate of its production is constant. Results from other studies have also indicated that serum concentrations of cystatin C are not influenced by muscle mass, diet or sex. It has no extrarenal routes of elimination, with clearance from the circulation only by glomerular filtration (Khan et al., 2014). Cystatin C is cleared from the circulation by only renal filtration and is freely filtered at the glomerular filtration barrier. Its serum concentration is not influenced by non-renal factors. Its small size enable it to be freely filtered at the glomerulus. The use of serum cystatin C to estimate GFR is based on the same logic similar to that for blood urea nitrogen and creatinine. But because it is neither reabsorbed nor secreted by renal tubules, it is suggested to be closer to the ideal endogenous marker (7).

Cystatin C is generated at a mostly constant rate, is freely filtered, reabsorbed and catabolized in the proximal tubule of the nephron. It is not affected by body habitus and muscle mass and as such, it is thought to be a more accurate measure of kidney function compared to serum creatinine. Limitations to its routine use in clinical practice has been primarily cost considerations where, for example, it costs up to ten times that of a serum creatinine assay and it can be affected by thyroid disease, adiposity, and underlying inflammation (8).

The results of the present study have shown that the level of serum irisin is significantly reduced in in CKD patient as compared with healthy subjects, this result agrees with Wen et al., (2013) and Ebert et al., (2014). Irisin, a novel polypeptide hormone, is proteolytically processed from fibronectin type (9-10). III domain containing protein 5 (FNDC5), which is highly expressed in skeletal muscle and heart (11). As sarcopenia is a frequent finding in CKD and irisin is a myocyte-secreted protein, it can be hypothesized that sarcopenia directly contributes to lower irisin levels in end-stage renal disease (9). Low physical activity in patients with CKD may interfere with its levels, as recent studies demonstrated that physical exercise induced the expression of peroxisome proliferator-activator receptor coactivator (PGC) 1 and its downstream membrane protein, fibronectin type III domain-containing 5 (FNDC5), which is cleaved to form irisin in skeletal muscle (11).

Conclusions

There is a remarkable decrease in the level of serum soluble alpha klotho proteins and irisin and increase in serum cystatin C in patients with chronic kidney disease; and these differences are positively correlated with the glomerular filtration rate.

Correlation between Total Ige and Cytokines (Interleukin-24 and Interleukin-4) in Patients with Allergic Urticaria

Hajır Salam Sabeeh Alghannami1, Özcan Özkan2, Fatih Bakır3

1Lecture, 2Prof., 3Assoc. Prof., Çankırı Karatekin University, Graduate School of Natural and Applied Sciences, Department of Microbiology

Abstract

Allergic disease refers to a variety of disorders including seasonal allergies, atopic dermatitis, urticaria, life-threatening anaphylaxis reactions to food, and allergic asthma. Curiously, the incidence of allergic diseases has increased dramatically in the past decades and continues to rise in developed countries. In this study, 20 patients with a pre-diagnosis of acute urticaria among the patients admitted to Çankırı State Hospital and 20 normal patient sera were used for control purposes. Total IgE - Interleukin 4 - Interleukin 24 serum levels were determined by ELISA method. IgE, IL4 and IL24 were determined as 19.62ng / L, 155.55 ng / L and 155.51 ng / L, respectively, in patient serum samples by ELISA method. The difference between the patient and control groups was not significant (p> 0.05). On the other hand, in the statistical analysis of the patient group, it was determined that the relationship between IgE and IL24 was strong (p = 0.01). The correlation between IgE and IL4 was found significant (p = 0.01). However, it was found to be significant between IL4 and IL24. Our results support that the levels of IgE, IL-24, IL-4 in their patients are associated with the disease.

Keywords: Allergic Urticaria; IgE; Interleukin-24; Interleukin-4

Introduction

Allergic diseases; It refers to various disorders including seasonal allergies, atopic dermatitis, urticaria, food-borne anaphylaxis reactions, and allergic asthma. There has been a dramatic increase in the incidence of allergic diseases in the last decade, and this increase continues to increase in developed countries (1). It was first suggested 75 years ago that blister production in patients with urticaria may have an underlying allergic mechanism. The efficacy of H1-antihistamines in patients with urticaria will support this hypothesis, although there is no apparent external allergen (2). This led Rorsman to think that urticaria might be an autoallergenic (i.e., type I hypersensitivity to allergens per se) reaction. IgE involvement in patients with urticaria has been suggested from two sources. First, chronic spontaneous urticaria (CSU) is associated with high levels of total IgE and increased levels of IgE directed against, for example, thyroid antigens and double-stranded DNA. The second is the efficacy of omalizumab (anti-IgE) (3). In patients with other autoimmune conditions such as systemic lupus erythematosus, the disease is complex and characterized by the production of autoantibodies against a wide variety of self antigens. In eight samples, it has been suggested that in patients with systemic lupus erythematosus, the double-strand-specific IgE antibodies DNA stimulate plasmacytoid dendritic cells, an immune cell dependent on viral defense, to secrete significant amounts of IFN-α (4). Pleiotropic cytokines interleukin4 (IL-4) and IL-13 cause the protection of the Th2 lymphocyte profile and increase the initial IgE levels (5). Murine models demonstrated the critical nature of IL-13 independent of IL-4. IL-13 is produced predominantly by T cells; In addition, human basophils and mast cells can also secrete IL-13. Regulation of IL-13 production is completely different from IL-4 (6). This has been explained by the fact that stimulation of T cells with anti-CD28 and phorbol myristate acetate (PMA)
resulted in optimal induction of IL-13 with virtually no IL-4 secretion. Local tissue expression of IL-13 is found in the nasal mucosa of patients with allergic rhinitis and in patients with allergic asthma after pulmonary allergen challenge.

It has been shown in bronchoalveolar lavage fluid, whereas normal controls were unable to express IL-13. Increased spontaneous expression of IL-13 was observed in mononuclear cells (PBMC) in peripheral blood samples from patients with atopic dermatitis, but IL-4 mRNA was not found. Little is known about the contribution of IL-4 and IL-13 to IgE production in patients with allergic rhinitis and asthma. It has been shown in bronchoalveolar lavage fluid, whereas normal controls were unable to express IL-13.

Increased spontaneous expression of IL-13 was observed in mononuclear cells (PBMC) in peripheral blood samples from patients with atopic dermatitis, but IL-4 mRNA was not found. Little is known about the contribution of IL-4 and IL-13 to IgE production in patients with allergic rhinitis and asthma. Increased spontaneous expression of IL-13 was observed in mononuclear cells (PBMC) in peripheral blood samples from patients with atopic dermatitis, but IL-4 mRNA was not found. Little is known about the contribution of IL-4 and IL-13 to IgE production in patients with allergic rhinitis and asthma.

We hypothesize that CSU is an autoimmune disease in which IgE recognizes several autoantigens possibly primarily of dermal origin. Their low level diffusion into the bloodstream will be consistent with the basopenia seen in patients with CSU. In addition, increased local production periods of such allergens will explain local exacerbations of CSU. To test this hypothesis, large-scale screening of autoreactive IgE in serum of patients with CSU has been used to investigate potential targets of IgE autoantibodies (IgE-AAbs) in those with this disease. IgE found in blood sera from patients with idiopathic anaphylaxis (IdA) and healthy subjects was used as a control. The relationship of primary IgE autoantibody has been further investigated both in vitro and clinically.

**Material and Method**

This study was conducted retrospectively in the blood serum of 20 patients (10 females and 10 males) and 20 normal patients (14 females and 6 males) for control purposes who were admitted to the Dermatology Outpatient Clinic of Çankırı State Hospital between August 2020 and January 2021. The study was planned regardless of age and gender. The approval of the Ethics Committee of Lokman Hekim University dated 11.12.2020 and numbered 2020/100 was obtained for the study.

- Determination of Total IgE - Interleukin 4 - Interleukin 24 Levels

In this study, Total IgE - Interleukin 4 - Interleukin 24 levels were carried out by ELISA method in the Biochemistry Laboratory of Çankırı Private Karatekin Hospital. For this purpose, Human Receptor 1 for The Fc Region of IgE ELISA kit [(Biassay Tecnology Laboratory - Cat.No E66212Hu) Standard Curve Range: 5ng / L-100ng / L, Sensitivity: 0.27ng / L], Human Interleukin 4 ELISA kit [(Biassay Tecnology Laboratory - Cat.No E00092Hu) Standard Curve Range: 5 ng / L-1000 ng / L, Sensitivity: 2.53 ng / L], Human Interleukin 4 ELISA kit [(Biassay Tecnology Laboratory - Cat.No E2162Hu) Standard Curve Range: 5 ng / L-1500 ng / L, Sensitivity: 2.56ng / L]. All materials in the kit were kept in the dark until they reached room temperature before analysis. The application was made in accordance with the manufacturer’s test protocol. All reagents, standard solutions and samples were prepared according to the instructions. Standards included in each analysis kit were used. The samples used in the study were calculated according to the layout plan and placed in the frame. 50μl of standard was added to standard wells and 40μl of samples were added to test wells. 10μl of anti-FcεRIβ antibody was added to sample wells (Figure 1,2).
50μl streptavidin-HRP was added to the sample and standard wells and mixed thoroughly by making circular motions. The plate was covered and incubated at 37 °C for one hour in the dark. After removing the cover, the plate was placed in an automated ELISA washer and washed five times with wash buffer. It was placed in the ELISA washer and washed again five times with wash buffer. After washing, 50 μl of substrate A and 50 μl of substrate B solution were added to the wells, respectively. After covering the plate tightly, it was left in the dark at 37 °C for 10 minutes. After standing, 50μl of test stop solution was added to each well. The plate was placed in the ELISA reader (Robonic Readwell touch) within 10 minutes and the optical density (OD) value was read at 450 nm wavelength.

Statistical Analysis

Statistical analysis was evaluated in the Statistics Department of Çankırı Karatekin University. The Mann-Whitney U test was used to compare the groups that did not conform to normal distribution in the investigation of the compliance of the data to normal distribution, the difference between the control and experimental groups. Determination of the direction and size of the relationship (correlation) between variables was examined using Spearman Rho coefficients for variables with normal distribution, and for variables that did not conform to normal distribution. SPSS Statistics 21.0 program was used in the implementation of the analyzes. A p <0.05 value was accepted as the criterion for statistical significance.
Result

In the serum samples included in the study, the patients who were diagnosed with allergic urticaria were equally (50%) distributed in males (n = 10) and females (n = 10). In the control group, male (30%) and female (70%) normal serum samples were used. In this study, total IgE, IL 4 and IL 24 levels in patient and control serum samples by ELISA method are given in Table 1. Figure 1. Total IgE, IL 4 and IL 24 ELISA test results (ng / L) in patient (H) serum samples.
While IL24 level could not be detected in 55% of patient serum samples, this rate was determined as 40% in IL4. When the number of samples was n <50, Shapiro Wilk test was applied. Since p <0.05 according to the Shapiro-Wilk test, the data are not normally distributed. Therefore, Mann Whitney test was used to compare the means of two independent groups. According to the analysis results, no significant difference was found between the mean of the patient and control groups. Since the data are not normally distributed, the relationship between variables was calculated with the Spearman correlation coefficient. According to the value of the correlation coefficient, the result being +1 indicates that there is a strong positive relationship between the two variables, while -1 indicates a strong negative relationship. Correlation coefficient to 0 As the relationship gets closer, the strength of the relationship weakens, and zero indicates that there is no relationship between the two variables ((0.90-1.00: Very strong, 0.70-0.89: Strong, 0.50-0.69: Moderate, 0.30-0.49: Low, 0.16-0.19: Weak and < 0.16: Very weak). In patient samples, there was a strong positive correlation between IgE and IL4 (P <0.05), a strong positive correlation between IgE and IL24 (P <0.05), and a moderate positive correlation between IL4 and IL24. has been seen to be There was no significant difference between samples and control groups (p> 0.05). On the other hand, in the statistical analysis of the patient group, the relationship between IgE and IL24 was found to be strong (p = 0.01). The correlation between IgE and IL4 was found to be significant (p = 0.01). However, it was observed that there was a significant difference between IL4 and IL24 (p = 0.01).

Discussion and Conclusion

Urticaria is a chronic, not just acute, skin disease that affects about 5% of the general population. Interleukins have been reported to play a role in the pathophysiology of urticaria. Antigen-specific IgE responses to T cell dependent antigens such as allergens can only be generated by cognate interaction between B cells and T helper (Th2) cells. Interleukin-4 plays a central role in the differentiation of antigen-stimulated naïve T cells into T helper (Th) 2 cells, which are the main sources of IL-4. Interleukin-4 also suppresses Th1 cell growth and directs the transition of human B cells to IgE. The fact that the number of patients was low due to the Covid19 pandemic during the period of your study was limited to the sampling. In the scope of retrospective study in archived patient sera, etiological and demographic data were excluded from the study. It was aimed to investigate the relationship between IgE, IL-24-IL-4 in serum of patients pre-diagnosed in the dermatology clinic investigated IL-4, IL-6, IL-8, IL-10 in 51 patients with urticaria in the acute period and the increase in IL-4 level was found to be statistically significant reported that high IgE-anti-IL-24 values were associated with disease activity in patients with chronic spontaneous urticaria, while IgE-anti-IL-24 levels increased in eighty percent of patients. As a result, IL-24 has been defined as a common, specific and
functional autoantigen of IgE antibodies in patients with chronic spontaneous urticaria. (14) reported that IL23, IL10 and IL4 levels were significantly lower in the patient group with chronic spontaneous urticaria compared to the control group. In addition, they found that the IL-4 level of the patient group with positive and negative autologous serum skin test was significantly lower than the control group. In our study, the relationship between IL24 and IgE was found to be strong in patients with a pre-diagnosis of acute allergic urticaria. There was no difference in serum IgE patterns between the patients and the healthy control groups.

Abstract

A single Memory impairment substantially reduces the quality of life in the elderly. It is associated with the alteration of neurotrophic (NT) factors, such as brain-derived neurotrophic factor (BDNF) and glutamate receptor N-methyl-D-aspartate (NMDA). Exercise is often used to reduce cognitive impairment. Previous studies show that the benefits of aerobic exercises on such impairments are correlated with increasing BDNF and preventing the production of NMDA. However, some results remain controversial. Thus, the association between exercise and Memory was addressed by examining increases in BDNF and the reduction of NMDA in ageing rats. The study used a randomized, post-test-only controlled group of 30 male one-year-old ageing Rattus norvegicus divided into three groups, namely, K0 (control) and K1 and K2 (aerobic swimming exercise). K1 and K2 animals differed in the frequency of exercise, which is three and four sessions per week, respectively. Memory was assessed using Y-maze performance. BDNF and NMDA were analyzed using enzyme-linked immunosorbent assays. A significant improvement in memory function and reduction in the NMDA level were observed in K1 and K2 group rats (p = 0.001; p = 0.041). No significant impact on the BDNF levels was observed (p = 0.387). Swimming may boost Memory by reducing the NMDA level but not by increasing BDNF. Swimming is a promising method for preventing or delaying memory loss in degenerative brain diseases. Further investigation is needed to fully understand underlying mechanisms.

Keywords: Memory; NMDA; BDNF; ageing rat; swimming

Introduction

Life expectancy has continuously increased during the last decades, which has led to increasing numbers of elderly individuals 1. In fact, the elderly are the fastest-growing segment of the United States population 2. The latest projections suggest that the number of individuals older than 60 years will increase from 810 million in 2012 to 2 billion by 2050 worldwide (United Nations Department of Economic and Social Affairs, 2012) 1.

The elderly are at a high risk of developing cognitive impairments 2. Previous studies show that cognitive impairment is associated with chemotherapy and age 2-4. Many elderly individuals experience difficulty performing complicated daily tasks 5. Physical and mental abilities markedly decline with age and hence reduced quality of life 1,6. Quality of life is an important concern in ageing societies 7. Various recent studies indicate that cognitive impairment, among degenerative brain diseases, are particularly common for elderly...
individuals\textsuperscript{2,6}.

Memory, the accumulated and stored aggregate of an individual’s experience, plays an important role in the overall cognitive function\textsuperscript{3}. Memory has multiple dimensions, including the ability to store, retain, and retrieve information\textsuperscript{2}. Memory problems include a tendency toward misplacing items, difficulty remembering appointments, and forgetting details of conversations and events\textsuperscript{2}. These and other memory issues substantially impact the quality of life of afflicted individuals\textsuperscript{3}.

The hippocampus, an important brain region for learning and memory, is the primary site of neurogenesis in adulthood and retains the greatest brain neuroplasticity\textsuperscript{3}. Brain-derived neurotrophic factor (BDNF) is expressed ubiquitously in the brain\textsuperscript{8}. BDNF, a fundamental neurotrophic factor in learning and memory\textsuperscript{8}, plays a pivotal regulatory role in the development, cognition, and plasticity of the hippocampus\textsuperscript{1,3,4,9}. BDNF is key to maintenance, growth, neuronal survival, differentiation, neurotransmitter release, dendritic remodeling, axon growth, the formation of neurons, regulation of hippocampal structure, synaptic transmission, synaptic modulation, promotion of synaptic growth and plasticity\textsuperscript{3,8,9}. BDNF exerts neurotrophic anti-apoptotic regulation in neurons by binding with tyrosine receptor kinase B, also known as tropomyosin-related kinase B (TrkB)\textsuperscript{3,9}.

BDNF is secreted at pre- and post-synaptic sites. Synaptic BDNF is secreted in response to activities and activates pre- and post-synaptic TrkB receptors. BDNF is important for long-term potentiation (LTP). BDNF mediates the regulation of excitatory synapses during early LTP. Presynaptic BDNF increases the exocytosis of glutamate-containing synaptic vesicles. Post-synaptic BDNF–TrkB signaling induces NMDA receptor (NMDAR) phosphorylation\textsuperscript{8}.

A key aspect of quality of life is health\textsuperscript{7}. Exercise, a major component of efforts to maintain and improve health, is an effective intervention for addressing degenerative brain diseases\textsuperscript{3,7}. Exercise may relieve stress and anxiety that can lead to deteriorating mental and physical health. Regular exercise is widely reported to help maintain and enhance a cognitive function, activate neurotransmitters, induce gene expression, and promote neuroprotection\textsuperscript{3}, but underlying mechanisms are not yet clear. Several studies have concluded that exercise can be a therapeutic strategy to increase the BDNF level and that a sedentary lifestyle may impair BDNF signaling\textsuperscript{9}.

BDNF and NMDA play important roles in hippocampal synaptic plasticity\textsuperscript{8}. Therefore, the current study aims to determine whether a cognitive impairment, neuroplasticity in the hippocampus.

**Materials and Methods**

**Setting**

This work was conducted in the animal research laboratory of the Department of Medical Biochemistry of Airlangga University, Surabaya, East Java, Indonesia. This study received approval by the Animal Care and Use Committee, Veterinary Faculty of Airlangga University with certificate number 745-KE.

**Animal**

Thirty-one-year-old male rats (\textit{Rattus norvegicus}), with an average weight of ±300 g, were used. Animals were acclimatized for one week and allowed free access to food and water \textit{ad libitum}. The exercise period lasted for eight weeks. Behavioral analyses were conducted upon completion of all exercise sessions. Brains (cerebral hemisphere) were removed and homogenized using a sonicator, and BDNF and NMDA were measured using enzyme-linked immunosorbent assays (ELISA)\textsuperscript{3}.

**Grouping**

The animals were randomly divided into three groups (\(n = 10\)):

- Group 1 (K0): control group, non-swimming
- Group 2 (K1): swimming exercise sessions three times/week for eight weeks
- Group 3 (K2): swimming exercise sessions five
times/week for eight weeks

2.1.3. Exercise Protocol

The rats in Groups 2 and 3 used a pool made for animal exercise sessions. Animals swam for 10 min during the first week, 20 min during the second week, and 30 min in weeks three through eight.

Y-Maze

The rat performance was assessed in a Y-maze after the exercise period. The performance in the maze measured the willingness of the rats to explore a new environment. The Y-maze allowed only two choices: right and left pathways. Food was placed at the end of one path as an incentive. An animal was placed in the middle of the maze and allowed to choose one of the paths. The rats were guided manually to the target if the food was not found after 90 seconds. A sign was provided in the maze to indicate the location of food. During the memory test, signs were eliminated to test whether the rats recalled the food location. The time of placement in the maze to achieving the target was measured. Re-entry into the path with food was taken as an indication that the animals recalled their previous maze experience. Entry to the path without food was taken as a sign of a lack of recall.

Determining the Level of NMDA and BDNF

The samples were collected from the left or right hemispheres of the hippocampus and analyzed using ELISA. The samples were homogenized using a sonicator suspended in a lysis buffer and centrifuged at 15,000 x g for 15 min at 4 °C. Supernatants were retained for the analysis. The samples were immediately frozen at −20 °C. BDNF and NMDA levels were measured using a Rat CREB Kit (category no. E0039Ra, Bioassay Technology Laboratory), Rat NMDA Kit (category no. E0999Ra, Bioassay Technology Laboratory) and Rat BDNF Kit (category no. E0476Ra, Bioassay Technology Laboratory).

Statistical Analysis

Normally distributed data were analyzed by one-way analysis of variance, followed by the least significant difference tests. Non-normal distributions were analyzed by the Kruskal–Wallis test, followed by Mann–Whitney U test. Statistical significance was set at p < 0.05. Data analysis using SPSS version 23.

*Significant with p<0.05
The BDNF, NMDA, and Memory results for each group are presented in Table 1. The BDNF levels between groups did not differ significantly ($p = 0.387; p > 0.05$). The NMDA levels were significantly different between Groups K0 and K1 ($p = 0.016$). Significant differences were not observed between Groups K0 and K2 ($p = 0.055$) and Groups K1 and K2 ($p = 0.749$).

Memory performance from K0 to K2 increased with increasing amounts of exercise. Between Groups K0 and K1 and Groups K0 and K2, significant differences in the maze recall were observed ($p = 0.001$ and $p = 0.000$, respectively). No significant difference was found between Groups K1 and K2 ($p = 0.962$).

**Discussion**

In this study, the cognitive function improved in elderly rats after eight weeks of regular exercise. Exercise has been shown to improve Memory at different ages, along with other beneficial effects \(^1\,^3\,^4\,^10\,^11\). Physical activity is needed for the elderly in exercising the muscles of the elderly from the condition of movement that tends to reduce function \(^14\). The treatment of cognitive impairments has emphasized the regulation of maintenance, growth, survival, and formation of neurons. Besides, physical activity is known to increase the BDNF level, which binds TrkB \(^3\,^9\), thus inducing an anti-apoptotic state \(^3\). Some authors have suggested exercise as a treatment for cognitive impairments. At the cellular level, mitochondria endow hippocampal neurons with neuroplasticity in several ways: control of Ca\(^{2+}\) uptake, redox signaling, developmental and synaptic plasticity, and cell survival and death. Furthermore, mitochondrial permeability transition pores, which are closely related to apoptosis, regulate various physiological functions at the cellular level, and play a key role in learning and synaptic plasticity \(^3\).

Exercise relieves stress and anxiety and thus augments mental and physical health \(^3\,^11\). Physical activity causes brain neuronal and biochemical changes that activate neurotransmitters and induce gene expression, which promotes proliferation and survival of neurons, maintain and improve cognitive function and confer neuroprotection against brain damage \(^3\). Exercise has also been associated with enhanced capacity of mitochondria for calcium toleration, with further consequences on the control of mitochondrial-driven apoptotic cell death \(^12\). Exercise also helps preserve brain function during ageing by enhancing BDNF signaling \(^4\).

Nagahara et al. found that BDNF treatments can decrease Aβ-mediated cell death, counter cognitive dysfunction, and synapse loss and even retard the cognitive decline in nonhuman primates and APP transgenic mice \(^9\). The effects of BDNF on neurogenesis, neuronal survival, and synaptic plasticity appear to be mediated by signal transduction pathways involving Akt kinase, Ca\(^{2+}\)/calmodulin and mitogen-activated protein kinases. The gene targets of BDNF signaling pathways include the anti-apoptotic protein Bcl-2, NMDA glutamate receptor subunits and neuronal nitric oxide synthase \(^4\). High levels of BDNF correlate with a low risk of developing dementia \(^1\). BDNF signaling can promote healthy ageing and protect the brain against age-related neurodegenerative disorders \(^4\).

Erickson et al. (2011) investigated relationships between chronic aerobic physical activity and peripherally assessed concentrations of BDNF, hippocampal volume, aerobic fitness (VO\(_2\) max) and cognitive performance (spatial Memory) in a 1-year RCT with older adults. This study demonstrates that changes in aerobic fitness from pretest to posttest were positively correlated with changes in hippocampal volume and the increase in hippocampal volume experienced in the physical activity group was positively correlated with better spatial memory performance and greater change in BDNF concentration \(^15\). Umm et al. (2008) demonstrated that treadmill running increases the BDNF level \(^1\). BDNF signaling is probably the key mechanism for triggering brain neuroplasticity \(^16\,^17\) and anti-apoptotic cell death that leads to the improvement of cognitive function \(^4\,^16\).

In this study, BDNF and NMDA were used to assess changes in brain chemistry associated with improved Memory after regular swimming exercise. BDNF plays
a pivotal role in neurogenesis, neuronal survival and synaptic plasticity in the brain. The lowest BDNF mean level was recorded in the hippocampus of rats in Group K0 (4.17 ± 0.64). This group did not exercise. BDNF gradually increased from Groups K0 to K2 along with the increasing frequency of swimming sessions. However, no statistically significant interaction between exercise and BDNF level was found. A protective effect of exercise against apoptosis demonstrated by the increased BDNF levels in a frequency-dependent manner was not demonstrated by a statistically significant increase in BDNF concentration.

Elderly with exercise swimming can improve their memory function compared to that without exercise. The molecular mechanism is suggested by inhibiting NMDA expression; thus, it could prevent intracellular calcium build up that results in the activation of Ca²⁺/calmodulin dependent protein kinase II (CaMKII) and c-AMP response element-binding (CREB) pathway. This pathway related to the maintenance of synaptic plasticity through increased BDNF expression.

BDNF is related to the NMDAR. One BDNF signaling pathway targets the NMDA glutamate receptor subunits. BDNF stimulates NMDAR autophosphorylation. Autophosphorylation and function of CaMKII protect synaptic function. An in vivo investigation showed that Met carriers reduced the hippocampal volume and changed synaptic plasticity, especially NMDAR-dependent LTP. These effects resulted in a loss of hippocampal-related Memory.

A meta-analysis found that physical activity positively influences cognitive function in patients with dementia, independent of the clinical diagnosis and frequency of the aerobic exercise program. In this study, swimming stimulated the BDNF levels but showed no significant interaction. The greater the time between the placement of animals into the maze to finding food, the worse the animals’ Memory. The slowest time to reach the target was observed in rats in Group K0 (52.31 ± 22.73 sec) and the quickest in Group K1 (19.85 ± 8.2 sec). In Group K2, rats were essentially as quick at solving the maze as Group K1 animals (20.69 ± 6.69 sec). Thus, exercising either three or five times a week had a similar positive impact on recall. Statistically, the results from Group K0 rats were significantly different and higher than those from animals in Groups K1 and K2 (p = 0.001, p = 0.000, respectively).

The results of the current study are consistent with those of previously published works, which show that exercise can help improve memory and neurodegenerative diseases. Investigators have used various methods and parameters in different settings to assess the impacts of exercise, and outcomes are always similar; that is, exercise improves the cognitive function.

Conclusions

The results of the current study help confirm that exercise can improve cognitive function and prevent and delay degenerative brain diseases in the elderly. Exercise may produce its effects via inhibiting the excessive increase of NMDA. Additional investigations on the relationship between BDNF and cognitive function are warranted.

Human Carbon Footprint as the Basis for Determining Healthy Indoor Volume Dimensions

Harida Samudro¹, Sarwoko Mangkoedihardjo²
¹Researcher, Department of Architecture, State Islamic University of Malang, Malang, Indonesia, ²Professor, Department of Environmental Engineering, InstitutTeknologiSepuluhNopember, Surabaya, Indonesia

Abstract
This paper was presented to determine the volume unit of indoor based on the human carbon footprint. The purpose of this approach was to formulate the ideal dimensions of an indoor, which was able to maintain human health. The basis for determining the dimensions was adapted to tropical conditions. For users in non-tropical areas, slight adjustments to temperature and ventilation may be required. Some examples of indoor dimension evaluation and planning were presented in this paper. In general, it was obtained that the indoor dimension could be found using the volume unit of a healthy room of $3.0 \text{ m}^3$/person/hour. The volume unit was linear with the number of users and time of existence in the room. This contributed significantly to people, who can easily and quickly find out the dimensions of space according to their needs.

Keywords: Carbon footprint; indoor; volume unit; public space; personal room

Introduction
Living organisms are physically composed of organic matter, which easily breaks down into other forms. This organic material can basically be represented as glucose, and integrated into the material as biomass. The simple evidence is physical growth, which indicates an increase in biomass. Along with that growth is breathing, which gives off mainly carbon dioxide gas. The process of converting biomass into carbon dioxide is evidence that biomass is organic matter that is easily biodegradable.

Naturally, organic matter is a complex chemical compound containing carbon, symbolically represented as C. Except for the gases carbon dioxide ($\text{CO}_2$) and methane ($\text{CH}_4$) and bicarbonate ions ($\text{HCO}_3^-$) in solution, all of which are categorized as inorganic materials. On earth, carbon is the most important element and influences the earth’s climate. The presence of carbon is in the atmosphere (the gases carbon dioxide and methane, which are known as greenhouse gases), the geosphere (hydrocarbon carbonate minerals), the biosphere (organic matter), and the hydrosphere (bicarbonate ions) (1–3). Especially for greenhouse gases in the atmosphere, which are the breathing medium for living organisms, there are safe levels for life, namely $\text{CO}_2$ of 360 ppm and $\text{CH}_4$ of 1.7 ppm (4). The content and/or the proportion of the two gases in the atmosphere is dynamic, which can be influenced by the dynamics of living organisms, especially the activities of human life (5,6).

In humans, the process of converting organic matter is known as respiration, which exhales a mixture of carbon dioxide, nitrogen, oxygen, water vapor and various volatile materials (7–9). Most of the time, the activities of human life are indoors, at least 8 hours of sleep rest as a time considered capable of maintaining human health. The activity room can be a personal...
space, for example a bedroom, family room, kitchen room, and others. The activity space is also in a format for the public, for example offices, shopping, tours, and the like. Every human being living in any place emits greenhouse gases and leaves a carbon footprint on the environment.

The carbon footprint can have a negative impact, both on the environment and on humans themselves\(^{(10–16)}\). This leads to the need for space, which is able to overcome the negative impact of these gases. So far there is no known way to determine the size of space, which is based on the results of human life activities, namely carbon from human life processes. Therefore, this paper has examined the human carbon footprint approach for determining the dimensions of spaces, both private and public places. The purpose of this approach is to provide an indoor spatial dimension capable of maintaining human health while in it.

**Methods**

The method of calculating carbon footprint products is based on the reactions of human life and consumption of various living necessities. The general reaction of life is expressed as follows:

- Under aerobic conditions: \( n\text{ME} + C_6\text{H}_{12}\text{O}_6 + 6\text{O}_2 \rightarrow 6\text{CO}_2 + 6\text{H}_2\text{O} + n\text{ME} \) \(^{(1)}\)

- Under anaerobic conditions: \( n\text{ME} + C_6\text{H}_{12}\text{O}_6 \rightarrow 3\text{CO}_2 + 3\text{CH}_4 + n\text{ME} \) \(^{(2)}\)

In these 2 equations, \( n\text{ME} \) are the many types (\( n \)) of materials and energy (\( \text{ME} \)) that are used for human life. For example, various kinds of drinking water, various kinds of food, various kinds of building materials, various kinds of energy sources, various kinds of vehicles, and various kinds of products.

Various kinds of gas products resulting from life activities (\( \text{CO}_2, \text{CH}_4, \text{SOx}, \text{NOx}, \text{HFC} \), etc.) can be equivalent to \( \text{CO}_2 \) gas and expressed in units of emission/person/time (for example: kg/person/day). The equivalence of greenhouse gases to carbon dioxide is measured by the global warming potential (GMP). In practice, the GWP of \( \text{CH}_4 \) is variable over the source of the generation\(^{(17–19)}\), however, to illustrate the magnitude of the effect of heating, 1 mol of \( \text{CH}_4 \) is 25 mol of \( \text{CO}_2 \) equivalent. Thus, equation 2) can be stated as follows:

- Under anaerobic conditions: \( n\text{ME} + C_6\text{H}_{12}\text{O}_6 \rightarrow 78\text{CO}_2 + n\text{ME} \) \(^{(3)}\)

Equation 3) is appeared to give a warning that a room with insufficient oxygen leads to an increase in room temperature as a result of the carbon dioxide equivalent increasing sharply. This is important to consider in determining room ventilation.

**Results and Discussion**

**Basics of calculation**

**Healthy concentration of carbon dioxide**

The outdoor \( \text{CO}_2 \) concentration is in equilibrium with ambient air, which is about 360-380 parts per million (ppm)\(^{(4,20)}\). Likewise, in the room that is balanced with the outside. This concentration is a level that supports the health of human life. However, indoor \( \text{CO}_2 \) concentrations can fluctuate and exceed these healthy concentrations, but humans still do not experience health problems. There are a number of concentrations that can be tolerated, but as a sustainable healthy concentration and for maximum protection for human life, the indoor \( \text{CO}_2 \) level is as follows:

\[
\text{Healthy indoor } \text{CO}_2 \text{ concentration} = 360 \text{ ppm} \quad (4)
\]

**Individual carbon dioxide emissions**

The average annual carbon emission from energy demand for household use is 6.744 kg \( \text{CO}_2 \)\(^{(21)}\). In general, people do indoor activities for more than 19 hours a day\(^{(22)}\). In these activities, humans need energy 34 MJ/person/day for the basic needs of life, such as eating and drinking; and various activities, such as transportation and works. Thermodynamic energy stated that 1 mol of glucose equals 2.8 MJ. Stoichiometric glucose requirement is 34/2.8 or 12 mol glucose/person/day. Emission of \( \text{CO}_2 \) is 12*6 mol CO\(_2\) = 72 mol CO\(_2\) = 72 * 44g = 3.2 kg CO\(_2\)/person/day\(^{(23)}\). About 25-40% of
them are sourced from human life, namely 0.8-1.2 kg CO$_2$/person/day. The calculations used are considered appropriate that confirmed to Prairie & Duarte$^{(24)}$ for the average human body weight of 70 kg, which releases 1.4 kg CO$_2$/person/day. It is also confirmed respirometrically 0.9 kg CO$_2$/person/day$^{(25)}$. For general calculations, the average individual CO$_2$ emission units is as follows:

$$\text{CO}_2\text{ emission units} = 1.0 \text{ kg CO}_2/\text{person/day} \quad 5)$$

**Carbon dioxide density**

The density of indoor air is in the same equilibrium as the outside air. The density of air is variable with temperature. The higher the temperature, the lower the air density. For tropical climatic conditions, the air temperature is in the range 20-35°C, which indicates air density in the range 1.12-1.20 kg/m$^3$.$^{(26,27)}$ While the density of carbon dioxide is about 50% higher than dry air$^{(28)}$. For general calculations, the average CO$_2$ density is taken as follows:

$$\text{CO}_2\text{ density} = 1.75 \text{ kg/m}^3 \quad 6)$$

**Room ventilation**

According to eq. 3) means that the ventilation system must be sufficient to maintain the aerobic conditions of the room. The ventilation becomes the gate for air transportation between indoor and outdoor spaces. In that case, there is a release of CO$_2$ from the room to the outside air. For a general calculation, the approximate CO$_2$ release from the room is as follows:

$$\text{CO}_2\text{ release} = 95\% \quad 7)$$

**Space volume calculation**

**Public space**

Two examples of defining indoor dimensions are given for workspaces and lecture halls. Its implementation can be applied to a large number of public meeting rooms.

Example 1: Workspace carbon footprint for indoor dimensional planning

- For 1 person, the CO$_2$ emission unit is eq.5): ($1.0$ kg CO$_2$/day)/(24 hours) = 0.04 kg CO$_2$/hour.
- The CO$_2$ volume is the CO$_2$ emission unit divided by CO$_2$ density eq.6): ($0.04$ kg CO$_2$/hour)/(1.75 kg/m$^3$) = 0.023 m$^3$/hour.
- Gas CO$_2$ in a healthy room eq.4) divided by normal working hours: (360 ppm) / (8 hours) = 45 ppm/hour.
- Total CO$_2$ in the room (95% release, eq.7) is [(100) / (100-95)] * 45 ppm/hour = 900 ppm/hour. This is to be converted into volume by volume = (900/1,000,000)/hour = 0.0009/hour.
- Volume of space = (0.023 m$^3$/hour) / (0.0009/hour) = 25.56 m$^3$/person.

Thus, the volume of space of healthy room works 8 hours for 1 person is rounded to 25 m$^3$, which is free of placement of length, width and height, and this follows the comfort of the architectural design of a workspace.

Example 2: Classroom carbon footprint to predict the length of the meeting in a certain dimensional indoor

- Assumed a classroom for 50 people, the CO$_2$ emission unit is eq.5): (50)*(1.0 kg CO$_2$/day)/(24 hours) = 2.08 kg CO$_2$/hour.
- The CO$_2$ volume is the CO$_2$ emission unit divided by CO$_2$ density eq.6): (2.08 kg CO$_2$/hour)/(1.75 kg/m$^3$) = 1.19 m$^3$/hour.
- Volume of room (assumed the dimensions of the existing space) = 20 m * 10 m * 3 m = 600 m$^3$.
- Room CO$_2$ concentration is the CO$_2$ volume divided by volume of existing room = (1.19 m$^3$/hour) / (600 m$^3$) = 0.0020*1,000,000 (this is the number to convert into parts per million, ppm) = 2,000 ppm/hour.
- Gas escaping out of the room is 95% (eq.7), then the indoor gas becomes(5%)*(2,000 ppm/hour) = 100 ppm/hour. Therefore, the maximum time of meeting for healthy conditions is (360 ppm) / (100 ppm/hour) = 3.6 hours.
Personal room

Often and many people ask about the size of a healthy personal space for bedrooms, living rooms, kitchens, and homes as a whole. Several examples below provide the answer.

Example 3: Bedroom carbon footprint, an evaluation of the size of the existing space:

- For 1 person, the CO₂ emission unit is eq.5): (1.0 kg CO₂/day)/(24 hours) = 0.04 kg CO₂/hour.
- The CO₂ volume is the CO₂ emission unit divided by CO₂ density eq.6): (0.04 kg CO₂/hour)/(1.75 kg/m³) = 0.023 m³/hour.
- Room volume (assumed with existing dimensions) = 3m x 3m x 3m = 27m³.
- Room CO₂ concentration = (0.023 m³/hour) / (27 m³) = 0.000852* 10⁶ (this is the number to convert into parts per million, ppm) = 852 ppm/hour.
- Gas escaping out of the room = 95% (eq. 7), then the indoor CO₂ becomes 43 ppm/hour.

These results can then be adjusted for the number of people and the length of time in the bedroom, such as:
- 1 person may stay in the bedroom for 360/43 = 8.4 hours.
- 2 people may stay in the bedroom for 360/86 = 4.2 hours.

Example 4: Bedroom carbon footprint, a new plan for a spouse for 8 hours stay at room:

- For a spouse (2 person), the CO₂ emission unit is eq.5): (1.0 kg CO₂/day)/(24 hours) = 0.08 kg CO₂/hour.
- The CO₂ volume is the CO₂ emission unit divided by CO₂ density eq.6): (0.08 kg CO₂/hour)/(1.75 kg/m³) = 0.046 m³/hour.
- Gas CO₂ in a healthy room eq.4) divided by normal working hours: (360 ppm) / (8 hours) = 45 ppm/hour.
- Total CO₂ in the room (95% release, eq.7) is [(100) / (100-95)] * 45 ppm/hour = 900 ppm/hour. This is to be converted into volume by volume = (900/1,000,000)/hour = 0.0009/hour.
- Volume of bedroom for a spouse= (0.046 m³/hour) / (0.0009/hour) = 51.11 m³ (rounded to 50 m³).

Example 5: House carbon footprint, a new plan for 24 hours (longest time on a holiday):

- For 1 person, the CO₂ emission unit is eq.5): (1.0 kg CO₂/day)/(24 hours) = 0.04 kg CO₂/hour.
- The CO₂ volume is the CO₂ emission unit divided by CO₂ density eq.6): (0.04 kg CO₂/hour)/(1.75 kg/m³) = 0.023 m³/hour.
- Gas CO₂ in a healthy room eq.4) divided by normal working hours: (360 ppm) / (24 hours) = 15 ppm/hour.
- Total CO₂ in the room (95% release, eq.7) is [(100) / (100-95)] * 15 ppm/hour = 300 ppm/hour. This is to be converted into volume by volume = (300/1,000,000)/hour = 0.0003/hour.
- The indoor volume unit is (0.023 m³/hour) / (0.0003/hour) = 76.67 m³ (rounded to 75 m³), which is for 1 person.

By knowing the indoor volume unit, it is easy to find out the volume of the house for a number of residents who live in the house during a healthy holiday. As an illustration for a family of 4 residents, they need a house with volume 300 m³. In dimensions, the house is 1 floor with a fixed height of 3 m, so a length and width of 10m are required.

Conclusion

Based on the calculation examples above, the volume of space is linear with the number of users and the time of existence. It is known that the volume unit of a healthy room is rounded to 3.0 m³/person/hour. The space volume calculation based on carbon footprint is applicable to all indoor functions, both for personal and public activities.

Diarrhea Prevalence in East Java, Indonesia: Does Access to Sanitation and Health Behavior Ecologically Related?

Hario Megatsari¹, Agung Dwi Laksono², Anita Dewi Moelyaningrum³

¹Lecturer, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, ²Researcher, National Institute of Health Research and Development, the Indonesia Ministry of Health, Jakarta, Indonesia, ³Lecturer, Faculty of Public Health, University of Jember, Jember, Indonesia

Abstract

Diarrhea is still a problem in East Java in Indonesia. The study aims to analyze the ecological relationship between sanitation access and health behavior with diarrhea prevalence in East Java, Indonesia. The research conducted the ecological analysis using secondary data from the Ministry of Health of the Republic of Indonesia report in 2018. The study takes all regencies/cities in East Java Provinces as samples. Apart from the diarrhea prevalence in children under five, four other variables analyzed as independent variables were access and clean water sources, the percentage of coverage of access to healthy latrines, the proportion of proper handwashing behavior, and the proportion of defecating behavior in healthy latrines. The study analyzed data using a scatter plot. The study results found that the higher the percentage of coverage of access and clean water source in regency/city, the lower the prevalence of diarrhea in children under five in that regency/city. The higher the percentage of access to healthy latrines in a region, the lower the majority of diarrhea in children under five. Meanwhile, the higher the proper handwashing behavior proportion in an area, the lower the prevalence of diarrhea in children under five in that area. Moreover, the higher the proportion of defecating behavior in healthy latrines in a region, the lower the prevalence of diarrhea in children under five. The study concluded that sanitation access and health behavior were related to the diarrhea prevalence in children under five.

Keywords: diarrhea, sanitation access, health behavior, ecological analysis, secondary data.

Background

Diarrhea is described as the passing of three or more loose or liquid stools per day, or more frequently than is typical for the person¹. East Java, as one of the provinces in Indonesia with the second largest population after DKI Jakarta Province, has a diarrhea prevalence rate that is close to the national prevalence rate, which is 6.5%². Based on the East Java Provincial Health Office data in 2019, the diarrhea service coverage from 2015-2019 experienced a downward trend, wherein 2019 the figure was 74.10%, indicating that people who had diarrhea have not been fully served by health facilities³.

Diarrhea diseases are some of the major contributors to global child mortality, resulting in 8 per cent of all child deaths under 5 years of age⁴. Diarrhea diseases, such as cholera, may be endemic, with continuous transmission, or epidemic, like during an outbreak⁵. Research conducted by Baral et al in 2020, states that the average cost spent by patients suffering from diarrhea with outpatient is US $ 36.56 and inpatient is US $ 159.90. Another judgment from the study is direct medical costs for 79% (83% for inpatient and 74% for outpatient) of the total direct costs⁶.

Access to clean water is an indicator of the Sustainable Development Goals (SDGs), which is also an effective way to prevent diarrhea cases⁷. Research conducted by
Otsuka in 2019, states that the management of drinking water at home and meaningful personal hygiene practices for children is essential for the sustainability and promotion of children’s health in urban slum areas in Indonesia. Other research conducted by Bidkhori in 2019 stated that the diarrhea-associated deaths in children under 5 years are influenced by factors such as Use of Improved Drinking-Water Sources (UIDWS) and Use of Improved Sanitation Facilities (UISF), and this rate can be reduced by making UISF and UIDWS available for people and especially people of rural areas.

Behavioral aspects with behavior are closely related. Research conducted by Auliaailahi in 2020 states that there is a relationship between healthy life behavior and cases of diarrhea in Indonesia. Another research conducted by Aftab et al in 2018, stated that many children may not receive prescribed medication for diarrhea and pneumonia on time. Taking into account the concerns of caregivers, an appropriate supply of medicines to lady health workers, enhanced facility-level care could strengthen care-seeking practices and child health outcomes.

The study aimed to analyze the ecological relation between access to sanitation (clean water and latrines), health behavior (defecating and washing hands), and the prevalence of diarrhea in East Java, Indonesia.

Materials and Methods

The author designed the study using an ecological analysis approach. Ecological studies focus on comparisons between groups, not individuals. The data analyzed is aggregate data at a particular group or level, which in this study is the provincial level. An ecological analysis variable can be aggregate measurements, environmental measurements, or global measurements.

The author conducted the study using secondary data from the 2018 Indonesia Basic Health Survey chapter of East Java Province. The study involved all regions in East Java (38 regencies/cities).

In this study, the dependent variable is the prevalence of diarrhea in children under five. Meanwhile, the study analyzed two groups of independent variables, namely sanitation access and health behavior. The sanitation access consists of two variables: the percentage of access and clean water sources and the percentage of coverage of access to healthy latrines. Healthy latrine is a type of latrine with a goose neck seat and uses a septic tank for disposal. The health behavior consists of two variables: The proportion of proper handwashing behavior and the proportion of defecating behavior in healthy latrines.

The study used univariate and bivariate analysis to examine the data. The review uses a scatter plot to perform bivariate analysis. The analysis employs a fit-line to assess the relationship between diarrhea prevalence in children under five and independent variables. The research used SPSS 21 program in the entire review process.

Results

Table 1 shows the diarrhea prevalence in children under five and other variables in East Java, Indonesia, in 2018. Table 1 indicates a very high variation between regencies/cities. The diarrhea prevalence in children under five was the lowest, 1.2% (Kediri City), while the highest prevalence was 17.9% (Bondowoso Regency).

Sanitation Access

Figure 1 showscatter plot of the prevalence of diarrhea in children under five and the percentage of coverage of access and clean water source in East Java Province in Indonesia in 2018. The figure indicates hubungan kedua variabel tersebut memiliki kecenderungan yang negatif. It means bahwa semakin tinggi the percentage of coverage of access and clean water source in a regency/city, maka semakin turun the prevalence of diarrhea in children under five in that regency/city.
Source: The 2018 Indonesia Basic Health Survey chapter East Java

Water supply is basic sanitation that must be fulfilled properly. The fulfillment of basic sanitation remains the best protection against diarrhea. Basic sanitation includes water supply, healthy latrine, waste and water disposal. Several previous studies at the individual level also found consistent results. Sources of clean water were found to be the factor that can reduce the incidence of diarrhea. Clean water supply continuously can reduce acute diarrhea among under-five children in slums. Clean water supply is a crucial factor for life. Clean water is needed by each individual for drinking and daily activities. For this reason, the supply of clean water plays a decisive role both in the survival of life and in preventing water-borne diseases such as diarrhea. The results showed that improvement in drinking water was associated with a decrease in the risk of diarrhea. Water supply associate with the incidence of acute diarrhea among children under five. The results show that improved water supply could reduce diarrhea in under-5 children by 11%.

Figure 2 shows scatter plot of the prevalence of diarrhea in children under five and the percentage of coverage of access to healthy latrines in East Java Province in Indonesia in 2018. The result shows the relationship between the two variables has a negative tendency. It informs that the higher the percentage of coverage of access to healthy latrines in a region, the lower the prevalence of diarrhea in children under five in that region.
The high level of access to healthy latrines in society makes feces as a polluting factor more easily localized. Feces is the main polluting factor that is often found in the environment. The distribution of feces in the environment needs to be controlled because it can become a medium for transmitting fecal-oral diseases such as diarrhea. Several studies have stated that the E. coli bacteria from feces often contaminate the environment like water sources. The data shows that there are 14% of countries in Europe and 52% of countries in Africa faecally contaminated. Several water sources in Indonesia are also proven to be contaminated. E. coli that comes from feces; Escherichia coli is a germ that exists in the digestive tract, so if the environment contains Escherichia coli, it can indicate that environmental contamination has occurred. Latrine cleanliness must be build up. Latrine can significantly reduce the incidence of diarrhea. One of the factors that influence the localization of feces depends on the type of toilet. Latrine type that is close with wastewater disposal, hand washing, and storage of water has a risk of diarrhea incidence \( p < 0.05 \). The presence of healthy latrine, water shortage in household consumption/water access at the individual level, water shortage in households had a statistically significant association with diarrhea occurrence in the Dangla district. Healthy latrine, include the availability of handwashing facilities around latrine, hand washing practice at the critical time for handwashing, storage of water were the determinant factors of diarrheal diseases.

Health Behavior (Hand Washing)

Figure 3 shows a scatter plot of the prevalence of diarrhea in children under five and the proportion of proper handwashing behavior in East Java Province in Indonesia in 2018. The scatter plot informs the relationship between the two variables has a negative tendency. It concludes that the higher the proportion of proper handwashing behavior in an area, the lower the prevalence of diarrhea in children under five in that area.

These findings further reinforce the results of previous studies that examined the same themes at the individual level. The habit of handwashing using soap in running water can reduce the risk of diarrhea. This is in line with previous research which said that The main sources of drinking water, domestic waste disposal place, and use of soap for handwashing were the most important factors for the prevention of childhood diarrhea. Hand washing practice have sig associate with diarrhea.
Figure 4 shows the bivariate analysis of the prevalence of diarrhea in children under five and the proportion of defecating behavior in healthy latrines in East Java Province in Indonesia in 2018. The figure informs that the relationship between these two factors has a negative tendency. It concludes that the higher the proportion of defecating behavior in healthy latrines in a regulation/city, the lower the prevalence of diarrhea in children under five in that regulation/city. In line with handwashing behavior, defecating behavior in healthy latrines is also a protective factor from the incidence of diarrhea.

Policymakers in East Java Province can use the results of this study to determine the target regency/city to be accelerated to reduce the prevalence of diarrhea in children under five. This regency/city is an area with low coverage in four respects, namely access and clean water sources, access to healthy latrines, proper handwashing behavior, and defecating behavior in the healthy latrine. The behavior of diarrhea prevention associated with knowledge \(^{28}\) so the level of knowledge in diarrhea prevention should be increasing to behavioral change.

The author conducted a study with an ecological analysis approach to capture the superficial phenomena needed by policymakers to reduce the prevalence of diarrhea in children under five in East Java, Indonesia. On the other hand, this study cannot capture specific local phenomena related to others’ behaviors. Some of them are behaviors that relate to the habit of feeding...
practices in children under five that was informed in previous studies 29–31.

**Conclusions**

Based on the research results, the study concluded that sanitation access and health behavior were related to the diarrhea prevalence in children under five. The percentage of access to clean water sources, the rate of coverage of access to healthy latrines, the proportion of proper handwashing behavior, and the proportion of defecating behavior in healthy latrines, were negatively related to the diarrhea prevalence in children under five.

Abstract

Background: The Spheno-occipital synchondrosis (SOS) has a significant role in the field of forensic, medical and anthropological sciences for age analysis. Therefore, SOS can help estimating age depending on different stages of closure. Therefore, the present study aimed to evaluate the timing of complete fusion of Spheno-occipital synchondrosis using computed tomography.

Methods: A prospective study including 110 subjects was conducted in which 55 males and 55 females between the ages of 15-25. All CT examinations were performed on a 128 slice incisive CT, Philips and 16- slice big bore CT, Philips. The sagittal image was used for analysis the stage of spheno-occipital fusion. Based on the stage of fusion of SOS, patients were categorized into stage 0 indicating partial/no fusion and stage 1 indicating complete closure of the SOS. An experienced radiologist scored all images.

Conclusion: The mean age of male cases with complete SOS closure was 20.3 ± 3 years for males and 20 ± 3.1 years for females. The study results show that by age of 20, no individual will belong to stage 0 irrespective of gender and all individuals would have completely fused SOS.

Keywords: Spheno-occipital synchondrosis, computerized tomography, age determination

Introduction

The Spheno-occipital synchondrosis (SOS) is a hyaline cartilage growth center joining the sphenoid and occipital bones and is largely present during the development of skull base and later gets ossified throughout maturation (¹). This has a significant role in facial development and the thorough examination of skeletal ossification plays an important role in the field of forensic, medical and anthropological sciences for age analysis. Therefore, SOS can help estimating age depending on different stages of closure. The fusion stage can help determine if the individual is minor as the SOS is undergoing fusion or considered as adults if the fusion is complete. As per literature, the SOS fuses between 11-16 years of age, however this remains controversial, as there are variable reports in literature of SOS fusion in individuals as late as 25 years (²-¹⁰). This variation of fusion reported in studies can be as a result of different methods of analysis employed, variation in population, sample sizes or age ranges (¹¹).
The various methods of analysis include dry skull method, histological sections, conventional radiographs, computed tomography, and magnetic resonance imaging. Conventional radiographs provide superficial information and therefore it is difficult to visualize areas of the skull due to superimposing structures. Although, direct inspection methods are cost-effective and the most commonly used method in forensic anthropology (11), computed tomography are high resolution and provide opportunities to perform three-dimensional investigation. Therefore, they can detect the state of fusion earlier due to superior visualization of skull base and is considered to have a greater accuracy in determining closure (4). Although a lot of studies have utilized SOS for age estimation, it is a well-known fact that standards vary in different populations and ethnic groups, there is a need for anthropological data that is specific to population (4, 12). Therefore the present study was aimed to evaluate the timing of complete fusion of Spheno-occipital synchondrosis (SOS) using computed tomography.

Materials and Methods

A prospective study including 110 subjects was conducted in a tertiary care hospital, Dakshina Kannada region. The study approval was obtained from the institute research and ethical committee, Kasturba hospital. The study population included 55 males and 55 females between the ages of 15–25. The participants included in the study were referred for CT scan of brain, spine, and temporal bone as part of their diagnostic package. Patients with congenital anomalies, developmental disorders and recent trauma were not included in the study. Informed consent was obtained from all patients and all the CT examinations were performed on a 128 slice incisive CT, Philips and 16 slice big bore CT, Philips. The patients were positioned in supine and placed head first. The scan was performed at 120 kVp and automatic tube current modulation. The image were acquired in 5 mm thickness and later reconstructed into thinner sections (1mm). The image was reformatted to sagittal plane using Multi Planar reconstruction technique and scored by an experienced radiologist. Based on the stage of fusion of SOS, patients were categorized into stage 0 and stage 1. Stage 0 indicated partial or no-fusion of SOS and stage 1 indicated complete closure of the SOS as shown in figure 1. The mean age of patients coming under each grade was calculated and noted for both genders.

![Stage 0 – No fusion](image1)

![Stage 1 – completely closed](image2)

Figure 1: Stages of SOS fusion in the mid sagittal plane
Statistical Analysis

The statistical analysis was done using R analysis. Age estimation in both genders as per spheno-occipital synchondrosis fusion stage was described in terms of mean, standard deviation, minimum and maximum values. Status of complete closure was compared in males and females using independent t test. To test the association between age and stage logistic-regression was used.

Results and Discussion

Among the 110 subjects included in the study, four male subjects of age 15 and 16 years showed partially closed Spheno-occipital synchondrosis, with the rest of them categorized into stage 1 indicating complete closure of SOS. The average age of male participants with open/partially fused suture was 15.5±0.5 years. In stage 0, the highest age of partially closed suture was 16 years. From the 110 subjects, 106 individuals showed complete fusion of spheno-occipital synchondrosis in which 51 were males and 55 were females. The mean age of male cases with complete SOS closure was 20.3 ± 3 years for males and 20 ± 3.1 years for females. The lowest age of complete suture closure was at 15 years for both males and females (table 1).

</table>
The study results showed no significant difference (p= 0.9) among gender in stage 1 of complete SOS closure. To evaluate the effect of age on fusion stages, logistic regression was performed. The test gave an odds ratio of 10.4 indicating that as the age increases by one unit the chance of getting stage one is 10 times more than the stage 0. The study results show that by age of 20, no individual will belong to stage 0 irrespective of gender and all individuals would have completely fused SOS.

The study on SOS development and its important role in age estimation is been studied over the years. By estimating the fusion of the joint, it is possible to determine the age of an individual that will be helpful in solving criminal activities like sexual offenses, child labour. The late stage of fusion of this particular joint has its own significance in forensic analysis as well as in medical and anthropological fields (5). The objectives of this research was to identify the time of complete-fusion of SOS in both males and females. As per the mean age of our study, we found there was complete SOS at 20.3 ± 3 years for males and 20 ± 3.1 years for female.

Similarly, a study conducted by Rajeshwar et al also showed similar results. His study included 198 samples within the central Indian population in which 117 were males and 81 were females. The study reported that SOS closure occurs at a mean age of 20.2 and 21.4 year among females and males respectively (8). The mean age of fusion can vary according to the population as well as genders. Although our study did not show a significant variation in mean age for SOS closure among genders, a notable amount of studies report variation in mean age of complete SOS closure between males and females (3, 7, 10, 11, 13). However, a study conducted by Richard B et al reported complete sphenoid occipital fusion by the age 17 years for both genders (4). He also reported that after an age of sixteen years there was no remarkable change in the progression of the fusion among genders. This was similar to the present study, which showed no significant difference of SOS fusion progress after an age of sixteen years in males and fifteen years in female.

Table 2 demonstrates summary of these research along with the present study showing age range, number of participants and mode of analysis for complete fusion of sphenoid-occipital synchondrosis.

</table>
The differences in the results can be due to methodological difference used for determination of SOS, also differences in population, selection of sample size, socio-economic status are factors that could influence the result. The present study evaluated the SOS closure using computer tomography. However, a lot of studies have been done to estimate age of SOS closure using direct inspection methods in cadavers, cone beam CT, MRI, X-ray etc. Our study is also in accordance with various studies in literature that report an interdependence of age with stage of closure. The study demonstrated that, by the age of 18 years the SOS is complete for both males and females as no notable progression occurs in SOS closure after 17 years of age. Therefore, an open suture or an incomplete SOS can indicate that the individual may be less than 18 years. Further population specific studies can be done to estimate age of unknown individuals.

The current study did have certain limitations, as it was a time-bounded study; the obtained sample size was small. The present study only investigated timing of closure of spheno-occipital synchondrosis, which as shown in the study occurs earlier than expected in females, therefore, further studies including a larger population involving younger children (7-14 years) is recommended.

**Conclusion**

As there is no significant progression in SOS fusion seen after an age of 15-16 years in both females and males, we can conclude that male subjects with open/semi closed suture will be below the age of 16 years and females with open/semi closed suture will be less than 15 years. In addition, the study indicates that SOS fusion stages increases with age. Therefore, it can be helpful in prediction of age.

Autism Spectrum Disorder A Review

Harshith N1, Kanakavalli K. Kundury2

1Assistant Professor, 2Department of Health System Management Studies, JSSAHER, Sri Shivarathreeshwara Nagara, Mysuru, Karnataka, India

Abstract

Autism Spectrum Disorder issue (ASD) infers a degree of conditions depicted by some level of debilitated social lead, correspondence and language, and an obliged degree of interests and exercises that are both unprecedented to the individual and did slowly. ASDs start in youth and will when everything is said in done proceed into energy and adulthood. An incredible piece of the time the conditions are clear during the hidden 5 years of life. It is assessed that overall one of every 160 youngsters has an ASD. This gauge speaks to a normal figure, and revealed commonness fluctuates significantly across contemplates. Some very much controlled investigations have, notwithstanding, revealed figures that are significantly higher. The predominance of ASD in some low-and centre salary nations is so far obscure People with ASD a great part of the time present other co-happening conditions, including epilepsy, incapacitation, weight and thought misfortune hyperactivity issue (ADHD). Intervention during early childhood is imperative to advance the ideal turn of events and prosperity of individuals with an ASD. Observing of kid advancement as a feature of routine maternal and youngster medicinal services is suggested.

Key Words: Autism Spectrum Disorder, debilitated, epilepsy, adulthood

Introduction

Autism Spectrum Disorder issue is a neurological and developmental issue that begins taking everything into account in youth and drives forward through all through a person’s life1. It impacts how an individual shows and teams up with others, permits, and learns. It joins what used to be known as Asperger condition and unavoidable developmental issues2.

A genuine formative issue that disables the capacity to convey and associate. Chemical imbalance range issue impacts the sensory system and influences the general intellectual, enthusiastic, social and physical wellbeing of the influenced person. The range and seriousness of side effects can fluctuate generally. Basic side effects incorporate trouble with correspondence, trouble with social communications, over the top interests and redundant practices.

Early acknowledgment, just as conduct, instructive and family treatments may decrease side effects and bolster advancement and learning.

It is known as a “run” issue since people with ASD can have a level of signs. People with ASD may have issues talking with you, or they evidently won’t take a gander at you without bouncing when you visit with them3. They may correspondingly have restricted interests and dreary practices. They may contribute a huge amount of noteworthiness overseeing things, or they may impart a relative sentence again and again. They may typically have all the stores of being in their “own existence.”

At well-kid tests, the social protection provider should check your youth’s new development. If there exhibit ASD, your child will have a broad evaluation. It may merge a party of bosses, doing various tests and evaluations to make an end.

**SIGNS AND SYMPTOMS**

People diagnosed with ASD have issues with social Communications and Interactions, restricted interests, and excess activities. The summary underneath gives a couple of cases of the sorts of practices that are found in people resolved to have ASD. Not all people with ASD will show all practices, anyway most of the children exhibits at least two symptoms.

**Social correspondence/affiliation practices may include:**

Coming to, Tending not to look at or take a gander at people, Once in some time sharing fulfillment in articles or activities by pointing or showing things to others, Neglecting to, or being surrendered to, respond to someone calling their name or to other verbal undertakings to get thought, Experiencing issues with the forward and in converse of conversation, Regularly talking at long last about a most esteemed subject without seeing that others are not interested or without permitting others to respond, Having outward appearances, redesigns, and advancements that don’t organize what is being communicated, Having a strange technique for talking that may sound sing-song or level and robot-like, Experiencing burden understanding another person’s viewpoint or being not set up to envision or appreciate others’ exercises.

**Prohibitive/dull practices may include:**

Reiterating certain practices or having puzzling practices. For example, rehashing words or verbalizations, a lead called echolalia, Having a mulling outrageous fervour over unequivocal subjects, for instance, numbers, nuances, or certifiable segments, Having incredibly focused interests, for instance, with moving articles or parts of things, Getting induced with slight changes in a bit by bit plan, Being in every way that really matters tricky than others to obvious data, for instance, light, unrest, dress, or temperature, Individuals with ASD may in like way experience rest issues and irritability. Notwithstanding the way that people with ASD experience various challenges, they may in like way have various characteristics, including, Having the decision to learn things in detail and review information for far reaching time frames, Being strong visual and hear-capable understudies Surpassing needs in math, science, music, or craftsmanship.

**Causes and Risk Factors**

While specialists have no idea about the particular explanations behind ASD, research suggests that properties can act near to impacts from nature to influence development in penchants that lead to ASD. Despite how experts are so far attempting to comprehend why a few people make ASD and others don’t, some danger factors include:

- Having a family with ASD
- Having more masterminded guardians
- Having certain inherent conditions—Down disorder, delicate X disorder, and Rett disorder are almost certain than others to have ASD

**Diagnosis**

An ASD assessment joins a reality orchestrating, which is used to show how much assistance kids need: Level 1 – kids need support, Level 2 – kids need stunning assistance, Level 3 – kids need monster help. These rankings reflect the way that a few people have smooth ASD appearances, and others have more authentic symptoms. The rating is given autonomously for the two zones of difficulty, so youngsters may have gathered reality rankings for social difficulties and dull practices.

**Medications and Therapies**

Treatment for ASD should begin as snappy as time grants after end. Early treatment for ASD is basic as sensible thought can diminish individuals’ difficulties.
while helping them learn new cut off points and piece of breathing space at any rate much as could be ordinary from their properties.

The wide level of issues standing up to people with ASD suggests that there is no single best treatment for ASD. Working before long with a force or therapeutic associations capable is a fundamental bit of finding the right treatment program11

Knowledge of Healthcare Providers toward New Corona Virus at Directorate of Military Medical Affairs Units

Muhammed Hussein Ali¹, Wasnaa Jomaa Mohammed²

¹MScN(C), University of Baghdad, College of Nursing, Community Health Nursing Department, Baghdad, Iraq, ²Assistant Professor, University of Baghdad, College of Nursing, Basic Sciences Department, Baghdad, Iraq

Abstract

Background: Coronavirus is a rapidly spreading disease also known as COVID-19. The epidemic is caused by a new human coronavirus, previously known as (SARS-COV-2), new coronavirus disease it first appeared in December 2019 among patients who had symptoms of viral pneumonia in Wuhan, China. This study aims to determine healthcare providers’ knowledge related to coronavirus.

Methods: A descriptive design is carried throughout the present study Directorate of Military Medical Affairs Units (Al- Muthanna Military Hospital, Al-Hussein military Hospital, Al-Shaheed Mubder Military Clinic, Al-Naser Military Clinic, Military Medical School) for the period from January 28th, 2021 to February 25th, 2021. The study included a non-probability “purposive” sample of (223) health care providers. The questionnaire encompasses two main parts (Health Care Providers Socio-Demographic Characteristics, and Health Care Providers’ knowledge’s Tool).

Data were analyzed using the statistical package for social science. The descriptive statistical measures of frequency, percent, mean, Relative Sufficiency, Percentile Grand Mean of Score, Percentile Global Mean of Score, Pooled Standard Deviation, and Grand/or Global Relative range, standard deviation, and inferential statistical measures of T-test, Chi-Square test, Binomial test, Mann-Whitney test, Contingency Coefficients test, and Wilcoxon Signed Ranks test.

Results: The study results showed that half of the study participants depend on their information about the studied diseases on the “Center for Disease Control of the World Health Organization”, then 158 (70.9%) depend on government websites and official media, then 109 (48.9%) depend on news media about 148 (66.4%) rely on Social media. About 26(11.7%) rely on Journals” only.

Conclusion: The researchers concluded that the overall evaluation of healthcare providers’ knowledge is moderate.

Recommendation: The researchers recommend that there is a need to conduct further studies on larger sample at the national level with the need for an educational program to increase the knowledge of health care providers about Corona virus in military medicine.

Keywords: Coronavirus; Healthcare Providers, Knowledge

Introduction

Coronavirus is a rapidly spreading disease also known as COVID-19. The epidemic is caused by a new human coronavirus, previously known as (SARS-COV-2), new coronavirus disease it first appeared in
December 2019 among patients who had symptoms of viral pneumonia in Wuhan, China (1-2).

The first cases of pneumonia of unknown source were discovered in Wuhan, capital of Hubei Province, in early December 2019, the pathogen was identified as the new, enveloped beta-corona RNA virus. This is now called severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), which is fairly similar to SARS-CoV. It was found linked to the Huanan seafood market in Wuhan, Hubei Province, China, where Aquatic animals were also sold before the outbreak (3-4).

The disease highly contagious, its main clinical manifestations include fever, dry, weakness, muscle pain and shortness of breath, which characterized by acute respiratory distress syndrome, septic shock, difficult-to-treat metabolic acidosis, bleeding and dysfunction. The incubation period for a novel coronavirus infection is about 2-5 days, after which symptoms begin to appear, however, this period varies according to the immune system and the age of the patient (5-6).

Health care systems in first world countries have failed to provide medical care due to the rapidly increasing numbers of infected patients, not to mention the developing or underdeveloped countries. In most cases, the initiative and management in the various countries appeared inconsistent, wasted, ill-equipped, and inadequate to contain the disease. Unprecedented in history, the active participation of everyone on earth, through testing, confinement, contact follow-up, social segregation, staying home, self-isolation, improving individual hygiene and using individual defense equipment, for example, blankets and gloves, is essential to containing COVID-19, prevent medical service workers from overcoming it, and give specialists time to establish treatment methodologies (7).

To control Outbreaks, China has taken some strict measures includes complete closure of public places, Public transportation and isolation of suspected cases. Authorities have locked down the entire Hubei province for months and days. Residents inside and outside Hubei Province are being asked to stay home and practice self-isolation to avoid any physical contact with others. Fight against the epidemic continues in China as well as around the world (8).

Many millions have sacrificed their self-sufficiency, well-being, position, jobs, transformation, and education. However, deliberate self-cooperation methods of responding to COVID-19 have led to difficulties in various countries due to changing information degrees and perspectives. As needed, the plan and implementation of antiviral activities is based on a complete and microscopic understanding of separate regions and within each country (7).

Around the world, the main challenges lie in providing the right services Caring for COVID patients and preventing the spread Infection among health care workers and the public General. Appropriate preventive measures for COVID-19 Infection are not effectively carried out both places and adherence to them is inconsistent (9).

In addition, implementation of the updated guidelines brings a host of communication challenges and guidance, availability of resources, access to equipment, and practice in using that equipment, simulation sessions and a willingness to participate in the application of those directions. These factors influenced by the knowledge and attitudes of health care providers regarding the disease and updated guidelines to be provided for their routine work (10).

Materials and Methods

A descriptive design was used to guide this study. The study included a purposive sample of 223 healthcare providers. The study was conducted at the Directorate of Military Medical Affairs Units (Al-Muthanna Military Hospital, al-Hussein military Hospital, Al-Shaheed Mubder Military Clinic, Al-Naser Military Clinic, Military Medical School) for period of from of January 28th, 2021 to February 25th, 2021. Data were collected through a self-reported questionnaire using the structured interview as a way of data collection. The questionnaire encompasses two main parts as follows:
**Part I:** healthcare providers’ sociodemographic characteristics: This part includes items of Workplace, gender, age, service Years, Occupation, level of education, have you participated in a course on methods of preventing the emerging corona virus, Duration of the course and socioeconomic status which are calculated through use Testing based on One-Sample Chi-Square test, and Binomial test.: where Non-significant at P>0.05, Significant at P<0.05 and Highly significant at P<0.01

**Part II:** healthcare providers’ knowledges: This part is comprised of 12 items that measure knowledge of healthcare providers’ knowledge which are measured as [(0.00 – 33.33) for Low (L) evaluation; (33.34 – 66.66) for Moderate (M) evaluation; and (66.67– 100) for High (H) evaluation].

The content validity and Pearson correlation coefficient reliability were determined through a pilot study.

**Data Analyses/Statistics**

Data were analyzed using the statistical package for social science (SPSS) ver. (21.0). The descriptive statistic measures of frequency, percent, mean, and standard deviation and inferential statistical measures of T-test, multiple linear regressions, person correlation coefficient, Chi-Square, and analysis of variance (ANOVA) were used.

</table>
Ev. = Evaluated (0.00 – 33.33) Low (L); (33.34 – 66.66) Moderate (M); (66.67– 100) High (H).

The observed responses of high evaluating assigned are accounted 4(33.33%) items, and responses of assigned a moderate evaluate are accounted 3(25.0%) items, while the leftover items were assigned a low evaluation, and accounted 5(41.67%), through using differentiated intervals, such that: [0.00 – 33.33) for Low (L) evaluation; (33.34 – 66.66) for Moderate (M) evaluation; and (66.67– 100) for High (H) evaluation.

For summarizes preceding results, it could be conclude that “Providers’ Knowledge towards” coronavirus at directorate of military medical affairs units items were non assigned at the established level in which that achieving the goal of this study, also results observed concerning estimates of the percentile grand mean of score due to knowledge main domain having a moderate evaluating

Discussion

The source of information for half of participants about Covid-19 is that they rely on their information on the “World Health Organization, CDC”, followed by governmental websites “official” and the media, followed by the media, the social media, and finally journals only.

This result may be due to the prevalence of the Internet and the ease of access to the WHO website, the Centers for Disease Control and Prevention, official government websites, the media, social media sites and magazines. This finding contradicts a study conducted by researchers from the United Arab Emirates, India, and Iran who stated that the main sources of participants’ information are official government websites Social media, with about 30% of them saying they used the news Media (TV/video, magazines, newspapers, radio) and social media (Facebook, Twitter, Whatsapp, YouTube, Instagram and Snapchat) for information about COVID-19. Moreover, nearly 40% of respondents occasionally discussed topics related to COVID-19 with family and friends.\(^{11}\)

Concerning participants’ knowledge, most have a moderate knowledge. This result may be due to the fact that the epidemic is modern and occurred suddenly, which caused confusion in most health systems in the world, not only Iraq, in addition to the lack of scientific resources related to the prevention of this disease and the frequent updating of information related to this disease.

This finding is consistent with a study conducted by Al-Thaqafi et al., 2020 in terms of lack of knowledge about the emerging corona virus\(^ {12}\).

Conclusion

The researchers concluded that the overall evaluation of knowledge healthcare providers is moderate.

Recommendations

The researchers recommend that more research be conducted at the national level on the size of a large sample of health care providers, with the need for an educational program to increase the knowledge of health care providers about Corona virus in military medicine.

Conflict of Interest: The researchers confirm that there is no any conflict of interest.

Source of Funding: This study is self-funded.

Ethical Clearance: The researchers obtained the ethical approval from the University of Baghdad, College of Nursing

Abstract

Background and Aim: In this study rats, a systematic analysis was conducted to examine the antioxidant properties of cinnamon (Cinnamomum Zeylanicum, Breyne) in controlling high blood sugar levels, and a pharmacological comparison made to investigate whether or not it had a positive effect on the antioxidant system.

Materials and Methods: Alloxan 60 mg injected into the marginal ear veins of eighteen diabetic rats. After this diabetic animal study, the rats were randomly assigned to 4 groups. There were six animals in each of the 4 groups: Group 1(C): Positive control, Received orally 5 ml normal saline (0.9% NaCl) daily. Group 2(D): Negative control, Diabetes rats only, received single-dose alloxan 60 mg/kg body weight. Group 3(K): Diabetes rats, received cinnamon orally 35 mg/kg body weight dissolved in 2 ml normal saline. Group 4(I): Diabetes rats, was given 2 I.U/animal of insulin subcutaneously daily.

Results: All animal groups were treated for four weeks. Blood samples were taken from these groups weekly for biochemical analysis to estimate: Blood glucose, malondialdehyde (MDA), Glutathione (GSH). The results showed high glucose and MDA concentration associated with an increased oxidant stress alloxan induces on diabetic animals. The statistical analysis showed that a cinnamon significant (P<0.05) reduction in glucose, MDA, GSH when compared to positive control. The level of MDA, GSH was also significantly reduced (P<0.05) in all period comparison with the period before treated with Cinnamon extract. There was 4.3-fold more Ins I upregulated in the Cinnamon -treated diabetic rats 35 percent of the control group were heterozygous and three percent of the experimental group were mutant for that trait.

Conclusion: Furthermore, Cinnamon-treated diabetic rats (group K) showed a significant increase in the activities of both enzymatic and non-enzymatic antioxidants with concomitant overexpression of insulin I genes when compared to diabetic control rats (group D). Cinnamon contains antioxidants and antihyperglycemic effects at the end of the experiment.

Keywords: Cinnamon, Antioxidant capacity, Diabetes mellitus, INS I gene.

Introduction

As part of normal physiological metabolism, small amounts of ROS and other reactive oxygen species (ROS) and other reactive oxygen species, also known as ROSs or ROS/ROSs) are constantly generated. An oxygen intermediate reactant; When ROIs, Reactive Oxygen Species, are partially reduced, the result is that they are transformed into atmospheric oxygen (O2). For redox reactions, they generally lead to the formation of single oxygen or to the transfer of one or two or three electrons to a superoxide radical (which yields O2 and HO)¹. There is a class of antioxidants called “non-enzymatic” that simultaneously removes reactive and “nonenzymic” antioxidants. The oxidation of polyunsaturated fatty
acids compromises food quality and can lead to damage to cell membranes, heart disease, and cancer\textsuperscript{2}. The human body is damaged by oxidative stress, which increases the risk of disease development and accelerates its progress\textsuperscript{3}. Damage from free radicals and reactive oxygen species has been studied and has been proven to play a role in atherosclerosis \textsuperscript{4}. The antioxidants in food have been used to increase shelf life and reduce wastage and nutritional losses due to oxidation, which means the antioxidants in food have become quite popular as a countermeasure against spoilage \textsuperscript{5}. 2,4- and 6-Di-t-butyl-caffeatechinol are commonly used in the food industry as synthetic antioxidants. Regardless, there are serious questions about the carcinogenic nature of these substances, and natural alternatives are sought after\textsuperscript{6}. As a result, significant efforts are being made to determine natural antioxidants with the ability to fight cancer and age-related diseases. Various natural antioxidants are obtained from all parts of plants, for example, fruits, vegetables, roots, and bark\textsuperscript{7}. Plant phenolics can neutralize free radicals (quench free radicals), as well as single- and double-oxygen agents (radical scavengers). Studies show that the correlation between phenolic food and beverage intake and reduced risk of heart disease\textsuperscript{8}. Flavonoids, coumarins, coumarins, and polyunivalent hydroxyacids are the most commonly occurring plant phenolic antioxidants\textsuperscript{9}. Several techniques have been employed to assess the antioxidant ability of a given substance. It is more commonly used for its accessibility, efficiency, speed, and sensitivity when referring to chromogenic antioxidants. The presence of the antioxidant allows these two widely used radicals, ABTS and DPPH, to vanish. Both ABTS and DPPH are acquired radicals that are enzymatically or chemically formed\textsuperscript{10,11}. Antiallergic, antiulcerative, analgesic, antidiarrheumatic, and anodyne properties\textsuperscript{12}. Cinnamaldehyde and eugenol are present in the bark oil. In short, in many biological activities, antitumorigenic, and anti-cancer activities, cinnamaldehyde has been said to have strong vasodilatory, antifungal, and cytotoxic properties\textsuperscript{13,14,15}.

**Methodology**

**Experimental animal**

In the experiment mature male rats, Sprague-Dawley was used. Male rats had to grow accustomed to the environment of the animal house for 4 weeks before beginning the experiment. Rats were fed all and drinking water ad libitum. Room temperature was kept at 23± 2 °C.

**Preparation of n-butanol**

cinnamon (Cinnamomum Zeylanicum, Breyne) was extracted from the local store and graded by the State Seed Testing and Identification Board. Ministry of Agriculture supplied 1 kg of a celery plant. Methanol extract dried, rotavaporated (40 °C and 50 to 60 rpm). lyophilized by a dry freezer. The dried extract had been measured and put under extreme conditions of congelation. Three forms of polarity-dependent solvents have been found\textsuperscript{16}.

**Induction of diabetes in rats**

32 mature male Sprague-Dawley rats. rated between 150 and 200 g (50 days old) for diabetes injection\textsuperscript{17}. Rats were injected with alloxan 60 mg/kg body weight in the marginal vein of the ear\textsuperscript{18}.

**Design of Experimental**

The rats were accordingly divided into 4 groups were fed on each group = 6 rats: Group 1(C): Positive control, Received orally 5 ml normal saline (0.9% NaCl) daily. Group 2 (D): Negative control, Diabetes rats only, received single-dose alloxan 60 mg/kg body weight. Group 3(K): Diabetes rats, received cinnamon orally 35 mg/kg body weight dissolved in 2 ml normal. Group 4(I): Diabetes rats, was given 2 I.U/ animal of insulin subcutaneously daily.

**Collection of Blood Samples:**

Blood samples were taken weekly from the insertion site, and the blood was placed in test tubes the following week. At 3,000 revolutions per minute, the blood was
centrifuged to break up the clots. Before the serum being stored at 20 degrees Celsius, the extract was extracted and bottled before freezing. Testers collected a sample after there had been no change in glucose and other chemical components after two days without changing anything.

**Determination of Malondialdehyde (MDA) concentration:**

Thiobarbituric acid (TBA) coupled with lipid peroxidation (MDA). The blood was centrifuged at 3,500g for 30 minutes, with the red cells removed (New). The RBCs were cooled to the homogenization buffer (pH 7.4, 1 M), and FCCl (1.7% w/v) was added. A lot of the supernatant centrifugate (10% homogenate) was taken out of the final homogenate (100-fold) volume. Xo.5 ml of 30% TCA and 0.2% TBA were then poured into it. The tubes were submerged in water in an agitated for 30 minutes at 80 degrees Incubation was carried out in ice-cold water for ten minutes. These were then separated by centrifugation at SOQ in fifteen minutes. The supernatant’s absorbance was found to be 540 nanometers. The test results of the MDA concentration were obtained using the standard calibration curve of tetrapropylene. Protein was estimated by the method of extraction and partial hydrolysis.

**Determination of total Glutathione (GSH) activity**

The estimated GSH content was calculated using the method.

**Realtime-polymerase chain reaction**

per the manufacturer’s directions (Qiagen, Courtaboeuf, France). Total RNA was extracted from the gel and eluted with a 35-fold greater amount of RNase-free water than RNase. Residual genomic DNA was incubated with 15 units of the DNase I-free MgCl with 90 °C for 10 minutes to in 2 mM of magnesium chloride (MgCl) to inactivate the DNase I. 20 µl of the DNase-treated RNA solution containing 50 mM Tris-HCl (pH 8.3), 10 mM dithi0.5 mg of blood protein concentrate, 3 mM Mg acetylated deoxyNTP, 30 units of Moloney Murine-MLV RTase free RNA, 200 units of M-MLV reverse transcriptase (Promega, Madison, WI), and 3 U of RNase-free RNase H. It was difficult to normalize the reverse transcription to equalize total RNA in both the beginning and the results. For 10 minutes at 26 °C, then for 45 minutes at 42 °C, followed by 3 minutes at 90 °C, and then left to cool to return to room temperature. To inactivate the reverse transcriptase, an additional 300 units of the enzyme were incubated at 42°C for 45 minutes, after which it was shifted to 75° for the required time required to complete the process. DNA controls for the RT procedure and negative controls were run in parallel samples. The cDNA samples were stored at a temperature of -80 degrees Celsius. Using all the same cDNA samples throughout the study allowed the researchers to gain complete confidence in their results. Primers for ratInsulin-1were forward (fw), 5’-TCAGCAAGCAGGTCAATGCC-3’, and reverse (rv), 5’-GGTGCAGCCTGATCCACAATG-3’. PCR conditions were 35 cycles of initial denaturation y’’’C for 5rain,95°Cfor45s,60°Cfor 30 s,72°Cfor 1 min, and, finally, 72°C for 5 min; viability of the RT ;>rr;duci was controlled by a separate PCR withprimers specific for the housekeeping mRNA (GAPDH) (fw: 5’- TGAACGGATTTGGCCGTATTGGGC3’;rv:5’- TCTCCTGGGTGGCAGTGGCATGCGAT-3’). conditioning for 3 min, then 25 cycles of denaturation, annealing at 95° for 45 seconds, 60° for 45 seconds,
and annealing for 1 minute at 72°C, the PCR was used to prove a theory. At 72°C, and, followed by 5 minutes, then 102°C Using 1.5% agarose gel, the electrophoresisilatated PCR products were run through it Real-standardized PCR performed with the Quantiect Green PCR (Qiagen) involved the use of Opticon-2 PCR machine (MSKIN965), with plain white 965 on the controls (MJ Research). The appropriate annealing temperatures for each primer type were also established by using PCR gradients.

The Statistical Analyses

The study was conducted with a one-wise robust analysis of covariance (1-way) except for the Malondialdehyde “S” test. We used the program for statistical analysis. Thus, the results of the data were presented as X ± two standard deviations. seems to perform the least significant differences (group ANOVA, LSD) (2016).

Results

Bodyweight gain

On the third day, results of daily weight clarification revealed significant differences (P<0.05) between the diabetic and normal control groups, but the differences disappeared with time. In contrast, the statistical comparison revealed that there were no significant overall differences in the three groups of diabetics’.as in (fig.1).

![Graph showing bodyweight gain](image)

Fig.1: The action of cinnamon (CinnamomumZeylanicum, Breyne) on Bodyweight gain in alloxan—induced mature male rats with diabetics. The mean values are ±S.D. (p < 0.05) .
Blood glucose

On The Fifth day, glucose in the diabetic rats has been checked for relevance. The research found that male rats given cinnamon and treated with insulin fared best. However, the normal levels of blood glucose in the control rats is higher than that in the experimentally treated rats. It was shown on the other hand that rats fed cinnamon syrup only had significant ($p<0.05$) glucose levels in their blood but those fed regular feed didn’t show any significant difference as in (fig.2).

![Graph showing blood glucose concentration](image)

**Fig.2:** The action of cinnamon (*Cinnamomum Zeylanicum, Breyne*) on blood glucose concentration in alloxan — induced mature male rats with diabetics. The mean values are $\pm S.D.$ ($p < 0.05$).

**Fig.3:** The action of cinnamon (*Cinnamomum Zeylanicum, Breyne*) on Glutathione (GSH) in alloxan — induced mature male rats with diabetics. The mean values are $\pm S.D.$ ($p < 0.05$).
Anti-oxidant activity

The results of this study have shown that oxidative stress induces alloxan-induced diabetes, which led to parallel increases in antioxidant enzymes in rats. These effects were observed both during the experiment and with control rats as in (fig.3)(fig.4).

Gene expression analysis:

Table 2 outlines the results of the InsI expression quantification experiment, which demonstrated significantly elevated levels of InsI expression in the tissue obtained from normal control rats as well as Cinnamon-treated group animals. However, In diabetic groups, and not in normal rats, InsI gene expression was increased, while in the group treated with the cinnamon. Insulin gene expression in pancreatic tissue extracted from cinnamon-treated diabetics was much lower than in standardas TABLE 1.

Discussion

because the acute ketosis increases the lipid peroxidation activity of diabetes, such as atherosclerosis is more quickly found in diabetics\textsuperscript{21}. The change in the number of the fluidity of the lipid membrane as a result of peroxidation affects enzyme activity, and the number of molecules, as well as on the molecules and activity in the membrane-bound enzymes you know, the mind is capable of a lot more than the body Lipids have been linked to heart disease, cancer, and nerve disorders in people who consume them frequently. schizophrenia and coronary heart disease\textsuperscript{22}. insulin stimulates the production of superoxide, which leads to an increase in reactive oxygen species, which in turn causes an increase in the oxidative stress of the death pathway in diabetics. Lowered levels of malondialdehyde and increased levels of MDA appear to be consistent with the claim. The overall administration of Cinnamon was odd, to say the least. Since we’ve cut back on the grain and the MDA, our system is out of balance. This denotes an increase in the level of oxidation of Cinnamon will experience\textsuperscript{23}. This may be due to the medication given to patients who are insulin-dependent Brewer’s warning: Pay attention to foods that enhance inflammation, as well as disease, because Cinnamon is an excellent source of disease-promoting foods\textsuperscript{24}. Enroflavassing French cheeses result in causes phagocytoblastisisis. This interesting and exciting finding was that the effectiveness increased at higher concentrations of H2O2, or peroxide levels in the presence of catalase and citrate, no substantial increase in oxidation was observed in the solution. diabetic rats exhibited significantly higher M concentrations than those who received insulin or grains to keep their sugar levels constant\textsuperscript{25}. I should have considered whether or get out of this line of work, that questions whether I should continue with my profession above the capability to neutralize free radicals had the same adverse effect on the enzymatic activity as free radicals. Reduced glutathione is needed to keep normal glutathione levels Consider this: As long as you make your album available, we’ll have you onstage at the VIP Lounge for the next five minutes (free stage time)\textsuperscript{26}. Whatever you are doing, your body takes a bit of a beating. Regardless of whether you’re sitting or moving, you experience some strain on your muscles or not\textsuperscript{27}. Some flavonoids are capable of the initiation stage interfering with free radical metabolism because of the presence of the peroxides and inhibiting the microsomal enzyme system There is another reason\textsuperscript{28}. They can scavenge other lipophilic substances They use their radicals or chelates to delay the Fenton reaction. In the experiment described here, we found that the efficacy of the INS I primer was first observed in this way. These have respective solution concentrations of InsI and GapdH at. primer efficiency was under 5% When we need real copy number It is the expression level of target genes of treatment samples as compared to control samples that is important to identify treatments\textsuperscript{29}. make decisions based on incomplete information. Thus, in this study, we used the InsI primers since their effectiveness was discovered to be at a concentration of (Livak and Schmittgen) a watched (began to watch) just as intently as (began to pay attention to) she paid attention (attended just as much too) as lack of insulin production and any deviations from normal insulin secretion are essential to almost all cases of adult-onset diabetes Also known as insulin-dependent or non-insulin diabetes, respectively a case of Type 2 diabetics, who have developed a specific version of the disease before and therefore do not have the proper antibodies, show up as incipient early signs of the more common forms of diabetes (MODY)\textsuperscript{30}. insulin has such a crucial effect on the body’s overall regulation of sugar levels, hyperglycemia can occur if there is even a small glucose imbalance in the diet. As both types of diabetes are caused by problems with the insulin gene, this form of diabetes has always been viewed as a possible, as well. Here, the researchers took special care to determine the temporal pattern of insulin gene initiation and expression (InsI) In mature male rats, the InsI gene expression was about 6 times that of females. The reduction in insulin sensitivity in the K group was while that in the D group was lower, and there were significantly higher blood glucose levels in the K group animals. In contrast, there was 4.3-fold more Ins I upregulated in the Cinnamon-treated diabetic
rats 35 percent of the control group were heterozygous and three percent of the experimental group were mutant for that trait. We also obtained quantitative data of InsI genes, to a small extent increase in the serum level of glucose and decrease in the level of insulin The findings in this study provide compelling evidence that Cinnamon treatment is effective. Whole-grain helps to regenerate beta-cell tissues especially in islands of the pancreas. As a result, it’s likely that Langer’s use of Cinnamon entire elements. This family was named the INS I after cDNA was extracted from a rat pancreas in the early 1990s. These have mostly been studied in terms of regeneration and growth, including the endocrine and exocrine pancreas. According to the same facts, these cells have an important role in beta-cell regeneration, i.e. the cell proliferation and hyperplasia in tandem with the rise in Ins expression. It is currently believed that FUS, MIP, and INS ITP1 (more specifically, the INS, MIP, and INS1) are the main insulin biosynthetic genes present in the FHA tissue, based on literature research conducted in the past few years. Thus, it was demonstrated that whole grain Cinnamon components could lower blood glucose levels by inducing proliferation of p-related cells. Consequent to which, in terms of Insulin-like mRNA expression, the current results are in agreement with) our previous research findings. Cinnamon flour canines enhances glucose regulation and raises the aminotrigin levels in Diabetic rats you should pay attention to them as they’re gnawing at the roots of the plant that grow higher as time goes on The results thus prove, since 2007, established in a study that Cinnamon -containing foods promote weight loss.” With the addition of whole grain, the glycemic and insiemic response to food was greatly reduced, but not to drink treatments. compared to non-treated subjects.

**Conclusion**

Concluded that cinnamon helps, as an anti-hypoglycemic and anti-oxidant in model rats given sufficient evidence of their own being diabetic. Elevating the expression of InsI gene expression levels also assists in the biosynthesis of insulin-secreting capacity in pancreatic β-cells. Additional studies are needed to ascertain the uses of cinnamon and its various components in disease states of compromised or stressful health.

The Role Sonographic Imaging Features in the Prediction of Necrotizing Enterocolitis Outcomes in Neonatal Patients

Hayder Neamah Hassan
Research Scholar, Faculty of Medicine, University of Kufa, Iraq

Abstract
Necrotizing enterocolitis (NEC) is a devastating inflammatory disease of the intestinal tract that represents a significant source of morbidity and mortality in preterm infants. The objective of the current study is to find out the correlation between sonographic imaging features and the outcomes of necrotizing enterocolitis in children, and their role as a predictive tool for the consequences resulted from necrotizing enterocolitis. Thirty two children (patients) have been included in this study, patients were divided into three groups according to the follow up outcomes: those that been recovered (Group I), those that needed surgery (Group II), and those that died (Group III). The study was achieved at Al-Zahra Teaching Hospital in Al-Najaf City, in Iraq, during the period between December 2020 to March 2021. The results showed that there is a significant difference (P value <0.05) among the three groups in terms of the following items: fluid-filled dilated bowel loop, decreased peristaltic movement, focal fluid collection, portal gas. The study concluded that the presence of Fluid-filled dilated bowel loop, peristaltic movement, local fluid collection, portal gas can be considered as predictive tool for the poor outcomes of necrotizing enterocolitis.

Keywords: Necrotizing Enterocolitis, Portal Gas, Focal Fluid, Prediction

Introduction
Necrotizing enterocolitis (NEC) is considered a crucial reason of neonatal deaths specially in pre-term infant. It was recorded that about 5.0% to 14.0% of infant patients with weights below than 1500 grams at birth may have (NEC) and approximately 25.0% to 40.0% may die due to this condition, and because of impaired neurodevelopment, such as high risk of cerebral palsy, visual cognition, and impairment psychomotor functions. The diagnosis and treatment of NEC are very important for good outcomes because of the rapid progression of the disease into intestine perforation, shock and inflammation of peritoneum. The majority of premature neonates need long-term hospitalization because of deteriorating factors such as decreased gestational age and low weight birth (BW). Necrotizing enterocolitis is considered the main cause of death because of gastro-intestinal disease in pre-term neonatal individuals, which affected 5.0–12.0% of neonatal patients with a very low BW (below 1500 grams)

The pathophysiology necrotizing enterocolitis is usually considered to be controlled by many factors, important risk factors include decreased gestational age at delivery, decreased birth weight, chorio-amnionitis. Researches about the pathophysiology of necrotizing enterocolitis have further revealed many causative factors such as genetic disorders, intestine immaturity, alterations in micro-vascular tone, and pathologic microbial infections. In spite of there are no data have discovered an obvious genetic pattern correlated strongly with necrotizing enterocolitis.

There are many studies that investigated the importance of sonographic imaging in the diagnosis and prediction of necrotizing enterocolitis outcomes.
researches have investigated the abdomino-sonography (AUS) as an accessory measurement in management of infant patients with necrotizing enterocolitis. Abdominal sonography can enable the accurate evaluation of the thickness and conditions of the intestinal wall on gray-scale images, peristaltic movement on real time images and intestinal wall perfusion. In addition, the abdominal sonography similar can enable assessment of the status of the cavity of the peritoneum for free fluids and focal-fluid collection, in addition to free gas\(^5\).

Neonatal patients who recover after medical or surgical management for necrotizing enterocolitis are high risk for prolonged GI and neuro-developmental consequences. Surgical therapies of necrotizing enterocolitis include re-section of ischaemic intestinal portions; the consequences of these neonates depend on the length of rest portions of intestine and its capability to absorb digested food efficiently. Typically, re-section of ileum might result in Gastrointestinal dysmotility, abnormal mucosal membrane, bacterial opportunistic growth, and deficiency of vitamin B12, resulting in mal-absorption of digested food\(^6\).

The objective of the current study is to find out the correlation between sonographic imaging features and the outcomes of necrotizing enterocolitis in children, and their role as a predictive tool for the consequences resulted from necrotizing enterocolitis.

### Methods

Thirty-two neonates (patients) with NEC have been included in this study, patients were divided into three groups according to the follow up outcomes: those that been recovered (Group I), those that needed surgery (Group II), and those that died (Group III). The study was achieved at Al-Zahra Teaching Hospital in Al-Najaf City, in Iraq, during the period between February 2020 to March 2021. The following data have been collected: ((Age, Gestational Age, Birth Weight, Pneumoperitoneum, Fluid-filled dilated bowel loop, Free peritoneal fluid, Decreased Peristaltic movement, Bowel perfusion, Focal fluid collection, Portal Gas, Bowel wall thickness)). Statistical analysis was done by SPSS program (version 25) including both descriptive (frequency and percentage) and inferential statistics (Chi Square).

### Results

Table (1) is General characteristics and differences between Group I (recovered), Groups II (need surgery) and Group III (died). This table shows that there is a significant difference (P value <0.05) among the three groups in terms of the following items: Fluid-filled dilated bowel loop, decreased Peristaltic movement, Local fluid collection, Portal Gas.

**Discussion**

The first indicator included in this study was focal fluid collections (table 1.), which were found in (50%) of those patients who died, indicating that these are significant sonographic findings for predicting a bad outcome. This is expected, because these findings are a direct complication of intestinal perforation. It was reported there was a high correlation between the sonographic findings of free intra-peritoneal gas or focal fluid collection and neonate demise or requirement for surgical therapy. This aids the interpretation that focal fluid collections are predictive of intestinal perforation.

Our Study showed that only one patient with a focal fluid collection recovered after medical therapy, while one other patient needs surgery for treatment.

The another factor that may have contribution to poor outcome is decreased bowel wall perfusion, resulting in the occurrence of echoic peritoneal fluid and the occurrence of free gas and focal fluid collections in those neonates who may have directly bowel perforation but have no prove for free gas on sonographic imaging which is also crucial for identifying which neonate may have necrosis in bowel before perforation, as these neonates may also have a bad outcome.

Necrotizing enterocolitis is considered as an ischaemic process of the intestine that results in necrosis and inflammation, including the progression of intra-mural gas. As necrosis develops, the mucosa, sub-mucosa and muscularis layers can slough, making very thin wall. The most intensively affected loops of intestine may perforate, and this is correlated with a high mortality. Detection of bowel necrosis by sonographic imaging before perforation may strongly affect surgical intervention and permit the surgical staff to manage those neonates with necrosis before the formation of free gases.

One of the sonographic imaging feature that was observed to make bad outcomes in neonates. Prediction of a bad outcome of NEC may result from the following sonographic imaging: Fluid-filled dilated...
bowel, Focal fluid collection, echogenic free-fluid, high intestinal wall echogenicity and high intestinal wall thickness.(11).

The portal venous gas (PVG) observed by X-ray or sonographic imaging is also considered as a typical diagnostic feature of confirmed necrotizing enterocolitis. Some data reported that PVG can be a predictive diagnosis for the onset of NEC, which was first identified by Yue et al., who discovered the occurrence of portal gas before the onset of NEC(12).

**Conclusion**

The study concluded that the presence of Fluid-filled dilated bowel loop, decreased peristaltic movement, local fluid collection, portal gas can be considered as predictive tool for the poor outcomes of Necrotizing enterocolitis.

Handwriting Change in Breast Cancer Patients

Heba H Rohym¹, Ghada Mustafa Al-Galad², Noha Abdel Rahim Mohamad³, Mohamed Ragab Teleb⁴
¹Lecturer, ²Professor and Head Department, Forensic Medicine and Clinical Toxicology, Fayoum University, Egypt, ³Fraud and Counterfeiting Officer Forensic Medicine Department - Ministry of Justice, Egypt, ⁴Demonstrator Department of Forensic Medicine and Clinical Toxicology, Fayoum University, Egypt

Abstract

Background: Breast cancer is the most common cancer. In the course of cancer progression, there are specific neuromuscular disturbances that directly affect coordination. Handwriting is regarded as a vital constituent when it comes to the tracing of neuromuscular coordination. The Study aimed to study handwriting analysis in female cancer breast patients trying to find simple useful, non-invasive way help in early detection and diagnosis and follow up of those patients

Methods: The study included 160 participants. The study participants were asked to write the same text (two Arabic sentences and her name in Arabic language) and draw lines in another paper, and then all handwriting samples were scanned and examined.

Results: Breast cancer patients age ranged from 30 – 76 years old with a mean ± SD of 50.3 ± 10.5. Patients according to Educational level parameter were 5 groups; Illiteracy eradication program, primary, middle, secondary, graduation and post gradates were 14 (8.75 %), 10 (8.75 %), 16 (10 %), (80) 50 %, 40 (25 %) respectively.

By analysis of handwriting samples: Tremor, wide spaces between words, heavy writing pressure, slop or slant of writing upward slant or down slant and heaviness of Initial and terminal strokes were observed.

After re-observation of pervious Handwriting changes and make a relation between these changes and cancer stages and lines of treatment which received, it was noticed that these changes were in samples of patient received multiple lines of treatment, in patients with metastasis or has another associated tumor as ovarian, bladder cancers or lymphoma.

Conclusion: There is no evidence of significant handwriting Changes in breast cancer samples unless patient received multiple lines of treatment, in patients with metastasis or has another associated tumor as ovarian, bladder cancers or lymphoma.

Keywords: handwriting analysis, cancer breast patients, writing traits

Introduction

Handwriting analysis is the window to the soul. It may be true that it can help to know a lot about someone’s personality from his handwriting. It’s been said that this science can be used to diagnose mental illness (6). Handwriting is a complex act, resulting from a combination of coordinated actions between the eye, brain, and muscles of the arm, hand, and fingers; a complex perceptual-motor task or a neuromuscular task (9).

Some researches named handwriting as” brain writing”. Experiments included having writers perform with their opposite hand, foot and even mouth, which established conclusive similarities indicating that writing, was centrally organized, the role of the writing central in brain is that it is responsible for the mental
image of writing. An example of this is when dictating a phrase that everyone writes according to its mental image of it in the brain. It also gives orders to the hand as a writing tool and thus implements the mental image in the brain. Therefore writing is brain write and the hand is just enforcer\(^5\). The main uses of handwriting and graphology include behavior analysis, forensic evidence and disease analysis. Script reveals the exact personality including emotional status, fears, defenses, honesty and much other individual personality attribute of a person through the strokes and patterns revealed by script\(^7\).

The authenticity of a person’s signature or script in the suicide note is frequently subjected to forensic document examination during investigation in order to verify authorship\(^2,10\).

Breast cancer creates from breast tissue. Signs of breast cancer may incorporate a knot within the breast; alter in breast shape, dimpling of the skin, liquid coming from the areola, a newly-inverted areola, or a ruddy or flaky fix of skin. there may be bone torment, swollen lymph hubs, shortness of breath, or yellow skin\(^13\).

The most common device that specialists utilize to portray the arrange is the TNM framework. Tumor (T)Node (N): the tumor spread to the lymph hubs, In the event that so, where, what measure, and how numerous? Metastasis (M) the cancer spread to other parts of the body. There are 5 stages of breast cancer: organize (zero), which is non-invasive ductal carcinoma in situ (DCIS), and stages I through IV (1 through 4), which are utilized for obtrusive breast cancer. The organize gives a common way of depicting the cancer, so specialists can work together to arrange the most excellent medicines\(^14\).

Early breast cancer detection is very important; helping early proper treatment and decreasing death rate due to cancer breast, and this can be performed through regular self-exam of the breast, regular physical examination and investigation including breast mammography, Contrast-enhanced (CE) digital mammography, Ultrasound, Magnetic resonance imaging (MRI). Each of these screening tools has strengths and weakness\(^13\).

In the medical field, handwriting can be used as an aid in diagnosis and following of diseases like Alzheimer’s disease, Parkinson’s disease, and even cancer as in Kanfer neuromuscular Test’s in cancer patients\(^12\).

Handwriting changes in case of cancers occur in case of metastasis, treatment by chemotherapy, sever pain, psychological disturbance or pressure of cancer on nerves or any condition affect nervous system in cancer patient. If cancer patient has these conditions, handwriting changes appear which help in early detections of cancer and follow up the patient\(^3\).

Handwriting changes as tremors which indicated by an involuntary, rhythmic, and recurrent movement of the pen from side to side. These tremulous strokes are instant changes from the desired direction of the pen lines and are attributed to nervous impulses affecting the muscles indicating loss of control of the pen. There are many different reasons that tremor occurs in handwriting including aging, illness\(^11\).

Pressure refers to the hand’s grasp on the writing instrument, and the amount of pressure used to push the pen across the paper. It varies for different writers from light to heavy\(^3,11\). Slant or slope refers to the direction in which the writing leans. It may in the right or in the left, or it may be vertical, when a writer in disease, there are change the slant, but not in all cases\(^3\).

Materials and Methods

Study design

This study started from September 2019 to September 2020 in forensic medicine and clinical toxicology department-faculty of medicine, aiming to studying handwriting analysis in female cancer breast patients trying to find simple useful, non-invasive way help in early detection and diagnosis and follow up of those patients.
Subjects

The local ethical committee approval was obtained before starting of the study. The aim and benefits of the study were discussed with participants before collection of handwriting samples. And a written consent for participation of the study was taken, and confidentiality of all data was ensured to all participants.

160 Participants of our study are 120 breast cancer patients and 40 breast cancer with other types cancer patients (lymphoma, bladder cancer and ovarian cancer) attending to different Fayoum hospitals

Prior to inclusion, personal and medical history was taken from each patient including age, Educational level, job, number of siblings, her age at first pregnancy, family history for cancer and treatment she received. At the time of testing all patients had stabilized general condition, adult age with at least primary educational level.

We excluded males patients and any patient with disease affecting handwriting i.e. hemodialysis patients, any neurological disease that affect hand movement as parkinsonism, CNS tumors, Thyroid disease including hyperthyroidism and thyroid tumors, Hepatic patients, Illiterate patients and Alcohol abstinence

Materials:

White papers (A4 60 gm), Floscape papers (70 gm), Finegrip s Blue Pen (0.7 mm), Laptop, Scanner (Hp PSC 1410), Digital camera with high resolution, Compact video microscope 2000 (CMV 2000), Leica microscope MRZ 420, Stereoscopic binocular microscope, Hand magnifiers.

Methods

Each patient was asked to write the same text (two Arabic sentences and her name in Arabic language, three times on two separate sheets of paper (one blank and one lined sheets - Floscape paper) and draw lines in another paper according to model they given in the same session. Subjects were asked to write on the blank sheets first then on the lined one, using similar blue pens (0.7 mm).

All samples of handwriting were obtained in the daylight, then the samples of handwriting of each participant (3 sheets of paper) were kept a in a file that was given a serial number from 1 to 160.

Patients were asked to bring a pervious handwriting sample before becoming diseased or receiving any treatment i.e. old signature, to be compared with handwriting samples after becoming diseased or receive treatment

All samples were scanned using Scanner machine (Hp PSC 1410) and their digital images were collected and collaged to gather by photo collage maker- photo editor & photo collage (a computer graphics application (version 1.28.92) which enables combination and editing of multiple samples. All samples (original and scanned versions) were examined; letter by letter, by experts of handwriting in Ministry of Justice-Egypt using hand magnifiers, Compact video microscope 2000 (CMV 2000), Leica microscope MRZ 420, Stereoscopic binocular microscope (giving 3D magnification) Every mark on the script or unusual movement in the trace was noted during the analysis and recorded individually for each participant.

Various writing traits were analyzed including writing speed, pen pressure grades, spacing between words, initial and terminal strokes, slop/slant and tremors

Statistical Analysis

The collected data were organized, tabulated and statistically analyzed using SPSS software statistical computer package version 22 (SPSS Inc, USA). For quantitative data, the mean, standard deviation (SD) and Range were calculated.

Results

According to age; Patient age ranged from 30 – 76 years old with a mean ± SD of 50.3 ± 10.5, as shown in table (1) The studied patients were 4 categories: age (30-40), (40-50), (50-60), above 60 years group.
34 (21.25 %), 50(31.25%), 48 (30 %) and 28(17.5 %) respectively as in Table (2). shows most cases between 40-60 years 98 (61.25%), less in age 30-40 years 34 (21.25%). Patients according to Educational level parameter were 5 groups; Illiteracy eradication program, primary ,middle, secondary, graduation and post gradates with Percentage 14 (8.75 %) , 10 (8.75 %) ,16(10 %),(80) 50 %,40 (25 %) respectively Breast cancer patients educational level, secondary level predominate other level; 50 % of all studied samples. as shown in table (3) Table (4) showed that according to cancer stage, our samples were three groups : group 1 (stage 0,1,2 TNM staging system) group 2 ( stage 3, 4 TNM) group 3 (breast cancer with lymphoma, bladder cancer and ovarian cancer) 80 (50 %), 40(25 %)40 (25 %) respectively. According to line of treatment used with cancer patients included in our study, our sample were grouped into seven group: group 1 (received no treatment), group 2 (underwent breast surgery) , group 3 (received chemotherapy), group 4 (received hormonal therapy), group 5 (underwent breast surgery and received chemotherapy), group 6 (underwent breast surgery and received radiotherapy) group 7 (underwent breast surgery, received chemotherapy, radiotherapy and hormonal therapy) 48 (30%), 32 (20 %), 12 (7.5 %), 4(2.5 %) , 32 (20 %) ,4(2.5 %), 28 (17.5 %) respectively many cases were early detected and haven’t received treatment yet as shown in table (5). By analysis of handwriting samples: Tremor was observed in 20 out of 160 writing samples(12.5%), which showed variations in the form of slight changes in writing impulses up to marked deteriorations to the level of illegibility. Few samples 14 of 160 writing samples(8.75%) showed wide spaces between words. 26of 160 writing samples(16.25 %) showed heavy writing pressure. It was observed that 8 samples(5 %) showed slop or slant of writing upward slant or down slant. By observation of the beginning and end of the word, 14 samples(8.75%)showed heaviness of Initial and terminal strokes. After re-observation of pervious changes and make a relation between these changes and age, cancer stages and lines of treatment which received, it was noticed that these changes were in samples of patient received multiple lines of treatment, in patients with metastasis or has another associated tumor as ovarian, bladder cancers or lymphoma (5 cases had breast cancer with ovarian cancers – 15 cases had breast cancer with bladder cancer – 20 cases have lymphoma).

**Discussion**

In Egypt; breast cancer occupied the second rank among different cancers (1).

Breast cancer is typically detected either during screening, before symptoms have developed, or after a woman notices a lump. Most masses seen on a mammogram and most breast lumps turn out to be benign (not cancerous). When cancer is suspected, tissue for microscopic analysis is usually obtained from a needle biopsy (fine-needle or larger core-needle) and less often from a surgical biopsy. Selection of the type of biopsy is based on multiple factors, including the size and location of the mass, as well as patient factors and preferences and resources (4).

Handwriting is fingerprint of the mind; therefore handwriting analysis can serve as x-ray of individual physical state. Handwriting analysis needs to be informed of any factors that could influence the handwriting being examined. The principle factors considered include age, health, substance abuse, and mechanical factors. Health factors include physical and mental health and any medication that may affect handwriting. Mechanical features cover the writing surface, writing instrument, and lighting. The writing position may also affect the writing act (11).

Changing your handwriting means changing life, in addition, what we write is controlled by the conscious mind, but how we write is controlled with sub-conscious mind. Cancer -or tumor- makes pressure on neurons that affects motor nervous system, controller of handwriting, which causes some dramatic changes in the patient’s handwriting. Hence, we worked on early detection of cancer through handwriting (1).

A typical criteria of normal hand writing that is a mature neuromuscular condition with a normal range of coordination. Normal handwriting is manifested in the smooth, continuous flow of movement, both in the descending and ascending strokes (uniform flow of ink throughout the strokes and sharp, continuous delineations to both sides of each stroke) In case of cancer as lymphoma: The strokes have an oval shape; the turns from descending to ascending strokes are narrow, curved, and show continuity of movement throughout. A regular pattern of heavier (wider and darker) descending strokes and lighter ascending strokes (9).

In our study, most distribution of age categories among the studied patients were 4 groups age, (30-40),(40-50),(50-60),above 60 years group 21.25 %,31.25 %,30 %,17.5 % respectively.

In this study; we noticed decrease in incidence rates

Most cases between 40-60years ; This agree with national cancer institute (NCI) and center of disease control (CDC) and prevention that most breast cancers are found in women are 50 years old or older (8).
in patients above 60 years, this agrees with American Cancer Society Surveillance Research 2019 (4).

In this study, Breast cancer patients according to Educational level parameter; Illiteracy eradication program, primary, middle, secondary, graduation and postgraduates with the Percentage 8.75%, 8.75%, 10%, 50%, 25% respectively. Breast cancer patients educational level, secondary level predominate other level; 50% of all studied samples. Most cases are from high level of education (secondary schools and graduates) may be due to patient awareness about the disease and doing self-examination and early asking of medical advice; in contrast of lack of disease awareness and delayed seeking medical advice in less educational level as in Illiteracy eradication program and primary school level this agrees with American Cancer Society Surveillance Research 2019 (4).

In our study; it is noticed that some writing samples showed changes as tremors, wide space between words, upwards and downwards slop and heavy pen pressure but all these changes were in patients of treated with multiple lines of treatment or cases associated with other cancers as lymphoma, ovarian and bladder cancer or metastasis.

**Conclusion**

By general observation and analysis of samples of handwriting from breast cancer patients, there is no evidence of significant difference between breast cancer samples and normal human standards ratio and no common characters in a breast cancer samples (no tremors in stroke, no unusual configurations).

**Recommendations**

- Establish clinical-radiological and graph logical coloration of cancer patient.
- Analysis of handwriting changes in others types of cancers i.e. hepatic cancer – brain tumors.
- Analysis of handwriting changes in Diabetes mellitus.
- Analysis of handwriting changes in thyroid diseases

Extraction and High Purification of Nicotine from Iraqi Tobacco Leaf Formanufacturing, Pharmaceutical, and Medicinal Uses

Husam Alaa Hameed Al-Khinuliu¹, Essam Fadel Al-wan Al-Jumaili²

¹Final Year Post Graduate Student, ²Professor, Biotechnology Dept. Genetic Engineering and Biotechnology Institute for Postgraduate Studies. University of Baghdad.Al-Jadriya Campus, 10071 Baghdad, Iraq

Abstract

Background: Nicotine is highly addictive plant derived alkaloid and the most important species in human use today is Nicotianatabacum. There are direct health effects of chronic nicotine exposure. Even in low doses, nicotine causes vasoconstriction and other cardiovascular effects related to catecholamine release and promote angiogenesis, neuroteratogenicity, and possibly some cancers. Methods: A preliminary investigation to analyze the nicotine contained in Iraqi tobacco leaves was carried out using gas chromatography-mass spectrometry (GC-MS). Nicotine is an alkaloid, and alkali methanol and Lipophilic solventsystem methods (LSS) have been extracted and determined by GC-MS from tobacco leaves. Results: The detection limit for nicotine was for non-selective monitoring at the ppm level and for selective detection at the nanogram level. This is a simple method of thin layer chromatography (TLC) and chromatography mass spectrometry (GC-MS) for the tobacco leave analysis of nicotine. The final purity of nicotine is 99%. Conclusion: the methods which used in this study gave very high purity of nicotine after converting the crude nicotine to its esters.

Key words: Nicotine, Iraqi tobacco, Lipophilic solvent, TLC, GC-MS chromatography.

Introduction

Nicotine is the predominant alkaloid in Tobacco plant (Nicotiana tabacum) represent above 90% from total alkaloid. In the recent decade there are increasingly demanded on it for industrial uses as one of the most important component in E-cigarette flavors and nicotine gum. In the pharmaceutical and medicinal fields using as a curative agent against some of psychotic disorders such as Schizophrenia, degenerative disease such Alzheimer. The aqueous two-phase system and solvent reverse extraction by using isopropyl alcohol/(NH₄)₂SO₄. The recovery rate of nicotine was 96.1% with a purity of above 99% when optimal conditions were used [(NH₄)₂SO₄ 25%, pH 9, temperature 35°C, isopropyl alcohol 5 mL]. Marked solubility differences of nicotine in the ionic liquids [C(2)mim][NTf(2)], [C(2)mim][EtOSO(3)], and [C(n)mim]Cl, 6 ≤ n ≤ 10, are observed through the analysis of the corresponding phase diagrams. These show the potential of commonly used ionic liquids to extract and purify this important compound. From a fundamental standpoint, the generally enhanced solubility of nicotine in these ionic liquids as compared to that of aromatic and aliphatic hydrocarbons can be assigned to the presence of the aromatic pyridine ring and the large aliphatic N-methyl-
The molecular genetics of tobacco alkaloids have not only provided plant biologists with insights into the mechanisms underlying the synthesis and accumulation of this important class of plant alkaloids, they have also yielded tools and strategies for modifying the tobacco alkaloid composition in a manner that can result in changing the levels of nicotine within the leaf, or reducing the levels of a potent carcinogenic tobacco-specific nitrosamine (TSNA). The chemical components of nicotine got the general formula C_{10}H_{14}N_{2} with molecular weight 162 Daltons, and the regular name pyridine 3-(1-methyl-2-pyrrolidinyl), maximum absorption in 254nM, its heterocyclic alkaloids have different tow rings (pyridine) and (pyrrolidine) the two nitrogen in pyridine and pyrrolidine rings capable of being ionized :N-pyridine pKa =3.4, N-methylpyrrolidine pKa =8.1. So, the behavior of nicotine is pH dependence, the entire nicotine soluble in lipophilic solvent in pH above 9 and not soluble in hydrophilic solvent, in pH =2 or less its miscible in the water at 25°C or less.Dalton et al.,[10] found that most regarded of nicotine derivatives is its esters that have many uses because it have less harsh test in mouth or burning feel on skin and in I.V injection. Physically nicotine is the oily liquid, colorless or pale yellow solution, turn to brown when exposure to air or light, fish-like odor when warm with density =1.000925 at 25°C and Boiling point (B.P) = 247°C at atmosphere pressure. The aim of this study is to purify the nicotine in high grade and prepare the salt of nicotine that used in industrial, pharmaceutical and medicinal fields.

**Materials and Methods**

The Iraqi tobacco leafs is purchased from local market, dried in the oven on 40°C for 60 min, crushed by electric grinder to fine powder. The powder (500gm) potted into closable glass container, add 500ml of D.W thin NaOH crystals was added till reached the pH to 13.35, heated in water bath to 80°C for 20 min, cooled to 50°C, add ethanol 99% 4:1 ethanol: mixture reheated to 60°C for 120 min let to cool to the 25°C, added chloroform in ratio 1:4, adjusted the pH to 1.0 by H_{2}SO_{4} 0.5 M, stirred for 60 min at 25°C, tow layer are preform, keep the mixture in [-5°C] overnight, separate by separation funnel took the ethanol layer and rewashed again by 1:4 by chloroform under same conditions, took the ethanol layer and adjusted the pH to 13.35 by NaOH solution 0.5 M added chloroform solvent in 1:4 ratio and stirred the mixture 60 min at 60°C in closed container thin separated, discarded the ethanol layer and took the chloroform layer rewashed by ethanol 75% pH 8.5 under the same conditions, took chloroform layer and evaporate the solvent by rotary evaporator. The pale yellow liquid obtained turn to brown yellow very thick slurry after exposure to air, this substance called crude nicotine.

Preparation of nicotine esters (Nicotine bitartarate salt): To prepare nicotine bitartarate mix approximately 1:3 mol/mol crude nicotine: tartaric acid. where: Molecular weight of nicotine is 162.23g/mol, so 8.1g =0.05 mol. Molecular weight of tartaric acid is 150.087 g/mol. so 7.505g= 0.5 mol.

Dissolved 7.505 g ×3=22.51g of tartaric acid in 100 ml cold methanol then added the 8.1g of nicotine and stirred the white crystals was observed the solution was potted in refrigerator at 4°C overnight, collected the crystals by filter paper, washed the crystals by 50 ml methanol then 50 ml chloroform, this crystals represent nicotine bitartarate. Recovered nicotine from nicotine bitartarate with some modification. 20g salt dissolved into 100 ml cold methanol then added 0.5 M NaOH till the pH reached to 13.35 heated the mixture to 65 for10 min, added 100 ml of chloroform adjusted the pH to 13.35 and stirred with heat 30 min at 60°C add a drop of distill water until separated the two layers took chloroform layer and dried, the yellow slurry material represent the pure nicotine.

**Results and Discussion**

The final material was examined by several tests first by preliminary screening by Wagner’s and Mayer’s reagent gave the result positive, Second by TLC 20×5 cm plate was used, system solvent was methanol: ammonia 200:3*, dyeing by iodine vapor, the RF=56.8 this result was very near compared to RF =57 (Figure 1)\textsuperscript{13,15}. Third test by using GC-MS test to identifying the identity of
substance on a specimen, the 99% of area mass was obtained to the nicotine component in specimen, this ratio is represent the purity of nicotine.

The solvent system, pH and temperature and time is a critical points in extraction efficiency of nicotine, chloroform - aqueous system have a good extraction ratio because the highest distribution coefficient between the two solvents, nicotine trend to dissolved in aqueous solvent whenever pH 3 or less and temp 25 or less than, vice versa nicotine dissolved in organic solvent at pH above 9 or higher and temp above 25°C. The purity of nicotine rose from 16.43% to 99% after converting crude nicotine to its esters (nicotine bitartarate)\textsuperscript{16}. Therefore, because of the capacity of nicotine and few substances under the above conditions to make crystal esters. Nevertheless, all compounds (hydrophilic and lipophilic) seeded by wash only leave filter paper to arrest nicotine salts. This technique can be adopted to purify nicotine at least from Iraqi Tobacco, based on the above findings.

![Thin layer chromatography plates of nicotine compound using solvent system](image)

**Figure (1):** Thin layer chromatography plates of nicotine compound using solvent system

(methanol : ammonia (200: 3) . A: pure nicotine B: crude nicotine .

The used of alkali material not only toinccrease pH value in extraction and recovery of nicotine, but return to capacity of this material with heat to break down the forms of nicotine esters (most nicotine contained in esters forms in plane tissue) and release nicotine in free form, the time, alkali concentration and temperatureare so important in nicotine extraction and yield due to nicotine degradation\textsuperscript{17,18} (Figure 2).
Figure 2: Critical points in extraction of nicotine: Alkali concentration, Time and Temperature.

Table 1: GC-MS analysis of crude nicotine.

Nicotine purity rose from 16.43% to 99% after converting the crude nicotine to its esters, According to figure 3 and 4 (nicotine bitartarate). Therefore, because of the capacity of nicotine and few substances under the above conditions to make crystal esters. Nevertheless all substance (hydrophilic & lipophilic) seeded by wash leave only filter paper to arrest crystals. Therefore in order to obtain the high purity of nicotine, the pH –dependent inversion solubility of nicotine from polar solvent is not necessary to obtain 99 percent purity of nicotine.

**Conclusion**

In this study, we can conclude that the nicotine high purity rose 99% after converting the crude nicotine to its esters and the technique used in this study can be adopted to purify nicotine at least from Iraqi Tobacco.

Association of the TP53 Codon 72 Polymorphisms with PCOS Female Infertility in Karbala City

Inam Joudah Radhi⁴, Abdulmutalb Badr Manhy Alkhaleeli², Hameedah Hadi AbdulWahid³
¹Assist. Lecturer, ²Lecturer, College of Pure Science, Department of Chemistry, University of Kerbala, Iraq,
³Consultant Gynecologist, Kerbala Obstetric and Gynecology Teaching Hospital, Kerbala Health Directorate,
Ministry of Health, Iraq

Abstract

To training the association of polycystic ovaries with p53 and 72 polymorphisms in the population of female infertility in central Karbala and to search for possible interaction with the polymorphism. The Iraqi environment was suffered from acts of profanation by due to wars in Iraq, since 1990 and after 2003, An enormous number of damages and deaths were affected by destructive chemicals and radioactive resources. These events resulted in either cancer or infertility. Infertility is one of the medical, social and psychological burdens in Iraqi society. After 12 months or more of failure to a clinical pregnancy lead to a regular unprotected sexual intercourse.

Keywords: Women sterility, PCOS, polymorphism, Codon p53 and 72.

Introduction

Infertility is defined as a disease of the failure to achieve a clinical pregnancy after 12 months or more of regular unprotected sexual intercourse [¹].

The disability to become pregnant consequences in an important affecting and profitable tolls, among artificial nervousness and sadness are more public in sterile couples than sterile couples, also Assisted Reproductive Technologies (ART) is accessible toward care for sterility, then these are pricey. The credit of changeable hazard influences for sterility might guide to economical then helpful interferences expected at preclusion [²]. It is accepted that cancers are the result of the mutation accumulation in the genome. Breast cancer has been a significant for P53 role in the formation and progression, it is also known as the genome guard. The results of different studies indicate that the p53 gene, one of the tumor suppressor genes, is involved at least in various cancers. P53 has been known “the guardian of the genome”, which aids in DNA stability by preventing genome mutation. (SNPs) in the p53 gene There are some different single nucleotide polymorphisms that the biological special effects of most of these polymorphisms have been planned and their clinical results are well known. According to the molecular epidemiological studies, p53 gene mutations are estimated to be identifiable in breast cancer cases. The codon 72 is one of the main SNPs through p53 that has been frequently studied in breast cancer. This polymorphism should be 15% worldwide, > 30% in some developing countries, and 17.28% in manufacturing countries. Polymerase chain reaction (RFLP-PCR) will be restricted by several methods such as fragment length and polymorphism. Direct DNA sequencing and amplification-refractory mutation system-PCR(ARMS-PCR) have been used to examine the polymorphism of the p53 gene codon 72. [³].

The 4 exon codon 72 regions are lies by the most significant is rs1042522. This praline-rich region is
primarily responsible for the show of the apoptotic feature of the TP53 gene. It is a functional polymorphism which is found on exon 4 and foundations the replacement of praline with arginine residue at the regulatory portion of the TP53 gene, causing in altered instruction of apoptosis. Different studies have been established by TP53 codon polymorphism in the growth of endometriosis [4].

The p53 is a growing suppressor gene, governing the instruction of cell tumor and the regulation of the cell cycle, which is complicated in cell spreading like the progression of different procedures of cancer and brings apoptosis or huns the cell cycle in according to DNA damage, which make it possible for cells to be damaged or returned before reinitiating of DNA replication [5]. In contrast, germline variants of the p53 gene are not regularly recognized, and many differences found about their importance in different malignant tumors. The p53 codon 72 gene are derived by two variants labelled from the replacement of a single nucleotide which is resulted in the attendance of proline or arginine in the protein product [6]. The improvement of cancer has been described by revisions the arginine homozygote in codon 72 because it is a danger feature, whereas others exposed a raised danger to persons with the proline homozygous genotype. The malignant transformation of some detectives, abnormalities, chromosomal and aberrations has been related toward p53 by ovarian endometriosis then can be associated with did not notice the different appearance of p53 in endometriosis [7]. The aim of this research has been determined by the frequency of p53 codon and 72 polymorphisms in PCOS in Karbala city women sterility and other symptoms of the disease.

Materials and Methods

The study was showed during the period from (2019). A cross-sectional study was designed; 70 persons, 40 patients and 30 healthies, aged from (19) to (40) years, the diagnosis was based on the clinical history, presentation long-established by UTS and numerous surveys of PCOS biomarker.

DNA extraction:

Two ml of blood sample collected in EDTA tube for genomic DNA extraction used for molecular analysis. DNA extraction kit was purchased from Gene aid (G sync DNA Extraction Kit).

P53 genotyping:

For each allele double autonomous polymerase chain reaction (PCR) tests were used. Genomic DNA improved by using PCR primers which notice p53 codon 72 in the proline form (178 bp. (5’GCCAGAGGCTGCTCCCCC-3’; 5’ CGTGCAAGTCACAGACTT-3’) and arginine form (142 bp) (5’ T C C C C C T T G C C G T C C C an A - 3’ ;5’ CTGGTGCAAGGGGCCACGC-3’) [8].

The PCR was obtained in a 20-µL final volume PCR (premix™) kit was used to amplify. It contained 2 µl of extracted DNA (1 µl of each primer and of 10 pmol/µl primers were mix in total volume of 20 µl. Then the mixture was added to lyophilized PCR premix formula PCR amplification was carried out (cleaver, USA) thermal cycler using the following protocol: 5 min at 95°C, 30 s at 95°C, 30 s at 58°C for Arg72 and 60°C for Pro72, and 45 Second at 72°C for 35 cycles, with an additional 5 min at 72°C after the last cycle The PCR products were separated on a two percent TBE agarose gel and stained with ethidium bromide. A DNA ladder marker (BIONEER, South Korea) was used to determine the size of DNA fragment.

Result

(PCOS) Poly Cystic Ovarian Syndrome is the most public endocrine complaint of reproductive-age women. The analysis of PCOS is mostly founded on the resulting three components: TSH, FSH, and BMI. Prominently, the diagnostic criteria and complications related to Poly Cystic Ovaries Syndrome PCOS are age-dependent, showed in table-1.

The allelic frequencies in the patient group were Arg 47% and Pro 33%; however, the genotype (P<0.001) and allele (P=0.01) distribution showed significant differences between cases and controls (‘P’ values < 0.05). There was a significant increase of P/P
genotype frequency in Poly Cystic Ovaries infertility that they were compared with healthies. The allele frequency also followed similar trend indicating that ‘P’ allele might confer risk of developing PCOS and ‘R’ allele provides protection against the disease, showed in table2

**Discussion**

P53 which are participated in the instruction of glucose are: fatty acid, amino acid (glutaminolysis) and influences mitochondrial integrity and oxidative phosphorylation, insulin sensitivity, antioxidant response, autophagy and mammalian Target of Rapamycin [10]. The unstable production and apoptosis of granulosa cells could result to unusual folliculogenesis [9].

Additionally, the use of oocytes with lacking tumor suppressor genes role may be prematurely eliminated, resultant in initial weakening of egg replacement and, as a result, principal ovarian deficiency [10].

The previous studies say that P/P genotype is related to an enlarged appearance of genes adaptable cell cycle apprehension, which consequently results with the stop of follicle growth [11].

Other Indian study ends with similar conclusion that P/P genotype of the TP53P/R polymorphism was related with developed danger of PCOS, associated to the P/P genotype, in addition to the occurrence of the allele which was expressively higher in Poly Cystic Ovaries Syndrome (PCOS) female than in healthy controls P/P.
variant of R/P polymorphism of TP53 is higher in PCOS patients [12]. These studies agree with our results but we still need extra studies and research in this field, because there are no local or even regional studies [13].

Immunological and Biological Manifestation of Rheumatoid Arthritis Patient in Iraq

RusulH Ahmad¹, AyaidK Zgair²

¹Instructor, ²Professor Department of Biology, College of Science, University of Baghdad, Baghdad, Iraq

Abstract

Rheumatoid arthritis is one of the highly incidence autoimmune disease. In present study the immunological and clinical biochemical test was checked in patients with RA in Iraq. Here 70 serum specimens were obtained from patients suffer from RA and 30 serum specimens from healthy control cohorts. Antinuclear antibodies (ANA) level, C-reactive protein level, erythrocyte sedimentation rate (ESR), activity of alanine aminotransferase (ALT), activity of aspartate aminotransferase (AST), concentration of blood urea and serum creatininand diseases activity score (DAS)-28 were evaluated in sera of patients and healthy control cohorts. The results showed that significant elevation in level of ANA, ESR, CRP and DAS-28 in patients group as compared to healthy control group (P<0.05). No significant difference between patients group and healthy control group in terms of activity of ALT, AST, concentration of blood urea and serum creatinine. The person test (r) was done to evaluate the correlation between ESR, ANA, CRP, ALT, AST, blood urea and serum creatinine. The results showed significant relation between levels of ESR, CRP and ANA and activity of disease in terms of DAS-28. The results showed no significant relation between level of CRP, ALT, AST, blood urea and serum creatinine in patient’s sera and DAS-28. It can be concluded from present study that the some laboratory parameters related with activity of RA such as ESR, ANA, CRP and other parameters do not related with activity of RA such as ALT, AST, blood urea and serum creatinine.

Key words: Rheumatoid arthritis, DAS28, CRP, ESR, Elisa, AST, ALT.

Introduction

Autoimmune diseases are characterized by intrinsic immune alterations, which may lead to chronic inflammation in multiple organ systems. The disease itself and many of its therapies are related to an elevated risk of serious infections [1]. Virtually every place in the body, including the endocrine system, connective tissue, gastrointestinal tract, heart, skin, and kidneys, can be affected by autoimmune diseases. The direct outcome of an autoimmune reaction is considered to be at least 15 diseases, although circumstantial evidence includes >80 autoimmune disorders [2]. DAS28 is a widely used indicator of the activity of the disease in RA patients. Our goal was to test the DAS28’s long-term reliability rather than its short-term error calculation. In order to estimate the pure instrument (method) error and situational effects of the DAS28 determination, short-term reliability is typically evaluated, while long-term reliability includes all short-term repetition effects plus the effects of nonsystematic changes in disease behavior under stable therapeutic conditions. In a study by Uhlig and colleagues, the short-term variability of DAS28 scores was assessed in 28 patients who were evaluated at 2 points 5-7 days apart by the same qualified study nurse [3]. DAS28 scores range from 0 to 9.4 and are calculated using tender joints, swollen joints, general health, and a laboratory measure of acute inflammation [4]. DAS28 can be characterized using erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP).
Despite the routine use of disease activity scores in guiding treatment, existing guidelines do not specify how cutoffs for high disease activity differ between DAS28-ESR and DAS28-CRP [5].

Some of the most common bacterial infections are urinary tract infections (UTIs), which affect 150 million people worldwide each year [6]. Patients with symptomatic UTI are often treated with antibiotics, which can lead to long-term alteration of the usual vaginal and gastrointestinal micro-biota and the development of multidrug-resistant micro-organisms [7].

Materials and Methods

**Collection of blood sample**

Patients and controls blood were collected by venipuncture; 5 ml of blood was drawn using disposable syringes. The blood was divided into two aliquots. The first aliquot (3 ml) was placed in gel tubes, then left to stand at room temperature (18-25°C) to clot. Sera were separated by centrifugation for 5 minutes at 3000 round per minute (rpm). The separated serum was distributed into 2 aliquots in Eppendorf tube and kept at -20ºC until being assayed [8]. Another 2 ml was place in anticoagulant tubes and use immediately for checking erythrocyte sedimentation rate (ESR).

**ESR**

ESR should be done within 2 h of the collection of the blood. Two hundred microliter of ESR solution (3.8-gm of Trisodium citrate dissolved in 100 mL of distilled water) was mixed with 1.8 ml of blood the Wintrobe ESR tube was filled with mixture of blood and ESR solution. The tube was mounted in the ESR stand. The results were checked after 1 h.

**Serological test (ANA and CRP)**

The instructions of manufacture companies of production of ANA (AESK, USA) and CRP (Linear, Spain) were followed to evaluate the level of CRP and ANA in sera of patients group and healthy control group.

**ALT and AST**

The instructions of manufacture companies that products ALT and AST were followed to evaluate the activity of liver enzymes (Linear, Spain) in sera of patients group and healthy control group.

**Kidney function tests (blood urea and serum creatinine)**

The instructions of manufacture companies that produced blood urea (Linear, Spain) and S. creatinine (Linear, Spain) were followed to evaluate the concentrations of blood urea and s. creatinine in sera of patients group and healthy control group.

**Statistical Analysis**

All data represented in mean and standard deviation the ANOVA test was used to identify the significant difference between patients and control groups The person test (r) was used to detect the relationship between all parametersthat used in present study with disease activity score (DAS)-28 [8,9].

**Result**

The results of the current study showed that the percentage of women that suffer with RA (85.71 %) is much higher than the percentage of men with RA (14.28 %). The average age of patients with RA was 51.92 ± 7.4 year, therefore, the average age of healthy people used in this study was 48.5 ± 6.1 year which is very close to the average of patients with RA in order to achieve an objective and scientific comparison between the group of patients with RA and control group (Table 1).

The present study showed increase in the level of ESR in patients with RA (44.6 ± 25.1 mm/h) when compared to the level of ESR in the healthy control group (16.1 ± 7.2 mm/h). The change in the level of ESR was significant (P<0.001). Significant elevation (P<0.05) in the level of CRP was seen when comparing that with the level of CRP in blood of a healthy control group. Similar significant results was found in case of ANA (Table 1) The results showed shows an increase in the level of ANA in patients with RA (0.29 ± 0.15)
when compared to the level of ANA in the healthy control group (0.13 ± 0.03). The change in the level of ANA was significant (P<0.05).

activity in patients group (a) and healthy control group (b). The positive and significant relation was found between ESR and CRP with DAS-28 value in RA subjects (P < 0.05).

Figure 3 showed no significant relationship between enzyme activity of ALT and AST with DAS-28 in patients and healthy control groups (P>0.05).

![Figure 3](image)

**Figure 3.** Relationship between ALT and AST with DAS-28 value as an indicator of RA activity in patients group (a and c) and healthy control group (b and d). No significant relationship was observed (P > 0.05).

Figure 4 showed no significant relationship between concentration of blood urea and S. creatinine with DAS-28 in patients and healthy control groups (P>0.05).

![Figure 4](image)

**Figure 4.** Relationship between blood urea and s. creatinine with DAS-28 value as an indicator of RA activity in patients group (a and c) and healthy control group (b and d). No significant relationship was observed (P > 0.05).
**Discussion**

Several studies indicated that the DAS-28 was higher in patients as compared with control groups\textsuperscript{[5,6]}. The several previous study showed that the clinical laboratory markers is higher in patients with RA as compared with healthy control\textsuperscript{[8]}. Present study showed significant relationship in patients and control group with RA activity that indication ESR and CRP is not specifically associated with the activity of RA\textsuperscript{[10]}.

Identifying and quantifying inflammatory disease activity in rheumatoid arthritis remains a challenge. Many studies have suggested that a large proportion of patients may have active inflammation. Although various disease activity scores had been validated, most rely to a large degree on biomarkers such as CRP and ESR. Using the DAS28-CRP with threshold values validated for DAS28-ESR may lead to errors in the determination of disease activity and therefore may lead to errors in the management of patients with rheumatoid arthritis. That are concomitant with our study in terms that these markers are not specific for the disease activity because we found the correlation between ESR and DAS28 in patients group and in healthy control group as well.

Antinuclear antibodies (ANA) are one of the most essential serological markers used for the diagnose of rheumatic diseases (RA), systemic lupus erythematosus (SLE), systemic sclerosis (SSc), mixed connective tissue disease (MCTD), and idiopathic inflammatory myopathy (IIM). The number of ANA positive group was higher than control group. In the ANA positive category, the female rate was clearly higher. Rheumatoid factor (RF) positivity, as well as anti-cyclic citrullinated peptide (CCP) antibody positivity was far higher in the ANA positive group\textsuperscript{[11]}.

The results of present study were agreed with the results that obtained by Hoblet\textit{ et al.}, (2012). The found no serious adverse events were noted. They showed no significant difference in AST in blood of patients suffering from RA and that was not related with DAS-28 because of the small sample size who received an initial oral dose of either 15 or 25 mg MTX per week did not reach the level of statistical significance\textsuperscript{[12]}.

The present study indicates that no relationship between disease activity and level of AST in sera of investigated cohort. The results of present study were in line with previous study of Kumar\textit{ et al.}, (2015). They showed no significant differences between DAS-28 and level of enzyme activity of AST because the using of specific treatment within the study for seven weeks in rheumatoid arthritis patients that is why normal kidney and liver function tests were obtained\textsuperscript{[13]}. The results of this study were coincided with previous study of Mahmoodet\textit{ et al.} (2018), they found that there is no significant differences between DAS-28 and kidney function (blood urea) for patient that administrate Azilsartan with methotrexate because Azilsartan can improve the effects of methotrexate on clinical scores and certain inflammatory biomarkers in patients with active RA\textsuperscript{[14]}. Current study were coincided with previous study of Guadagninet\textit{ et al.}, (2021), they found that no differences between DAS-28 and serum creatinine levels in patient that suffer from RA. That happened because the effectiveness of the combined MTX and LFN treatment is equivalent to that of LFN alone. For the combination treatment, there was no rise in toxicity\textsuperscript{[15]}.

**Conflict of Interest:** The authors declare that there is no conflict of interest regarding this study.

Isolation and Identification of Bacterial Burn Wound Infection in Iraqi Patient

Jenan A. Ghafil¹, May. T. Flieh²

¹Lecture, ²Professor, College of Science, Department of Biology, University of Baghdad, Baghdad, Iraq

Abstract

Burns are one of the most common and devastating forms of trauma. Patients with serious thermal injury require immediate specialized care in order to minimize morbidity and mortality. In current study, 120 samples were collected from 120 patients suffering from contaminated burns. The study was conducted after obtaining ethical approvals from the ethics committee in the Department of Biology, College of Science, University of Baghdad as well after obtaining the patients’ consent. Samples are collected from patients after they have stopped using antibiotics for 48 hours. After the swabs had been cultured on different media, conventional biochemical tests to identify bacterial isolates and antimicrobial sensitivity to the most common antibiotics were performed by vitek 2 compact. The results showed that the highest percentage of bacterial species was Proteus mirabilis (31.1%). The percentage of isolation of P. aeruginosa was 17.78%. The lowest percentage of bacterial isolates that isolated from infected wound was found in case of Staphylococcus aureus, Pseudomonas fluorescens, Acinetobacter haemolyticus, Burkholderia cepacia, Salmonella ser. gallinarum, Sphingomonas paucimobilis, Comamonas testosterone with 2.2% for each isolate.

Key word: Burn, wound, Antibiotic, Comamonas testosterone, Sphingomonas paucimobilis

Introduction

Burns are one of the foremost common and destroying shapes of injury. Patients with effective thermal injury require prompt specialized care in arrange to reduce morbidity and mortality. Information from the National Center for Injury Avoidance and Control within the United States appear that roughly 2 million fires were investigated each year which result in 1.2 million individuals with burn wounds [¹]. Direct to extreme burn wounds requiring hospitalization account for roughly hundred thousands of the cases, and around 5% of patients with burn wound infection were died on each year from burn-related complications [²].

The survival rates for burn patients have made strides significantly within the past few decades due to progresses in advanced therapeutic care in specialized burn centers. Improved outcomes for seriously burned patients have been credited to restorative progresses in liquid revival, wholesome back, pneumonic care; burn wound care, and disease control. As a result, burn-related deaths are depending on the degree of damage, have been split inside the past 40 years [³]. In patients with serious burns over more than 40% of the total body surface area (TBSA), 75% of all deaths were related to sepsis from burn wound disease or other contamination complications and/or inhalation injury [⁴].

Microbes quickly colonize open skin wounds after burn damage. Microorganisms colonizing the burn wound start from the patient’s endogenous skin and gastrointestinal and respiratory vegetation. Microorganisms may too be exchanged to a patient’s skin surface by means of contact with contaminated external environmental surfaces, water, air and the
dirtied hands of health care persons [5]. Quickly taking after damage, gram-positive bacteria organisms from the patient’s endogenous skin vegetation or the outside environment transcendentally colonize the burn wound [6]. Endogenous gram-negative microbes from the patient’s gastrointestinal greenery too quickly colonize the burn wound surface within the to begin with few days after damage [7].

Staphylococcus aureus got to be the vital etiological agent of burn wound infection. After the discover penicillin G within the early 1950s, which come about within the virtual reducing of Streptococcus pyogenes as a cause of contamination in thermally harmed patients [8]. In spite of the fact that S. aureus remains a common cause of early burn wound contamination, Pseudomonas aeruginosa and Proteus mirabilis from the patient’s endogenous gastrointestinal vegetation and/or a natural source is the foremost common cause of burn wound contaminations in numerous centers. The rate of diseases due to less commonly experienced organisms, counting other gram-positive and gram-negative microscopic organisms, fungi, and viruses, has too expanded relentlessly in subsequent decades [9].

Material and Method

Specimen Collection

In current study, 120 samples were collected from 120 patients suffering from contaminated burns. Samples were collected under sterile conditions using sterile swabs. The samples were immediately transported to the laboratory to be implanted in the appropriate media.

The average age of the patients was 42.6 ± 5.8 years. The number of males was 72 and the number of females 48. The study was conducted after obtaining ethical approvals from the ethics committee in the Department of Biology, College of Science, University of Baghdad as well after obtaining the patients’ consent. Samples are collected from patients after they have stopped using antibiotics for 48 hours.

Bacterial isolation

The collected samples were cultured on MacConkey agar, Blood agar under aerobic and sterile conditions. To diagnose the isolated bacteria the select colonies were re-cultured on mannitol salt agar, SS agar, nutrient agar, XLD agar and EMB agar. For further identification of isolated bacteria catalase test, oxidase test and Gram stain were used to identify the pure isolated bacteria [10].

Microscopic Examination

The morphological identification of the isolates as bacilli was confirmed microscopically by performing Gram staining, for which single colony of each isolate was picked up and stained as per the standard protocol and viewed under oil immersion for similar type of cells.

Catalase test

The collected samples were cultured on MacConkey agar, Blood agar under aerobic condition and sterile conditions, use a loop or sterile wooden stick to transfer a small amount of colony growth in the surface of a clean, dry glass slide then Place a drop of 3% H2O2 in the glass slide the result observed for the evolution of oxygen bubbles [10].

Oxidase test

The collected samples were cultured on MacConkey agar, Blood agar under aerobic condition and sterile conditions, strip of Whatman’s No. 1 filter paper are soaked in a freshly prepared 1% solution of tetramethylp-phenylene-diaminedihydrochloride, After draining for about 30 seconds, the strips are freeze dried and stored in a dark bottle tightly sealed with a screw cap, for use, a strip is removed, laid in a petri dish and moistened with distilled water. The colony to be tested is picked up with a platinum loop and smeared over the moist area. A positive reaction is indicated by an intense deep-purple hue, appearing within 5-10 seconds, a “delayed positive” reaction by colouration in 10-60 seconds, and a negative reaction by absence of colouration or by colouration later than 60 seconds [10].
Identification using the VITEK 2 fluorescent system (ID-GNB card)

The VITEK 2 DensiCheck instrument, fluorescence system (bioMérieux) (ID-GBB card and ID- GNB card) includes 43 non enterobacterial gram-negative taxa and gram positive. Testing was performed according to the instructions of the manufacturer. Briefly, strains were cultured on nutrient agar for 18 to 24 h at 37°C before the isolate was subjected to analysis. A bacterial suspension was adjusted to a McFarland standard of 0.50 to 0.63 in a solution of 0.45% sodium chloride using the VITEK 2 DensiCheck instrument (bioMérieux). The time between preparation of the solution and filling of the card was always less than 1 h. Analysis was done using the identification card for gram-negative and gram positive bacteria (ID-GNB card) and (ID-GBB) containing 41 fluorescent biochemical tests. Cards are automatically read every 15 min. Data were analyzed using the VITEK 2 software version VT2- R03.1 [11].

Antibiotic susceptibility

The standard method of Mazzarioiet al. (2008) was followed to test the susceptibility of identified bacteria to the several antibiotics (Cefotaxime, Ampicillin, amoxicillin/Clavulanic acid, ampicillin/Sulbactam, Piperacillin/ Tazobactam, cefazolin, ceftazidime, ceftriaxone, cefepime, imipenem, gentamicin, tobramycin, ciprofloxacin, levofloxacin, nitrofurantoin, trimethoprim/sulfamethoxazole, ticarcillin, amikacin). VITEK 2 DensiCheck instrument (bioMérieux) was used to check the supportability of isolated and identified bacteria [12].

Results and Discussion

Isolation and identification of bacterial species

In present study, 120 swabs were collected from infected burns. The samples were collected from 120 patients. The swabs were inoculated onto number of culture media (Blood agar, MacConkey agar, Manitol salt agar, SS agar and XLD agar) for growing and isolating and then for pre-identification. Most of isolates were grown on blood agar with different shape according to the genera of isolates. The suspected staphylococcus isolates were cultured onto mannitol salt agar to identify the staphylococcus species. Some of isolates were grown on MacConkey agar with pale or pink color. The bacteria that grown onto MacConkey agar with pale color were cultured onto SS agar and XLD to identify whether they were Salmonella or Shigella isolates [13]. Total pre-identified species of bacteria was 50 species but when further identification was done by VITIK 2 technology, only 45 species was identified and 5 was specified as unidentified organism. Thus the further study was done only on the 45 species that isolated from infected wound and identified by VITIK 2 technology (Table 1). The results showed that the highest percentage of bacterial species was Proteus mirabilis (31.1 %). The percentage of isolation of P. aeruginosa was 17.78%. The lowest percentage of bacterial isolates that isolated from infected wound was found in case of Staphylococcus aureus, Pseudomonas fluorescens, Acinetobacterhaemolyticus, Burkholderiacepacia, Salmonella ser. gallinarum, Sphingomonaspaucimobilis, Comamonas testosterone with 2.2 % for each isolate .

Previous study of Forsonet al. (2017) mentioned that P. aeruginosa represented the highest percentage of bacterial species that isolated from burn wound, while Church et al. (2006) reported that the highest percentage of bacterial species that isolated from infected burn wound was P. aeruginosa followed by E. coli and the lowest percentage was found in case of Acinetobacterspp and Bacteroides spp. Similar finding was reported by other investigators[16].

The diversity of bacteria species isolated from infected wounds was one of the features that distinguished the present study. Bacteria rapidly colonize open skin wounds after burn injury. Microorganisms colonizing the burn wound originate from the patient’s endogenous skin and gastrointestinal and respiratory flora [17]. Microorganisms may also be transferred to a patient’s skin surface via contact with contaminated external environmental surfaces, water, fomites, air, and the soiled hands of health care workers [15]. Immediately following injury, gram-positive bacteria from the patient’s endogenous skin flora or the external environment predominantly colonize the burn wound [18]. Endogenous gram-negative bacteria from the patient’s gastrointestinal flora also rapidly colonize the burn wound surface in the first few days after injury [15]. Microorganisms transmitted from the hospital environment tend to be more resistant to antimicrobial agents than those originating from the patient’s normal flora [19].

Previous study, 185 (61.87%) bacteria were isolated from the wounds of burnt patients. Among the culture positive samples, 112 (60.54%) were from female patients and 73 (39.46%) were from male patients. The most commonly isolated organisms were Pseudomonas species (43%). K. pneumoniae and A. baumannii were second and third predominant bacterial pathogen with a prevalence of 28% and 14.83% respectively. Similar finding with P. aeruginosa a predominant isolate followed by K. pneumoniae and A. baumannii in tertiary care hospital in India were also reported [20]. High
prevalence of these pathogens is associated with their ability to flourish well in a moist environment and persistence in hospital environment [20]. In present study, P. aeruginosa was reported as one of domain species that isolated from burn wound infection.

**Antibiotic susceptibility**

The susceptibility of 45 isolates to different antibiotics was done by VITIK 2 DensiCheck instrument. The antibiotics that used were different according to the group of species of bacteria because the routinely antibiotic that used clinically was different according to the clinical cases and species [21] that covered in the study.

The current results showed that the effect of antibiotics varies greatly according to the species of bacterial used and the type of antibiotics. Where, many types of antibiotics were used in present study. Through an overview of the results, it can be confirmed that there are no bacterial species sensitive to all antibiotics used, and no bacterial isolate that resists to all antibiotics . Figure (1) shows that the P. mirabilis gave the highest percentage of resistance to different kinds of antibiotic, followed by the P. aeruginosa. While, the lowest percentage of sensitivity to different kind of antibiotics was shared among S. paucimobilis: C. testosterone and B. mallei. The present study showed that the highest percentage of intermediate response of bacteria to antibiotics was seen in case of S. paucimobilis followed by P.fluorescens.

Nosocomial infection in the burnt patients is major challenge for a clinician. It has been estimated that 75% of all deaths in burnt patients were associated with infections. Prolonged use of antibiotic leads to the development as well as selection of multidrug resistant (MDR) bacteria which results in treatment failure and intensifies the complications. Thus, the information of microbial flora and the current antibiotic susceptibility patterns are important for the clinician treating burn sepsis [21].

Evaluation the Genotoxicity of PHB Nanoparticle by Micronucleus Assay

Jenan A. Ghafil¹, May. T. Flieh²
¹Lecture, ²Professor, College of Science, Department of Biology, University of Baghdad, Baghdad, Iraq

Abstract

Determining the toxicity of substances in vivo is one of the most important tests that judge whether or not they are used in the pharmaceutical field. In the present study, the genetic toxicity of treatment doses of Polyhydroxybutyrate (PHB), PHB nanoparticles, Cefotaxime and complex of PHB nanoparticles and cefotaxime was evaluated. The effect of these substances on the number and percentage of white blood cells (WBCs) in mice was also tested (in vivo). Micronucleus assay was used to assess genotoxicity of above materials in vivo, as well as the technique of WBCs chamber was used to estimate the total number of WBCs in mice administrated with above substances. The differential count of WBCs was measured by staining the smears with leishman stain. The present study demonstrated that there were no significant differences (P>0.05) in the number of micronucleus cells in the mice injected with treatment doses of PHB nanoparticles, Cefotaxime and complex of PHB nanoparticles and cefotaxime when compared with mice injected with normal saline. Similar finding was obtained in terms of counting of total WBCs and differential count in mice injected with treatment doses of PHB, PHB nanoparticles, Cefotaxime and complex of PHB nanoparticles and cefotaxime when compared with WBCs total count and differential count in mice injected with normal saline (P>0.05). It can be concluded that there is no toxic effect of treatment doses of PHB, PHB nanoparticles, Cefotaxime and complex of PHB nanoparticles and cefotaxime on mice.

Keyword: Polyhydroxybutyrate, micronucleus assay, Genotoxicity.

Introduction

Polyhydroxyalcanoate (PHB), a polymer belonging to the polyester classes, is a biodegradable and biodegradable plastic of interest. The poly-3-hydroxybiotrate (P3HP) form of PHB is probably a polyhydroxyalconoate type, but other polymers of this class are produced by a variety of organisms: including poly-4-hydroxybiotrate (P4HPHP).Polyhydroxyhexanonate (PHH), polyhydroxyoctanone (PHO) and their copolymers [1].

In the medical field, many drugs are used to treat bacterial infections [2], and this requires determining their toxicity. The same applies to the PHB, as it has many applications in vivo, including anti-bacterial [3], as well as to contribute to limiting the activity of some diseases such as cancer in the human body [4]. To determine the possibility of its use, it is required to determine cytotoxicity of PHB.

There are a number of methods by which it is possible to determine the extent of the body’s response to foreign substances, including by measuring the number and percentage of white blood cells [5]. These are useful for determining the state of the immune and cellular system in case the body is exposed to foreign substances [5].

There are many methods that can be used to determine the genetic toxicity of medicinal materials, the most important and the most common of which is the Micronucleus assay [6]. A micronucleus (MNs) test is a test used in toxicological screening for...
potential genotoxic compounds. The assay is now recognized as one of the most successful and reliable assays for genotoxic carcinogens. This test is based on the formation of number of MN in treated cells \(^7\). MNs are formed during anaphase from chromosomal fragments or whole chromosomes that are left behind when the nucleus divides. Over time, the assay has evolved to include a pretreatment with cytochalasin-B (Cyt-B), a cytokinesis blocking agent that inhibits cell division, thereby giving the cells a binucleated appearance. This enables more accurate scoring and the ability to sieve out the dividing cells from the non-dividing ones, thereby reducing the incidence of false positives\(^7\).

In the absence of a previous study dealing with the effect of PHB nanoparticles on the state of white blood cells in the body as well as the genotoxic effect of this substance, so the genotoxicity of PHB nanoparticles in vivo was evaluated by using the micronucleus assay and the effect of PHB nanoparticles on the status of white blood cells in terms of number of cells and percentage in vivo was evaluated by using animal models (mice).

Material and method

Polyhydroxybutyrate nanoparticles

Polyhydroxybutyrate (PHB) as a powder was purchase from Sigma-Aldrich, USA the PHB was derived from microbial fermentation. The preparation of PHB nanoparticles was prepared by adding 1 gm of PHB to 50 ml of distilled water and pH was adjusted to 4 by HCl (1 N). The mixture was put in ultrasonic path at 4500 kh for 25 second. The pH was readjusted to 10 by NaOH (1N). The mixture was mixed by magnetic stirrer for 2 h at 21 °C. The mixture was incubated at 21 °C for 18 h and then the pH was readjusted to 7 by HCl (1 N). The synthesis of PHB nanoparticles was evaluated by Atomic force microscopy (AFM), Fourier-transform infrared spectroscopy (FTIR), Ultraviolet (UV) spectrophotometer, X-ray powder diffraction (XRD) and Scanning electron microscopy (SEM).

Mice

BALB/c mice 6–8 weeks old, weighing 20–25 gm was procured from central animal house, AL-Nahrain University, Baghdad, Iraq. Animals were kept in clean polypropylene cages and fed on standard antibiotic free diet. The mice that used in current study were male.

Micronucleus assay

The standard method of Sousa et al. (2016)\(^8\) with little medication was followed to evaluate Percentages of micronucleated polychromatic erythrocytes (PCEMNs) in bone marrow of mice after 48 hours of injection subcutaneous with Polyhydroxybutyrate (PHB), PHB nanoparticles and PHB nanoparticles plus cefotaxime (complex). Briefly, four groups of mice were used in this experiment. Each group consisted of three mice. Group A, mice injected under skin with treatment dose of PHB (1 mg). Group B, mice injected under skin with treatment dose of PHB nanoparticles (1 mg). Group C, mice injected under skin with treatment dose of PHB nanoparticles + cefotaxime (500 µg). Group D (Control group), mice injected under skin with normal saline. The mice were sacrificed 48 hours post administration of treatment doses of above materials under skin. All mice were dissected. Bone marrow cells were collected immediately after the sacrifice of animals. Leg bones of mice were collected and homogenized by mortar aseptically. The bone marrows were collected from homogenised bones. In a Falcon tube previously marked with the animal group. Bone marrow material was re-suspended with fetal bovine serum until homogeneous. The suspension was centrifuged for 5 minutes at 1,000 rpm and the supernatant was discarded and the pellet was re-washed three times with fetal bovine serum. At the end of procedure the pellet was re-suspended with 500 µl of fetal bovine serum then the tube was homogenization gently and smears were prepared dripping off 2 drops of suspension on the tip of a slide (previously labelled with the animal’s group) and with the aid of another slide bent at a 45 degree angle to make the smear and the slides were air dried, two slides per animal were made and stained by leishman stain\(^9\).
The analysis was performed in blind field in an increase of 100x (immersion objective) in a short time by the same observer. Micronuclei were measured in 2,000 polychromatic erythrocytes (PCEs) / animal in bone marrow of adult mice.

**White blood cells (WBCs) total count and differential count**

The standard method of Liu et al. (2020) with little modification was followed to count the number of WBCs in peripheral blood that collected by anticoagulant capillary tube (heparin) inserted in the lateral canthus from the retroorbital sinus of mice. The specific WBC pipette and WBCs solution were used. The blood specimen was diluted 1:20 in a WBC pipette with the diluting fluid (WBCs solution) and the cells were counted under low power of the microscope by using a counting chamber. The number of cells in undiluted blood is reported per microliter of whole blood\(^{[10]}\). The standard method of Nurhayati et al. (2019) was followed with little modification to be in line with approach of the present study\(^{[11]}\) to measure the percentages of WBCs in peripheral blood of mice post smear preparation and stained witleishman stain. The WBCs total count and the percentages of different types of WBCs were measured in blood that collected from different mice groups. Group A, mice injected under skin with treatment dose of PHB. Group B, mice injected under skin with treatment dose of PHB nanoparticles. Group C, mice injected under skin with treatment dose of PHB nanoparticles + cefotaxime. Group D (Control group), mice injected under skin with normal saline.

**Statistical Analysis**

All values have been taken as mean value and standard deviation (SD) calculated. The differences were analyzed using Student’s t-test employing Origin version 8.0 software. A value of \(P < 0.05\) was considered to be statistically significant.

**Result**

**Micronucleus assay**

To ensure the presence or absence of the toxic effect of PHB, PHB nanoparticles, PHB nanoparticles plus cefotaxime, the percentage of micronucleated polychromatic erythrocytes (PCEMNs) in the bone marrow of mice was estimated after they were injected with the therapeutic dose of the following substances, PHB (1 mg) and PHB nanoparticles (1 mg) and the complex consisting of a mixture of PHB nanoparticles plus cefotaxime (0.5 mg). The results of number of PCEMNs in bone marrow of upper groups were compared with a number of PCEMNs in bone marrow of control group (mice injected with normal saline).

The results showed that there were no significant differences in number of PCEMNs in bone marrow of treat groups of mice and number of PCEMNs in bone marrow of control group of mice (\(P < 0.05\)) (Fig. 1). This finding proves that no toxic effect of treatment dose of PHB or PHB nanoparticles or PHB nanoparticles plus cefotaxime (complex). The micronucleus test suggested that the PHB, PHB nanoparticles and PHB nanoparticles plus cefotaxime have no biological toxicity in order to not change the incidence of polychromatic erythrocytes. That confirmed the safety of using of these compounds in vivo.
Figure 1 a, Percentages of micronucleated polychromatic erythrocytes (PCEMNs) in bone marrow of mice after 48 hours post injected subcutaneous with normal saline (control), Polyhydroxybutyrate (PHB), PHB nanoparticles and PHB nanoparticles plus cefotaxime (complex). NS, non significant difference from control group. b, micronucleus in PCEMN.

White blood cells (WBCs) total count and differential count

Fig. 2 shows the number of WBCs in blood of different groups of mice post administrating with treatment dose of PHB (1 mg/kg), PHB nanoparticles (1 mg/kg), PHB nanoparticles plus cefotaxime (0.5 mg/kg) and 0.5 mg/kg of cefotaxime. The results showed no significant difference (P<0.05) between any experimental groups with control. This finding proves that the administration of treatment dose of above materials do not effect on the number of WBCs in vivo.
After calculating the total number of leukocytes (WBCs) in peripheral blood of different groups of mice, the percentages of polymorphonuclear cells (neutrophil, eosinophil and basophil) and mononuclear cells (monocytes and lymphocytes) were calculated in the peripheral blood taken from retro-orbital sinus of mice eyes. The percentages of polymorphonuclear cells and mononuclear cells were calculated in blood samples of groups of mice administrated orally with treatment dose of PHB (1 mg/kg), PHB nanoparticles (1 mg/kg), PHB nanoparticles plus cefotaxime (1 mg/kg), and cefotaxime (1 mg/kg). Fig. 3 shows no significant difference (P<0.05) in percentages of all types of leukocytes [polymorphonuclear cells (neutrophil, eosinophil and basophil) and mononuclear cells (monocytes and lymphocytes)] that obtained from all peripheral blood of experimental groups of mice as compared with percentages of all types of leukocytes that obtained from blood of control group (mice administered orally with normal saline).

![Figure 3](image_url)

**Figure 3.** Differential count of leukocytes that collected from retro-orbital sinus of mice eyes and smeared on slides and stained with leishman stain. There is no significant difference in percentages of all types of leukocytes that obtained from different groups of mice that administrated with treatment dose of PHB, PHB nanoparticles and PHB nanoparticles plus cefotaxime (complex) and cefotaxime. The results were compared with corresponding cells in blood samples that collected from control group.

**Discussion**

During almost 40 years of use, the micronucleus assay (MN) has become one of the most popular methods to assess genotoxicity of different chemical and physical factors, including ionizing radiation-induced DNA damage [7]. In a modern world, humans are exposed to different genotoxic agents present in the polluted environment. Hence, tests are needed to determine the level of exposure and health risk. Although many tests classified as “in vivo biomonitoring” are available, a micronucleus test (MN) is one of the best and the most popular [12]. The assay is also widely used to test genotoxicity in vitro (7). Many previous studies used micronucleus assay (MN) to detect the toxicity of some of the materials used in different field such as therapeutic purpose such as drugs or as a food [13].
There are very few studies assessed the genotoxicity of PHB in vitro or in vivo. It was found only one study focused on this issue. de Sousa et al. (2016) checked the toxicity of membranePHB/Norbixin/Ethylene glycol by micronucleus test and they found that there is no toxicity in the natural material of membranePHB/Norbixin/Ethylene glycol and they can be used for biological purposes and these will contribute to future studies on the effects of the membrane on the healing of skin wounds[8]. This finding is matching with what we got in our study about the safety of PHB that is why we also suggest the possibility of using this material as a medicine for treatment in future.

Estimating the number of white blood cells in the blood is one of the indicators of the state of the immune system, since these cells represent the cellular arm of the immune response. Therefore, estimating its levels gives an indication of the body’s response to an external stimulus, as well as a non-specialized picture of the state of the immune system. Estimating the number and percentage of Polymorphonuclear cells such as neutrophil, eosinophils and basophil and mononuclear cells such as lymphocytes and monocytes gives a more specialized picture of the state of the immune response after the occurrence of infection. However, these two indicators represents non-specific indicators through which it is not possible to determine the nature of the response and for which disease factor, even these to indicators will not give accuracy answer to the causative of the disease but they give general picture about the status of immune response. In present study the total number of WBCs and percentages of these cells were evaluated post PHB, PHB nanoparticles and PHB nanoparticles plus cefotaxime administration to mice orally.

Through searching the literature on the effect of PHB (nanoparticles and non nanoparticles) on the total number of leukocytes (WBCs) in laboratory animals, no article was found dealing with this topic, which supports that the present study is the first study that deals with the effect of PHB, PHB nanoparticles, PHB nanoparticles plus cefotaxime on the total number of leukocytes in peripheral blood of laboratory animals (mice). The finding of no effect of PHB in different form on the total numbers of white blood cells in laboratory animals confirms the safety of using these materials in treatment, and this opens the door for new research dealing with the possibility of using these materials in treatments, especially with regard to infectious diseases.

According to our knowledge there is no published literature covered the effect of PHB (nanoparticles and non nanoparticles) on the percentages of leukocytes [polymorphonuclear cells (neutrophil, eosinophil and basophil) and mononuclear cells (monocytes and lymphocytes)] in laboratory animals. That supports the present study as the first study that deals with the effect of PHB, PHB nanoparticles, PHB nanoparticles plus cefotaxime on the differential count of leukocytes in peripheral blood of laboratory animals (mice).

Several previous studies focused on the effect treatment doses of different medicine especially antibiotics on the number and percentages of polymorphonuclear. Shuman et al. (2012) have identified one category of medications that may cause decreased white blood cell/absolute neutrophil counts when combined with clozapine[14]. Their study supported the use of either ciprofloxacin or moxifloxacin as agents that may have less risk of reductions in white blood cell/absolute neutrophil counts than are seen with penicillins, cephalosporins, and other antibiotics that may ultimately require interruption or discontinuation of clozapine therapy. Similar finding was reported by Nguyen et al (2016) they found that using antibiotics increase the maturation of neutrophil and that reflect on the total count of leukocytes as well[15]. Previous study support strongly that the total count of leukocytes and differential count of all types of leukocytes in blood gives a good indication about the safety of the substances such as drugs or food to be administrated by human and animal [16, 17]. That is why; in this study it was focused on the differential count of leukocytes in peripheral blood of mice post administration with PHB to help in identifying the safety of these substances.
The present study proved that oral administrated of with treatment dose of PHB (1 mg/ kg), PHB nanoparticles (1 mg/ kg), PHB nanoparticles plus cefotaxime (1 mg/ kg), and cefotaxime (1 mg/ kg) do not effect on the total count of leukocytes and percentage of all types of leukocytes. That give another evidence about the safety of these substances (PHB, PHB nanoparticles, PHB nanoparticles plus cefotaxime and cefotaxime) to be using as a treatment substance and that attract us to go further in using of these substances in treating the burn mice model prepared in our laboratory.

2Professor, Department of Biology / Faculty of Science / University of Kufa

Abstract

KIPyV and WUPyV were recognized based on commercial standard and PCR techniques. To occurrence of KIPyV and WUPyV DNA among chronic kidney disease (CKD) and UTI patients using VP2 gene for detection of KIPyV and VP1 gene for WUPyV. Molecular assay results of this study revealed the presence of KIPyV in 6 (5.3%) of CKD patients and 3 (2.7%) of UTI patients while the presence of WUPyV was 1 (0.88%) in CKD patients and negative result in UTI patients. WUPyV DNA and KIPyV DNA was not detected in plasma of healthy persons. The distribution of KIPyV and WUPyV according to gender among CKD showed a no significance difference among both sexes in which (P value = 0.27) and (P value = 0.36) respectively while the distribution of KIPyV and WUPyV among urinary tract infections showed a no significance difference among both sexes in which (P value = 0.13) and (P value = 0.79) respectively .The current study survey about both viruses show that female was higher than male in KIPyV in which 2 (3.22%) of KIPyV DNA were detected in male and 4 (7.84%) in female out of 113 (100%) among chronic kidney disease patients while in urinary tract infection, patients revealed a higher percentage rate of KIPyV in female than male in which 0 (0%) of KIPyV DNA were in male and 3 (4.54%) in female out of 111 (100%) while doesn’t detect any isolate of WUPyV in both sexes.

Keywords: KIPyV, Chronic kidney disease, WUPyV, Urinary tract infections.

Introduction

Polyomaviruses are another type of emerging pathogens that generally cause infection to the urinary tract of humans (1). Primary infection of polyomavirus happens in childhood and it persists for the whole life of the persons, especially in the epithelial cells of the kidneys and urinary tract as well as leukocytes in the blood (2). In the secretions of children with acute respiratory symptoms using high-throughput sequencing technologies, two forms of polyomaviruses have recently been identified, one known as Karolinska Institute Polyomavirus (KIPyV) and the other named Washington University polyomavirus (WUPyV) (3).

The site of persistent infection of these two viruses across the lifespan still unclear (4). These two viruses are closely related to each other than to SV40, BK and JC, but, as shown by the amino acid identity and phylogenetic analysis ratio, they vary greatly from each other (5). Seroepidemiological surveys have shown that the initial infection with KIPyV and WUPyV that occurs early in life could be via the respiratory and oral-fecal pathways, similar to BK and JC polyomaviruses (6). A high rate of co-infection with other major respiratory viruses, such as influenza viruses, parainfluenza viruses, adenoviruses, respiratory syncytial viruses, rhinoviruses,
human coronaviruses, human bocaviruses, and human metapneumoviruses is typically associated with the identification of the genome of these two viruses in respiratory tract samples (7).

In the view of the above mentioned introduction, the design of this study to determine the presence of KIPyV and WUPyV in patients suffering from UTI and CKD in AL-Najaf city-Iraq.

**Materials and Method**

A total number of 224 clinical samples were collected from patients who suffer from chronic kidney disease (CKD) and urinary tract infections (UTI) at age range (15-80 years) and 100 healthy persons as controls at age range (25–65) years. All subjects were admitted to one of the biggest Hospital including Al-Sadr Medical City as well as some chief clinical laboratories in Al-Najaf City/Iraq within the time two months started in January 2020. The patients in this study included 107 males and 117 females while healthy controls was 50 males and 50 females. Blood plasma were collected from each participant was used to extract DNA for detection of KIPyV and WUPyV.

The complete genomic DNA of 113 patients with CKD and 111 of patients with UTI was extracted employing a traditional kit of the entire genomic DNA extraction (iNtRoN, Biotech. Inc., Korea), wheressoever, the extraction was performed based on the guidance of manufacture corporation. The nucleic acid was conserved under -20°C state using the deep freezing device, the PCR technique was employed to examine and detect all the genes described in table (1) that suggested by Gozalo-Margüello et al (2015)(8). The process of gel document (Cleaver, United Kindom), demanded to check and distribute the migration of PCR bands applying 1% agarose (iNtRoN, Biotech. Inc., Korea), back dyeing the gel with ethidium bromide at 0.5 μg/ml concentration.

**Statistical Analysis**

The SPSS V.24 program was used in statistical analysis of the data. Chi- Square was used to compare and extract duplicates and percentages

**Result and Discussion**

This study revealed that WUPyV and KIPyV can be detected in both plasma samples from UTI and chronic kidney disease patients, but these viruses were not found in plasma of healthy blood donors. A higher prevalence of KIPyV was observed compared with WUPyV (9/10 vs. 1/10).

Detection of KI and WU polyomavirus in plasma of both groups occurred by using sensitive molecular techniques which include conventional PCR as showed in figure (1). To our knowledge, there is limited studies have been published on KIPyV and WUPyV using conventional PCR in UTI and chronic kidney disease...
patients and this considered the first study that conducted locally. Co-infection with other pathogens has been reported in 74% of KIPyV patients, 68% to 79% of WUPyV patients, and 10% of KIPyV and WUPyV co-infections in the absence of other respiratory viruses\(^9\). In this study, we investigated the KIPyV and WUPyV in the absence of respiratory tract infections.

Neither WUPyV DNA nor KIPyV DNA was detected in plasma of healthy persons in the current study as shown in Table (2). This results is similar to Csoma et al., (2011)\(^{10}\) which doesnot detect these virus in healthy subjects. It also in line with recent study conducted by Kamminga et al., (2019)\(^{11}\) which detected only one of WUPyV DNA in healthy blood donors but contrast to Šroller et al., (2015)\(^{12}\) which revealed about 58% of KIPyV in serum of healthy blood donors as well as to Song et al., (2016)\(^{13}\) which reported 12.5% of KIPyV VP1 DNA in blood specimens from healthy individuals. The role of the KIPyV and WUPyV in the pathogenesis of the urinary tract and their effect on kidney function is not well explained. Some investigations have shown the presence of both these viruses in asymptomatic people\(^{(14,15)}\).

**Prevalence of KIPyV and WUPyV in study groups**

The KIPyV DNA was detected in (6 out of 113) or (5.3%) in patients with chronic kidney disease, and (3 out of 111) or (2.7%) in patients with urinary tract infection while in control group was (0 out of 100). There was no significant difference (Chi-square = 3.5 ; P value = 0.16) among study groups (CKD patients, UTI patients and control group) as shown in Table (2).
Table (2). Prevalence of KIPyV and WUPyV in study groups

</table>

The present study detected 6 (5.3%) out of 113 (100%) of KIHPyV DNA in chronic kidney disease patients. These result is similar to Csoma et al., (2011) (10) which detect (7/195) to KIHPyV in plasma of renal transplant patients and to Csoma et al., (2014) (16) which revealed the occurrence of KIHPyV in plasma of renal transplant patients also to Badura et al., (2014) (17) and Hansen-Estruch et al., (2018) (18). On the other hand the present result is incompatible to Porrovecchio et al., (2013) (19) which seen that All plasma samples from transplant patients were negative for KIPyV DNA. The present study revealed about 3 (2.7%) out of 111 (100%) were positive to KIHPyV DNA in plasma of urinary tract infection patients. These result is similar to csoma et al., (2012) (20) which detected KIPyV DNA in two plasma samples from non-pregnant women out of 200 plasma samples and to Csoma et al., (2015) (21) but is unsimilar to Limam et al., (2020) (22) which not detected any KIPyV out of 112 from Tunisian patients.

The WUPyV DNA was detected in 1 (0.88%) out of 112 or (0.88%) in plasma of patients with chronic kidney disease and (0 out of 111) in plasma of patients with urinary tract infection while in control group was (0 out of 100). There was no significant difference for WUPyV detection and distribution (Chi-square = 0.77 ; P value = 0.67) as shown in table (2) . The current study detected 1(0.88%) out of 113 (100%) of WUPyV DNA in plasma of chronic kidney disease patients while dosent detect any isolate of WUPyV in plasma of urinary tract infections patients. The result of both groups is compatible to with Csoma et al., (2011) (10) which detect 0.8 of WUPyV in blood from renal transplant patients as well as to csoma et al., (2012) (20) which dosent detect WUPyV DNA in plasma of pregnant and non-pregnant women as well as to Limam et al., (2020) (22) which not detected WUPyV out of 112 from Tunisian patients but is incompatible to Csoma et al., (2014) which record from 9.1% and 5.3% of WUPyV in plasma samples in addition to Aghamirmohammadli et al., (2020) (4) which revealed 1.5% of WUPyV in children under 5 years of age in Tehran, Iran. The low detection of WUPyV in samples from chronic kidney disease and UTI groups may be related to the seasonal distribution and environmental conditions which are important for WUPyV transmission.

Table (3) show the differences in the detection of KIPyV and WUPyV DNA by conventional polymerase chain reaction (PCR) among CKD patients classified by gender. This table shows the positive KIPyV DNA was detected in (7.84 %) and (3.22 %) for female and
male patients respectively. There was no significant difference (Chi-square = 1.19; P value = 0.27) among male and female according to KIPyV detection and distribution. These result is contrast to prezioso et al., (2019)(23) which detected KIPyV in 12/31 thalassemic patients (6 females/6 males) as well as incompatible to Al-Obaidi et al., (2018)(24) which reported 27 (43.55) in male and 4 (44.44) in female of JCPyV in patients with kidney transplantation.

The same table shows the positive WUPyV DNA was detected in (0%) and (1.61%) for female and male patients respectively. There was no significant difference for WUPyV detection and distribution (Chi-square = 0.83; P value = 0.36). These result is similar to Sharp et al., (2009)(25) which recorded only one of WUPyV from a 41-year-old man but un similar to Neske et al., (2010)(26) which reported 49.4% of WUPyV were in male and 46.3% of KIPyV in female in plasma of German blood donors. The plasma viral loads of KIPyV and WUPyV in both gender with this disease might be detectable and their impact on the kidney remains to be determined.

</table>

Table (4) show the differences in the detection of KIPyV and WUPyV DNA by conventional polymerase chain reaction (PCR) among UTI patients classified by gender. This table shows the positive KIPyV DNA was detected in (4.54%) and (0%) for female and male patients respectively while did not detect any isolate of WUPyV in both male and female. There was no significant difference (Chi-square = 2.23; P value = 0.13) among male and female according to KIPyV detection and distribution nor for WUPyV detection and distribution (Chi-square = 0.07; P value = 0.79). These result is similar to Bialasiewicz et al., (2009)(27) which did not detect WUPyV from different biological samples include blood, urine, and CSF. The high rate of KIPyV among female in UTI group may due to the physiology...
of genital tract in female and the incidence of bacterial infection that possibly regard the risk factor for infection with KIPyV.

### Conclusions

The study describes the prevalence of these two viruses in patients with CKD and UTI without respiratory symptoms in Iraq, which demonstrates how these two viruses can be applied as part of virological screening when suspected of etiology of the viral urinary tract and indicate that a candidate respiratory pathogen, KIPyV and WUPyV in the urinary tract can also be identified.

**Effect of Noise on General Health Status of Electrical Generator Workers in Iraq**

Mohammed Fakhri Azeez¹, Fatima Wanas Khudair², Ali A. Al-Fahham³

¹Research Scholar, Faculty of Nursing, University of Kufa, University of Kufa, Iraq, ²Professor, Faculty of Nursing, University of Kufa, Najaf, Iraq, ³Assistant Professor, Basic Sciences Department, Faculty of Nursing, University of Kufa, Iraq

**Abstract**

Electrical generators in Iraq have been a series problem regarding occupational and environmental pollution. The current study aimed to determine the level of general health status among generator workers in Al Diwaniyah City Iraq, and its correlation with noise and demographic data. A descriptive cross-sectional design was conducted in the current study. It was carried out at the private electrical generators in A-Diwaniyah City from the period between the 15th of October 2020 until the 15th of March 2021. A purposive study of 150 generator workers has been selected. General health was determined by General Health questionnaire (GHQ-28) which is comprised of 28 items, and include four aspects: somatic, social, depression and anxiety. Noise intensity level was measured by sound level meter (SLM). The results of the present study revealed that average level of noise intensity inside the workers’ room was (78.12 db); while it was (104.14 db) near the generator. The results also showed that the assessment of most domain (social, depression, and anxiety) was moderate, except for somatic domain which it was good. There was a significant negative correlation between noise and depression and anxiety. It has been concluded that: Most of the generator workers showed a moderate level of general health status; Most of the generators workers had moderate level for anxiety, depression and social aspects; Noise intensities inside the generator rooms exceeds the upper limits accepted for human health.

**Keywords** - Noise, GHQ-28, General Health Status, Generator Workers

**Introduction**

Based on the World Health Organization’s (WHO) definition, health is a state of complete physical, mental, and social well-being and not merely the absence of disease. Also, General Health (GH) as a sub-directory of the health system is the general condition of the body or mind with reference to soundness and vigor. On the other hand, GH is defined as systematic activities and social acts based on the prevention, Science & Art for disease management, increasing expectancy of life and health promotion that lead to welfare (1).

Workers in their own workplaces are exposed to many different hazards and hazardous conditions that can threaten health and life. Although some hazards are less likely to happen in some work spaces than others, it’s important to assess which hazards are most damaging to the organization and its employees (2).

Electric generators while in operation produce gaseous emissions and high sound levels. These pose serious health risk to not only users but to individuals in the surrounding communities. A recent study conducted in Ibadan revealed high generator noise level of between 91.2 and 100.5 dB(A). This noise level is capable of inducing hearing impairment. Noise Induced Hearing Loss (NIHL) can be caused by one time exposure to noise as well as repeated exposure to noise at various levels of loudness over an extended period (3).

Health effects from generator use can range from auditory (hearing) to non-auditory. Noise and carbon monoxide pose serious health risk and due to the
insidious nature of noise on hearing, many individuals may not discover they have hearing difficulty until it has become worse. In addition, due to the strive to achieve financial sustenance, many often neglect their health and work at relatively short distances from generators, and at long hours. A lack of knowledge is identified as one of the barriers to change. Knowledge about occupational hazards (such as noise from electric generator) is suggested to be a predictor of preventive behaviour at work. Effective behavioural change is facilitated by greater knowledge, experience, and personal risk perception (3).

The current study aimed to determine the level of general health status among generator workers in Iraq, it also aimed to determine the noise levels (by a decibel meter) at the generator location and its correlation with the workers general health domains.

**Methods**

A descriptive cross-sectional design was conducted in the current study. It was carried out at the private electrical generators in A-Diwaniyah City in Iraq from the period between the 15th of October 2020 until the 15th of March 2021. A purposive study of 150 generator workers was taken in the current study. The final study instrument consists of three parts:

**Part 1: Demographic Data**

This part is concerned with participants’ socio-demographic data. A demographic data sheet, consists of (10) items, which contain (age, marital status, educational level, monthly income, residency, duration of work at the generator, type of work, smoking status, alcohol intake, BMI).

**Part 2: General Health questionnaire**

The General Health questionnaire (GHQ-28) is comprised of 28 items include somatic symptoms domains (7 items); anxiety domain (7 items); social dysfunction domains (7 items) & depression domain (7 items), the general health questionnaire is a self-administered screening instrument used to measure the psychological distress and general mental health in non-psychiatric persons. The scale was first developed by Goldberger and Hillier (1979).

**Part 3: Noise intensity measurement**

Noise intensity level was measured by sound level meter (SLM), model: UNI-T; UT352, China, with the ranging of 40dB – 160dB.

**Statistical Analysis**

Descriptive statistics presented as mean, standard deviation, frequencies and percentages. Chi-square test was used to compare frequencies. Pearson’s correlation test was used to assess the correlations. Level of significance of ≤ 0.05 was considered as significant difference or correlation.

**Results**

**Table (1) Mean levels of noise (dBA) at the generation locations**

</tbody>
</table>

* Significant correlation at p value < 0.05

Table (3) shows correlation (Pearson Coefficient) between noise inside and outside workers’ room and domains and total assessment of 28-GH, it shows that there is a significant negative correlation between depression domain and noise level inside the workers’ room (r = -0.172; P<0.05); it also explain that there is a significant negative correlation between social domain and noise level inside the workers’ room (r = -0.170; P<0.05); a significant negative correlation between social domain and noise level inside the workers’ room (r = -0.170; P<0.05).

Discussion

The current study recorded that the noise level near the generator is higher than that inside the workers’ room, this is a logical result, where the walls and the door were used as isolating agents for the noise that resulting from the operation of the generator.
The average level of noise inside the workers’ room in this study is (78.12 ± 6.15 dBA), this level is higher than the lower limit of acceptable indoor noise level, this result agrees with the study conducted by Alnayli et al., they have evaluated noise pollution in three locations in Al-Diwaniya City, and found that noise pollution was about 21% higher than the accepted levels identified by WHO. It was found that noise has undesirable effects on the cardiovascular system exposure to noise greater than 70 dB(A) results in increases in vasoconstriction, heart rate and blood pressure reported a case of persistent ventricular fibrillation upon arousal from sleep by noise, and several reports have suggested that transitional periods during waking from sleep may provoke cardiac arrhythmias. A study conducted by Mohammad have reported that cardiovascular effects are associated with long-term exposure to noise in the range of 65–70 dB or more, indicating the private electrical generators as the main source of noise pollution in urban areas.

The current study has also revealed that the mean level of noise intensity near the generator was (104.14 ± 2.87 dBA) as in table (1). This results is similar to the result recorded by Al-Naemi and Abdel who found that noise intensity inside the generator room was (95.18 ± 0.78 dBA) which had negative effects on the hearing capabilities of the workers, and resulted in increase in lipid profile markers, and decrease in anti-oxidant indicators, in workers compared to healthy control group. Table (3) shows a negative correlation between the level of noise and the level of general health status in all its dimensions, and this result is identical to what has been scientifically proven that noise has effects on health, a loud and continuous voice causes temporary or permanent loss of hearing, increased blood pressure, distorted heart rate, increased adrenaline, disrupted the proper functioning of the kidney. Damage to the human psyche, a feeling of fear and pressure on the nerves and the ability to focus on thoughts, work and learning. Excessive noise is considered a form of violence because it provokes a sense of helplessness, fatigue, and the desire to use violence against the source of the noise.

According to the International Programme on Chemical Safety (WHO 1999), an adverse effect of noise is defined as a change in the morphology and physiology of an organism that results in impairment of functional capacity, or an impairment of capacity to compensate for additional stress, or increases the susceptibility of an organism to the harmful effects of other environmental influences. This definition includes any temporary or long-term lowering of the physical, psychological or social functioning of humans or human organs. The health significance of noise pollution is given in this chapter under separate headings, according to the specific effects: noise-induced hearing impairment; interference with speech communication; disturbance of rest and sleep; psychophysiological, mental-health and performance effects; effects on residential behaviour and annoyance; as well as interference with intended activities.

It was reported that oxidative stress induced by noise and hazardous effects of toxic gases may have direct effects on cardiovascular dysfunctions, hormonal disturbances, and hearing disabilities that may interfere with both physical and mental health domains. A recent study have investigated deeply the environmental pollution resulting from the combustion of fuel used in electric power generators in Iraq, especially in the summer and you are the national electric power supplied by almost non-existent state where this problem is a local phenomenon that has serious dimensions to human health; they found that many types of gases emitted from burning fuel electric generators operating in the province of Baghdad indicating the amount of environmental pollution, which is more risk to humans with permitted by the World Health Organization.

Conclusions

It has been concluded that: Most of the generator workers showed a moderate level of general health status. Most of the generators workers had moderate level for anxiety, depression and social aspects. Noise intensities inside the generator rooms exceeds the upper limits accepted for human health. The is a correlation between...
noise produced by the generators and the decline in the anxiety and depression aspects of the workers.

Effect Phenytoin Therapy to Fibroblasts and Angiogenesis of Enterocutaneous Fistula in Wistar Rat

Muhammad Budiman Irpan Bachtir1, Hermawan2, Hardian3, Ignatius Riwanto4
1Master Biomedical Student at Diponegoro University Biomedical Master’s Student, 2Lecture at Departemen of Anatomic Pathology, Faculty of Medicine, Diponegoro University, 3Lecture at Department of Physiology, Faculty of Medicine, Diponegoro University, 4Lecture at Department of Digestive Surgery, Faculty of Medicine, Diponegoro University

Abstract

Background: Comprehensive wound care in enterocutaneous fistula (ECF) is the therapeutic of choice currently, which may increase of closure rate without surgery from 19 to 92%. Phenytoin has been reported to have anticolagenase effect on wound healing is hoped to improve the ECF closure.

Aim: The study was aimed to demonstrate the effect of phenytoin on closure of enterocutaneous fistula seen from the number of fibroblasts and angiogenesis

Methods: This study was “Randomized Controlled trial with post test only group design” on 18 male wistar rats with ECF, that were divided randomly into three groups: group(K) control, P1(topical phenytoin), P2(oral phenytoin). After 7 days of treatment, they were terminated and histopathological examinations were performed to do fibroblast cell counting and the amount of angiogenesis by Hematoxilin Eosin staining.

Results: Mean of the number of fibroblast in groups K, P1 and P2 were 69.50 ± 10.07, 155.50 ± 13.50 and 182.16 ± 11.85 respectively (One way Anova P=0.001) and mean of the number of angiogenesis in groups K, P1, and P2 were 95.66 ± 9.72, 178.66 ± 11.75, and 205,16 ± 9.74 respectively (One way Anova P=0.001). Post Hoc Test LSD showed that the number of fibroblast of group P1 vs K(P=0.001), P2 vs K(P=0.001), P1 vs P2(P=0.004) and the number of angiogenesis of group P1 vs K(P=0.001), P2 vs K(P=0.001), P2 vs P1(P=0.002).

Conclusion: The therapy of topical and oral phenytoin increased the number of fibroblasts and angiogenesis in Wistar rat with ECF. Outcome of oral phenytoin therapy better than topical.

Key words: Enterocutaneous fistulas, phenytoin, fibroblasts, angiogenesis

Introduction

Enterocutaneous fistula (ECF) is an abnormal communication between the intra-abdominal digestive tract and the skin.1,2 The ECF occurs spontaneously on 30% due to malignancy, sepsis, radiation or inflammatory diseases of the intestine, whereas due to postoperative complications of more than 75%.2,3 ECF patients are faced with conditions of increased morbidity and mortality due to it complications. Comprehensive wound care accompanied with parenteral nutrition (TPN) is currently the treatment of choice, with closure of fistulas without surgery increasing from 19% to 92%.5-7

After the ECF occurs, therapy must be immediately carried out with optimal patient stabilization and non-operative therapy which is conventional therapy.1
Prognostic factors that allow spontaneous closure of fistulas are influenced by several factors, namely ECF that occurs due to surgery, transferrin value > 200 mg/dl, fistulasize of < 2 cm, absence of obstructive, inflammatory, and intestinal infections. Presence of components in the form of foreign bodies, radiation, inflammation, infection, inflammatory bowel disease, epithelization of the fistula tract, neoplasms, distal obstructions, and steroids (FRIENDS) are indication for surgical intervention. In conventional therapy of ECF wound care plays an important role in the process of spontaneous closure, so that the administration of therapy to the wound in order to speed up closure is very necessary. The healing of passage in fistulas consists of various processes, including cell migration and the formation of new extracellular matrices, one of which is increased of fibrosis.

Presently, wound care at ECF also has many methods that can be done with moist dressing until the treatment using negative pressure wound therapies (NPWT) or one of which is often known as vacuum assisted closure (VAC). The use of VAC is currently reported to improve the quality of life for patients EFC, which the skin around the EFC wound is protected. The implementation of this method has a high cost and expertise of trained stoma nurses, so that there is still a need for an EFC wound care method that can more easily be developed.

Phenytoin drug has long been known as an anti-seizure drug is currently reported from several studies showing it had a therapeutic effect on wound healing. This has been supported by many studies and studies that reported since decades. Several studies have shown the advantages of therapeutic effect of the administration of phenytoin on healing burns, trauma wounds, venous static ulcers.

The mechanism of phenytoin in wound healing at this time is still uncertain, but in vitro research, it is known that there are several mechanisms that can support wound healing. The mechanism consists stimulation of proliferation of fibroblasts, increasing angiogenesis, increasing the formation of granulation tissue, glucocorticoid antagonists, decreasing collagenase activity, increasing collagen deposits, decreasing exudate in wounds and also finding antibacterial effects. In other studies phenytoin was found to have a mechanism to reduce MMP-1 and 9 which prove the anti-collagenase effect of phenetoin. This mechanism is the basis for the application of the case in ECF, with an increase in the number of fibroblasts and angiogenesis will enable the closure of the fistula canal.

Jaber reported in 2013 a case series of studies conducted with intravenous phenytoin giving a positive effect on the healing of gastrointestinal fistulas. The positive effects of phenytoin shown through systemic stimulation are significant because of the side effects that can occur in long-term administration. Teo, in vitro studies show safety in topical phenytoin administration and therapeutic effect on wound healing. So that research into the effects of phenytoin on ECF healing needs to be further developed by topical administration and oral administration which has not been done at this time.

**Materials and Method**

**Subject**

This research is an experimental study with a “Randomized Controlled Trial with Post Test Only Group Design” design. The study used Wistarrat\textit{RattusNorvegicus} strain which will be divided equally into three random groups, 1 control group and 2 intervention groups. All groups were made to have the presence of ECF by surgical procedures. One group will be a control group treated with ECF wounds treated with moist gauze which will be terminated on the 7th day, while other subjects according to the group division will be treated with topical and oral phenytoin wounds which will be terminated on the 7th day.

Experimental animals are Wistarrat strain\textit{(RattusNorvegicus)}. Inclusion criteria were 8-10 weeks old who performed the procedure for making ECF, body weight ± 150-200 grams after acclimation
for a week in individual cages and no visible anatomical abnormalities. While the exclusion criteria were rat appeared to be sick (inactive movements) during the treatment of ECF. Rats that lost > 10% and died at the time of the study were included in the drop out criteria. In this study, the number of samples used 6 ratsin each group. The sample was 18 rats. Each rat was then labeled number 1-18. The division of groups is done randomly by drawing lots.

The research and data collection were carried out for 3 months from April-June 2019. The topical phenytoin production site was conducted at the Chemistry Laboratory of the Sekolah Tinggi Ilmu Farmasi (STIFAR) Yayasan Farmasi Semarang. Procedures for making enterocutaneous fistula conditions, treatment of rats, tissue retrieval, the process of making preparations and HE staining were carried out at the Laboratory of the BioSains Institute of Brawijaya University, Malang.

The independent variables are:
1. Topical phenytoin
2. Oral phenytoin
3. Without the administration of phenytoin

The dependent variables are:
1. Number of fibroblasts in histopathological preparations
2. Number of total angiogenesis in histopathological preparations

**Experimental design**

Rats were acclimatized in the laboratory for one week in individual cages with periods of 12 hours of light and 12 hours of darkness. Rats were fed and drank ad libitum. Providing food with feeds whose nutritional value composition has been standardized. After acclimatization, the rats were carried out the procedure of making enterocutaneous fistulas.

Animals were anesthetized intraperitoneally with 80 mg/kg ketamine (Pantex Holland, Duizel, Netherlands) and 10 mg/kg xylazine (Pantex Holland) diluted in PBS. The cecum was accessed through a standard 7-mm stab incision on the lower left side of the abdomen, sparing the colon upon exposure, and a 5-mm enterotomy was performed and sutured to the abdominal wall to create an enterocutaneous fistula. To allow spontaneous closure of the fistula, the opening in the cecum wall was secured to the borders of the surgical wound without maturation. At this point, the animals were randomly allocated into one of three groups:

1. Control group (CG)—the enterocutaneous fistula wound that was treated with moist gauze and terminated on the 7th day,
2. Topical phenytoin group (TPG)—the enterocutaneous fistula wound that was treated with 10% phenytoin ointment and terminated on the 7th day
3. Oral phenytoin group (OPG)—the enterocutaneous fistula wound that was treated with oral phenytoin and terminated on the 7th day. Oral phenytoin given with a maximum human dose (300 mg/day) is converted into a rat dose (200gr) through a conversion table. Based on the conversion, the dosage is 0.03 mg/grBB given once a day. Drug administration is made by dissolving phenytoin with aquabidest and given orally with a sonde.

**Statistical Analysis**

After the data is collected, editing, coding, tabulation and entry are carried out. Data analysis includes descriptive analysis and hypothesis testing. In descriptive analysis the dependent variable is presented in the form of a mean table, SD, median and box plot graph. The data in this study were normally distributed after the data normality test with the Saphiro-Wilk test both on the number of fibroblasts and the number of angiogenesis in each treatment group. Data analysis continued with the hypothesis test used was the One Way Anova test followed by a Post-Hoc Test to determine differences between groups.

**Research Ethics**

The animal experiments were performed in
8-10-weekold Wistar rat strain (*Rattus Norvegicus*) in which an enterocutaneous cecal fistula was created. The study was submitted and approved by the Diponegoro University Faculty of Medicine Research Ethics Commission No. 78/EC/H/KPEK/FK-UNDIP/V/2019. Eighteen animals were used in the experiments.

**Results**

The study was conducted on 18 Wistar rats, which were divided into 3 groups; i.e. groups of rats who treated with fistula wound treatment with moist gauze (C), topical phenytoin (P1) and oral phenytoin (P2), each group consisted of 6 rats, and until the end of the study were healthy and not included in the dropout criteria.

**Characteristics of Research Samples**

The average calculation result of 18 rats body weight, on the 7th day of acclimatization where that day is also the first day of the treatment process. This can be seen in table.

**Number of Fibroblasts**

Information: * Significant (p < 0,05); ** Homogen (p > 0,05)

From table 1, it can be seen that the rat weight data are normally distributed and homogeneous. The highest rat weight was found in the group with topical administration of phenytoin, which was 182.17 ± 5.981 grams.

**Distribution of data**

Variable data on the number of fibroblasts obtained an average number of 69.50 ± 10.07 in the group without phenytoin (C) therapy, 155.50 ± 13.50 in the group of topical phenytoin (P1) and 182.16 ± 11.85 in the oral phenytoin therapy group (P2). From the results of the normality test obtained normal distribution results (p> 0.05)

**Statistical Test for the Number of Fibroblast**

![Figure 2. Boxplot graph of the number of fibroblasts from each group. C: fistula wound treatment with moist gauze, P1: fistula wound treatment with topical phenytoin, P2: fistula wound treatment with oral phenytoin (P2). There was a statistically significant difference (One Way ANOVA P <0.05). Also found significant differences when compared to each group (Post Hoc test); * significant P <0.05)
From the box above, it shows that there are differences in the number of fibroblasts. The lowest number of fibroblasts was seen in the control group without phenytoin therapy, 69.50 ± 10.07, while the highest number of fibroblasts was seen in the treatment group with oral phenytoin administration, which was 182.16 ± 11.85. Based on the One way ANOVA test, it can be seen that the p value <0.05, which means the difference is significant. In the Post-Hoc test there were differences in the number of fibroblasts from the groups given both topical and oral phenytoin therapy had a significant difference compared to the control group in each group (p <0.05), and there were significant differences in the groups given topical phenytoin compared the group was given oral phenytoin (p <0.05).

**Total angiogenesis**

![Histopathological picture of the amount of angiogenesis by painting hematoxylin-eosin with 400x magnification. a. Without treatment, b. Topical phenytoin, c. Oral phenytoin; arrows indicate angiogenesis.](image)

**Distribution of data**

Variable number of angiogenesis data obtained an average number of 95.66 ± 9.72 in the group without phenytoin (C) treatment, 178.66 ± 11.75 in the topical phenytoin (P1) and 205.16 ± 9.74 groups in the oral phenytoin therapy group (P2). From the results of the normality test obtained normal distribution results (p>0.05).

From the boxplot graph, figure 4 shows that there are differences in the number of angiogenesis. The lowest
number of angiogenesis in the control group without phenytoin therapy was 95.66 ± 9.72, while the highest number of angiogenesis was seen in the treatment group with oral phenytoin administration which was 205.16 ± 9.74. Based on the One way ANOVA test, it can be seen that the p value <0.05, which means the difference is significant. In the Post-Hoc test there were differences in the number of angiogenesis of the groups given both topical and oral phenytoin therapy had significant differences compared to the control group in each group (p <0.05), and there were significant differences in the groups given topical phenytoin compared the group was given oral phenytoin (p <0.05).

**Statistical Test of Total Angiogenesis**

![Boxplot graph of the number of angiogenesis of each group. C: fistula wound treatment with moist gauze, P1: fistula wound treatment with topical phenytoin, P2: fistula wound treatment with oral phenytoin. (P2) There is a statistically significant difference (One Way ANOVA P <0.05), and also a significant difference when compared in each group (Post Hoc test); * significant (P <0.05)](image)

**Discussion**

This study aimed to see the effect of phenytoin administration on the spontaneous closure of ECF. The effect was assessed on the number of fibroblasts and the number of angiogenesis in the healing process or spontaneous closure of ECF in Wistar rats. This study was conducted on Wistar rats that met the inclusion criteria and were treated for 7 days and subsequently assessed in fistula tissue by looking at the number of fibroblasts and angiogenesis through HE staining.

From this study, fistula tissue was taken on the 7th day after each group was treated, which time was the end of the inflammation phase of the wound healing process. In the treatment group using topical and oral phenytoin therapy it was found that there was a significant difference in
the number of fibroblasts with the group giving oral phenytoin having the highest number. The higher number of fibroblasts in the administration of phenytoin therapy indicates the effect of phenytoin therapy on ECF, this is in accordance with the theory that the administration of phenytoin has a stimulating effect on fibroblasts proliferation. Increased fibroblast proliferation in the ECF induction will have an effect positive in spontaneous closure of ECF. One of the factors expected to occur in fistula closure therapy is the presence of fibroblasts to support the wound healing process.

In conventional ECF therapy currently popular using VAC which in its application has a mechanism of reducing proinflammatory cytokine and inducing microdeformation on the wound surface and complex wound healing. Lu, Feng et al show that microdeformation in wound healing is related by induction of fibroblasts. The positive effect of the differences in the number of fibroblasts in this study could be a factor in the process of spontaneous closure of ECF. Intravenous administration of phenytoin to ECF in previous studies also showed good results with reduced output of the fistula.

This study also assessed the amount of angiogenesis in skin tissue, on the 7th day after each group was given treatment and found the highest value for the amount of angiogenesis found in the group giving oral phenytoin therapy. Whereas the treatment group that was not given phenytoin therapy had the lowest amount of angiogenesis. From these results it was found that there were significant differences in the number of angiogenesis between groups not given phenytoin therapy and groups who were given phenytoin therapy either topically or orally.

Angiogenesis is an important factor in the tissue’s ability to repair itself and eliminate debris, providing nutrients and oxygen to the wound layer. The formation of granulation tissue which is a dense network of blood vessels, macrophages, and fibroblasts embedded in loose matrix fibronectin, hyaluronic acid, and collagen depends on the vascularization of the wound tissue and begins to appear in the wound about four days after injury.

The higher number of angiogenesis in the treatment group of phenytoin proved that the effect of phenytoin therapy was most likely through M2 stimulation to increase the expression of growth factors, one of which was VEGF which played a role in increasing the amount of angiogenesis. In the process of spontaneous closure of the fistula angiogenesis is also needed so that collagen deposits and granulation tissue can occur.

The treatment using oral and topical phenytoin therapy also aims to see the difference from topical and systemic phenytoin therapy. Systemic administration of phenytoin is known to have side effects in long-term administration, namely osteomalacia, gingival hyperplasia, and hepatic and renal disorders in rare prevalence. The positive results of the phenytoin treatment group in this study also showed a significant difference between the groups given topical and oral therapy both in the number of fibroblasts and the number of angiogenesis observed, so that the study assumed the selection of phenytoin therapy in enterocutaneous fistulas was superior to oral administration. or systemic. Jaber reported in 2013 a case study conducted with intravenous phenytoin giving a positive effect on the healing of gastrointestinal fistulas, in this study, Jaber chose systemic therapy because healing that was considered more important in fibrosis in the fistulacan be achieved through systemic therapy compared to topical given on the surface of the fistula wound.

Conclusion

This conclusion was followed by the number of fibroblasts and angiogenesis in the administration of topical phenytoin in the ECF of Wistar rats, higher than those not receiving phenytoin therapy. In addition, the number of fibroblasts and angiogenesis in oral phenytoin administration in the Wistar rat ECF were higher than those not receiving phenytoin therapy. It can also be concluded that the number of fibroblasts and angiogenesis in oral phenytoin administration in Wistar rat ECF, is higher than those without topical phenytoin.
The author recommends further research with a longer observation time to see the process of closing the ECF on the administration of phenytoin therapy and research on patients who have criteria for spontaneous closure with VAC and phenytoin therapy both oral and topical as additional therapy.

Legal Policy in the Prevention of Narcotics in Indonesia

Muhammad Yunus Idy1, Marif1, Handar Subhandi Bakhtiar2
1Faculty of Law, Universitas Islam Makassar, Indonesia, 2Faculty of Law, Universitas Pembangunan Nasional Veteran Jakarta, Indonesia

Abstract
The purpose of law enforcement against criminal acts of narcotics and psychotropic abuse is to improve the health status and human resources of Indonesia. The new law concerning narcotics has two approaches to parties using narcotics illegally or in other words, abusing narcotics. The first approach is to see the drug users as victims so that they must be rehabilitated, and the second approach is to look at drug users as perpetrators of criminal acts. Criminal acts related to narcotics crimes can generally be divided into 3 (three) types, namely supplying which is usually done by producers or importers. The act of distributing narcotics and other illegal drugs carried out by dealers or sellers and then the users or people who abuse the narcotics. Therefore, the efforts to eradicate narcotics abuse must include all those three types of activities or actions. The efforts to eradicate it must start from the upstream part of the supplier. The policy in combating narcotics abuse is a positive legal policy which is not only merely the implementation of normative juridical laws, but also requires a factual juridical approach that is comprehensive and integral.

Keywords: Legal Policy, Narcotics, Psychotropics.

Introduction
Each country has a legal system that reflects the history and experience of the country’s people in the development of their economic, political, cultural and traditional structures. A good legal system seeks to limit actions that harm the society for the security of the community itself. When people feel insecure, vigilante acts will occur.

The opening of the Constitution of the Republic of Indonesia, the fourth paragraph, states that the state intends to protect the entire Indonesian nation, and the whole of the Indonesian bloodshed. The philosophical juridical statement contains 2 (two) fundamental meanings, namely: one of the principles of the administration of the state (government) which must be oriented towards the goal of protecting all Indonesian people, and the principle of protecting the state (government) based on equality before the law. The relationship between the principle of protection and the principle of equality before the law in the overall activities of state administration leads to the framework of law enforcement.

Law enforcement is closely related to the legal system and legal objectives, explain that discussing law enforcement can begin by examining the issue of what will be upheld. When talking about law enforcement, it is essentially talking about the enforcement of ideas and concepts which are beneath abstract. Law enforcement is an attempt to turn these ideas into reality and the state must intervene to realize abstract laws by holding various bodies for this purpose. The legal system which consists of legal substance, legal structure, and legal culture are always directed towards achieving legal objectives, namely: to achieve legal certainty, benefit, and justice. Radbruch taught that we must use the principle of priority where the first priority is justice,
benefit, and finally the certainty. Law enforcement which is controlled by the legal system will be able to realize legal objectives when positioned on a balance between the formal law enforcement which tends to pursue legal certainty and the substantial law enforcement which seeks to achieve legal benefit and justice.

Law Enforcement is covering the duty and authority to defend the law (handhaving van het recht) against a person or group of people who violate the law or committed an unlawful act or denial of a legal commitment including enforcing the law, namely the act of establishing the law regarding things such as the status of an object or objects. Both in theory and tactics, this traditional understanding is incomplete because of the connotation of law enforcement only by mere repressive actions. Whereas in a broader sense, law enforcement also includes preventive measures even broader than that. Law enforcement in the context of the rule of law/legal state (rechtstaat) has 3 (three) main pillars, namely: (1) the legality of all actions of law enforcement officers including citizens; (2) the guarantees for the recognition, protection, respect and enforcement of human rights, and (3) the implementation of a free, fair and impartial court. The imbalance between the three pillars of law enforcement causes discrimination and arbitrariness, and leads to the destruction of the joints of legal life in the legal state.

The relevance of law enforcement (various legal fields) in the context of a legal state with its main pillars (principle of legality, human rights, the impartial court) requires a good judicial system and is able to accommodate all the sub-systems of the judiciary. One justice system that has direct contact with law enforcement against narcotics crimes is the criminal justice system (hereinafter referred to as SPP). The discussion in the field of criminal law policy (penal policy) will be oriented towards the efforts to criminal law reform in the future, specifically related to legislative policy against criminal acts of narcotics abuse in Indonesia. The Criminal Justice System is essentially a criminal law enforcement process. Therefore it is very closely related to criminal law itself, because criminal law is basically a criminal law enforcement system in abstracto which will be realized in law enforcement in concreto. For this reason, this article will discuss about the concept of government policy in the efforts to combat the criminal acts of the narcotics and psychotropic abuse in Indonesia.

Research Methods

This research is a normative-legal research using a statute and conceptual approaches. Those legal material collected are analysed descriptively related to the problems and prescriptively.

Analysis and Discussion

Today’s law enforcement has a broader meaning, which not only concerns law enforcement, but also includes preventive measures. This is different from the English term of law enforcement; the Indonesian law enforcement is more repressive. While the preventive form is the provision of information and instructions called law compliance, which means compliance or legal arrangement.

Law enforcement is essentially an effort to enforce legal norms, both in the form of orders and prohibitions. The purpose of law enforcement against criminal acts of narcotics and psychotropic abuse is to improve the health status and human resources of Indonesia. Therefore, in order to realize people’s welfare, efforts should be made to improve the field of medicine and health services, among others by seeking the availability of certain types of narcotics which are urgently needed as medicines and preventing and eradicating the danger of abuse and illicit trafficking of narcotics and narcotics precursors. The policy of eradicating crime through the making of criminal laws is an integral part of the public protection policy and is an integral part of social politics. Social politics can be interpreted as all rational efforts to achieve people’s welfare and at the same time protect the community.

Pancasila is the source of all legal sources. Therefore, the values contained in Pancasila should be the basis of law enforcement in combating narcotics and psychotropic
crimes, especially the values of justice, legal certainty and the same legal treatment for everyone as contained in Article 27 paragraph (1) of the 1945 Constitution of Republic of Indonesia regulates that all citizens are equal in law and government and are obliged to uphold the law and government with no exception. Whereas the values of humanity as contained in the second principle of Pancasila are closely related to the purpose of punishment. In this case, the punishment imposed on the perpetrators of narcotics and psychotropic crimes must not exclude the values of humanity, in the sense that the punishment continues to uphold human dignity.

Provisions that give the authority to the National Narcotics Agency to carry out arrests that exceed the arrest period in the Criminal Procedure Code states that the Arrest as referred to in Article 17, can be carried out for a maximum of one day, are contrary to the principles of justice and legal certainty as contained in Article 3 of Law No. 35 of 2009 concerning Narcotics, and the same legal treatment for each person.

One of the authorities possessed by the National Narcotics Agency as an investigator is to make arrests for 3 x 24 hours from the date the arrest letter is received by the investigator and can be extended for a maximum of 3 x 24 hours. This is one form of difference in authority between the National Narcotics Agency and other law enforcement officers, namely the police. The authority to arrest done by the police is based on the Criminal Procedure Code. Based on the provisions of Article 19 paragraph (1) of the Criminal Procedure Code that arrests can be made for a maximum of one day. This difference in authority will lead to differences in treatment of suspects who are allegedly involved in narcotics and psychotropic crimes. Suspects in narcotics and psychotropic crimes can only be arrested by the police for a maximum of 1 day, while suspects arrested by the National Narcotics Agency can be held for up to 6 days.

The difference in treatment between the suspects arrested by the National Narcotics Agency and the police will lead to injustice and legal uncertainty. Therefore, in order to realize justice, legal certainty and equal treatment for every suspect of narcotics crime, efforts need to be made to provide the same basis to the National Narcotics Agency and the police in handling or enforcing the law against narcotics and psychotropic crimes. This effort can be done by formulating a separate regulation that gives the same authority to the police and the National Narcotics Agency, or by revising the narcotics law specifically related to the authority of the two law enforcement agencies.

The regulation concerning the Narcotics and Psychotropic Crime in Indonesia cannot be separated from international policies related to the Criminal Actions of Narcotics and Psychotropic abuse. This international policy is formulated in various kinds of conventions. The UN Conventions on Narcotics and Psychotropics include Single Convention on Narcotic Drugs in 1961 and United Nation Convention Against Illicit Traffic in Narcotic Drugs and Psychotropic Substances in 1988. Single Convention on Narcotic Drugs in 1961 along with protocols that change the convention namely Protocol Amending the Single Convention on Narcotic Drugs in 1961 was accepted and ratified by Indonesia with the enactment of Law No. 8 of 1976. While the United Nation Convention Against Illicit Traffic in Narcotic Drugs and Psychotropic Substances in 1988 has also been accepted and ratified by Indonesia with the enactment of Law No. 7 of 1997.

The United Nations Single Convention on Narcotic Drugs 1961 is an international agreement that prohibits the production and supply of narcotics and illegal drugs except under licenses for certain purposes such as medical care and research. The convention was aimed at renewing the Paris Convention on July 13, 1931. This Convention included a number of synthetic opioid products found in the last 30 years and also to facilitate the incorporation of new types of narcotics into the agreement. The previous agreement only controlled the production and illicit traffic of opium, coca, and derivatives such as morphine, heroin and cocaine. This 1961 Single Convention was a consolidation of the previous agreements that expanded the coverage by
including marijuana and other drugs which effects were similar to certain types of narcotics.

The international conventions mentioned above become a reference for Indonesia in making regulations relating to narcotics and psychotropic crimes. These regulations are formulated in several forms of legislation, the last of which is Law No. 5 of 1997 concerning Psychotropic and Law No. 35 of 2009 concerning Narcotics.

Based on the new narcotics law, the use of narcotics can be seen from two perspectives. The first is the legal use of narcotics which is used in accordance with the applicable legal provisions. The second is the use of narcotics which is illegal or contrary to the law which is referred to as narcotics abuse. Narcotics can be used legally and not against the law, if it is done for medical purposes and the development of science.

The new law concerning narcotics has two approaches to parties using narcotics illegally or in other words, abusing narcotics. The first approach is to see the drug users as victims so that they must be rehabilitated, and the second approach is to look at drug users as perpetrators of criminal acts. Elucidation to Article 54 of Law No.35 of 2009: What is meant by victims of Narcotics abuse is someone who unintentionally uses Narcotics because he was persuaded, tricked, deceived, forced, and / or threatened to use Narcotics.

Criminal acts related to narcotics crimes can generally be divided into 3 (three) types, namely supplying which is usually done by producers or importers. The act of distributing narcotics and other illegal drugs carried out by dealers or sellers and then the users or people who abuse the narcotics. Therefore, the efforts to eradicate narcotics abuse must include all those three types of activities or actions. The efforts to eradicate it must start from the upstream part of the supplier. The supplier of narcotics or psychotropics can be a producer or importer. The efforts to eradicate upstream parts can be carried out in the form of strict supervision so that the illegal production and importation of narcotics can be prevented. If this can be done well, the illegal circulation can also be reduced. Furthermore, if the illegal distribution is reduced or even eliminated, then its illegal use can also be reduced or even eliminated.

The focus of efforts to eradicate narcotics and psychotropics should be directed towards the efforts to prevent the occurrence of illegal distribution, not only solely focusing on efforts to eradicate the abuse. If illegal drug trafficking can be handled properly, the distributors will find it difficult to get narcotics to be traded. If they still can get the drug, the price will be very expensive because the supply of the drug is very limited. Thus, illegal users will also find it difficult to obtain narcotics and other illegal drugs because of the limited supply, and the very high prices. The main objective to be achieved in this regard is the creation of a condition that can make it difficult for dealers and illegal users to easily get narcotics and illegal drugs.

The law enforcement in the effort to eradicate criminal acts of narcotics and psychotropics should be more focused on efforts to prevent the occurrence of illegal circulation. This effort can be realized in the form of strict supervision to the producers and importers. Based on the results of the research conducted in 5 (five) sample regions, it is known that the current effort to eradicate narcotics crimes is more focused on the aspect of abuse, not on the efforts to prevent illegal distribution of the drugs. It shows that the law enforcement efforts are directed more at the illegal users. This is difficult to be expected to reduce the occurrence of criminal acts of narcotics abuse because narcotics and other illegal drugs can still be easily obtained. The main factor that causes the crime of narcotics abuse is because narcotics and other illegal drugs can be obtained easily. If the narcotics and illegal drugs cannot be obtained illegally, the use of illegal drugs can also be reduced or even eliminated. Therefore, the efforts to eradicate narcotics crimes must be carried out comprehensively starting from the upstream part, which is the suppliers, either producers or importers, up to the downstream, which is the users.

The policy in eradicating criminal acts of narcotics abuse is a positive legal policy which in essence is not
merely an implementation of normative juridical laws. In addition to the normative juridical approach, criminal law policy also requires a comprehensive and integral factual juridical approach. The law has provided a sufficient legal umbrella and has regulated the suppliers, importers or producers, and the users, but at the level of implementation, law enforcement efforts still need to be improved. This is more related to the performance of the law enforcement officers themselves.

Based on the description in the previous sections, it can be understood that the fundamental problem faced in eradicating criminal acts of narcotics abuse is the lack of legal factors, namely legislation in anticipating the development of the modus operandi of narcotics crime and because of internal systems and performance law enforcement itself. As stated by Friedman, there are 3 (three) main components in the legal system that are effectively related and affecting each other in the law enforcement efforts. The three components are the factors of law (the substance), the structure, and the legal culture. If the legal factors are weak but the law enforcement officers are consistent and firm and supported by adequate management and facilities, then supported by a conducive community legal culture, the performance of law enforcement will take place effectively. However, if the legal arrangements are good but the law enforcement agencies are not firm and inconsistent; the facilities and management are disproportionate; the society is not conducive, the performance of law enforcement becomes ineffective.

Based on the provisions of Article 4 of Law No. 35 of 2009 concerning Narcotics, it can be understood that the policies related to narcotics and psychotropic crimes are inseparable from the objectives of the law, namely: (a) guarantee the availability of Narcotics for the benefit of health services and/or the development of science and technology; (b) prevent, protect and save the Indonesian people from narcotics abuse; (c) eradicate narcotics and narcotics precursors illicit traffic and; (d) guarantee the regulation of medical and social rehabilitation efforts for abusers and drug addicts. Therefore, the formulation of the offense in the narcotics law covers planting, production, distribution, traffic, circulation to the users, including personal use.

Even the results obtained from criminal acts of narcotics and psychotropic abuse, whether in the form of movable or immovable assets, tangible or intangible assets as well as goods or equipment used to carry out narcotics and narcotics precursors crimes are confiscated for the state. This is in accordance with the provisions of Article 136 of Law No. 35 of 2009 concerning Narcotics.

The policy of eradicating crime by using penal means is a form of repressive action that focuses on prosecution after the crime has occurred, namely the imposition of criminal sanctions. The success of the efforts to eradicate psychotropic crime is largely determined by the existence of good integration and cooperation between law enforcement officials both the police and the National Narcotics Agency. This integration will ultimately lead to harmony and balance of life in the society.

Law enforcers have made serious efforts to eradicate criminal acts of narcotics and psychotropic abuse. There have been many parties who have been arrested and have even been convicted, ranging from illegal users, dealers, importers, to the producers. However, other facts show that the level of abuse of narcotics and psychotropic substances in Indonesia continues to increase from year to year. This shows that law enforcement efforts carried out by the law enforcement officials in eradicating criminal acts of narcotics and psychotropic abuse are still less effective.

**Conclusion**

The policy in eradicating criminal acts of narcotics abuse is a positive legal policy which in essence is not merely the implementation of normative juridical laws. In addition to the normative juridical approach, criminal law policy also requires a comprehensive and integral factual juridical approach. The new narcotics law also has two approaches to the parties using narcotics illegally or in other words, abusing narcotics. The first approach is to see the drug users as victims so that they
must be rehabilitated and the second approach is to see the drug users as perpetrators of criminal acts. Criminal acts related to narcotics crimes can generally be divided into 3 (three) types, namely supplying narcotics and other illegal drugs, which is usually done by producers or importers; distributing the drugs, which is carried out by dealers or sellers; and using the drugs or abusing the drugs. Therefore, efforts to eradicate it must also include all three types of activities or actions.

Abstract

Background: Malaria remains a global leading cause of morbidity and mortality. The absence of effective vaccines is still the vital hindrance to the management and elimination of malaria. From that standpoint, accurate laboratory diagnosis could be the right hand for disease management. Objective: This review intended to assess the recent perspectives and upcoming directions in molecular diagnosis of malaria. Methods: This review was conducted by using internet searching tools where 35 published papers were retrieved from the credible online publishers and among them, 27 papers that satisfy the inclusion criteria were profoundly reviewed.

Results: Among the 27 articles, 22(81.48 %) papers focus on contribution of PCR based-method in malaria diagnosis, 4(14.8%) report on comparison between polymerase chain reaction(PCR) and other molecular techniques, 7(30%) emphasize on advantages and disadvantages of PCR, 4(14.8%) represent relationship among PCR and LAMP, 3(11%) discuss the most promising molecular diagnostic tools, 5(18%) focus on comparative designs of different PCR methods, whereas 1(3.7%) emphasizes on parasite density and 2(7%) on pigment containing monocyte.

Conclusion: This review conclude that microscopy remains the gold standard method for malaria diagnosis and speciation in limited resource settings but also molecular based-methods provide significant alternatives with superior sensitivity and specificity.

Keywords: Malaria, Molecular Diagnosis, LAMP, PCR, Microscopy.

Introduction

Malaria is one of the major public health problems hampering developmental efforts in most developing countries (1). Malaria is spread by contaminated mosquito with parasitic protozoans (a group of single-celled microorganisms) belonging to the genus Plasmodium (2). Plasmodium genus have five species of parasites that affect vertebrates (humans), these species are Plasmodium falciparum, Plasmodium vivax, Plasmodium malariae, Plasmodium knowlesi and Plasmodium ovale (1). The disease is most frequently transmitted by an infected female Anopheles mosquito. After biting, the mosquito introduces the parasites from its saliva into a person’s blood (2).

Malaria symptoms typically develop within 10 days to four weeks following the infection. Common symptoms of malaria include: shaking chills that can range from moderate to severe, high fever, profuse sweating, headache, nausea, vomiting, diarrhea, anemia, muscles pain, convulsions, coma and bloody stools (2).

In terms of diagnosis, for more than 100 years, microscopy has been the gold standard diagnostic tool for malaria (3). The World Health Organization (WHO) suggests that malaria can be diagnosed by standard
microscopy or immunochromatographic lateral flow assays (known as rapid diagnostic tests, RDTs) before treatment (4) . The other diagnostic tests for malaria are, serology, fluorescence microscopy and nucleic acid-based amplification techniques like PCR and isothermal amplification where the mostly known is loop mediated isothermal amplification (LAMP) (5). Rapid diagnostic test and quantitative real-time PCR (qPCR), are techniques that are applied to malaria studies and were used to detect Plasmodium species in 10⁹ whole-blood samples from patients after their return from malaria endemic areas (6). Methods of real-time PCR are particularly designed for large scale screening and they can be used in malaria control and elimination programs (7). Even if WHO recommenced the use of PCR to detect the asymptomatic patients and low parasitemia, PCR requires technical expertise, expensive reagents and infrastructures which make it inaccessible in low- and middle-income countries (5).

Blood smear microscopic examination remains the current gold standard method, because of its availability, low cost and ability for detection of malaria and speciation. PCR assay present an alternative to microscopy which has shown a superior sensitivity and specificity (8). Microscopy is most frequently used, but at low parasitemia (<20 parasites/µl), the technique becomes less sensitive and time consuming (9). Rapid diagnostic tests based on Plasmodium antigen detection do frequently not allow discrimination of species as microscopy does, but also become insensitive at <100 parasites/microliter. Judgment concerning malaria treatment depends on the right identification of species causing the disease. Therefore, there is a need for developing new tools of diagnosing malaria that are sensitive, cost effective and capable of performing large scale diagnosis. Here, we review the most promising molecular diagnostics developed so far and give some viewpoints for the near future (9).

This review is intended to describe the recent and upcoming directions in molecular diagnosis of malaria for the detection of low parasitemia in asymptomatic patients from the perspective of high-throughput and practicability in constrained resource environments for the sake of malaria elimination. This review also emphasizes on the advantages and disadvantages of most promising molecular diagnostics and present recommendations on possible future directions in molecular diagnosis of malaria.

Material and Methods

This review was carried out by using important internet searching tool: PubMed. It is actually consisted by the analysis of specific segment of published papers to a given research topic related to malaria diagnostic tools. In other words, it describes, summarizes, evaluates and report on the retrieved papers. This study context provides an update on what is going on in malaria molecular diagnostics and what has been done so far whether it is beneficial to Malaria patients or not. The published articles were carefully searched through PubMed search board in order to obtain different papers which could be perfectly related to the review topic for reviewing. PubMed have been chosen to be the best searching tool due papers accessibility (regularly uploaded and updated research papers), reliability and specificity to medical domain and contains a collection of most of medicine and biomedical sciences that fulfill medical evidence-based guidelines.

PubMed covers most papers in medicine domain and allows a quick and advanced search. A computer-based papers’ search was done on two different dates (12th and 28th February, 2020) to avoid any search bias that may result; as day after day, in the same database more newly published papers get uploaded. This data was retrieved from searching engine based on different research keywords related to the study title. The keywords used were malaria, malaria diagnosis and molecular diagnosis of malaria. The targeted reviewed papers were those related to malaria, malaria diagnosis and molecular diagnosis of malaria. This research reviewed most of the published papers on current and future direction in molecular diagnosis of malaria. It considered and extracted different published papers examining factors associated with either malaria diagnosis or molecular
diagnosis of malaria. All the current and updated papers that are straightly relevant to the topic were considered and reviewed in this work.

During this study, different inclusion and exclusion criteria were set. For a paper to be included in this study had to be published in English, giving information on development of molecular diagnosis of malaria, and being published in 2000 to 2020. The papers that were published before 2000, published in a different language other than English, published as a book, papers having a title which is not related to our topic or having insufficient information were rejected.

After considering the inclusion and exclusion criteria and other described research considerations, a detailed review strategy can be demonstrated on the following flowchart which shows the reviewed 35 Published papers which yielded 27 papers that were used in this current evaluation.

**Reliability and Validity**

The results of the 27 reviewed studies are reliable because all these papers considered for our review were retrieved from PubMed which hosts reliable data. PubMed database uploads health related papers with standard quality, from highly cited journals. For instance, our retrieved papers were published in different good journals as follows: Malaria Journal (impact factor: 3.109); Journal of infectious disease (impact factor: 5.997); Journal of Clinical Microbiology (impact factor: 3.993); A Peer-reviewed Open Access Journal (impact factor: 3.234); Korean Journal of Parasitology (impact factor: 1.151); American Journal of Tropical Medicine and Hygiene (impact factor: 2.699); Tropical Medicine International Health (impact factor: 2.329); Journal of tropical medicine (impact factor: 0.926); Clinical Microbiology and infection (impact factor: 5.768); Southeast Asian Journal of Tropical Medicine public health (impact factor: 0.719); Pathogen Global Health (impact factor: 1.656). The final reviewed paper’s validity is extremely ensured as well, as their content falls within the broad aim of our review.

**Results**

Research results were obtained by using the identification for analysis where common themes used are PCR based-assay, comparison between PCR and other molecular techniques in malaria diagnosis, advantages and disadvantages of PCR based-method, relationship among PCR based assays, most promising molecular diagnosis of malaria, comparative designs of PCR, pigment containing monocyte based-assay which are presented within the selected twenty-seven articles.

**Theme 1: PCR based-assay**

PCR based-assay in malaria diagnosis was reported within by 22 of the 27 selected studies. PCR will be used in the future to screen samples from clinically suspected foci to increase the proportion of detected malaria cases. PCR products can also be analyzed using gel-electrophoresis. For instance, the samples that were found to be negative by db-PCR-NALFIA but positive for *Plasmodium* in their initial diagnosis were determined to be negative by gel analysis as well (10).

Nested-PCR belongs to PCR based-method and was performed in samples from 30 non-human primates nine samples (30%) of them were found to be positive for *Plasmodium* (11). Different PCR forms have been reported including: two single-PCR reactions which are nested 1PCR and nested 2PCR designed to detect *Plasmodium falciparum* infections, one single PCR to detect *Plasmodium vivax* infections, and one multiplex one-step PCR reaction to detect both parasite species (12).

Nested PCR assay was also successful in detecting mixed infections that are not detected by microscopy (13). The study concluded that nested PCR and real-time PCR may be highly suitable for asymptomatic malaria detection in large numbers of clinical samples from areas of endemicity (14). The mixed infections detected by nested-PCR assay were 6.5, 22 and 23.5 percent in samples collected from Afghanistan, Iran and Pakistan respectively (15). Nested PCR, multiplex and real-time PCR were investigated for their sensitivity and specificity for the overall detection of Plasmodium.
species. They were reported to be 96.6% and was 89.4%, respectively while microscopy is still considered as the gold standard for malaria detection and identification(8). PCR based diagnostic tools are capable of detecting very low parasitemia due to high sensitivity. *Plasmodium falciparum, P. ovale, and P. vivax* which are the species of malaria parasite were detected by a TaqMan-based real-time PCR qualitative assay(16); and Polymerase Chain Reaction (PCR) is a popular nucleic acid-based tool that is used in the diagnosis of various infectious diseases(17).

Molecular methods, including nested polymerase chain reaction (PCR) and loop-mediated isothermal amplification (LAMP) and histidine-rich protein 2 (HRP-2) based rapid diagnostic tests (HRP-2-RDTs) were used for the malaria diagnosis (18). LAMP presents a high diagnostic accuracy for parasite detection among both fever patients and asymptomatic individuals(19). The same technique is claimed to be a molecular diagnostic test for malaria which is simple and inexpensive to detect the conserved 18S ribosome RNA gene of *P. falciparum* (20). Malaria LAMP displayed diagnostic accuracy similar to that of nested PCR, by using pan-*Plasmodium* genus primers, LAMP did not differ in performance from nested PCR (P = .3447) (21). The method which was found to be the most efficient for the detection of mixed infections is the PCR-based method because of its high sensitivity and specificity (22). The three molecular assays (real-time multiplex polymerase chain reaction, merozoite surface antigen gene [MSP]-multiplex PCR and the PlasmoNex Multiplex PCR Kit) were reported to be involved in detection of plasmodium species, for the real-time multiplex PCR was more sensitive (81%) in detecting *P. vivax, P. falciparum and P. knowlesi* infections compared with the PlasmoNex Multiplex PCR Kit (62%) and MSP-multiplex PCR (50%) and they displayed 100% specificity for detecting malaria samples (23).

Identification of specific malaria parasite infection through PCR often is followed by DNA sequencing of the 18S rRNA gene for confirmatory purpose(24). For instance, quantitative real-time PCR (qPCR) is commonly used as a confirmatory method for malaria diagnosis; it was performed with high efficiencies of more than 94%. The multiplex qPCR assay detects simultaneously *Plasmodium spp., P. falciparum, P. vivax* and human RNaseP gene(25).

The PET-PCR is a new molecular diagnostic tool with similar performance characteristics as commonly used PCR methods that is less expensive and easy to use (26). The RFLP-dHPLC method detected many more mixed species infections than did microscopy. Their use revealed a high prevalence of sub-microscopic infections. The overall prevalence detected by the RFLP-dHPLC method and microscopy were (68.4% and 30.7%) respectively (27).

**Theme 2: Comparison between PCR and other molecular techniques in malaria diagnosis**

Four out of 27 reviewed studies (14.8%) report the comparison between PCR and other molecular techniques in malaria diagnosis. The sensitivities of the two nested PCR and real-time PCR techniques were higher than that of microscopy examination (sensitivity, 100% versus 26.4%; kappa values, 0.2 to 0.5). PCR-based molecular methods for malaria parasite detection are relatively simple and provide improved sensitivity and various advantages compared to microscopy and RDTs (14).

Malaria LAMP also demonstrated diagnostic sensitivity significantly superior to that of expert microscopy (21). Comparison of nested PCR to HRP-2-RDTs show that the poor sensitivity of HRP-2-RDTs indicates that low parasitemia may not be detected after treatment, whereas the low specificity of HRP-2-RDTs indicates that it cannot be applied for treatment follow-up. However, HRP-2-RDTs have similar sensitivity as microscopy but less specific. The db-PCR-NALFIA is much more sensitive than RDT, especially for the detection of *P. vivax* (17).

**Theme 3: Advantages and disadvantages of PCR based- method**
The advantages and disadvantages of PCR based-method in diagnosis of malaria were reported within 7 out of 27 reviewed papers (30%). PCR-based molecular methods for malaria parasite detection are relatively simple and they are highly specific and capable of reporting highly sensitive test values (13). PCR is known to be highly sensitive and specific as an advantage but it presents some barriers including its high cost, and the amount of infrastructure required in terms of equipment and a sophisticated laboratory setup with stable power and refrigerators for reagent storage (16). PCR based-methods have demonstrated high sensitivity and specificity in detection of plasmodium infection and have the ability to quantify parasitemia when used in a quantitative real-time PCR format. The ease and speed of PCR make it an important tool in malaria elimination programs (27). LAMP is simpler and faster as compared to nested PCR with the advantage of detecting low parasitemia becoming a potential point-of-care test for treatment follow-up. The low sensitivity and the high false positive rate of HRP-2-RDTs is the major limitation of its application for monitoring of the therapeutic response; and PCR tools are too sophisticated and expensive as a disadvantage to apply them in most malaria endemic countries (17). Real-time PCR does not require post-PCR processing; this reduces sample handling and minimizes the risk of contamination (15). PCR can be used for precise parasite quantification through qPCR methods (25). Nested PCR, multiplex and real-time PCR are capable of detecting very low parasitaemia (7).

**Theme 4: Relationship among PCR based assays**

This theme was presented by 4 out of 27 selected studies (14.8%), giving an explanation on relationship among PCR based assays. Nested PCR-2 and real-time PCR displayed similar results with higher sensitivities of 100% reported (13). LAMP has similar sensitivity and specificity to nested PCR. With high PPV and NPV (17). Malaria LAMP had a diagnostic accuracy similar to that of nested PCR among collected positive blood samples, one sample characterized as *P. vivax* monospecies infection by nested PCR was found to be positive for *P. falciparum* (20). Specificity of all three assays (real-time multiplex polymerase chain reaction [PCR], merozoite surface antigen gene [MSP]-multiplex PCR, and the PlasmoNex Multiplex PCR Kit) were tested using gDNAs of all five malaria. And in species of human addition the PlasmoNex Multiplex PCR Kit and real-time multiplex PCR showed similar sensitivity for detecting *P. vivax* (22).

**Theme 5: Most promising molecular diagnosis of malaria**

The findings obtained from 3 out of 27 reviewed papers (11%), reported on the most promising molecular diagnosis techniques for malaria. The malaria LAMP is the most promising molecular diagnosis for malaria because it has advantages over other molecular tests in speed, sensitivity, and minimal need for specialist training (20). The same advantages of LAMP have been reported as of being cheaper, simpler and faster. The 100% sensitivity and specificity of real-time PCR methodology supports its status as the best PCR methodology to detect *P. falciparum* and *P. vivax* (8).

**Theme 6: Comparative designs of PCR**

Comparative designs of PCR were encountered within 5 out of 27 selected studies (18%). Real-time PCR technique is based on primer and probe sequences for the gene encoding the 18S Plasmodium rRNA genes; whereas for the nested PCR-2, the species-specific nucleotide sequences of the 18S rRNA genes of *P. falciparum*, *P. vivax*, *P. malariae*, and *P. ovale* are targeted and for the nested PCR-1 strategy is based on use of primers (13). All PCR reactions can be performed in a 20 μL volume containing 250μM each oligonucleotide primer, 10μL of master mix (Promega) (0.3 units of Taq Polymerase, 200μM each deoxyribonucleotide triphosphates and 1.5 mM MgCl2) and 2μl DNA (11). Nested-PCR assay uses 18S small sub-unit ribosomal RNA (ssrRNA) gene (16). Nested polymerase chain reaction (PCR) primers were designed from the 3R region of the 28SrRNA gene (13). A multiplex qPCR assay was designed to simultaneously detect *Plasmodium* species such as *P. falciparum*, *P. vivax* and human RNaseP gene.
as an endogenous control (25).

**Theme 7: Parasite density per microliter of blood**

Only one reviewed paper out of the twenty-seven, is reporting on parasite density per microliter technique. Parasite density per microliter of blood in a patient is determined using parasite count adjusted by average WBC count (8000/microliter) observed in microscopic fields of the thick film (28).

**Theme 8: Pigment containing monocyte based-assay**

Pigment containing monocyte based-assay was reported within two out of twenty-seven selected studies (7%). Those studies include (29–31). At a discrimination level of one or more atypical pigment-containing monocytes (PCM), negative and positive agreement was found to be 95.6% and 91.6% respectively and many analyses showed that the only significant risk factor for the presence of PCM (odds ratio > 200) was malaria infection (31). Malaria PCM as a distinct cluster in scatter diagrams that is well separated from normal leukocytes. From microscopic inspection of sorted cells and PCM has a different average relative frequency according to the patients: for nonimmune patients is 1.5 x 10^-4 (median), for semi-immune patients 8.8 x 10^-4, and for malaria-negative persons 4.4 x 10^-6 (29).

**Discussion**

All the 27 reviewed research and review articles were selected based on molecular diagnosis of malaria. Some of those studies focus on advantages and disadvantages of PCR based essay in diagnosis of malaria. Currently, diagnosis of malaria by use of microscopy or RDT are not sufficient in specificity or sensitivity to detect low-parasite-density infections. Microscopy and RDTs become relatively less sensitive at parasite densities below 100 parasites/μl (11,29–32).

RDTs are inexpensive, simple to perform, and provide results in 15-20 minutes. Despite high sensitivity and specificity for Plasmodium falciparum infections, RDTs have several limitations that may reduce their utility in low-transmission settings: they do not reliably detect low-density parasitemia (≤200 parasites/μL), many are less sensitive for Plasmodium vivax infections, and their ability to detect Plasmodium ovale and Plasmodium malariae is unknown (33). Microscopic examination of blood smears remains the current gold standard for malaria detection and speciation. However, PCR assays present an alternative option to microscopy which has been shown to have superior sensitivity and specificity (8).

PCR based molecular method when compare to thick blood smear this test displayed a sensitivity ranging from 65% to 81% and specificity was close to 100%; and this method of assay detects all five Plasmodium species (22). The highly sensitive and specificity of PCR makes it an advantageous technique, but the same technique presents some barriers including its high cost, and the amount of infrastructure required in terms of equipment and a sophisticated laboratory setup with stable power and refrigerators for reagent storage (17). In a different study, the prevalence of asymptomatic parasitemia was reported at 17% by microscopy and 47% by PCR (34). The easiness and speed of PCR makes it an important tool in malaria elimination programs and should be improved to detect asymptomatic infections (34). The diagnosis of malaria parasites by one of the PCR based assays, nested PCR, in the present assessment is at medium level with an accuracy of 84.21% (48/57). In comparison of microscopy to nested PCR, microscopy showed the sensitivity and specificity of 85.39% and 100% respectively, whereas the sensitivity and specificity of the nested PCR assay was found to be 99.08% and 100% respectively. Nested PCR assay was also successful in detecting mixed infections that are not detected by microscopy (13).

The PCR-based method was used as the reference standard because of its high sensitivity and specificity over microscopy, particularly in cases with low-level parasitemia. When the three PCR-based methods (nested PCR-1, nested PCR-2 and real-time PCR) were examined for detecting malaria infection in residents of regions of Myanmar where malaria is endemic, two
nested PCR and real-time PCR assays showed that asymptomatic infection was detected in about 1.0% to 9.4% of residents from the surveyed areas; and they showed similar sensitivity in genus-specific tests. However, it was observed that nested PCR-1 showed a lower sensitivity in detecting *Plasmodium spp*, especially *P. falciparum* and *P. malariae*, compared to nested PCR-2 and real-time PCR. The limited detection by nested PCR-1 resulted in 14 samples being positive in a genus-specific assay, while reported negative in a species-specific assay. The results suggest that nested PCR-2 and real-time PCR may be highly suitable for asymptomatic malaria detection in large numbers of clinical samples from areas of endemicity(6,14).

All three PCR methodologies (nested, multiplex and real-time PCR) investigated, were sensitive, specific and capable of detecting very low parasitemia. Although economies of scale can be applied to PCR methods to reduce the time and cost involved in processing each sample, the results from the three molecular speciation techniques (nested PCR, multiplex PCR, and real-time PCR) were used to develop a molecular consensus (two or more identical PCR results) as an alternative gold standard. According to the molecular consensus, 9.6% (13/136) of microscopic diagnoses yielded false negative results. Multiplex PCR failed to detect *P. vivax* in three mixed isolates, and the nested PCR gave a false positive *P. falciparum* result in one case. Although the real-time PCR melting curve analysis was the most expensive method, it was 100% sensitive and specific and least time consuming of the three molecular techniques investigated (8).

The sensitivity and specificity results for the four speciation techniques differed depending upon whether microscopy or molecular consensus was used as the gold standard. Using microscopy as gold standard, the sensitivity of all three molecular techniques for the overall detection of *Plasmodium spp* was 96.6% (86/86+3) and the specificity was 89.4% (42/42+5). However, when Molecular Consensus Was Used As The Gold standard the sensitivity and specificity of microscopy was 94.5% (86/86+5) and 93.3% (42/42+3) respectively(8). By evaluating A TaqMan-based real-time PCR, qualitative assay was performed on 122 whole blood samples from patients who presented with malaria-like symptoms and fever, real-time PCR assay showed a detection limit with analytical sensitivity of 0.7, 4, and 1.5 parasites/μl for *P. falciparum*, *P. vivax*, and *P. ovale* respectively. Real-time PCR can yield results within 2 hours and does not require post-PCR processing, which reduces sample handling and minimizes the risks of contamination(16).

The db-PCR-NALFIA is also used for the detection of Plasmodium species directly from blood samples and is much more sensitive than RDT, especially for the detection of *P. vivax* as well as for *P. falciparum*. There were differences in results between the db-PCR-NALFIA and microscopy and RDT. Although in both field settings there were false-negative db-PCR-NALFIA samples that were determined to be positive by microscopy and/or RDT, there was a greater number of false-positive db-PCR-NALFIA samples that were negative with the other methods. The db-PCR-NALFIA is a relatively easy-to-use method that is robust, sensitive, and specific and could have great potential in locations where malaria is endemic; especially in areas where there is low transmission of malaria, and thus a very sensitive technology is warranted (10).

Microscopy remains the gold standard method for malaria diagnosis because of its simplicity, affordability and the ability to quantify the parasite density. As molecular techniques become much more widely used and acceptable as alternate or as confirmatory assays to microscopy, they must meet and exceed qualities and characteristics that have made microscopy popular. Absolute quantitative multiplex qPCR assay simultaneously detects three *Plasmodium* targets (*P. falciparum* and *P. vivax* parasites) and the human RNaseP as an endogenous control. If qPCR assay is going to replace microscopy as the gold standard diagnostic method, the absolute quantification is
reported as parasites/µl, the same units as those used in microscopy. Currently, qPCR assays use relative standard quantification methods to quantify parasite density in a sample where cultures or clinical samples with known parasite density are used.\(^{(25)}\)

PCR-based molecular methods are good for both their sensitivity and specificity values, but too sophisticated and expensive to be applied in most malaria-endemic countries\(^{(28)}\). LAMP has similar sensitivity and specificity to nested PCR, with high PPV and NPV. LAMP is a cheap, simpler and faster method as compared to nested PCR; with its advantage of detecting low parasitemia, it is becoming a potential point-of-care test for treatment follow-up\(^{(18)}\). In a 128 febrile children study, a complete set of four malaria tests was carried out. Positive results for HRP-2-RDTs, microscopy, nested PCR, and LAMP, were 68(53%), 47(37%), 64(50%), and 65(51%) respectively. When nested PCR was used as a reference standard, only LAMP was comparable and both HRP-2-RDTs and microscopy had moderate sensitivity. HRP-2-RDTs had poor positive predictive value (PPV) and a moderate negative predictive value (NPV) for the treatment follow-up. HRP-2-RDTs have similar sensitivity as microscopy but less specificity. However, as compared to nested PCR, the poor sensitivity of HRP-2 and RDTs indicates that low parasitemia may not be detected after treatment; and the low specificity of HRP-2-RDTs indicates also that it cannot be applied for treatment follow-up\(^{(18)}\).

Malaria LAMP had a diagnostic accuracy similar to that of nested PCR, with a greatly reduced time to result. Malaria LAMP demonstrated diagnostic sensitivity significantly superior to that of expert microscopy. In the analysis, using pan-Plasmodium genus primers, LAMP did not differ in performance from nested PCR (P = 0.3447). LAMP with P. falciparum primers was found to have significantly different diagnostic accuracy than PCR (P = 0.004), with a positive predictive value of 83.5% and a negative predictive value of 99.8%. The current format of pan-Plasmodium genus and P. falciparum–specific LAMP is able to identify all P. falciparum–infected individuals. The costs of LAMP reagents are close to those used for nested PCR, but comparing both techniques in terms of equipment and labor costs, reveals that LAMP would be more affordable for laboratories in malaria-endemic countries. The malaria LAMP test, evaluated for the primary diagnosis of malaria has advantages over other molecular tests in speed, and minimal need for specialist training; and it is a suitable test for diagnosing imported cases of malaria in minimally equipped clinical laboratories\(^{(21)}\).

**Conclusion**

In this review on malaria diagnosis, microscopy remains the current gold standard method due to its availability, low cost and its ability to detect and identify various *Plasmodium* species. PCR assay is a molecular diagnostic method presents an alternative tool to microscopy and has shown a superior sensitivity and specificity. Molecular tests are valuable tools for the confirmation of *Plasmodium* species and in detecting mixed infections in malaria endemic regions. However, most of molecular techniques used in malaria diagnosis present some bottlenecks including the high cost of labor and less access to reagents, compared to the examination of blood smears. Among PCR based-assay methods, real-time PCR is ranked the best due to its high sensitivity and specificity (100%) to detect both *P. falciparum* and *P. vivax*. As a major outcome of our review, the LAMP technique is claimed to be a simple and inexpensive malaria- molecular diagnostic test that detects the conserved 18S ribosome RNA gene of *P. falciparum*. In other studies, the same technique has shown high sensitivity and specificity, not only for *P. falciparum*, but also for *P. vivax*, *P. ovale* and *P. malariae*. LAMP appears to be easy to conduct, sensitive, quick and lower in cost than PCR.

Synthesis and Characterization of New Oxo-Aztedine, Imidazolidine and Thiazolidine Rings on Creatinine and Evaluation of their Biological Activity

Raad M. Muhiebes, Entesar O. A. Tamimi

1 Research Scholar, Chemistry Department, Faculty of Science, University of Baghdad, Iraq, 2 Professor, Chemistry Department, Faculty of Science, University of Baghdad, Iraq

Abstract

This work included preparation of new imine from the reaction of creatinine with aldehydes (4-nitro benzaldehyde, 4-amino benzaldehyde, cinnamaldehyde) and ketone (acetophenone) in ethanol and the presence of few drops glacial CH₃COOH to obtain Schiff bases (1a, 1b, 1c, 1d). Schiff bases were treated with monochloroacetyl chloride to produce (2a, 2b, 2c, 2d), with glycine to synthesize (3a, 3b, 3c, 3d) and with 2-mercaptoacetic acid to prepare (4a, 4b, 4c, 4d). The prepared compounds had been measured by (FT-IR, and ¹H NMR) spectroscopic techniques. Some of the derivatives were studied activity against antibacterial, antifungal and antioxidant.

Keyword: Schiff bases, β-lactam, Oxo imidazolidine, thiazolidine derivatives.

Introduction

Schiff bases are the compounds containing (–C=N–) as a functional group. They are a condensation products of 1 amines with C=O compounds, these compounds were first reported by Hugo Schiff (1-3). Schiff bases have also been reported to have a broad range of biological activities, like antifungal, antibacterial, antimalarial, anti-inflammatory, antiviral, and antipyretic properties (4). Heterocyclic compounds containing four and five-member rings have given industrial and medical reasons. Azetidinone derivatives are one of these compounds, they represent an important commonly known as β-lactam, due to their antibacterial, antifungal, anti-tubercular, antianthelminic, and enzymatic activity (5). Furthermore, they are found to inhibit cholesterol absorption (6). The imidazoles are an important class of heterocyclic and many naturally occurring imidazoles are known to possess biological activity, anti-fungal, anti-bacterial, anti-anthelmintic, anti-neoplastic, antipyretic and anti-spasmyotic activities (7). On the other hand, thiadiazole, fused heterocyclic ring compounds have many biological activities as antimicrobial activity (8), anti-inflammatory (9).

Materials and Methods

All initial chemicals necessary for Schiff bases preparation were obtained from Fluka, Sigma- Aldrich, Alfa Aesar, Japan and BDH used without further purification. The Stuart melting point apparatus was used to measure melting points. IR Affinity-1 Shimadzu as KBr disc, results are given in cm⁻¹. ¹H NMR BrukerSpectrospin ultrashield magnets 300 MHz instruments, using DMSO-d₆ solvent.

Schiff bases (10) (1a, 1b, 1c, and 1d) preparation procedure

Schiff bases were prepared by the reaction of creatinine (0.113g, 0.001 mol) with variable aldehydes and ketone (0.001 mol), in 30 ml EtOH and few drops of glacial acetic acid. This mixture was refluxed for (10-12hrs). The excess solvent was evaporated and the formed product was recrystallized from absolute C₂H₅OH. Physical properties are listed in Table 1.
Synthesis of azitidine-2-oxo derivatives (11) (2a, 2b, 2c and 2d)

Schiff base (1a,1b,1c, and 1d) solution (0.003mol) in (25 ml) THF was quantitatively poured into the mixture of ClCH$_2$COCl (0.34 g, 0.004 mol) and TEA (0.56 g, 0.004 mol). Solutions was well mixed at (0-5ºC), then the reaction was conducted for (6-8) hrs at room temperature. The mixture then kept for additional 2 days in the sealed containers at RT., after that the mixture was poured in a container with ice to obtain the compound in a solid form. The products were filtered and washed by distilled water then dried and recrystallized. Table 1 show the physical properties of the newly generated compound.

Synthesis of 4-oxo-imidazoline derivatives (12) (3a,3b,3c and 3d)

A mixture of Schiff base (1a,1b,1c and 1d) (0.001 mol), glycine (a-amino acetic acid), (0.07g, 0.001mol) in (25ml) ethanol and few drops DMF was refluxed for (20h.), the excess solvent was evaporated. The solid product was collected and recrystallized from absolute CH$_3$CH$_2$OH. Physical properties are listed in Table 1.

Synthesis of 4-oxo-thiazolidine derivatives (13) (4a, 4b, 4c and 4d)

To a mixture of Schiff bases (1a,1b,1c and 1d) (0.002 mol) and 2-mercaptoacetic acid (0.92g, 0.01 mol) dissolved in DMF (25 ml), anhydrous ZnCl$_2$ (0.21g, 0.0016 mol) was added and refluxed for (18-20 hrs). The reaction mixture was then poured into crushed ice, filtered and washed with water, dried, and recrystallized from absolute ethanol. Physical properties are listed in Table 1.

Biological Activity (14)

Using the culture media called Muller-Hinton for determination of the biological effectiveness of the following material (2a to 4d) on ranges of isolated microorganism (Bacteria and Fungi). After being dissolved, Muller-Hinton was sterilized by using autoclave (121ºC for 15 min.) and poured onto petri-dishes (plate-count). Once Muller-hinton and been left to solidify and to be ready for use, the specific microorganism were used in this study. Then 0.1 mm had been added to the material mentioned in the middle of the plates contaminated previously with bacteria or fungi to determine the biological effects of each material. After then the plates were incubated with a particular incubator (37ºC for 24hr.) the inhibition zones were seen clearly after 24hr, for bacterial and 48hr. for fungi incubation on each plate-count. However, these zones were differed according to material in addition to isolated microorganisms used on each Petri dish. The result of all tested compound is listed in table (3).

**Conclusions**

The prepared compounds were confirmed by using spectroscopic techniques (FT-IR and $^1$HNMR). The biochemical studies revealed that the new aztedine, imidazolidine and thiazolidine caused activator effects on two types of bacteria Staphylococcus aureus and Escherichia coli, and one type of fungi Aspergillus flavous. The organisms Staphylococcus aureus, Escherichia coli and Aspergillus flavous show very high activity toward the compounds (2a, 2b, 2d, 3c, and 4c).

Evaluation of Diagnostic Accuracy of Ultrasonography and Low Dose Computed Tomography in Acute Appendicitis

Saradiq Mudhafar Jebur1, MahmoodRadhi Jobayr2, Haider Abdulameer Ghayad3

1Research Scholar, Medical City, Welfare Hospital Teaching , Baghdad, Iraq, 2Professor, Middle Technical University (MTU), College of Health and Medical Technology, Dept. Radiology Technology, Baghdad, Iraq
3Research Scholar, Medical City Complex, X-Ray Institute, Baghdad, Iraq

Abstract

In acute appendicitis, abdominal Ultrasonography (USG) to reach a stable diagnosis and use of Low Dose Computed Tomography (LDCT) in the diagnosis of acute appendicitis is crucial. This study aimed at assessing of the accuracy of imaging modalities (USG and LDCT) in the diagnosis of children and adults with acute appendicitis to minimize the rate of negative appendectomy. A total of 42 patients, children and adults were examined, were included in this research (16 females and 26 males) ages was ranged from 5 to 45 years. All patients were examined by USG and LDCT to diagnosis acute appendicitis. The sensitivity of low dose a LDCT scan was used to diagnose acute appendicitis (96.0%) that means LDCT was able to diagnosed (96.0%) Correctly diagnose acute appendicitis patients. The specificity of LDCT in the diagnosis of acute appendicitis was (50.0%) that mean LDCT was able to diagnosed half of those with diagnosis other than acute appendicitis correctly, But the sensitivity of USG in diagnosis of acute appendicitis was (54.1%) that mean ultrasound was able to diagnosed (54.1%) of patients diagnosed by CT scan as acute appendicitis correctly. The use of low-dose computerized tomography (LDCT) provides significantly higher diagnostic accuracy compared to ultrasound for the detection of acute appendicitis.

Keywords: USG, Computed tomography, acute appendicitis, LDCT.

Introduction

Acute appendicitis remains a significant cause of morbidity in children and adults as the most frequent acute surgical condition; appendectomy is the primary basis of care (1). Delay in making decisions can lead to severe problems such as perforation and development of abscesses, while rushing to surgical is related to a high rate of negative appendectomy (up to 15% - 47%) (2). Appendicitis diagnosis of all ages is difficult, acute appendicitis diagnosis can be tough for the reason that medical symptoms and symptoms correlate with different ailments due to the fact they have got comparable symptoms (3). A hole in efficaciously diagnosing appendicitis can result in a worse prognosis, and misdiagnosis can cause useless operations (3, 4). Therefore, precision of diagnosis appendicitis is important. Although it’s essential to have diagnostic accuracy and physical examination outcomes, imaging is frequently used to get a proper diagnosis. Therefore, established diagnostic protocols propose Ultrasonography (USG) because the number one method of imaging and CT as extra image follow-up in misleading situations (5, 6). Nevertheless, in lots of cases, USG effects of sufferers with suspected appendicitis are deceptive, and this confusion can cause delays in prognosis and care and extra costs. There have been additionally tries to restriction to radiation from a
CT examination due to sensitivity from CT detection to radiation. And to limit the quantity of CT scans which are needless. Low-dose CT (LDCT) has emerged as choice to examine sufferers with abdominal discomfort, as correct diagnostic reliability and reduced to ionizing radiation were proven (7). Indeed, different protocols, like those using Iv contrast material alone (8), orally contrast material alone (9), none oral or Iv contrast material (10, 11), and LDCT (12), have additionally been proven to be responsive and specific to appendicitis, because of worry of reduced precision, but LDCT shows fine effects. We consequently suggest the proportional output in LDCT with the detection of acute appendicitis. We were unable to evaluate low and usual dose CT an order to get accurate dose reduction measurements in both cases (13).

In this work, a systematic study comprehensive has been carried out to assess the accuracy of imaging modalities (USG and LDCT), in the diagnosis of children and adults with acute appendicitis. To demonstrate minimize the incidence of negative appendectomy from the emergency department in referred patients suspected of having an acute appendicitis.

Methods

There were 42 patients in total, children and adults were examined were included in this research project (16 females and 26 males) ages was ranged from 5 to 45 years. The data have been collected from November/20/2020 to March/23/2021. City of Medicine (Welfare hospital teaching and Baghdad Teaching Hospital), A Samsung ultrasound device was used to test all patients with suspected acute appendicitis, and a linear high frequency transducer was scanned on the right iliac fossa region, using “a graded compression technique”. Following a USG review, all patients with clinically suspected acute appendicitis had a CT scan. And Using a Siemens SOMATOM definition, a LDCT scan was performed. Scanner with 64 detectors, (Siemens, Germany 2016) tube voltage: 100 kVp tube current: 87/190 mA slice thickness: 5mm rotation time 0.5s with or without dye for the lower abdomen and pelvic, Most scans are quick enough that patients do not need to be sedated to be scanned.

Sedation may be required in some cases for children who are unable to remain still. Motion causes image blurring and degrades the quality of the examination in the same way that it degrades the quality of images. If contrast agent is used, it will be swallowed and intravenous injection (IV), or, rarely, administered by enema.

On USG the inflamed appendix appears as a blind-ending, tubular structure with bowel signature. When pressure is applied, the inflamed appendix is noncompressible. On transverse images that the appendix will have a “target”-sign configuration consists of the alternating layers of the appendix wall. Although no specific measurement describes an acutely inflamed appendix, free fluid in the abdomen or pelvis, swollen mesenteric lymph nodes, and fluid collections adjacent to the appendix that represent abscesses include secondary signs of appendicitis. Acute appendicitis CT results include a cumulative outer luminal diameter greater than 6 mm”, lack of lumen oral contrast (if oral contrast was administered), appendicolitis, and inflammatory changes in periappendiceal. The related effects include swollen mesenteric lymph nodes, free fluid, and adjacent bowel inflammatory changes. The appearance of free air and the development of abscesses are major indicators that the appendix is possibly perforated.

Result and Discussion:

A total of 42 subjects were included: underwent abdominal US and CT Our patient’s ages range from 5 to 45 years old, and they are children and adults were (16 females and 26 males).
Table 1: The sensitivity, specificity US results in diagnosis of acute appendicitis in comparison to Low Dose CT results.

The sensitivity of LDCT scan was used to diagnose acute appendicitis (96.0%) that mean LDCT was able to diagnosed (96.0%) of patients incidence of acute appendicitis correctly. The specificity of LDCT in the diagnosis of acute appendicitis was (50.0%) that mean LDCT was able to diagnose half of those with diagnosis other than acute appendicitis correctly. Positive predictive value was (96.0%) that mean those diagnosed as acute appendicitis by LDCT was (96.0%) being acute appendicitis by surgery and negative predictive value was (50.0%) that mean half of those diagnosed as other diagnosis rather than acute appendicitis by LDCT being diagnosed as other diagnosis by surgery and overall accuracy was (92.59%).

In this study, sensitivity of LDCT scan in diagnosis of acute appendicitis was (96.0%) that mean LDCT was able to diagnosed (96.0%) of patients incidence of acute appendicitis correctly. The specificity of LDCT in the diagnosis of acute appendicitis was (50.0%) that mean LDCT was able to diagnosed half of those with diagnosis other than acute appendicitis correctly, as other diagnosis by surgery and overall accuracy was (92.59%). In the diagnosis of acute appendicitis, CT plays an important role. By offering detailed appendix and peril-appendicular changes information and calling
the gold standard technique for determining whether or not a patient has acute appendicitis. These findings are consistent with Fallon et al., Alshamari et al. and Dae Yong Yi et al. (14-16).

Figure 1: shows distribution of patients according to CT diagnosis including (acute appendicitis and normal appendix). Majority (N=37, 88.1%) of patients diagnosed as acute appendicitis by CT scan. Also, in this study, the sensitivity of US in diagnosis of acute appendicitis was (54.1%) that mean ultrasound was able to diagnosed (54.1%) of patients diagnosed by LDCT scan as acute appendicitis correctly. The specificity of USG in diagnosis of acute appendicitis was (40.0%) that mean ultrasound was able to diagnosed (40.0%) of those with normal appendix by LDCT correctly. As normal appendix by USG being diagnosed as normal appendix by LDCT and overall accuracy was (52.38%). Expert graded compression employees can achieve high diagnostic precision, but the technique is highly reliant on the operator’s abilities, experience, and perseverance. It’s especially useful when examining children with low body mass and women with a predisposition to gynecological disorders (15). Recent publications have highlighted the importance of LDCT in reducing false negative findings during surgery (2).

Conclusion

The results of this study indicate that low-dose CT is more effective than USG diagnosis acute appendicitis in children and adults, decreasing the rate a negative appendectomy in patients admitted to the emergency department with clinical suspicion of acute appendicitis. These findings highlight the importance of Low-dose computed tomography (LDCT) for the patients at acute appendicitis to minimize risk of the patient being subjected to the complications of anesthesia and inflammation at the surgical site. Our results confirm Low-dose computed tomography (LDCT) is found to have a better diagnostic value of acute appendicitis. Also, further support control of time as a way to diagnosis of appendicitis to prevent disease complications and costs associated with delayed diagnosis. In addition, In this study, although statistically significant difference is seen in the diagnostic potential of LDCT, however, might be Ultrasonography useful for detecting early of acute appendicitis because ultrasonography is relatively safe and noninvasive.

The Inhibitory Effect of local *T.bovei* Volatile Oil Against ESBL- *E.coli* and *Klebsiella pneumoniae* Isolated From Patients with Urinary Tract Infections

Sawsan Qahtan Taha Al-Quhli¹, Safaa Abed Latef Al Maeni²

¹Research Scholar, Department of Microbiology, College of Medicine, University of Anbar, Iraq; ²Professor, Department of Biotechnology, College of Science, University of Anbar, Iraq

Abstract

This is the first research in Iraq to look in the *T. bovei* volatile oil’s ability to prevent the development of ESBLs. To find successful treatment-combinations for “ESBL-producing” bacteria’s emergent infections, we are evaluating antibacterial properties of phytochemical substances against bacteria that produce ESBL and investigating the effects of phytochemical substances in the presence of antibiotics. The volatile oil of the studied plant was extracted by steam distillation. Oil compounds were detected after extracting the volatile oil from *Thyme bovei* using a Gas chromatography–mass spectrometry (GC-MS). “REMA” was used to determine the MIC of the volatile oil and antibiotic solutions, with minor modifications. The checkerboard approach was used in 96 well microplates to see whether there was a synergy relationship between the volatile oil and antibiotics. *Tbovei* volatile oil had an inhibitory influence on β - Lactamase, according to the findings. Antimicrobial properties Thymol, p-cymene, and “Linalool” were the key constituents contained in GC-MC of *Thymus* volatile oil, which has already been shown to have antibacterial efficacy. The combination of *T.bovei* volatile oil and antibiotics had a synergistic effect on *E.coli* and *K.pneumoniae* producing ESBL growth in the current study.

Keyword: *T. bovei*, Volatile Oil, ESBL, Urinary Tract Infections

Introduction

Bacterial antimicrobial resistance is a worldwide issue that necessitates production new antibacterial agents. As a result of this issue, scientists are increasingly focusing on natural products in order to develop better treatments for multidrug-resistant microbial strains (¹). Antibiotic-resistant bacteria would be more successful if plant extracts with target sites were used (², ³). As a result, essential oils have been used to treat a variety of infectious diseases due to their high concentration of bioactive compounds with anti-oxidant and antimicrobial properties (⁴).

The most common bacterial infections in humans are urinary tract infections (UTIs). They’re also the most popular source of both population- and hospital-acquired infections (⁵). Many conventional antibiotics, such as third-generation cephalosporin’s, are ineffective against UTIs caused by *Enterobacteriaceae* that produce ESBLs (⁶). The evolution of ESBLs, on the other hand, has given these enzymes a new weapon in their arsenal. As a result, ESBLs producers are becoming more prevalent, and ESBLs producer strains are increasing morbidity, morality, and health-care costs (⁷).

Materials and Methods

Clinical isolates

Clinical *E.coli* and *K.pneumoniae* were collected from urinary tract infection (UTI) patients. Traditional Morphological methods and biochemical analysis, as well as automated systems such as Api 20E and Vitek 2, were used to identify them. They were classified as ESBL-producing *E. coli* and *K. pneumoniae* using
screening test, as well as various phenotypic and genotypic approaches according to Al-Quhli, and Al Maeni (2021) (8, 9).

Collection and preparation of medical plant

In July 2019, the leaves of Thyme bovei were brought from Hadethia city’s local plantations. The leaves were cleaned with tap water to remove any dirt that had adhered to their surfaces, and then washed with purified water once more.

Volatile oil extraction

The volatile oil of the studied plant was extracted by steam distillation using a Clevenger-type apparatus (10). After extracting the volatile oil for Thyme bovei, oil compounds were identified by a GC-MS, in Baghdad; Ministry of Ecology.

Determination of minimum inhibitor concentration (MIC)

The Resazurin Microtitre-plate Assay (REMA) was used for determining the MIC of the volatile oil and antibiotic solutions with slight modifications. In aseptic conditions, to all wells of microtitre-plates, a hundred µl Mueller-Hinton Broth was added, followed by transferring the first row of the 96 well plates with a hundred µl material test (volatile oil). Pipette 100 µl of the substance measure in serially decreasing concentrations from the first row to the other rows “(1/2, 1/4, 1/8, 1/16, 1/32, 1/64, 1/128, and 1/256)” was used to conduct serial dilutions. Every well was filled with ten microliters of bacterial suspension containing “1×10⁸ CFU/ml”. They were wrapped loosely in para-film and incubated at “35±2°C for 18-24” hours to ensure that the bacteria did not get dehydrated. Following the incubation period, ten microliters of “resazurin- solution” (Alamar- blue) was added to each well, and after another 24 hours, the plate was re-incubated. to observe color change. The findings were visually examined by looking at the color variations in resazurin, with changes from purple to pink, red, or colorless being considered positive. The MIC value was determined as the lowest concentration that caused no change in resazurin color (11).

Study the synergism between volatile oil and some antibiotics on bacterial growth using checkerboard technique

The checkerboard approach was used in 96 well microplates to see whether there was a synergy relationship between the volatile oil and antibiotics (12). The checkerboard assay was planned so that the two antimicrobials to be examined were serially diluted against each other in a cross fashion on two standard 96-well plates. The first antimicrobial “volatile oil” is serially diluted vertically, while the second antimicrobial “antibiotic” is serially diluted horizontally in this manner. The assay was created in such a way that the MIC calculated from the REMA assay for volatile oils could be used (13). The standard technique for assaying hydrolyzed Beta-lactam antibiotics is similar to Sargent’s description (14).

Results and Discussion

The volatile oil was extracted by steam distillation GC-MC; 100 g of leaves were placed in a Clevenger flask with 500 ml distilled water, and after 3 hours of extraction, 1 ml of T. bovei volatile oil was collected. The major compounds in T. bovei volatile oil were beta-ocimene, 3,7-Dimethyl-1,3,7-octatriene, Sabinene hydrate, Y-Terpinene, Linalool, Thyme camphor, p-cymene, p-thymol, thymol, Carvacrol, Thyme bovei. We also found the existence of other active substances, noting that they were the same active substances found in T. vulgaris in the previous analysis (15).

T. bovei volatile oil had an inhibitory effect on β-Lactamase, according to the findings. In the absence of T. bovei volatile oil, E. coli β-lactamase activity was (0.003640) u/ml, while in the presence of T. bovei volatile oil, E. coli β-lactamase activity was (0.001115) u/ml. k.pneumoniae β-Lactamase activity was (0.004443) U/ml in all isolates without T. bovei volatile oil, while the β-lactamase activity of K.pneumoniae isolates was (0.001918) U/ml in the presence of T. bovei volatile oil. Antimicrobial properties Thymol, p-cymene, and
Linalool were key constituents contained in GC-MC of Thymus volatile oil, which is already known to have antibacterial activity \(^{(16)}\).

REMA is characterized by its simplicity, low cost, speed, performance, and dependability. This is a colorization process focused on the oxidation and reduction of resazurin, which is used to test the sensitivity of medicines, antibiotics, plants, and bacteria. The ability to calculate a small volume of plant extracts separates this approach from other conventional methods. A blue reduction pigment (Resazurin) that is widely used as chemical proof is not harmful to cells in the media. Resazurin is a bacterial growth indicator that can be used without a spectrophotometer to assess bacterial growth in a small amount of solution in microliter-plates \(^{(17)}\). The MIC of *T. bovei* volatile oil against growth of bacteria–producing ESBLs was determined in this study and the findings are shown in the tables (1 and 2). Figure (2) showed MICs values of volatile oil, where blue color represent indicate to inhibited of bacterial growth by volatile oils due to not reduce the resazurin, while the pink and red colors were due to the reduction of Resazurin to resorufin by the bacteria \(^{(18)}\).

Where in *E. coli*, the isolates 1 and 5 were more resistant than isolates 2, 3, 4 and 6 which its resistance to *T. bovei* volatile oil was less. In *K. pneumoniae*, the isolate 3 was less resistant than the isolates 1,2,4,5 and 6. While the stander isolates of *E. coli* and *K. pneumoniae* were not resistant to *T. bovei* oil. Table (1) and (2) shows that *T. bovei* oil has a good effect on bacterial isolates. The ability of volatile oil in inhibiting the growth were due to phenolic compounds that Disrupt the cytoplasmic membrane, the proton motive force, electron flow, active transport, and cellular coagulation are all disrupted (19).

A present study, showed synergistic result of combining *T. bovei* volatile oil with antibiotics on *E. coli* and *K. pneumoniae* producing ESBL growth tables (3) & (4). A rise in bacterial resistance to antibiotics, as well as a shortage of new antibiotics on the market, necessitated the development of alternative methods to deal with infections caused by drug-resistant bacteria (20). Among the possible solutions suggested are the creations of antibiotic alternatives and the discovery or development of adjuvants (21). Some attempts have been made to improve or restore antimicrobial activity against multidrug-resistant bacteria. When volatile oils are added to antibiotics, the antimicrobial MIC is reduced (22). According to Al Dossary & Al Meani (2019), Since volatile oils are multi-component in nature, compared to many traditional antimicrobials that only have a single target site, they are thought to be more promising in preventing bacterial resistance (23). Antibiotic efficacy can be improved by enhancing antibiotic diffusion through bacterial membranes, and/or inhibiting efflux pumps, which are a common mechanism of resistance; in Gram-negative bacteria (24, 25).

Thyme is an important medicine that has been used for centuries and has been known as a rich source of bioactive substances with substantial properties that are anti-oxidant and anti-inflammatory, potentially useful in the treatment and prevention of pathological circumstances, but its popularity as an antibacterial molecule that prompted us to choose it (26).

**Conclusion**

In conclusion, our findings revealed that *T. bovei* volatile oil has an inhibitory effect on the growth of “*E.coli* “and “*Klebsiella pneumoniae*” - generating ESBLs, in addition inhibition activity against β-Lactamase enzyme. When combined with antibiotics including “Ceftazidime, Cefpodoxime, Cefotaxime, Ceftriaxone, Cefepime, and Aztreonam”, *T. bovei* volatile oil has a synergistic effect. As well as, *T. bovei* essential oil had strong biological activities and was a potential source of various natural compounds. It’s a powerful inhibitor of *E.coli* and *K.pneumoniae*-producing ESBLs isolated from UTI patients at Al-Anbar Hospital, and it’s led to the development of new medicinal plant-based therapeutics.

Abstract

Background: Parkinson’s disease is the second most common neurodegenerative disorder which affects around four million people globally. Many of the signs of Parkinson’s disease are found in the head and neck. The typical “masklike” facial appearance with infrequent blinking and lack of expression is caused by bradykinesis. Abnormalities in oral behaviour, such as purposeless chewing, grinding, and sucking movements, are also well recognized in patients with Parkinson’s disease.

Aim and Objectives: The aim of this study is to assess the overall oral health status of the patients with Parkinson’s disease and to analyze the impact of Parkinson’s disease on the oral cavity of the individuals surviving with the disease.

Materials and Methods: The study sample included 50 Parkinson’s disease patients. The patients of all age groups and both genders were included.

Results: Out of fifty patients, majority of the patients were above 60 yrs. 6% of the patients reported with positive family history of Parkinson’s disease. 14% of the patients had gross facial asymmetry, 68% of the patients showed dryness of mouth, 8% of the patients suffered loss of taste, 14% of the patients showed hyper salivation, 54% of the patients showed gingivitis, and 76% of the patients were found having periodontitis.

Conclusion: Treatment for oral and dental problems of Parkinson’s disease affected patients is mandatory. Treatment can be done by supplementing artificial saliva for dryness of mouth, dental fillings for dental caries, periodic scaling for periodontal problems, oral rehabilitation measures and regular dental check up.

Key Words: Parkinson’s Diseases, Oral Manifestations, Facial Asymmetry, Loss Of Taste.

Introduction

Parkinson’s disease is the second most common neurodegenerative disorder after Alzheimer disease which affects around four million people globally. It is a progressive neurological condition which is characterised by both motor and non-motor symptoms such as rigidity, tremors, bradykinesis, impaired postural reflexes, cognitive impairment, and bradyphrenia.

In 1817 James Parkinson first described this disease on his book ‘‘An essay on the shaking palsy’’¹, Charcot also recognised non-tremulous forms of Parkinson disease and exactly pointed out that slowness of
movement should be distinguished from weakness or ‘lessened muscular power’, a term originally used by Parkinson. These clinical manifestations of Parkinson’s disease are caused by a selective degeneration of dopamine-producing neurons in the substantia nigra in the brain stem and the consequent dopamine shortage in the striatum.

There are four cardinal clinical features of Parkinson’s disease - Tremor at rest, Rigidity, Akinesia (or bradykinesia) and Postural instability.

Many of the signs of Parkinson’s disease are found in the head and neck. The typical “masklike” facial appearance with infrequent blinking and lack of expression is caused by bradykinesia. The muscle rigidity also causes difficulty in swallowing, resulting in drooling. Abnormalities in oral behavior, such as purposeless chewing, grinding, and sucking movements, are also well recognized in patients with Parkinson’s disease.

Due to dysphagia and an altered gag reflex, special precautions must be taken to avoid the aspiration of water or materials used during dental procedures. In patients who suffer with hypersialorrhea, maintaining a dry field in certain procedures can be difficult. Xerostomia, on the other hand, is a common side effect of antiparkinsonism medications; the consequent root caries and recurrent decay must be diligently treated. Patients also often have difficulty maintaining their dentition because of their physical disability.

Since the oral aspect of this peculiar disease is less explored, the present study aims at understanding the dental risk among the patients of Parkinson’s disease.

Materials and Methods

The present random sampling study was conducted in Chennai. The patients were comprised of 50 individuals suffering from Parkinson’s disease. Out of 50 patients, 41 were males and 9 were females. All the patients were of varied socioeconomic status and different age group. Patients with other systemic diseases were excluded from this study.

After obtaining a written consent from every participant, a detailed case history was recorded, followed by which intraoral examination was conducted for the study group to observe the oral manifestations.

Results

Among 50 Parkinson’s disease patients 41 patients were males and 9 patients were females of which 12 patients were between 30 - 49 years, 13 patients were between 50 - 59 years and 25 patients were above 60 years of age. Among the oral manifestations dental caries was in 42 patients(84%) , periodontitis was in 38 (76%), Dryness of mouth was in 34 patients(68%), Gingivitis was found in 27 people(54%), Attrition was diagnosed in 14 patients (28%), Hyper salivation, Cervical abrasion and Difficulty in speech was seen in 7 patients (14%), Loss of taste sensation was seen in 4 patients (8%), facial asymmetry and Family history of Parkinson’s disease was seen among 3 patients(6%). Overall, oral manifestations of both hard and soft tissues of the oral cavity was found in Parkinson’s disease patients. (TABLE-1 AND CHART 1)

**GRAPH 1 – ORAL FINDINGS**
Discussion

Age Range

In our study we examined fifty patients of Parkinson’s disease, out of which forty one were males and nine were females with male predominance of 82%, which was similar to the study by Stephen K. Van Den Eeden et al., among five hundred and eighty eight Parkinson’s disease patients, out of which 91% were men. He had also concluded that incidence of Parkinson’s disease varies by race/ethnicity.

In our study of fifty patients, nine were females and they were above 65 years, whereas most of the males were above 55 years. The age distribution between the gender was similar to the study by Charlotte AHaaxmaet al.

WeerasakMuangpaisan et al., conducted a study to find the Worldwide Prevalence and Incidence of Parkinson’s Disease, in his study a literature search was conducted on Medline and EMBASE for studies worldwide investigating the prevalence and incidence of Parkinson’s disease and included publication between 1965 and January 2010. He concluded that Parkinson’s disease is common in the elderly, which was correlating with our study of fifty Parkinson’s disease patients out of which thirty eight were more than fifty years of age.

Family History

In our study, three patients (6%) reported with the family history of Parkinson’s disease that was analogous to the study by Jaan M Autere et al., on two hundred and sixty eight patients, among Finnish population where, ten per cent of them reported an affected first degree relative.

It is noted from the above table that the p value is greater than 0.05 for the demographic variable of Sex and hence the result is not significant at 5% level.

Taste sensation was altered among 8% of our study population howeverSienkiewicz-jarosz H et al., concluded that Parkinson’s disease is not associated with any alterations in pleasant or unpleasant taste stimuli, which is controversial to our study.
Kalf J. G.et al\(^9\) systematically reviewed the prevalence of drooling of saliva and hyper salivation in Parkinson’s diseased patients. Analysis of the data showed that drooling occurred with a frequency of 22–26%. In our study 14\% of the patients were presented with hyper salivation and drooling of saliva which proves that it is a common finding in Parkinson’s disease patients.

Periodontal disease and dental caries take up the highest rank in the oral diseases among Parkinson’s disease patients with 78\% and 84\% respectively. Marco Cicciu et al.,\(^11\) also noted that the frequency of untreated caries, periodontal diseases, and missing teeth of the Parkinson’s disease patients was significantly higher, when he evaluated their Periodontal Health and Caries Prevalence.

Speech impairment remains a challenging issue among the Parkinson’s disease patients where 14\% of our patients presented with difficulty in speech. Aileen K. Ho et al.,\(^12\) had noted that there was leading deficit in the Voice. The study by Hartelius L. et al.,\(^13\) also suggested that approximately out of four hundred and sixty patients with Parkinson’s disease 70\% of the patients had experienced impairment of speech.

Seidler. A et al.,\(^14\) in a quest to identify the possible etiologic relevance to Parkinson’s disease, they identified various factors leading to the Parkinson’s disease, which includes farming activity, pesticide exposures, and animal contacts, toxic exposures such as wood preservatives, heavy metals, solvents and head trauma. Likewise Stewart D. O. et al.,\(^15\) confessed that there exists a relationship between head injury and Parkinson’s disease. In our study, there were history of head injury but it was only up to 2\% out of 50 Parkinson’s disease patients.

Therapeutic management of Parkinson’s disease include Levodopa which has its own side effect of causing decreased salivation leading to dryness of mouth with burning sensation, and our study revealed the same with 30\% of the patients having the manifestation. A study by Melisa Proulx et al.,\(^16\) and Clifford T.J.et al.,\(^17\) concluded that salivary secretion is influenced by levodopa, and Burning sensation in the mouth was 5 times greater than that of the general population.

**Conclusion**

Mastication and orofacial functions are impaired in moderate to advanced Parkinson’s disease and becomes more marked with progression of the disease. One of the frequently observed features of the disease is hyper salivation, usually termed as sialorrhea is probably because of difficulties in swallowing and the loss of facial muscle tone than any actual increase in salivary flow. The condition is progressive and leads to restrictions in mobility and muscular rigidity. This can lead to problems in maintaining oral health.

Treatment for oral and dental problems of Parkinson’s disease affected patients is mandatory. Treatment can be done by supplementing artificial saliva for dryness of mouth, dental fillings for dental caries, periodic scaling for periodontal problems, oral rehabilitation measures and regular dental check up. The seriousness of the dental problems of these patients should be taken into consideration and depending upon the need, multidisciplinary approach upon referral may also be necessary.

Correlation between Superoxide Dismutase 1 and 2 Polymorphisms in Asthma Patients

Walaa Najah Majid1, Layla Mohsen Mehdi2
1Research Scholar, Biology Department, Faculty of Science/University of Thi-Qar, Iraq,
2Professor, Biology Department, Faculty of Science, University of ThiQar, Iraq

Abstract

This study was designed to investigate the effect of polymorphisms of Superoxide dismutase 1 and 2 genes and how they contribute to the risk of developing asthma. A total 120 were involved in the present study and divided into four groups and each group included 30 samples. First group consisted 30 asthma male patients with waterpipe smoking and second group was also 30 asthma male patients with no smoking, third group was control (no disease) with waterpipe smoking and the fourth group was control group (no disease and without waterpipe smoking). Blood samples were collected from Muthanna hospital and private laboratories from the period mid-August to the mid-November 2020. To study the polymorphism phenomenon of SOD1 and SOD2 genes were assessed using RFLP-polymerase chain reaction (RFLP-PCR) technique. This study confirmed that the phenomenon of polymorphism of the SOD1 gene was not associated with the group of patients infected with asthma compared to control group. This study conducted that the phenomenon of polymorphism of the SOD2 gene is not associated with the group of patients infected with asthma compared to control group in presence and absence of waterpipe smoking.

Keywords: Asthma, Waterpipe Smoking, Oxidative stress, SOD1, SOD2

Introduction

Asthma is a multifaceted inflammatory airway disease with a variety of clinical and molecular phenotypes. In asthma genetic, immunologic, and environmental factors all combine to cause chronic inflammation in the airways. Cigarette smoking is a significant factor in asthma. Asthmatic smokers have a pronounced deficiency in asthma control, a faster deterioration in lung function, increased airflow obstruction, and a worsening of disease severity, according to the data. Normally, oxidative products found in environmental contaminants are inhaled by humans. However, the inflammatory condition of asthmatic patients’ airways can promote oxidative stress by increasing levels of reactive oxygen and nitrogen species (ROS and RNS). This may lead to the inflammatory response’s maintenance and development, as well as disease exacerbation. The NADPH oxidase pathway produces anion superoxide (O2•-) in activated inflammatory cells. The activity of superoxide dismutase enzymes (SODs), catalase (CAT), and glutathione peroxidase (GPX) neutralizes the (O2•-) .

Furthermore, the enzymes that produce nitric oxide (NO) are known as nitric oxide synthase (NOS), another common free radical that forms RNS quickly in the presence of ROS. Peroxidation of membrane lipids, depletion of nicotinamide nucleotides, increased intracellular Ca2+, cytoskeleton breakdown, and DNA damage have all been linked to an excess of ROS and RNS. Tobacco smoke is a significant exogenous cause of oxidative stress in asthma, leading to the maintenance and development of the inflammatory response as well as disease chronicity. Cigarette smoke contains a variety of oxidant compounds that can cause direct and indirect oxidative harm. The current study aims to study polymorphism phenomenon of the SOD1 35 A / C gene and the SOD2 Ala-9Val gene (C / T) of Asthma patients by using (RFLP-PCR) technology to investigate SOD1...
and SOD2 polymorphisms and risk of asthma.

**Materials and Methods**

Samples were collected from blood from asthma patients. As well as the control group from the asthma center of Al-Muthanna hospitals. As the average age of the patient was (15±35) years, collected 120 samples, were examined. A biochemical test was performed on (60) samples had been measured between superoxide dismutase 1 and 2 Polymorphisms in Asthma Patients by immunological method, by using RFLP-PCR reader (Huma Korea origin). Before using the samples, they were placed at room temperature, as well as the reagents. All fluids were used with great care to prevent any errors as the checks were done step by step. All examinations were carried out by the apparatus of the College of Science, The-Qar University. Used RFLP-PCR kit as follows from the global company (measured between superoxide dismutase 1 and 2 Polymorphisms) INtRON Korea.

**Results**

A total 120 were involved in the present study and divided into four groups and each group included 30 samples. First group was consisted 30 asthma male patients with waterpipe smoking and second group was also 30 asthma male patients with no smoking, third group was control (no disease) with waterpipe smoking and the fourth group was control group (no disease and without waterpipe smoking). When genotypes of SOD1 35 AA, AC and CC were compared between groups (Table 1), the distribution rate was considered insignificant. There was no statistical difference for genotype and allele frequency between the groups (p = 0.76). Similarly, genotypes of SOD2 Ala9Val CC, CT and TT were compared between groups (Table 1), the distribution rate was considered insignificant. There was no statistical difference for genotype and allele frequency between the groups (p = 0.83, 0.81, 0.7) respectively.

**Discussion**

The SOD enzymes play a critical role in protection a cell against free radicalsgenerated by glutathione peroxidase and catalase. SOD enzymes comprise redox metals in the centers of their catalytic zones that transform superoxide radicals to hydrogen peroxide and oxygen\(^{(12)}\). The current study was conducted to find out the association between the SOD1 and SOD2 genetic polymorphism and the incidence of asthma. This study found that the was no relationship between the SOD1 and SOD2 genes and the severity of asthma in terms of the SOD1 35 A/C, CC genotyping frequency and SOD2 Ala-9Val (C/T), the TT genotype frequency in the patient group was statistically no significantly than the control group implying that there is no link between genetic polymorphisms in the SOD1 and SOD2 genes and the occurrence of asthma this corresponds to a study\(^{(13)}\). They discovered that these two genes are unlikely to function as major players in asthma on their own, based on their results. Along with genes involved in oxidative degradation, variants that interact with these genes have yet to be identified, and SOD genes may become significant in inflammatory airway diseases where oxidative stress is common.

The current study was conducted to find out the link between the SOD1 and SOD2 between smokers and non-smoking patients. There was no statistical difference for genotype and allele frequency between the groups (p = 1) between asthma patients with waterpipe smoking and control. At the same way, when the patient smoker’s cohort and control group were compared for the presence of the SOD2 Ala9Val (C/T) polymorphism, the distribution of the genotypes (p = 0.996). The findings of the present study may explain why smoking isn’t considered a risk factor for developing asthma in the samples examined, and the findings of this study were consistent with those of \(^{(14)}\), interpretation of the results might be that another unknown polymorphism, which is in linkage disequilibrium with the SOD1gene and SOD2gene polymorphism and contributesususceptibility to asthma. Although the results have shown a statistically significant enrichment of specific SNPs in SOD genes across the asthma population, however, it is possible that the presence of these polymorphisms increases the probability or enhances the development of asthma through other unknown genetic mutations (such as polymorphic genes coding for enzymes involved in the metabolism of foreign chemicals (xenobiotics) as well as external factors (including pesticides, organic solvents, and metals including iron, copper, and manganese)\(^{(15)}\).

**Conclusions**

Incapabilityto obtain enough patent sample to accurately measure SOD1 and 2 polymorphisms and measuring the enzyme activities of SOD1 and SOD2 genes and this is the ne of limitations of the current study. This may be usefulto highlight the effects of polymorphisms studied, and correlate the genotyping data with different factors

The Biological Activity of Alcoholic Extracts of *Cordia myxa* Plant Against *Klebsiella*. Isolated from Infected Patients

Bassam M. Shamkhy¹, Yass K. Abbas²

¹Research Scholar, Department of Biology, Faculty of Education for Pure Sciences, University of Thi-Qar, Iraq, ²Professor, Faculty of Education for Pure Sciences, University of Thi-Qar, Iraq

**Abstract**

Plants have been used as drugs by humans since thousands of years ago. The study aimed to investigate the effectiveness of alcoholic extracts of the fruits, leaves and seeds of *Cordia myxa* plant against pathogenic microorganisms (i.e. Klebsiella). This was done in the laboratories of the Department of Life Sciences / College of Education in Nasiriya southern of Iraq. The results showed that the alcohol extract of the leaf was significantly superior to that of the fruit and seed extract. The results also showed that the growth inhibition and the effectiveness against *Klebsiella* bacteria was at the average concentration of 300mg / mL 32.66 ± 2.08, representing the highest inhibitory concentration. It was concluded that leaves of the *Cordia myxa* is one of the best parts of the plant that have inhibitory effects on Klebsiella bacteria compared to the fruit and seed.

**Keywords:** alcoholic extracts, inhibition, *Cordia myxa*, Klebsiella, infections

**Introduction**

Medicinal plants are the Nature’s gift to human beings to help them pursue a disease-free healthy life. Plants have been used as drugs by humans since thousands of years ago. As a result of accumulated experience from the past generations, today, all the world’s cultures have an extensive knowledge of herbal medicine. Two thirds of the new chemicals identified yearly were extracted from higher plants. 75% of the world’s population used plants for therapy and prevention. In the US, where chemical synthesis dominates the pharmaceutical industry, 25% of the pharmaceuticals are based on plant-derived chemicals(1). The emergence of herbal medicine goes back to about 6000 years with the discovery of a tomb in the cave in northern Iraq in the year (1960). The analyzes conducted on the soil surrounding the skeleton resulted in the presence of pollen grains for eight plants, seven of which are medicinal, which are still used all over the world (2). *Cordia.myxa L* belongs to the family Ehretiaceae, which contains more than 300 genus and that are distributed in tropical, subtropical and warmer regions around the world. It is a medium-sized deciduous tree, the circumference of the whole bearing tree of the trunk is 75.5 cm, with pruned tree branches, soft wood, light gray, no heartwood(3). *Cordia.myxa* Tree is a perennial evergreen tree, medium in size if it reaches a height AD 5-7 and lived to 60 years (4). The fruit is almond with a stone core and is yellow in color and sweetish when ripe. The seed is oval in shape Several chemicals have been identified. Leaves are simple in shape, green in color (5).

The genus Cordia (containing more than 200 species) is one of the largest genera of this family. The fruits are used to make pickles and have many common antibacterial and anti-worm uses (6). It is also widely used in the treatment of diseases of the urinary tract and thoracic tract (7). A botanical study conducted in northeastern Ethiopia reported that *Cordia africana* was traditionally used to treat liver disease, dysentery, stomach pain, and
diarrhea\(^{(8)}\). The dried leaf powder is used to treat malaria and its associated symptoms by traditional healers\(^{(9)}\). Klebsiella species are routinely found in the human nose, mouth, and gastrointestinal tract as normal flora; however, they can also behave as opportunistic human pathogens, it can lead to a wide range of disease states, notably pneumonia, urinary tract infections, sepsis, meningitis, diarrhea, peritonitis and soft tissue infections it may be treated by leaves of *Cordia leucocephala*, popularly known as “Maria Brita”, are used as an infusion to treat dysmenorrhea\(^{(10,14)}\). The genus Cordia belong to the Kingdom : Plantae; Subkingdom: Tracheobionta; Superdivision: Spermatophyta; Division: Magnoliophyta; Class: Magnoliopsida; Subclass: Asteridae; Order: Lamiales, Family: Eretiaceae, Genus: *Cordia* L., Species: *myxa* L\(^{(1)}\).

### Materials and Method

The parts of the *Cordia myxa* tree collected all of the fruits, leaves and seeds from some scattered areas in the city of Nasiriyah, where they were cleaned and washed well with running water to get rid of impurities and dried, and left in the shade to dry, exposed to the air, after which they were ground by an electric grinder and placed in opaque bottles. The alcoholic extract (ethanol) extract was prepared according to the method of Harborne\(^{(11)}\). In this study, *Klebsiella* bacteria were used that were previously diagnosed from patient samples and were taken from the Microbiology Laboratory in the Department of Life Sciences at the College of Education for Pure Sciences at. Dhi Qar University, in order to evaluate the effectiveness of the and alcoholic extract towards the pathological bacterial isolate used during the study, the agar well diffusion method was used as it was mentioned in Hammer\(^{(12)}\). Muller Huntington agar medium was prepared and the bacterial isolates used were activated on this medium and then placed in the incubator at a temperature of 37 °C for a period of 24 hours after which a bacterial suspension was prepared from the developing colonies at a concentration (6 x 10\(^6\)) Using the physiological solution, and comparing the number of bacteria to the previously prepared McFarland. Take 100 ml of the bacterial suspension by means of a sterile micropipette and pour it over the culture medium, then spread the suspension with a glass diffuser spreader sterilized with alcohol and flame, then leave the dishes for one hour to dry the suspension. Three pits with a diameter of 7 mm were made in each dish using a sterile metal cork borer, then 100 micrometers of each concentration of the extract were placed in each hole using a small volume pipette micropipette, as one dish contains three concentrations (100 micrograms / ml and 200 micrograms / ml. And 300 μg. The dishes were incubated in the incubator at 37 °C for 24 hours, after which a transparent corona was observed around each hole, which represented the diameter of the inhibition zone. The diameter of the inhibition zone was measured using a ruler by taking the average of two perpendicular diameters measured in mm. were measured.

### Results and Discussion

*Klebsiella* organisms can lead to a wide range of disease states, notably pneumonia, urinary tract infections, sepsis, meningitis, diarrhea, peritonitis and soft tissue infections. *Klebsiella* species have also been implicated in the pathogenesis of ankylosing spondylitis and other spondyloarthropathies\(^{(14)}\). The majority of human *Klebsiella* infections are caused by *K. pneumoniae*, followed by *K. oxytoca*. Infections are more common in the very young, very old, and those with other underlying diseases, such as cancer, and most infections involve contamination of an invasive medical device. It was noted through Table (1) that all the concentrations of the ethanol solvent used were effective and with all the concentrations used, and the concentration of 300 mg was one of the best alcohol concentrations used, and through the statistical analysis of the fruit, it was noticed that there were no significant differences between the average concentration of 100 mg / mL of 25.66 ± 1.52\(^b\) and the average The average concentration of 200mg / mL was 26.66 ± 1.52\(^b\), but there was a significant difference in the concentration of 300mg / mL 29.66 ± 0.57\(^a\), as a significant difference was found between it and the concentration of 100mg / mL and the concentration of 200 mg / mL in the paper, through the statistical analysis, it was noticed that
there are significant differences between the average mean concentration of 100mg / mL 24.33 ± 1.15c, the average concentration 200mg / mL 28.33 ± 1.52b, and the average concentration rate 300mg / mL 32.66 ± 2.08a. As for the seeds, it was observed that there are significant differences between the average mean concentration 100mg / mL 23.55 ± 1.50c, the average concentration rate 200mg / mL 27.55 ± 1.66b, and the average concentration 300mg / mL 31.11 ± 1.76a. and the results of the current study are consistent with the results of the study he did(13). The inhibitory action of the alcoholic extract of the Cordia myxa plant may be attributed to the presence of alkaloids and phenols, in addition to triple terpenes, saponins, glycosides, tannins, flavonoids and carotenoids. These substances possess positive and negative bacterial activity as they cause inhibition of the formation of the cell wall of the microorganism or inhibition of the synthesis of essential proteins in it, and the formation of complexes with the cell wall that impede the regularity of permeability, and inhibition of some enzymes that have an important metabolic role in growth and reproduction, and the rupture of cell membranes or change their function. These reasons made the extract an antibiotic and antibacterial(15).

Figure (1) inhibitory effects of the alcoholic extract for the (A) leaves, (B) fruits, (C) seeds of the *Cordia myxa* plant, against *Klebsiella* bacteria that cause infections in human.

**Conclusion**

The possibility of adopting the *Cordia myxa* as an influential medicinal plant, as an important and essential source of effective compounds and nutrients, and this confirms the importance in terms of nutritional and therapeutic. The results of the study showed that the *Cordia myxa* contains high concentrations of total phenols that act as antioxidants and have proven their efficiency in scavenging free radicals, in addition to resistance to dangerous diseases related to free radicals. The leaf of the *Cordia myxa* is one of the best parts of the plant used in the current study in terms of the inhibitory effectiveness of bacteria (*Klebsiella*) compared to the fruit and seed used in the study.

Comparison of Akt Expression in the Cerebrum and Cerebellum of Newborn *Mus musculus* Exposed to Physical Stress and Psychological Stress During Pregnancy

Herlina Puji Angesti¹, Hermanto Tri Joewono², Widjiati³

¹Posgraduate student of Reproductive Health Science, Faculty of Medicine Universitas Airlangga, Surabaya, Indonesia, ²Obyn MFM Consultant, Department of Obstetry and Gynecology, Faculty of Medicine Universitas Airlangga/RSU Dr. Soetomo, Surabaya, Indonesia, ³Prof. Department of Embriology, Faculty of Veterinary Medicine Universitas Airlangga, Surabaya, Indonesia

Abstract

**Introduction:** Prenatal stress prevalence is almost half of the population of pregnant women worldwide. Stress will stimulate glucocorticoids which can disrupt the PI3K-Akt cascade. PI3K-Akt deficiency will cause impaired fetal brain growth and development.

**Objective:** To compare the Akt expression in the cerebrum and cerebellum of newborn *Mus musculus* exposed to physical stress, psychological stress, the combination of psychological and physical stress, and without stress exposure.

**Method:** This study was experimental laboratory research. Twenty-four female mice were used as samples and divided into four groups: physical stress exposure group, psychological stress exposure group, the combination of psychological and physical stress exposure group, and control group. Akt expression was tested by immunohistochemistry (IHC) staining. Statistical analysis used the One Way Anova and Kruskal Wallis test.

**Results:** There were significant differences in cerebrum Akt expression (p = 0.008) and cerebellum Akt expression (p = 0.047) between the control and stress exposure groups.

**Conclusion:** There were statistically significant decreases in mean Akt expression in the cerebrum and cerebellum of newborn *Mus musculus* exposed to stress during pregnancy.

**Keywords:** Stress, Akt, cerebrum, cerebellum, and *Mus musculus*.

---

Introduction

The brain is an organ that controls all body functions. Intelligence, creativity, emotions, and memory are some of the many things regulated in the brain. The brain is a stress adaptation center that triggers a behavioral and physiological response to stress. Stress increases hormone secretion on the hypothalamus-pituitary-adrenal (HPA) axis. After acute experience stress, the HPA hormone axis quickly returns to pre-stress levels, but chronic stress triggers a sustained response that affects mental and physical distress.
Depression and anxiety occurred in pregnancy, with estimated prevalence of 12% for depression and 15.2% for anxiety. Mild to moderate stress has been reported in half of the population of healthy pregnant women worldwide\(^1\). Prenatal stress increased glucocorticoids (cortisol) that can damage the brain\(^12\).

High concentrations of glucocorticoids (GC) combined with glucocorticoid receptors (GR) will inhibit neurotrophic factor (NTF) signaling expressed by many tissues in the brain, especially in the cerebrum and cerebellum. NTF is known to increase cell survival by activating Akt/protein kinase B signaling\(^4\). Phosphatidylinositide 3 Kinase (PI3K)-Akt cascade dysfunction has been recognized as a cause of neurodevelopmental and neuropsychiatric diseases, such as autism, epilepsy, brain injury, and developing brain malformations\(^17\).

**Objectives**

To compare the Akt expression in the cerebrum and cerebellum of newborn *Mus musculus* exposed to physical stress, psychological stress, the combination of psychological and physical stress exposure, and without stress exposure.

**Materials and Methods**

This research is a study laboratory experiment with post-test only with a control group design. Samples were 24 female mice (*Mus musculus*), 2-2.5 months old, weighing 20-25 grams. The research was conducted in Faculty of Veterinary Medicine Universitas Airlangga, from January to March 2021.

After adaptation for a week, female mice were divided into four groups, which are: the physical stress exposure group (K1), the psychological stress exposure group (K2), the combination of psychological and physical stress exposure group (K3), and control group (K4). Below are some explanations:

1. K1 is the group with forced swimming for 5 minutes every day in a box measuring 50 cm x 30 cm x 25 cm with a water height of 18 cm. Water temperature ranging from 24°C-28°C and room temperature of 20°C-25°C.

2. K2 is the group with noise exposure with sound intensity 90 dB through TrueRTA software and measured by the real-time sound analyzer (TES 1358) given for 1 hour per day.

3. K3 is the combination of K2 and K1. Both types of treatment are given on the same day with noise exposure for 1 hour. 5 minutes after that, forced swimming for 5 minutes.

Stress exposure to K1, K2, and K3 is given simultaneously at 09.00. Stress exposure is given starting from day 6-15 of pregnancy.

At the end of the 16th day of the experiment, mice were anesthetized with ketamine (Ketamine Hydrochloride Pfizer®, New Jersey, USA) and acepromazine (Castran®, Venray, Netherlands). Delivery by sectio caesarea (SC). The newborn mice were sacrificed through neck decapitation, and the brain organs were dissected.

Akt expression was tested by immunohistochemistry (IHC) and analyzed using the Remmele semi-quantitative scoring system. This Immuno Reactive Score (IRS) is a multiplication between immunoreactive cells (A) and the color intensity score of immunoreactive cells (B).

The Shapiro Wilk test was used to determine the data’s normality and the Levene test to determine its homogeneity. If the data’s distribution and homogeneity were normal (p> 0.05), then the One Way Anova test was used, followed by Post Hoc LSD (Least Significant Difference). If the data distribution is not normal, then the Kruskal-Wallis test is used, followed by the Mann-Whitney U test to determine the difference between the two groups with abnormal data distribution. Meanwhile, to determine the difference between the two groups with normal distribution, it is necessary to use the T-test analysis. Data analysis using IBM SPSS Statistics version 26.00 (New York, USA).
Results

The research sample consisted of 24 female mice based on inclusion criteria and randomized into four groups.

The results showed the mean difference between K1, K2, K3, and K4, as shown in Table 1. Cerebrum Akt expression was higher in the control group (K4) than the stress exposure group (K1, K2, and K3).

Table 1. Akt expression in the cerebrum of newborn mice in each group.

<table>
<thead>
<tr>
<th></th>
<th>Mean ± SD</th>
</tr>
</thead>
<tbody>
<tr>
<td>K1</td>
<td>8,300 ± 0,726</td>
</tr>
<tr>
<td>K2</td>
<td>6,616 ± 1,487</td>
</tr>
<tr>
<td>K3</td>
<td>5,017 ± 1,038</td>
</tr>
<tr>
<td>K4</td>
<td>9,617 ± 3,468</td>
</tr>
</tbody>
</table>

Statistical analysis used the Kruskal-Wallis test with the result p-value = 0.008. That means there was at least one significant difference between the two groups. The data were normally distributed, so the comparison between the two groups was analyzed using the T-test. T-Test showed significant differences between K1 and K2, K1 and K3, and K3 and K4.

Figure 1. Akt expression (red arrow). Cerebrum Akt expression in the control group (K4) was strongest among the other groups (immunohistochemistry, 400x magnification, Nikon H600L microscope from Nikon Instruments Inc. ™, New York, USA).
Table 2. Akt expression in the cerebellum of newborn mice in each group.

<table>

</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>K1</td>
</tr>
<tr>
<td>Akt expression</td>
<td>9,100 ± 2,767</td>
</tr>
</tbody>
</table>

The results showed the mean difference between K1, K2, K3, and K4, as shown in Table 2. The decrease in Akt expression occurred in the stress exposure group. This Akt expression decrease was in line with the increased stress exposure. Statistical analysis used the One Way Anova test with p-value = 0.047, which means significant differences between groups. Post Hoc LSD test (Least Significant Difference) shows significant differences between K1 and K3 and K3 and K4.

Figure 2. Akt expression (red arrow). Cerebellum Akt expression in the control group (K4) was strongest among the other groups (immunohistochemistry, 400x magnification, Nikon H600L microscope from Nikon Instruments Inc.™, New York, USA).

Discussion

The results showed that stress exposure during pregnancy decrease Akt expression in the cerebrum and cerebellum newborn mice. Stress during pregnancy causes an increase in placental GC². The fetal HPA axis is very sensitive to excess GC levels that can alter the regulation of HPA function¹⁶. High GC levels can suppress neurogenesis which endangers cell survival, causing an imbalance in several neurotransmitter systems¹⁰.

The interaction of GC and active GR in adrenocortical cells causes the neurotrophic factor (NTF) signaling pathway to be suppressed. Several proteins have been
classified as NTF: BDNF (Brain-Derived Neurotrophic Factor), IGF-1 (Insulin-Like Growth Factor-1), and GDNF (Glial Cell Line Derived Neurotrophic Factor)⁴. The BDNF system is essential for neural survival and synaptic plasticity in the CNS¹³. BDNF has broad expression in the brain¹⁸. IGF-1 is an important growth factor in CNS (Central Nervous System) development. In early brain development, IGF-1 has an essential role as an autocrine, proliferative, and prosurvival factor⁵. GDNF activates the PI3K / Akt signaling cascades⁴.

NTF plays a role in determining PI3K-Akt regulations. PI3K-Akt signaling activity triggers the catalytic lipid domain of PIP2 to become PIP3⁴. Inactive Akt binds to PIP3 in the plasma membrane, allowing PDK1(Phosphoinositide-Dependent Protein Kinase 1) to access phosphorylate T308 and mTORC2 (Mammalian Target of Rapamycin-2) to phosphorylate S473 as part of the activation of Akt⁷.

The Akt signaling pathway has important biological effects on cells, such as increased survival, inhibition of aging, and physiological activity¹⁹. Akt is a growth factor-induced cell survival mediator and has been shown to suppress apoptotic death in several cell types⁹.

The Akt pathways are negatively affected by glucocorticoid exposure¹¹. PI3K deficiency causes a significant reduction in brain size during embryogenesis³. Many experiments have shown that glucocorticoids can inhibit IGF-1 expression in many tissues and cells⁶. It shows the importance of Akt in brain growth and development³.

The results showed that Akt expression in the cerebrum and cerebellum was significantly higher in the control group than in the stress exposure group. Akt expression in the cerebrum and cerebellum of newborn mice decreased significantly in line with the stress exposure.

**Conclusion**

This study concluded that physical and psychological stress exposure during pregnancy could decrease the expression of Akt in the cerebrum and cerebellum of newborn mice.

Clustering of Provinces in Indonesia based on Maternal Health Indicators

Herti Maryani1, Lusi Kristiana2, Astridya Paramita2, Pramita Andarwati3, Nailul Izza3
1Senior Researcher, 2Junior Researcher, 3Assistant Researcher, Functional Unit of Health Technology Innovation, National Institute of Health Research and Development, Ministry of Health, Republic of Indonesia, Surabaya, Indonesia

Abstract

Indonesian health issues that deserved top priority was maternal and child health because it determines the quality of the human resources of future generations. The objective of this research is to analyze the clustering of provinces in Indonesia based on maternal health indicators. This cross-sectional study was conducted in 34 provinces using secondary data from the Basic Health Research and Statistics Indonesia. Analysis of provincial clustering used FUZZY C-MEANS. Analysis produces six clusters. Cluster 2 has a high mean value of maternal health indicators that exceeded the Indonesian target, consisting of the provinces of DKI Jakarta, DI Yogyakarta, and East Nusa Tenggara. Cluster 2 was formed by the value equation variable Age of first mating, Ownership of maternal and child health monitoring book, Vitamin A Provision, K4, postpartum visits, Iron supplementation tablets consumption and Childbirth delivery in health facilities. Indicators of ownership of the maternal and child health monitoring book for pregnant women had met Indonesia target in all clusters. Meanwhile, the active participation of family planning program indicator was still below the Indonesia target in all clusters.

Keywords: maternal health, indicator, cluster, fuzzy-c-means.

Background

The Maternal Mortality Rate (MMR) and Infant Mortality Rate (IMR), the reduction in the prevalence of stunting, as well as the control of infectious diseases and non-communicable diseases are priority health programs in the Indonesian for 2015-2019 (1).

In developing countries, including Indonesia, maternal mortality is still a major problem. The Indonesia maternal mortality rate in 2018/2019 is 305 per 1000 live births, meaning there are 38 mothers die every day due to illness/ complications related to pregnancy and childbirth. Compared to this, there are 830 mothers die every day in the world because of the same thing. The maternal mortality rate in Indonesia is second highest in ASEAN after Laos. Third place and so are the Philippines, Myanmar, Cambodia, Vietnam and Malaysia (2).

Labor complication is one of major maternal death cause in Indonesia. Based on 2018 Basic Health Research (Riskesdas), the proportion of childbirth complications in women aged 10-54 years in Indonesia was 23.2 percent (3). Based on 2018 National Social Economic Survey (Susenas), it was stated that women in Indonesia who had health complaints the last one month were 45.24 percent (4).

Indonesia’s health problems that need top priority is Maternal and Child Health (MCH) because it greatly determines the quality of human resources (HR) in future generations. The high maternal and child mortality rates reflect MCH services that urgently need improvement,
both in terms of range and quality of services (5).

So far, research conducted related to maternal health was still rarely done. Existing research on maternal mortality and related factors. Research conducted by Nurrizka and Wahyono (2018) on Maternal Mortality Disparities in Indonesia stated that there was still a disparity in maternal mortality that involved an intermediate factor between districts/cities in Indonesia, with the highest risk of maternal mortality occurred in Eastern Indonesia. This study used secondary data from Statistics Indonesia and the Ministry of Health as many as 8 variables, including health variables and demographic variables in 2013 (6).

Research conducted by Mukti and Wibowo (2017) on the Mapping of Maternal and Children Health Areas in East Java Province in 2014 used secondary data on 2014 maternal and children health programs in the East Java Provincial Health Office. This study applied a non-hierarchical cluster analysis method or K-Means Cluster. Eight variables were analyzed, ranging from maternal health service coverage, complications of labor and neonatal health service (5).

Based on the description above, research that has been done related to maternal health area mapping was still limited in one particular province, none of which has been done at the national level. Researcher is interested in analyzing the clustering of provinces in Indonesia based on maternal health indicators and using more health variables.

Cluster analysis produces information that differentiate cluster having maternal health indicators that perform beyond Indonesia’s target and which do not. Indonesian government can employ this cluster analysis to arrange more precise monitoring and evaluation of health program, by prioritizing programs according to the needs of each region.

Methods

This research is cross sectional study that applies Fuzzy-C Means analysis which was conducted in 34 provinces. The research uses data from three sources, namely the National Health Research (Riskesdas) 2018 (3), Welfare Statistics in Indonesia 2018 and Profile of Maternal and Child Health 2018 (4,7).

Riskesdas is a community-based health research that its indicators represent both national level and district/city level. Conducted once every five years, Riskesdas considered having appropriate interval to assess the development of public health status, risk factors, and the progress of health development efforts.

The Statistics Indonesia (BPS) collects data on demographic, education, health, fertility and family planning, housing, information and communication technology, crime, and social protection. These data are presented at the national and provincial levels thus allowing comparisons between regions.

FUZZY C-MEANS was applied to analyze the data. Research conducted by Maheswari (2018), Rahayu (2018), and Wang (2018) shows that cluster analysis using factor analysis results can improve clustering results by providing shorter time data processing. Factor analysis is considered for this study due to its stable clustering characteristics (8–10).

The steps of the analysis are:

1. Perform data adequacy test and correlation test.
2. Perform factor analysis.
3. Perform grouping using FUZZY C-MEANS.
4. Determine the optimal number of clusters using Pseudo F-Statistics.
5. Compare the performance of the method using ICD rate.

The highest Pseudo F indicates optimum number of groups created from data available, meaning the group is highly homogeneous while the intergroup diversity is highly heterogeneous (11). The selection of the best clustering method can be done by choosing the smallest icd rate. The value of icd rate describes the disperse level in the cluster (12).
Results and Discussion

Before clusters is formed, factor analysis is carried out to change the independent variables that correlate with other variables into new variable that is not interrelated.

This new variable is called the principal component (13). The first step in conducting a cluster analysis is to check the adequacy of the data using the Kaiser-Meyer-Olkin (KMO) value. In this analysis the KMO value is 0.707 (> 0.5), indicating that the amount of data used is sufficient to be calculated.

The next step to do is a Barlett test to find out the correlation between variables. This test yields $p$-value = 0.000 (< $\alpha = 0.05$), resulting in a decision to reject $H_0$. It is concluded that there is a correlation between maternal health indicator variables in Indonesia.

Determination of the optimal clusters number is based on the highest Pseudo F-Statistics value. This shows that two optimal clusters are formed. On the other hand, FUZZY C-MEANS method with factor analysis produces the highest Pseudo F-Statistics value of 12.537, which forms six optimal clusters (Table 1).

Cluster Interpretation

FUZZY C-MEANS method with factor analysis is a good method for grouping provinces based on maternal health indicators. Interpretation of results uses the mean value (centroid) of each variable in each cluster. The mean values of all clusters are shown in Table 3.

</table>

Source: *Ministry of Health (Riskesdas) 2018; **Statistics Indonesia (BPS) 2018
Table 3 shows that cluster 2 has the highest average and cluster 4 has the lowest. Cluster 1 has the highest average percentage of active participants of family planning program. The variable with the highest percentage is delivery with the help of health professional, and the variable with the lowest percentage is iron supplementation tablet consumption. Cluster 2 has seven variables with the highest average compared to other clusters which are age of first mating, having maternal and child health monitoring book, vitamin A provision, K4, postpartum visits, iron supplementation tablets consumption, and childbirth delivery at health facilities. The normal birth weight of newborn and active participants of family planning program variables in this cluster show inferior performance compared to other five clusters.

Cluster 3 has two variables with the lowest percentage compared to other clusters, which are age of first mating and national insurance health participant. Other variables in this cluster have a good average percentage. Cluster 4 have the lowest average percentage of maternal health indicators among other clusters. Cluster 4 has eight variables with the lowest average percentage of normal birth weight newborn, having maternal and child health monitoring book, K1, K4, postpartum visits, childbirth delivery at health facility, giving birth with the help of health professional, and active participant of family planning program. The indicator of maternal health with the highest mean in cluster 4 is the age of first mating. Whereas the lowest is iron supplementation tablets consumption.

Cluster 5 has two variables with the highest average percentage than other clusters, that are normal birth weight infant and giving birth with the help of health professional. The provision of vitamin A in this cluster is the variable with the lowest average percentage among all clusters. Indicators of maternal health with the highest mean in cluster 5 is giving birth with the help of health professional, the lowest is postpartum visits. Cluster 6 has the variable with the highest and lowest average percentage of the other clusters, which is national health insurance participation of mother and the iron supplementation tablets consumption, respectively. The variable of iron supplementation tablet consumption is indicator with the lowest mean value in cluster 6. While indicator with the highest mean value is childbirth delivery with the help of health professional.

Provinces with a low average indicator of maternal health are cluster 4 consisting of Maluku, North Maluku and Papua. Provinces with the highest average maternal health indicators are cluster 2, which consists of DKI Jakarta, Yogyakarta and East Nusa Tenggara.

The results shows that the childbirth delivery assisted by health professionals variable is the maternal health indicator with highest mean, almost 100 percent (90.96%). According to Nurhapipa and Seprina’s research in Center of Public Health (Puskesmas) XIII Koto Kampar I Riau (2015), the factors of affordability, family support and attitudes determined the mothers’ choice of childbirth delivery attendants type. When mothers had limited access to health facilities, then the chances of mothers choosing traditional childbirth delivery attendants (“dukun”) were fifteen times greater than those who had better access. While lack of family support gave four times greater chance to choose traditional childbirth delivery attendants (14).

The results of Zahtamal, Tuti Restuastuti and Fifia Chandra’s study (2011) showed that 81.1 percent of health service providers contributed to good maternal health practices, although it was statistically insignificant. Better maternal health practices were more likely influenced by the ease of accessing health services. Substandard maternal health practices were experienced 2.5 times greater by respondents with limited health services access (15).

The Number of pregnant mothers receiving iron supplementation tablets (ITD) are still lower (31.96%) than expected number, which was 98% according to The Indonesian National Strategic Plan 2015-2019. Dewantoro and Muniroh’s (2017) mentioned that limited supply of iron supplementation tablets in Center of Public Health led to low number of iron supplementation tablets utilization. Each Center of Public Health had a
distinct amount of funds spent to meet the needs of the iron supplementation tablets depending on the size of the capitation funds. Thus contributed to pregnant mothers’ compliance on consuming iron supplementation tablets (16).

An interesting finding to be analysed is the low average value on iron supplementation tablets consumption in all clusters. Further finding reveals that the ownership pregnancy monitoring book are quite high in all clusters. This finding is quite contradictory to the fact that maternal and child health monitoring book should be a communications, information and education media on healthy pregnancy issue including information on the importance of iron supplementation (17). The use of maternal and child health monitoring books are still limited to record medical history of pregnant women and have not been as an educational medium for pregnant women yet, as Sulistingsih reported (18). According to Kalsum and Yeni, one of the factors that affecting optimum utilization of the maternal and child health monitoring book were number of parity and the active role of health workers (19).

The provincial grouping results presented by images 1 shows cluster 4 (Maluku, North Maluku, and Papua Province) has the lowest mean value of maternal health indicators among others. This finding is consistent with Rahmah Hida N and Tri Yunis MW’s (2018) study result on the Maternal Death Disparity in Indonesia, which stated the high maternal death toll found in the district/city located in Eastern Indonesia. The provinces with a low maternal health indicator had higher risk on maternal mortality (6). The result of our research is consistent with Rivan D and Robert K’s study finding (2017) on the modeling of the Maternal Mortality Rate in Indonesia using GWPR. The study showed that the eastern Indonesia region had the smallest number of K4 visits (maternal visit on third semester) in comparison to other districts, leading to lack of sufficient health observation of pregnant women in the area, followed by increasing risk of maternal mortality (20).

The results of this research is also consistent with Syafrina and Sumertajaya’s study finding (2019) on Regency and City Clustering in Indonesia and also Fuzzy K Radala’s study finding that state most of the regencies and cities on Java Island are situated in cluster 2, which is upper middle class of Indonesian Human Development Index (HDI). The lower middle-class Indonesian HDI category is mostly occupied by Eastern Indonesia regencies and cities, whilst West Papua Province has the lowest Indonesian HDI. In contrast, some parts of Special Region of Jakarta, West Sumatra, and North Sumatra managed to reach high Indonesian HDI (21).

Family planning programme participation rate is one of the indicators of maternal health. The highest of active family planning programme participants (58.81%) is in cluster 1 which consist of six provinces. Based on the 2017 Indonesian Demographic and Health Survey (SDKI) 2017, active participation rate of family planning programme, both traditional and modern method, of the majority of the provinces in the cluster 1 (except Southeast Sulawesi 35.2%) are beyond Indonesia’s National average (46%). However, this is still below the national’s target set in 2019 which is 66%. Family planning programme is not entirely successful as measured through Contraceptive Prevalence Rate (CPR). The family planning program’s achievement in 2017 reached 63 percent, which was increased by 1.1 percent compared to 61.9 percent in 2012 (22).

The Indonesian Demographic and Health Survey showed that the proportion of unmet need was increasing from 9.1% in 2007 and 11.4% in 2012. These also depict shortage on contraception supply contributes to The family planning program’s underperformed condition. This condition should be important because it causes unexpected pregnancy to trigger abortion that escalates the risk of maternal mortality. Nurul Huda F., Ratno Widoyo and Fauziah Elytha (2016) found that lacking of husband’s support in participating birth control, raising the risk of unmet need to be 2.2 times (23).
Cluster 2 has the highest average value on all 7 maternal health indicators, amongst all clusters. This also indicates provinces in cluster 2 perform better in implementing health programs amongst all provinces in Indonesia. Cluster 2 consists of three provinces which have similarities on value of the variables. The average value of childbirth delivery at a health service facility (90.89%) on clusters 2 has exceeded the national target of 2018 (82%) \(^{(24)}\). Indonesian Demographic and Health Survey 2017 mentioned that most provinces in the clusters 2 (except East Nusa Tenggara) performed beyond national target, which was 79.4%, on childbirth delivery at health service facilities program. Similarly, healthcare staff-attended childbirth delivery average values in cluster 2 (except East Nusa Tenggara) exceeded the national average of 90.9\% \(^{(22)}\).

The visit 1 (K1) or minimum once visit to health care facilities during first trimester of pregnancy is one of the maternal health indicators that reaches the highest average value (86.30%) in cluster 2, which is also exceeds the national target of 2018 (85%) \(^{(24)}\). Indonesian Demographic and Health Survey 2017 showed that provinces in cluster 2 (except East Nusa Tenggara) performed better than the national average of K1, which was 97.5%. Likewise, average value for visit 4 (K4) or minimum four times visit to health care facilities during pregnancy (once in the first trimester, once in second semester and twice in third trimester of pregnancy) in cluster 2, which was 79.57%, performed beyond the national target 2018 (78%) \(^{(24)}\). According to Indonesian Demographic and Health Survey 2017, most provinces in cluster 2 (except East Nusa Tenggara) implemented K4 above the national target 2017 (77.4\%) \(^{(22)}\).

Analysis results show the mean value of the KMS ownership in cluster 2 is higher than other clusters, surpassed the targeted achievement rate by General Directorate of Family Health, 50% \(^{(25)}\). The analysis indicated that the average value of the postpartum women received vitamin A in cluster 2 is higher than the other clusters. Despite this, the results of the Nutritional Status Monitoring (PSG) (2017) nationally is still high at 53.5\% \(^{(26)}\).

Analysis results show that clusters 3 had satisfying mean value of most maternal health indicators, but still have the lowest average on indicator of the first mating age and mother having National Health Insurance. Cluster 3 consists of 10 provinces dominated by provinces situated in West Indonesian region. Over the past three years, many of the pregnant women in Indonesia’s western region have rarely utilize the NHI scheme as they prefer pay for medical service. On the other hand, most women in Central and Eastern Indonesia area had higher utilization rate of NHI \(^{(27)}\). Desra and Idris’s study (2019) on the mass-level Determinant in West Sumatra province indicated that the mother’s age had a significant influence on infant mortality in West Sumatra. The older the mother’s age, the higher risk for infant mortality. Furthermore, first mating age also plays significant role in infant mortality rate issue \(^{(28)}\).

Cluster 4 has the lowest average value of eight maternal health indicators. Normal birth weight leads to optimum growth and healthy generation. The low percentage of normal birth weight infants increase the risk of infant mortality and health disorders. Indonesian Demographic and Health Survey (SDKI) 2017 showed provinces in cluster 4 (Maluku 67\%, North Maluku 68.3\%, Papua 52.4\%) had much lower normal birth weight infants number than national average (87.5\%). The ownership of toddlers growth chart and milestones card (KMS) in cluster 4 is the lowest amongst others. Through this KMS, children’s growth are monitored every months. According to SDKI 2017, Papua, which is grouped in Cluster 4, had the lowest average in ownership of KMS (67.2\%) among all provinces in Indonesia \(^{(22)}\).

The childbirth delivery assisted by health professionals variable has the highest average amongst all variables. The results of Alhidayati and Asmutiliyanti (2016) study showed that the coverage of childbirth delivery assisted by health professionals in Hulu-Riau Center of Public Health (Puskesmas) was 79.86\%, while the rest 20.14\% assisted by non health professionals.
The percentage of iron supplementation tablet consumption is the lowest amongst all variables in cluster 5, also the lowest compared to all provinces in Indonesia. Contrary to Nutritional Status Monitoring (PSG) 2017 results, provinces grouped in cluster 6 which got sufficient amount of iron supplementation tablets was only 31.3%. While the rest 16.5% did not get any iron supplementation tablets and the other 52.2% only got less than 90 iron supplementation tablets. This clustering analysis can be employed by the central government to conduct more targeted monitoring and evaluation, by providing special programs with the requirements of each cluster. Out of the 12 variables analyzed, the iron supplementation program needs even greater effort to increase the participation level of pregnant women across the clusters. The enactment of maternal iron supplementation means improving the maternal mortality rate due to bleeding as well as reducing the neonatal mortality rate.

**Conclusion**

The Indonesian provincial group based on Maternal Health Indicators using FUZZY C-MEANS Clustering produces six clusters, which is found with high, medium and low in average value of maternal health indicators. Indicator for ownership of pregnancy monitoring book has met national targets in all clusters. Indicator for active family planning participation is still below the national target on all clusters. Cluster 2 which consist of the Special Region of Jakarta, Special Region of Yogyakarta and East Nusa Tenggara is a cluster with high average maternal health indicators and perform beyond the national target. Meanwhile, the clusters of the Maluku, North Maluku and Papua provinces are clusters with low average maternal health indicators and many indicators under the national target. Other clusters have maternal health indicators with medium and varied average values.

Abstract

Male fertility can be defined as the ability of the male reproductive system to impregnate a woman, while infertility is the condition of a married couple who have been married for one year or more and have had sexual intercourse regularly or without using contraception but do not have a pregnancy or offspring. About 10% of married couples experience infertility. The main organ of male reproduction is the testes because in the testes the process of forming spermatozoa and the hormone testosterone occurs. The hormone testosterone plays a direct role in the continuity of spermatogenesis. Testosterone is produced through a series of steroidogenesis mechanisms in testicular Leydig cells. Several factors influence the course of steroidogenesis such as Leydig cells, steroidogenesis proteins, related genes to the influence of free radicals. These factors are closely related to diet and lifestyle. This study is important to understand in efforts to prevent infertility in men.

Keywords: Male fertility, Steroidogenesis, protein StAR, steroidogenesis disorder, reproduction, animal trials.

Introduction

The health of the reproductive and sexual systems is closely related to mental, physical attitudes, and the social relations of each individual. The incidence of sexual dysfunction (SD) is estimated to be able to affect the sexual activity of men aged over 40 years by 52% and has the same potential for fertility in men aged under 30 years. Feldman et al.¹ A decrease in reproductive function in men can be indicated by a decrease in the quality and number of spermatozoa which can be used as biomarkers for male reproductive health.² Disease and lifestyle such as cardiovascular disease, obesity, depression, anxiety, and smoking are some examples of “classic” risk factors that correlate with reproductive and sexual system problems.³

Spermatogenesis is a biochemical process in the body that is regulated and acted on by endocrine hormones and several other related regulatory factors such as Luteinizing Hormone (LH), Folliclestimulating hormone (FSH), and testosterone and growth hormone in men. Spermatogenesis is facilitated by the presence of other hormones, but only the hormone testosterone plays a very important role in maintaining and maintaining the stability of the spermatogenesis process. Testosterone can be produced by changing cholesterol through a steroidogenesis process initiated by the StAR protein (Steroidogenic Acute Regulatory Protein). StAR protein works under the stimulation of Luteinizing Hormone (LH) in mobilizing and transporting cholesterol to the inner membrane of the mitochondria of Leydig cells.⁴ Research shows that there are several roles played by the
StAR protein as a biomarker of steroidogenesis activity, one of which is that the inhibition of this protein is capable of causing disruption of the hypothalamus-pituitary-testis axis which subsequently impacts LH secretion\(^5\,^6\). Apart from stimulating the performance of Leydig Cells for Steroidogenesis, LH together with androgens also play an important role in the proliferation and differentiation of Leydig cells\(^7\).

Currently, disease monitoring using biomarker and molecular approaches has been widely practiced in the field of health research and clinical practice. One of the uses of biomarkers that can be done in monitoring sexual and reproductive health is through understanding the pattern of steroidogenesis. The steroidogenesis process is regulated at various levels, especially at the level of transcription of genes encoding steroidogenic enzymes as well as several co-factors to post-translational processes associated with Steroidogenesis. Understanding steroidogenesis factors can also be facilitated by identifying genetic lesions/defects that can disrupt this process. An understanding of steroidogenesis is very important to be able to determine the occurrence of sexual differentiation, reproduction, fertility, hypertension, obesity, and physiological homeostasis\(^8\).

In this review, we will provide information and some important findings regarding the mechanism, disorders factors, gene function, and the role of steroidogenesis in male fertility. Several examples of research on Steroidogenesis disorders will also be represented in this review.

**Methods**

This study is based on the results of scientific research related to Steroidogenesis published from various local and international scientific sources, thesis, and dissertation. The internet is also used for data collection that has been published in various scientific journals\(^9\).

**Testis and Leydig Cells**

The testes are the reproductive organs in male and male animals. Men have two testes that are wrapped with a scrotum. In mammals, the testes are located outside the body, are connected by the spermatic tube, and are located inside the scrotum. This is consistent with the fact that the spermatogenesis process in mammals is more efficient at temperatures lower than body temperature (<37°C). The testes are covered by a fibrous layer called the Tunica Albuginea. In the spermatic tube, there is a cremaster muscle which when contracted will lift the testicles closer to the body. When the temperature of the testicles will be lowered, the cremaster muscles will relax and the testes will move away from the body. This phenomenon is known as the cremaster reflex\(^10\,^11\).

The testes have two main functions, namely, where spermatogenesis and steroidogenesis occur. Spermatogenesis occurs in a structure called the seminiferous tubule. These tubules are grooved in lobules where all the ducts then leave the testis and enter the epididymis. Androgen production by Leydig cells contained in the interstitial space. The hormones testosterone and spermatozoa are the two main products of the testes. The seminiferous tubule is the site of the Spermatogenesis process and Leydig cells which have a role in producing the hormone testosterone are located in the cavity between the seminiferous tubules. Leydig cells can be a single number or in groups. Apart from Leydig cells, there are also cells in the interstitial space such as macrophages, mast cells, fibroblasts, nerves, and endothelium cells. Leydig cells are surrounded by fibroblasts, macrophages, and binding tissue\(^12\).

**Biomarker Related to Steroidogenesis**

The regulation carried out by steroid hormones includes various processes both in development and physiology from the fetal phase to the adult phase. All components of steroid hormones are synthesized from cholesterol and have a structure known as Cyclopentanophenanthrene. This structure was discovered in the 1930s and became a precursor to the understanding of steroidogenesis\(^13\).

Substantially, studies have focused more on the performance of steroid hormones than on how they occur. This could be because steroids are a widely used drug and
something that steroid hormone disruption only occurs in people with rare genetic lesions. Advances in science and technology, especially in the health sector, have succeeded in providing the latest information regarding steroidogenic enzymes and the role of their genes used in the diagnosis of certain diseases such as hypertension and polycystic ovary syndrome through this approach. A list of genes in humans that can be used as biomarkers in studying steroidogenic function is presented in Table 1 below.

**SEVERAL FACTORS INHIBITOR OF STEROIDOGENESIS PROCESS**

Several factors can cause Steroidogenesis disorders in men, including:

a. Decrease in the Number and Function of Leydig Cells

The incidence of infertility in men is a fundamental problem from the initial failure of the spermatogenesis process(44,45). Genetic factors are only a small part of several factors causing the decrease in the number of Leydig cells(46–48). One indicator that can be used as a basic reference regarding the potential for male infertility is lower serum testosterone levels(49). In addition, the decline in the function of Leydig cells in increasing age is also the reason for the incidence of infertility in men(50) but until now, this is still being debated. This is evidenced by the results of research from Petersen et al(51) who conducted experiments using male subjects of various ages and paid attention to the total number of Sertoli and Leydig cells in their testes. These results indicated that there is a significant decrease in the number of Sertolicells as men age. It is interesting that there was no decrease in Leydig cells with a unilateral mean number of $99 \times 10^6$ (range: $47 \times 10^6$ to $245 \times 10^6$, coefficient of variation (CV) = 0.48).

Food has been reported to reduce the number of Leydig cells in several studies. As reported by Dantas et al(52) that food contaminated by synthetic herbicides such as Ametryn can cause reproductive performance disorders (decreased Leydig cells, lipid peroxidation, Superoxide dismutase, catalase) and animal life (male Wistar rats). Consumption of foods high in fat can also cause a decrease in the number and diameter of Leydig cells in male Wistar rats(53).

b. Adrenal steroidogenesis defects

The incidence of defective adrenal steroidogenesis can cause impaired sexual development. This incident not only affects the disruption of sexual development but is also capable of causing mild to severe disturbances in the synthesis of glucocorticoids and mineralocorticoids. Therefore, an examination of glucocorticoids and mineralocorticoids can be done to find out information about steroidogenesis defects in patients.

c. StAR protein

**Steroidogenic acute regulatory protein** (StAR) is a mitochondrial protein that has a molecular weight of 30 kDa in the adrenal and gonads and plays an important role in facilitating the rapid movement of cholesterol from the outside to the inner mitochondrial membrane(54). On the other hand, StAR protein has a characteristic role in regulating steroid biosynthesis in steroidogenic tissues(55).
The role of StAR in regulating steroidogenesis has been demonstrated in patients suffering from congenital lipoid adrenal hyperplasia (lipoid CAH), an autosomal recessive disorder that causes impaired adrenal and gonadal biosynthesis due to mutations of the StAR gene\(^{56–58}\). Recent research has shown that hormone-sensitive lipase (HSL), a neutral cholesteryl ester hydrolase (NCEH), plays an important role in regulating the expression of the StAR gene in adrenal and gonadal cells\(^{59}\).

The results of other studies confirm that StAR protein plays an important role in the steroidogenesis process. According to the results of research by Walsh et al.\(^{60}\) using environmental pollutants, organochlorine insecticide lindane and organophosphate insecticide Dimethoate on MA-10 cells directly inhibits the expression of StAR protein which correlates with steroidogenesis in Leydig cells during consumption of vegetable and fruit products contaminated with insecticides.

d. Free radicals by cytochrome P450

Free radical production and lipid peroxidation are potential initial mediators in the physiological processes of the testes and their disruption. Increased levels of Reactive Oxygen Species (ROS) are seen in 80% of infertility men. Certain levels of free radicals are necessary for normal sperm function, but in excess, they can have a detrimental effect on the steroidogenesis process. Oxidative stress can occur when an imbalance arises between the process of free radical formation and antioxidant levels in the male reproductive system, especially in the spermatogenesis process.

**DEVELOPMENT OF STEROIDOGENESIS RESEARCH IN ANIMAL STUDIES**

Currently, molecular mechanisms have led to the use of biomarkers in understanding the function of steroidogenesis in the testes. Several growth factors such as fibroblasts 9 (FGF9) are also reported to be able to be used as an indicator of early gonadal development and testicular steroidogenesis function during the process of sexual maturity\(^ {61}\). The role of the steroidogenesis gene can be identified from histone H3K9 trimethylation (H3K9me3) which was studied in vivo in rat testes exposed to arsenic for a long time. The function of steroidogenic genes such as Lhr, Star, P450scc, Hsd3b, Cyp17b, and Arom decrease after arsenic exposure, but increased histone H3K9me3 methyltransferase. These results indicate that arsenic exposure is able to suppress steroidogenic gene expression by activating the H3K9me3 status in the process of inhibiting steroidogenesis in rat testes\(^ {62}\). The following are some of the results of research reports on the effects of several toxic substances on steroidogenesis in the testes (Table 2).

</tr>
</tbody>
</table>
Conclusion

Nearly 40% of the incidence of married couples’ infertility is caused by male factors. Steroidogenesis is an important aspect of male fertility. The important point of steroidogenesis is the transport of cholesterol as a base material for testosterone from the outer membrane to the inner mitochondria by the StAR protein. Testosterone as a result of steroidogenesis is a male sex hormone produced through steroidogenesis which functions to maintain the spermatogenesis process. Several factors can inhibit steroidogenesis, including Leydig cells, adrenal steroidogenesis defects, StAR enzyme activity, cytochrome P450, and exposure to free radicals.

Nurses’ Knowledge about MCH Services at Primary Health Care Centers in Rural Areas of Babylon Governorate - Iraq

Ibraheem Abdul-Hifid Hussein¹, Aysen Kamal Mohammed Noori²
¹MScN(C), ²Instructor, University of Baghdad, College of Nursing, Community Health Nursing Department, Baghdad, Iraq

Abstract

Background: If you truly believe that every mother and every child deserve the best possible care, whether or not the newborn comes into this world or during that time or after, that means that you are with us on the same train. The study aims to assess nurses’ knowledge about MCH; and determine the relationship between nurses’ knowledge and their demographic characteristics.

Methods: A descriptive study was used to guide this study. The study included a convenience sample of (98) nurses.

Data were collection using a self-report questionnaire. Data were analyzed using the statistical package for social science. The descriptive and inferential statistical measures were used.

The study results revealed that nurses have a moderate knowledge. Nurses’ education, years of experience, and training courses significantly correlate with their knowledge.

Conclusion: Nurses’ knowledge about maternal and childcare were moderate and their knowledge were influenced by educational level, years of experience, and training. Longer years of experiences in maternal and childcare and more training on MCH program help to increase their knowledge.

Keywords: Knowledge; Maternal and Child Health Services; Nurses

Introduction

Maternal wellbeing in most developed countries is a giant project. With the loss of 673/100,000 and 19,000 maternal deaths each year from mother’s lives, it makes the largest contribution to the death of all mothers around the world (¹). Under the country’s reproductive health coverage, maternal health is among the six most significant problem areas. A point out about the rise in women who from time to time receive maternal fitness treatment preferences. Nevertheless, the maternal health care searching for lady’s stuff to do is then again low down. One reason for terrible health penalties among women is the lack of the use of up-to-date health care providers with the assistance of a significant proportion of women in the country’s way of traveling (²). Around 1,200 girls face fatal pregnancy and birth problems every 12 months in the United States and 60 fatal problems - the cost of birth care in the United States reaches 60 billion in 2012 (³). “Globally, over 90% of births and infants die in developing countries, depending on the highest number of deaths due to population distribution. No contact or inability of maternal health priorities will increase the risk of pregnancy and childbirth problems, which may impact the high cost of maternity and death, reducing the chances of the unborn child. In Asia, the health care system does not meet the needs of women

Corresponding author:
Aysen Kamal Mohammed Noori
University of Baghdad, College of Nursing, Community Health Nursing Department, Baghdad, Iraq, Email: dr.aysin@conursing.uobaghdad.edu.iq
in healthcare. The maternal mortality rate in Asia remained inappropriately high, with more than 510 maternal deaths per 100,000 live births (4). Iraq as one of the developing countries has been subjected to some of the most complex emergencies, conflict and security situations in the world today”. Poor birth practices are the main causes behind this high rate; insufficient referral or availability of emergency obstetric care, a high level of anemia among pregnant women (35%), especially affecting rural women and those in the Central and Southern regions, and the lack of adequate health professionals and structural damage to facilities (5).

Verify the awareness, mindset, and practice of these women during the time of pregnancy about maternal and child health services. Awareness of complications of pregnancy, educational history and belief in women, providers of prenatal health care, transport and postnatal health care, and person, institutional, social and cultural qualitative data were established to determine a mean (6). Therefore, this study amid to assess nurses’ knowledge towards MCH; and determine the relationship between nurses’ knowledge and their demographic characteristics.

**Materials and Methods:**

A descriptive design was used to guide this study. The study included a convenience sample of (98) nurses who were recruited from five health sectors which are Hilla First, Hilla Second, Al-Musayyib, Al-Mahaweel, and Al-Hashimya for primary health care sector in Babylon Governorate, Iraq. Data were collected using a questionnaire constructed by the researchers which includes socio-demographic sheet and nurses’ knowledge.

**Data Analyses/Statistics**

Data were analyzed using the statistical package for social science (SPSS) for windows, version 26. The descriptive statistical measures of frequency, percent, and mean of score (MS), and inferential statistical measure “Chi-square test” was used.

**Results and Discussion**

**Table 1. Nurses’ demographic characteristics (N = 98)**

“χ^2 obs.= Chi-square observer, χ^2 crit. = Chi-square critical, df = Degree of freedom, P-value= Probability value, S= significant, NS= non-significant, S= significant, HS= high significant”.

Findings indicate that there was no substantial association between maternal and childcare nursing expertise and demographic characteristics at p-value > 0.05, but that nursing education at p-value < 0.05 was significantly related. Their knowledge at p-value <0.01 has been closely correlated with years of experience and training courses.

**Discussion**

Knowledge tests, such as the one we performed in this report, may be a helpful complement to surveys on service availability and readiness evaluation to assess where and on what topics training is most needed. Where it is difficult to maintain routine training, treatment may be best concentrated in larger, better resourced facilities. If such an approach is to be considered, appropriate referral structures would need to be in place and existing overcrowding and staff shortages in larger primary health care centers in Babylon should be resolved to accommodate a larger number of customers.

Of the (98) subjects who participated in this study, their age ranged from (20-29) years of age and constituted (50 percent) of the study sample, as young workers, especially MCH, must be the primary health care staff to cover all duties. Our results come from research findings conducted at the Ibadan Primary Health Centre. The findings indicate that the majority of nurses are young adults (7).

It is evident from our findings that more than half of the study sample are female nurses. It represented (56.1 percent) of the total number of the study population, since most of the health care reviewers are women, so it includes female health workers, as in our findings. In our community, it is also normal for women nurses to be more than male nurses, since it is considered a feminine occupation by Iraqi society. These results are in line with the research conducted in Erbil City and address the expertise of nurses in primary health care. The majority of his research sample is stated to be females (59 percent) (8).

The distribution between married and single research samples. Where the proportion of married couples was the majority, the total amount accounted for 66.3 percent. It’s also, the small proportion of those divorced among those results, since most of these age groups are the marriage age. These results consist of a cross-sectional design carried out in Oman. Most of the participants were married and made up 92.0 out of 199 subjects in total. (9).

Regarding work variables, most of them medical assistants and graduates have 1-4 years of experience without training sessions, due to the diploma degree, due to the large number of institutions that graduate such degrees, the main proportion of staff nurses in health organizations are considered to be the diploma degree. The majority of nursing staff in primary health centers graduated with diplomas and lack of interest in training sessions were reported in the results of standard precautions among nurses in health facilities (10).

In order to minimize maternal and infant mortality, maternal and child health care is just as important. According to our study, the majority of nurses (60.2 percent) were moderately competent at mean + SD.= 1.68 + 0.5499. These results are in line with the findings of a study conducted in Nepal dealing with the awareness of rural areas of primary health centers in the Midwest. The results indicate that the participants were almost aware of maternal and child health due to the few years of work and discrepancies in educational levels (11). As well as serving in maternal and childcare, the Egyptian nurses wanted an effective educational program because of a lack of information about those programs (12).

“Another study also found that nurses interviewed showed a good to fair level of knowledge of maternity and routine newborn care management guidelines, but knowledge of small and sick newborn care guidelines was weaker and gaps in knowledge were reported”. Given the key role of nurses in providing day-to-day
treatment for maternal and newborn patients and the frequent shortage of specialist medical staff in the environment, it is important that nurses have appropriate expertise and skills to provide quality care (13).

In addition, nurses ranked highest for awareness of active mother management after birth and immediate routine neonatal treatment. In infant resuscitation, checking signs and symptoms of sick newborns, and controlling hypertension in pregnancy, output was worse. There was a particularly low overall awareness of treatment for sick newborns (score 0.62 of 1). Nurses who had undergone training after qualifying performed better than those who had not, in all areas evaluated. In contrast with better-resourced and busier facilities, poorly resourced and low case load facilities had lower overall information ratings (14). Several studies have shown that low resource environments have also found deficiencies in the expertise of health workers for maternal and newborn care (15)(16)(17).

At p-value <0.05, nursing education was significantly related. Their awareness at p-value <0.01 has been strongly correlated with years of experience and training courses. Nurses with a longer duration of work experience tended to understand more. Bases on findings of Al-Busaidi and others (2019), confirmed that those with less clinical nursing experience should be supported by potential educational initiatives and programs(9).

The importance of the total years of nursing experience and expertise was also established, as the knowledge increased with more years of experience. Also, Murphy and others (2019), Nurses with more years of experience and those who have undergone additional training since qualifying appeared to have higher awareness scores, confirmed in their results (14).

**Conclusion**

This research found knowledge in terms of maternal and childcare, nurses were moderately competent, and their knowledge was influenced by educational achievement, years of experience and training. More years of maternal and childcare experience and more training of MCH program workers by local officials help to increase the knowledge of nursing practitioners. Providing health services and the manipulation of young nurses’ energies, which actually helps to improve their skills.

Case Report: A Rare Case of Glioblastoma in Patient with HIV-AIDS

Ilham Munandar¹, M. Vitanata Arfijanto²

¹Resident Department of Internal Medicine Dr. Soetomo Hospital – Faculty of Medicine Airlangga University, Surabaya Indonesia, ²Doctor at Division of Tropical and Infection, Department of Internal Medicine, Dr. Soetomo Hospital – Faculty of Medicine Airlangga University, Surabaya Indonesia

Abstract

Patients with HIV_AIDS have an increased risk to develop neurological disorders include a complication of intracerebral mass. Primary CNS tumors in this condition are rare and difficult to diagnose because it has uncommon presentation, unusual tumor growth and manifests at a young age in a patient with HIV-AIDS. Advanced imaging techniques with contrast-enhanced magnetic resonance scans should be used to guide diagnosis in this condition. in a patient with HIV-AIDS, biopsy should be carried out if standard imaging showed atypical features or in a patient who has a poor response to empirical treatment for neurotoxoplasmosis. In this case, we reported a case of A 26 years old male with HIV-AIDS with neurological deficits who later diagnosed with glioblastoma.

Keywords: HIV-AIDS, Glioblastoma, Glioma.

Introduction

Patients with HIV-AIDS are at risk to develop either infectious or non-infectious complications. Neurological disorder occurred in up to 60% of patients with AIDS and 10% of patients have an intracerebral mass as a complication of its condition.

Glial central nervous system (CNS) malignancy found in 0.05 percent of all CNS tumors, and although this tumor recognized as the most common primary CNS tumors, it is very uncommon to found in the patient with HIV-AIDS and very difficult to diagnosed because they present with uncommon features of tumor localization and unusual tumor growth as well as presenting at a younger age in a patient with HIV-AIDS. Incidence of glioblastoma in HIV-AIDS patients increasing mortality risk that already substantially high in those populations. (1, 2)

This case report discussing a rare case of new diagnosed young HIV-AIDS patient with a glioblastoma who has neurologic deficit as initial manifestation.

Case Description

A 26 years old male was admitted to the emergency department of RS Dr. Soetomo, Surabaya, Indonesia because of loss of consciousness 2 days before admitted to the hospital. Heteroanamnesis from other family members revealed that initial symptoms developed fluctuating. This complaint is accompanied by limb weakness but no complaint of facial palsy. History of projectile vomit was denied but there was a history of prolonging headache and febrile. In the last 1 month, the patient frequently complained of fever that gone with over-the-counter medicine but denied any history of recurrent oral ulcer, profuse diarrhea, weight loss, or history of swollen skin or tumor. There was no history of hypertension or diabetes mellitus.

In the last two days, the patient started to feel shortness of breath with an occasional cough. There was no history of head trauma. The patient was admitted to the emergency department and then tested positive for HIV/AIDS. Head imaging showed a brain tumor and the patient was offered to undergo a surgical removal but the family denied any surgical approach. The patient...
worked as a metal worker and is currently not married with limited social interaction. The family didn’t know about a history of sexual activity but denied a history of alcoholism or drug abuse.

From the physical examination, the patient was somnolent with Glasgow Coma scale E2 V3 M4, the vital sign was blood pressure 11/70 mmHg, heart rate 96 beats per minute, respiratory rate 24-26 times per minute, body temperature was 37.2o. On head examination, the patient was dyspneic but was not anemic, not icteric, oral thrust and there was no lymphadenopathy. Chest examination was symmetric, with normal heart sound and crackle on pulmonary examination. Abdomen examination within normal limit without liver or spleen enlargement. There was no edema on extremity.

Laboratory examination was Hb 11.3 g/dl, HCT 32.1 %, MCV 81.5 fl, MCHC 35.2 g/dl, leukosit 7600 /mm³, neutrophil 85.3 %, lymphocyte 6.2 % mmol/l platelet 229.000/mm³, serum creatinin 0.43 mg/dl, BUN 13.0 mg/dl SGOT 57 U/l, SGPT 63 U/L, serum albumin 3.8 g/dl, Sodium 128 mmol/l, Potassium 3.8 mmol/l, Chloride 91 mmol/l, PPT 14.2 seconds dan APTT 28.8 seconds with non reactive HbsAg and anti-HCV. Blood gas analysis results was pH 7.45, pCO2 33 mmHg, pO2 131 mmHg, TCO2 23.9 mmol/L, base excess -1.1 mmol/l, HCO3 22.9 mmol/L, and SO2 99%. 3 methods HIV test was 3 positives and CD4 was 5 cells/µL (1.05%).

Chest radiography showed a diffuse pulmonary infiltration and normal cardiac imaging Head CT imaging with contrast showed a rim enhancing solid lesion 2.5x2.5x3.2 cm in internal capsule with an irregular inner wall and perifocal edema caused by narrowing down of right lateral ventricle dan midline shift to the left up to 1.9 cm suggesting a primary brain tumor (Glioblastoma). Later, evaluation with contrast-enhanced MRI of the head showed peripheral enhancing intra-axial, supratentorial lesion with hemorrhaging part and a necrotic area within internal capsule suggesting a glioblastoma.

The patient was assessed as HIV-AIDS, glioblastoma multiforme, suspected Pneumocystis Carinii Pneumonia, oral candidiasis, and mild hyponatremia. Patient treated with liquid diet 200 ml every 4 hours, IVFD NaCl 0.9% 1500 ml every 24 hours, 02 on a nonrebreathing mask 10 liters per minute, Ceftriaxone intravenously 1000 mg every 12 hours, Dexamethasone intravenous 5 mg every 6 hours tapered down based on clinical improvement, cotrimoxazole 960 mg every 12 hours, paracetamol tablet 500 mg every 6 hours and nystatin 2 drips every 12 hours. Laboratory examination planning was blood gas analysis evaluation, electrolyte serum, LDH serum, and smear sputum gram and culture and sensitivity of sputum. The patient denied to surgical approach for the tumor. 2 days after admission, the patient died in the hospital because of respiratory failure.

Discussion

HIV infection/AIDS is a global pandemic, with cases reported from virtually every country. It is estimated that 95% of people living with HIV/AIDS live in low-and middle-income countries; 50% are female, and 3.2 million are children aged under 15 years.(3)

Concerning HIV and malignancy, A study showed that HIV patients had a 5.4-fold higher incidence of malignancy compared to the general population. Even after removing the incidence of Hodgkin’s disease in the population with HIV-AIDS, there was still a 3.4-fold increase in the risk of malignancy. This includes an elevated risk of brain tumors, though not all of these were confirmed histologically.(4) Between 1986 and 1998, the population of patients with HIV-AIDS seen at Memorial Sloan-Kettering Cancer Center had a 45-fold higher risk to develop glioblastoma than normal patient.(5)

Glioma is a broad term used for primary brain tumors that are categorized based on their suspected cell of origin, for example, astrocytic tumors, ependymomas, oligodendrogliomas, and mixed gliomas. Account for almost 80% of all malignant primary tumors, it becomes the most common tumors of the central nervous system with glioblastoma multiforme as the most malignant and most frequent type of primary astrocytoma. Glioblastoma
was called glioblastoma multiforme because it varies in size and shape, but that term has not used nowadays. This type of tumors has a feature as highly invasive and infiltrating in brain parenchyma but typically limited in the central nervous system.\(^6, 7\)

Some studies to link this disease to particular environmental and occupational exposures still inconclusive and underpowered. Ionizing radiation is one of the few recognized risk factors for glioma progression that has been proven. Ionizing radiation is one of the few recognized risk factors as seen years after radiation indicated for therapeutic for another tumor or condition.\(^8\) Some specific genetic diseases are suspected to increase the risk of glioma development such as neurofibromatosis, tuberous sclerosis, Li-Fraumeni syndrome, and Turcot syndrome, but Glioma patients with a proven genetic disease account for fewer than 1% in all cases.\(^9\) Glioblastoma has not been confirmed to be caused by other environmental factors such as smoking, synthetic rubber, electromagnetic field, or nonionizing radiation from cell phones.\(^10\)

Gliomas develop from the malignant transformation of neuroectodermal-derived supporting cells and are presumed to link with mutation of tumor suppressor gene.\(^11\) The immunocompromised condition of the patient with HIV/AIDS may facilitate the development of neoplasms, as seen in primary cerebral lymphoma and Kaposi sarcoma.\(^12\) Evidence of interplay between immune system and pathogenesis of glioma in large epidemiological studies showed that patients with a history of the allergic disease have a lower risk for developing glioma, suggesting that a stronger immune system could be linked to a more effective intracranial response against certain neoplasm. Otherwise, immunosuppression caused by immunosuppressive drug therapy has been closely linked to a rise in the incidence of intracranial gliomas in organ transplant recipients.\(^1\)

Some of the hypotheses associated with an increased risk of patients with HIV-AIDS for to develop brain tumor were associated with HIV gene regulators such as \textit{nef} that alter astrocyte growth and morphology similar to neoplastic transformation in vitro studies. Besides, HIV infection also induces the secretion of proinflammatory cytokines such as IL-1, II-6, IL-8, and TNF alpha which can facilitate the development of glioblastoma.\(^1, 13\)

Initial symptoms of a patient with glioblastoma may vary depending on the size, location, and anatomic structure involved in the brain. The majority of typical symptoms are caused by increased intracranial pressure, such as headache and focal or progressive neurologic deficits.\(^14, 15\) Three mechanisms that account for glioblastoma signs and symptoms are the direct effect of the tumors that resulted from damage in brain tissue, by secondary effect of increased intracranial pressure, and symptoms related to specific tumor location.\(^6\) Concerning HIV-AIDS, a case report by Hall and Short showed most patients with HIV /AIDS who developed Glioblastoma were young (mean age is 38 years) with a CD4 count mean 400 cells/mm.\(^16\)

Glioblastoma in a patient with HIV-AIDS is difficult to diagnose because of its uncommon features of tumor localization, unusual tumor growth, and presence at a younger age in a patient with HIV-AIDS.\(^2\) referred non-invasive imaging techniques for brain tumors are MRI scans to visualizing the tumors. MR scans are the gold standard imaging because of their superior soft-tissue contrast to better visualization of complexity and heterogeneity of tumor lesion. CT scans are often recommended where a patient cannot perform an MR scan for several reasons, such as patients with pacemakers. T1–weighted MR scans can visualize hypointense lesions whereas proton density-weighted and T2-weighted images visualize hyperintense lesions. Gadolinium-enhanced MR scan of patients with glioblastoma typically shows a central area of necrosis, surrounded by white matter edema. Tumors are usually unifocal but can be multifocal. Latest imaging techniques with MR can also help to detect the hemodynamic changes, lesion architecture, and even cellular metabolism of tumors. This technique can be used to differentiate between active tumor or treatment effect on tumor itself.\(^7, 17\)
Figure 1. Patients head MRI with contrast showed a peripheral enhancing intra-axial, supratentorial lesion with hemorrhaging part and the necrotic area within the internal capsule suggesting a glioblastoma.

For intracerebral mass in a patient with HIV-AIDS, most protocols also recommend biopsy as the next diagnostic step if image features are atypical for neurotoxoplasmosis or after administration of empirical treatment not improved patient condition after 2 weeks. Current therapeutic options for glioblastoma in a patient with HIV-AIDS are similar to another patient, include surgery followed by radiotherapy and chemotherapy (temozolomide). The efficacy of specific antitumor therapies ultimately determines symptomatic treatment relief, but corticosteroids may temporarily help relieve neurologic symptoms caused by peritumoral edema.

Surgical resection should be considered in glioblastoma to reduce the mass effect, cytoreduction, and diagnostic procedures such as histologic and molecular characterization, even in suspected low-grade glioma to provide more reliable tumor grading. However, glioblastoma is known as a very invasive tumor that may relapse in approximately 80% of cases.

Radiotherapy following surgical resection has been shown to improve life expectancy, therefore this approach should be considered in all patients with glioblastoma. To improve patient survival, several chemotherapeutic agents have been tested for the treatment of glioblastoma. Temozolomide and biodegradable polymers containing the alkylating agent carmustine, implanted into the tumor bed after tumor resection used to improved survival glioblastoma. Because glioblastoma express a high level of vascular endothelial growth factors (VEGFs), protease inhibitor preferred to use in HIV-AIDS treatment since it promoted inhibition of VEGF and decreased angiogenesis.

In terms of prognosis, whether the tumor was a contributing factor for the accelerated progression to HIV-AIDS or, conversely, whether HIV-AIDS led to the faster growth of a tumor is still being studied. Despite a multimodal treatment, the prognosis is still grim and mostly determined by tumor progression.
Conclusion

It has been reported a young male recently diagnosed with HIV-AIDS with glioblastoma. The patient later died because of respiratory failure because of PCP. Because the increased incidence of non-AIDS-defining malignancies in patients with HIV-AIDS, it is important to include glioblastoma in the differential diagnosis of intracranial lesions, especially in patients presenting with neurological symptoms.

Abstract

Coronavirus disease 2019 (COVID-19) is significant global treat including to pregnant woman in Indonesia. A point-of-care diagnostic tool that is able to early diagnose and has a good sensitivity and specificity is critical during the pandemic. The aim of this study was to describe the clinical, laboratory and outcomes of pregnant women with presumptive COVID-19 and to compare the sensitivity and specificity between COVID-19 rapid test (lateral flow immunoassay) and real-time reverse transcription polymerase chain reaction (RT-PCR). Pregnant women with presumptive COVID-19 symptoms were recruited at Arifin Achmad General Hospital between April 2020 and December 2020. Demographic and clinical data were collected and patients were tested with COVID-19 rapid test as well as RT-PCR. Analyze was conducted to determine the sensitivity and specificity. We included 120 patients with presumptive COVID-19 of which 48 (40%) and 72 (60%) of patients were reactive for IgM and IgG antibody anti severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), respectively and 51 (42.5%) were reactive for both IgM and IgG. The sensitivity and the specificity of rapid test was 64.0% and 33.3%, respectively. The positive and negative predictive value was 61.5% and 35.7%, respectively. In conclusion, lateral flow immunoassay-based rapid test has relatively low sensitivity and specificity in diagnosing COVID-19 in pregnant women.

Keywords: Sensitivity, specificity, rapid test, RT-PCR, COVID-19

Introduction

On December 2019, coronavirus disease 2019 (COVID-19) cases, cause by a new coronavirus, severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), were firstly reported in Wuhan, China. World Health Organization (WHO) then declared COVID-19 as pandemic on March 11 2020. SARS-CoV-2 is a single-stranded ribonucleic acid (RNA) virus. The virus is able to survive at least for 12 hours on plastic surface, sensitive to sunlight and heat, easy to be inactivated with lipophilic substance such as ethanol and disinfectant contained chlorine, peroxyacetic acid and chloroform. The incubation of SARS-CoV-2 is about 5 to 7 days and is transmitted through droplet from symptomatic

persons.\textsuperscript{2,3,4} The natural reservoir of SARS-CoV-2 is bats; however, some evidence suggested that weasel or raccoon are also potential natural hosts.\textsuperscript{5}

COVID-19 causes an acute respiratory syndrome result in death which clinical and laboratory findings are similar between pregnant and non-pregnant woman. Pneumonia is the main finding in thorax CT-scan in patients with COVID-19 and some of frequent complications are acute respiratory distress syndrome (ADRS) and disseminated intravascular coagulopathy.\textsuperscript{2,5} A study in New York found that pregnant woman with COVID-19 were more likely to be hospitalized, required intubation, mechanical ventilation, and admitted to the intensive care unit (ICU) than non-pregnant woman.\textsuperscript{2} This is mainly because of the physiologic changes during pregnancy, such as decrease functional residual capacity, increased diaphragm, edema of respiratory mucosa, and change of immune system lead to increased susceptibility to virus infection.

In Indonesia, the first COVID-19 cases were identified in the capital Jakarta in March 2, 2020. As of March 26, 2021 more than 1.4 million cases and more than 40,000 deaths have been reported.\textsuperscript{6} COVID-19 has caused multisectoral disruptions including economics, healthcare system including children vaccination.\textsuperscript{7,8} Riau is one of the provinces in Indonesia with the highest COVID-19 cases.\textsuperscript{9} In Indonesia, COVID-19 rapid test is a screening tool that mainly to early detect COVID-19 and the result of rapid test will be confirmed with real-time reverse transcription polymerase chain reaction (RT-PCR). In the early of the COVID-19 pandemic, multiple brands of rapid test are available in the country with relatively limited in sensitivity and specificity assessments in the population. The aim of this study was to determine the sensitivity and specificity level of COVID-19 rapid test in comparison to gold standard RT-PCR in pregnant women.

**Methods**

A cross-sectional study was conducted from April 2020 to December 2020 at Arifin Achmad Hospital, Pekanbaru, Riau, Indonesia. Pregnant women with presumptive COVID-19 were tested with COVID-19 rapid test. In the first visit, data of demographic, exposure to COVID-19 cases and clinical data were collected. The COVID-19 rapid test was Healgen COVID-19 IgG/IgM Rapid Test Cassette (Healgen Scientific LLC, Houston, TX, USA). This kit detects both IgM and IgG antibodies to SARS-CoV-2 from whole blood serum or plasma and the test was conducted per manufacture protocol.

The patients with reactive for IgG/IgM rapid test then were re-tested with RT-PCR targeting at least two gene of SARS-CoV-2 using available kits at Arifin Achmad General Hospital Riau Indonesia (mainly using LiliF COVID-19 Real-time RT-PCR(iNtRON Biotechnology, Gyeonggi-do, Korea) or Live Rifer Novel Coronavirus COVID-19 (2019-nCoV) Real-Time Multiplex RT-PCR Kit (Shanghai ZJ Bio-Tech, Shanghai, China)). The samples for RT-PCR were nasal and oropharynx swabs. All run of RT-PCR were conducted per manufacture protocol.

The patients were also followed and data of outcome, time of stay in the hospital, intrapartum treatments or procedures were collected. The RT-PCR results of the new born baby was also collected. The sensitivity, specificity, positive prediction value (PPV) and negative prediction value (NPV) of rapid test were calculated.

**Results**

We included 120 patients with presumptive COVID-19. Characteristics of demographic, clinical, laboratory and outcomes of the patients are presented in Table 1. Almost 45% of the patients aged between 26–30-year-old (Table 1). There were 48.3% patients who were housewife, 28.3% general employees and 23.3% civil servants. More than two-third of the patients (76.6%) had caesarean section and only 13 (10.8%) had normal vaginal delivery. Our data suggested that less than 10% of the total patients had at least one of COVID-19 comorbidity.

Based on IgM and IgG antibody rapid test, 48 (40%) and 72 (60%) of patients were reactive for IgM and IgG anti-SARS-CoV-2, respectively (Table 1). Out of total
patients, 51 (42.5%) patients were reactive for both IgM and IgG anti-SARS-CoV-2.

</table>

We compared the sensitivity and specificity of rapid test with RT-PCR. Our data suggested that the sensitivity and specificity of COVID-19 rapid test was 64.0% and 33.3%, respectively (Table 2). The positive prediction value (PPV) and negative prediction value (NPV) of rapid test compared to RT-PCR was 61.5% and 35.7%, respectively.

**Discussion**

RT-PCR as a gold standard has a high sensitivity and specificity in detecting the presence of SARS-CoV-2 in specimens although in very small quantities. However, it requires high-skilled staff as well as high standard laboratory. Therefore, easy to use and cheap point-of-care diagnostic modality is critical during the COVID-19 pandemic particular in low- and middle-income countries. One of the rapid tests developed during the pandemic was lateral flow immunoassay that detects and differentiate IgM and IgG antibodies anti-SARS-CoV-2. We tested one of the lateral flow immunoassay rapid tests developed by Healgen Scientific LLC, Houston, TX, USA in pregnant women. Our data indicated that the sensitivity and specificity of COVID-19 rapid test was 64% and 33.3% with 61.5% and 35.7% PPV and NPV, respectively. The data suggest that the COVID-19 rapid test has relatively low power in diagnosing COVID-19 in pregnant women.

There are some possible reasons of low sensitivity and specificity of lateral flow immunoassay found in this study. Some of the patients in this study probably in the early phase of infection since the sensitivity of this kit for those in their early infection is unknown and negative.
results do not preclude acute SARS-CoV-2 infection. In addition, faults during nasal and oropharyngeal swab procedure could also be reasons since inadequate amount of virus could cause negative results during the rapid test. Some of the samples in this study were processed in virus inactivated viral transfer media and inactivation of the virus might affect the test results of rapid test. In addition, false positive results may occur due to cross-reactivity from pre-existing antibodies against other viruses.

**Conclusion**

The sensitivity and specificity of IgG and IgM lateral flow immunoassay in diagnosing COVID-19 of pregnant women at Arifin Achmad Hospital was 64% and 33.3%, respectively with PPV and NPV was 61.5% and 35.7%, respectively. Apart from sampling time and cross-reactivity, some other factors related to personnel and instrumental issues might associate with the results.

Varicella Pneumonia in an Elderly Patient

Isidro Lumanpauw¹, Usman Hadi²

¹Resident, Internal Medicine, Faculty of Medicine, Airlangga University – Dr. Soetomo Academic General Hospital, Surabaya, Indonesia. ²Lecturer, Department of Internal Medicine, Faculty of Medicine, Airlangga University – Dr. Soetomo Academic General Hospital, Surabaya, Indonesia

Abstract

Varicella pneumonia is a common complication in adults, while it is a mild and self-limiting disease in children. Elderly patients may have severe manifestations compared to adults due to the weakening of their immune system in clearing the virus. Treatment with intravenous acyclovir and varicella-zoster immunoglobulin (VZIG) offers a good prognosis, while the use of steroids is still debated. Despite standard management, our case presents a fatality in an older woman with varicella pneumonia.

Keywords: Varicella pneumonia, ARDS, septic shock, elderly, Indonesia

Introduction

Varicella is a highly contagious disease with the airborne transmission. Adults have more chance to develop severe cases affecting multiorgan manifestations of which most common is liver and lung involvements[1]. Studies in England and Wales showed a death rate of 4-9 per 100,000 population, 80% more are adults[2,3]. Epidemiology study reported tropical countries to yield less immunity to varicella in adult general populations, with only 42-76% being immune[4]. With the elderly being susceptible to infection compared to healthy adults, more severe forms of complications might occur and potentially lethal[5]. It is imperative to encourage vaccination in the elderly who has not contracted varicella before as a preventive measure.

Case Report

A 65 years old female presented to us with a chief complaint of cough and shortness of breath. The patient also had a fever for three days, diffuse skin rash turning into fluid-filled vesicles for five days, nausea, and abdominal pain for one day before hospitalization. As an elderly, she was independent without known comorbid, and her grandchild was discharged two weeks prior due to varicella. The patient had no history of varicella infection nor vaccinated before.

Vital signs on her admission was as follow: BP 110/70, tachycardia 120 beats/min, tachypnea 32 times/ mins, fever at 38.7°C, pulse oximetry at 89% under high concentration mask at 12 L/m, bilateral basal rhonchi on auscultation with diffuse papulovesicular rash on her skin. The arterial blood gas before intubation and mechanical ventilation was as follows: pH 7.42, PaO₂ 74, PaCO₂ 27.9, BE 3.4, SO₂ 95% and after pH 7.36, PaCO₂ 42, pO₂ 108, HCO₃ 24.2, BE -1.4 SO₂ 98%. The laboratory showed hemoglobin 15 g/dL, leukocytosis 16160/µL, granulocyte 62.9%, lymphocyte 15.6%, thrombocyte 101000/µL, random blood glucose 98 mg/dL, albumin 3.28 g/dL, CRP 165 mg/L, AST 550 U/L, ALT 441 U/L, mildly increased direct bilirubin 1.27 mg/dL, SC 1.14 mg/dL, BUN 17 mg/dL and normal APTT 25.2 (23.5) and PPT 10.6 (10.9).

She was admitted to an isolation intensive care unit with an initial diagnosis of acute respiratory distress syndrome (ARDS) due to varicella pneumonia dd severe bacterial pneumonia with hepatic dysfunction due to varicella infection. Treatment of 800mg/8h intravenous acyclovir was started along with levofloxacin 750mg/24h and methylprednisolone 62.5mg/8h. Due to unavailability, VZIG was administered on the 2nd day of care. Tzanck smear showed multinucleated
giant cells. Abdominal ultrasound showed mild hepatic enlargement, the serologies viral hepatitis and HIV were negative.

Her chest X-ray showed worsening infiltrate. Leukocyte count was increased to 19,110/μL, granulocyte 80.5%, AST and ALT were lowered to 130 U/L and 104 U/L, direct bilirubin was normal 0.4 mg/dL, and lactate 1.9 mmol/L on the 3rd day. During the care we were able to reduce the FiO2 down to 0.6 from the initial 1.0 and the positive end-expiratory pressure (PEEP) at 12 down to 6 cmH2O with SIMV mode to maintain oxygenation. Later on that day, she had a decline in her condition, and vasopressor was started. On the 4th day, she passed away due to septic shock. Sputum and blood culture came back negative both on the 1st and 3rd day.
**Discussion**

Varicella or chickenpox is an airborne disease caused by the VZV. Despite primary infection usually occurring in childhood, adult cases are often seen with more severe manifestations. Symptoms usually begin 10-21 days after exposure\(^6\). The diagnosis of varicella is usually made by generalized vesicular skin rashes manifestation along with a history of exposure. IgM anti-VZV can be used to confirm the infection, but it may be negative on early infections\(^7\). Tzanck smear is a quick, accurate, and useful addition in confirming varicella diagnosis. Microscopically, multinucleated giant cells with or without intranuclear inclusion bodies can be seen\(^8\). The onset of symptoms, in this case, was around 9-15 days. The diagnosis of varicella was obvious by the skin manifestation and history of contact supported by Tzanck tests done showing multiple nucleated giant cells.

A previous study mentioned common complications in varicella infection are raised ALT, thrombocytopenia, pneumonia, secondary skin infection, and meningitis\(^1\). Pulmonary symptoms, which are shortness of breath, cough, pleuritic chest pain, and hemoptysis, may appear 1-6 days after the onset of the rash\(^9,10\). Hepatic involvement in varicella showed symptoms of vague epigastric pain, nausea, vomiting, and a possible increase in liver volume\(^11\). An increase in liver function test panel is expected, a couple of studies reported AST raised higher than ALT along with the increase of INR and bilirubin\(^12,13\). Risk factors for complications in varicella are newborns, adults, immunocompromised, males, smokers, and pregnant women. While references are not mentioning the elderly as immunocompromised, immunosenescence in the elderly causes susceptibility to infection due to thymic involution, altered innate, and adaptive immunity, which would result in more severe infection\(^5\). In this case, we suspected the infection had caused the liver involvement, excluding the cause of ischemic hepatitis and viral hepatitis.

Radiologic chest X-ray features of varicella pneumonia are multiple bilateral nodules 5-10mm with unclear margin and can be overlapped but not always present. High-resolution CT-Scan might enhance the feature along with ground glass halo appearance, which diffusely spread on both lungs. Lymphadenopathy, reticular opacity, and pleural effusion can be found on occasion. On recovery progress, calcification can be found\(^14\). In this case, we found only infiltrate on both lungs.

Intravenous acyclovir 10mg/kg/8h for 7-10 days is the standard treatment of severe varicella and should be started immediately after diagnosis is made. After 48 hours of rash onset, there is no evidence of the benefit of acyclovir\(^15\). The role of corticosteroid is still debated and is thought to alter the uncontrolled immune host response to the virus by inhibiting T cells function and neutrophil adherence to epithelial cells\(^16\). Some studies showed clinical improvement, but some mentioned at risk of superinfections\(^16,17,18,19\). Reports showed that use of steroids prior varicella infection might cause fulminant hepatitis\(^12,13\). Nevertheless, the use of steroids remains a clinical decision\(^19\). Our decision to add another antibiotic and stop the steroid was based on clinical judgment regarding the occurrence of bacterial superinfection. The increase of leukocyte and granulocytosis might be attributable to the use of the steroid. We found a reduction level in our liver test functions on the 3rd day with the use of high dose steroid in our initial therapy.

The use of VZIG for severe varicella may be useful if administered 72 hours after exposure and indicated for immunocompromised patients, seronegative VZV antibody, and after significant exposure to individuals with varicella\(^16\). A study showed severe varicella mortality is attributed to ARDS, MODS, septic shock, and fulminant hepatitis. Multiple organs involvement increases mortality and morbidity\(^18\). In this case, acyclovir and VZIG administration were way past the guidelines recommendation and resulted in unfavorable outcomes in this patient. Adults in Indonesia are presumed to be immune to varicella because most have contracted it in childhood. Hence, society often forgets the importance of vaccination, especially in the elderly.
Conclusion

We reported a fatal case of an elderly patient with no comorbidities with several complications due to the infection. Immunosenescence in the elderly may be the cause of this severe infection due to the weakening of the immune system in eliminating the virus causing severe complications. Vaccination is encouraged in the elderly who has no prior history of primary varicella infection and has not been vaccinated before to avert severe manifestation of the disease.

Author’s Note: This case was presented at the department case report in February 2018.

Abstract

Skull identification is extremely important in today’s society, especially in medico-legal circumstances. As a result, all technological advancements in this field can contribute to the growing need for precise and robust tools that allow for the establishment and verification of human identity. Identification of skulls when all other proof and evidence are destroyed or limited requires the usage of facial reconstruction for the forensic team. The facial graphics serve as an emphasis for public attention to specifics of the case to generate additional investigative guidance. The physical appearance of the face is at its best a significant cause for the purposeful identification and communication to the investigating authorities of knowledge. Human identification is one of the most remarkable approaches in the field of forensic medicine. The identification mission is performed in the field of forensic anthropology by the examination of the skeletal remains. Anthropologists have been paying attention to improve the techniques that allow accurate and clearer identification. Therefore, forensic identification has become an active field of study and skull detection has emerged as a vital source for identification. Skull identification is attracted and applied in many forensic areas. This review article is a summation of the various facial reconstruction approaches and their role in forensic science to identify the individual.

Keywords: Craniofacial superimposition (CFS), Forensic Identification, Skull Detection, Facial Approximation, Forensic Anthropological Analysis

Introduction

Anthropologists advocated forensic application in the early days. In the early 1990s, computerized face alignment approaches were initiated. The term “Facial Approximation” was used as a synonym for “Facial Reconstruction.” The morphological and anatomical correlations of the skull and face have been primarily studied in various fields of research such as maxillofacial and plastic surgeries, genetics, and prominently in the craniofacial reconstruction area. Therefore, several decades of consistent landmarks were identified in both the skull (craniometric) and face (cephalometric).

Numerous studies were conducted using data from different populations and techniques that measured the soft tissue depth between the relevant landmarks.

Egyptians implemented several measures to preserve many details of their ancestors. In the late 19th century, the similarity of the surface soft tissues of the face and the skull’s underlying ossic structure started to be studied by anatomists and anthropologists, and forensic odontologists. Modern times have seen the emergence of facial reconstruction to assist archaeologists in demonstrating the appearance of the early person. Recently, forensic science play a significant role in producing an image from the skull. For hundreds and millions of years, skulls can exist and offer incomparable means of identification. Identification will be needed if a skull is unintentionally restored from a backyard, forest,
etc. Conventional methods such as dental examination, radiography, DNA analysis, etc, can neither be employed nor have been unsuccessful. Forensic facial reconstruction can be applied as a major tool to aid in skull identification and to identify the individual³.

Skeleton-Based Forensic Human Identification

When other technologies fail, forensic facial reconstruction can be used to identify unknown human remains⁴. Numerous techniques are available for facial reconstruction, ranging from 2D graphics to 3D models. With the advancement of 3D technology, a fast and cost-effective computerized 3D forensic face reconstruction method has been developed, which reduces the level of errors previously encountered⁵. Forensic facial reconstruction is a combination of scientific methods and artistic skills. It can be used to reconstruct soft tissues on the skull to obtain images of individuals for identification and recognition⁶. Some commentators believe that forensic facial reconstruction is a method of facial approximation.

Various facial patterns can be created from the same skull. However, other researchers believe that each skull can only produce one face, so it is certain that a person uses the term “face reconstruction”⁷. Forensic facial reconstruction is used in both forensic science and archaeology. In forensic science, this method is used to identify individuals who are unsuccessful in conventional/common identification methods. In archaeology, it is used to identify the faces of people in the past, bone remains, embalmed bodies, etc.⁸. A person’s face has several different types of exclusive features, so it is crucial in recognizing a person. When a body is found, a facial photograph is taken. Sometimes the photo is digitally processed to make it suitable for witness identification or newspaper publishing that eventually leads to the identification of the body. The victim’s family, friends/acquaintances are visually identified, but not found to identify the only body part of identification is the face. Sometimes, due to animal damage, physical attacks, or environmental factors, the face of the deceased cannot be identified because the face cannot be recognized. In cases where little or no other evidence is available, forensic facial reconstruction is another method in the identification process⁹. Reconstruction techniques can be divided into two types: two-dimensional (2D) and three-dimensional (3D) techniques¹⁰. They can be performed manually or analyse specific software (computerized). The 3D manual methods used in forensic facial reconstruction are anatomical (Russia), anthropometric (US) and Manchester combined (UK) methods developed by Gerasimov, Krogman, and Neave, respectively¹¹,¹².

Forensic Anthropological Analysis

The active scientific identification of human remains recovered in the context of forensic medicine is the main goal of forensic anthropological analysis. Many aspects of anthropological activities, including search and recovery, identification of species, the estimation of gender, age of death, body size, time of death, detection of ancestry, and unique anatomical features, can be used to narrow the search for missing persons¹³. In the end, forensic anthropologists will contribute to active scientific identification directly or through a large amount of supplementary information provided. Direct contributions such as evaluating various anatomical features and compare them with pre-existing information are revealed through radiography and related images. The recognition types include provisional, environmental, presumptive, and positive types¹⁴. The first three types listed indicate that actual identities cannot be excluded, so these remains or other inspection evidence represent specific individuals. Research and case studies have shown that facial recognition is unreliable, especially when performing advanced decomposition¹⁵,¹⁶.

Positive recognition represents a higher level of probability and involves a two-step process. First, it is necessary to discover the anatomical features shared between the examined evidence and the known prior information about the specific individual. Second, the analyst should determine that the compared features are sufficiently unique to be able to be identified. Besides, any discrepancies should be recorded and explained.
Recognition errors are divided into two categories: 1 the difference is evidence of exclusion representing other factors; 2 the uniqueness is not fully considered when presenting shared features to support the recognition. There is a particular need for contributing forensic anthropologists to identification, and especially in the analysis of extensive decomposition and skeleton human remains. Experimental research reported by Sauerwein et al. pointed out that the process of decomposition can quickly destroy many indicators commonly used for identification, although the speed of destruction depends on many variables. In their study, fingerprints survived for 4 days after death at high temperature and survived for more than 50 days at low temperature. The time for iris recognition after death is 2 to 34 days, depending on the variable.

Accurate recovering, documenting, and evaluating the biological characteristics of human remains are important factors leading to active identification. To focus on the appropriate missing persons for identification, investigators must have meaningful information about the age of death, gender, ancestry, body size, and time since death. All evidence must be retracted together with detailed documents. It should be restored and analysed in a way that meets the requirements of legal procedures.

The unique function required by identification can be provided through surgical procedures, especially those that remain in bone tissue. For example, Hogge et al. detected postoperative defects associated with unilateral lambdoid combined resection, the body can be actively identified. The remains were identified as people who underwent neurosurgery for this rare congenital abnormality. Many orthopaedic devices with human remains provide information to the manufacturer. According to current laws, certain devices contain digital information that can be traced back to specific operating rooms or even individual patients.

Forensic anthropologists discovered these inorganic materials in their case. For example, Bennett et al. reported the identification of burned wreckage recovered from automobiles through inspections of internal fixtures. Radiographic examination of the recovered residue revealed that many wires were identified as osteostimulators. The serial number is not recorded, but it is a material related to the documented bone stimulator used to treat a patient's back injury to stimulate bone production during surgery.

Dental characteristics often provide the information needed for identification. Forensic odontologists explain dental restorations and other characteristics related to the dental practice. However, anthropologists and dentists have common interests and expertise in tooth morphology, which can provide evidence for positive scientific identification. Useful features for identification include the number of teeth present, missing front teeth, the pattern of tooth displacement, and pattern of abnormal rotation. Typically, comparative antemortem data are available via radiographs and related imaging. Murphy et al. recorded that 60 percent of the scientific identification in the St. Louis region of the United States resulted from radiographic evaluation in a 15-month period from April 1978 to July 1979. Most of the specific data used in positive scientific identification were provided by anatomical variants, disease alteration, and postoperative features. As noted by Fitzpatrick et al., to promote contrast, positioning, magnification, beam centring, angulation, and bone orientation techniques should be used properly.

Craniofacial Superimposition

A forensic technique for detecting the skull known as craniofacial superposition (CFS) is used to investigate the anatomical and morphological connection between a skull and the face. It includes overlaying the skull with a varying number of facial images. Most people now have images with identifiable faces and hence, this technique plays a significant role in skull detection.
craniofacial superimposition\textsuperscript{30}. From the viewpoint of recognition approaches, Yoshino et al. divided computer aided CFS into two groups. The first approach is to digitize the skull and face pictures\textsuperscript{31}. Image processing tools were employed to compare the two images morphologically. The second step is to perform a morphometric test to assess the match between the skull and facial images. The above contributions were made before the last decade’s image-processing boom\textsuperscript{32}. Damas et al. analyzed the current approaches contemplating a computing-based classification standard and are further concerned with the use of computers at various stages of CFS processing. To properly characterize any CFS method, and the authors have specified various stages involved in the craniofacial process\textsuperscript{33}. “These stages include face enhancement and skull modelling, skull-face overlay, and decision making.” The first stage entails creating a digital model of the skull and improving the image of the face. Instead of creating a 3D model of the skull, the oldest and most modern systems still obtain a photograph and a sequence of video shots of it.

Regarding face images, most modern systems employ a 2D digital image. This stage demands image-processing techniques to improve the quality of the face image that was given when an individual is missing. The skull-face overlay is the second level. It involves finding the best overlay of a 2D image of the skull/face or a 3D model of the skull/face obtained during the first stage. The final and third stage of CFS are decision making. Based on the skull-face overlay attained, the identification decision is made by examining the framework and soft-tissue thickness at different anthropometric landmarks, as well as anatomical details to determine the spatial relationships of the skull to face sections\textsuperscript{34}.

Forensic identification and technology involve two (or more) separate images/models/data and explore similar and compatible patterns. The data applied for comparison are the same ‘object’ in methods such as DNA, fingerprints, facial recognition, dental identity; for example, two DNA string comparison, fingerprint images, photographs of the face, and teeth x-rays. This is not the case for CFS, a human identification technique in which photographs of the face and skull are contrasted to determine the identity of a given subject. The entire CFS method can be divided into 3 subsequent steps: 1) The acquirement and processing, e.g., skull and ante-mortem (AM) face images and somatometric marks on both sides; 2) skull-face overlay (SFO) to perform the potential overlay for the skull and a single AM picture of the person that is missing. This is done in reiterative aspect with each photograph, attain different overlays; and 3) decision-making aimed at deciding the degree of match support, based on SFOs obtained in the earlier step\textsuperscript{35}. The technique of CFS identification has tremendous potential for use today because many people have photos (AM), where their faces are visible. A bone that deteriorates with the impact of fire, humidity, high or low temperatures, and distant future; is the counterpart skull.

Craniofacial superimposition the characteristics of the recovered skull with the ante-mortem picture of the missing person who may be represented by the remains. This technique can be used when it has not been positively identified by molecular analysis, dental reconstruction comparison, or anthropological radiological evaluation\textsuperscript{36}. Usually, this method can be used when a complete skull or crania can be used for comparison, but it is even tried using fragmentary evidence\textsuperscript{37}. Once a clear image of the compare crania that can be used to compare the recovery is found, forensic anthropologists must spend some time adjusting the orientation of the skull, usually using Q-tips as placement markers so that the images can be placed correctly on each other. Comparison techniques have become more complex and complicated, which mainly allow rejection rather than active scientific identification. Images are taken from police records, surveillance, or directly from relatives of possible individuals. The quality of the image corresponds to the accuracy of the exclusion process\textsuperscript{38}. Dorion pointed out that if used improperly, photographic superimposition can lead to recognition errors\textsuperscript{39}. He noted that this technology should not be used as the only way of identification. The research reported by Austin et al. supported this expression of
concern. They compared the front and side views of the three skulls with pictures of ninety-eight people. They reported a positive comparison with 9.6% and 8 of the side view and 5% of the front view. However, the consistency percentage is reduced to zero and 6% when using both front and side views.

Skull/photo video superimposition

Kahana defined this approach for the first time. This technique is effective if photographs of one or more probable progeny are available. On adjustable support is attached the skull to be marked. While the antemortem photograph is placed at right angles with a high-resolution video camera, the skull is aligned with a 2nd video camera. The lens center position should be on an equal level as the photograph's horizontal centre. Both the cameras process the two images in a vision mixer to achieve horizontal, vertical, super-imposed, and negative stimulus. In the case of the presence of teeth, the enlargement can be done until the teeth of the antemortem photograph intersect the teeth exactly in the super-imposed picture. If there are no teeth present, it is important to estimate the vertical height of the skull photograph.

Computerized 3D facial reconstruction

This approach uses computer programs to convert 3D skull images scanned with a laser into faces. Even though the findings are reproducible rather than sculpted reconstructions, certain subjectivity will continue to be added to the digitized skull matrix by a composite face image. A list of head models with their age, race, nutrition status, and other personal characters either skulls, faces, or soft tissue depths is essential. Remains of the dead are checked and used to pick the suitable skull and soft tissue models by the medical team and the evidence given. The skull is mounted in an upholstered head holder. The length varies as the skull rotates on the platform and with each latitude, the radius is determined. A wireframe with 256 x 256 radii must be converted to produce the basis of facial reconstruction using measurements of tissue depth. The facial characteristics unforeseen by the skull contour (nose, eyes, mouth) ought to be applied to the wireframe face to create a wire colour and texture.

Facial Approximation

Facial approximation means trying to generate the individual’s facial similarity from the skull. Although this method cannot be used directly for identification, the resulting images can be used to communicate with the public to collect information about missing persons who may be represented by recovered remains. Major advances in methodology include new soft tissue in-depth population data, new guidelines for evaluating facial features, and innovative computerized methods. Although several studies on the depth of soft tissues have been published, Stephen et al., note that the data show that there is no clear secular trend, and the value is increasing. They recommend that existing data be aggregated for use by adults. They also found similar results in sub-adult data and suggested that the data be divided into two age groups (0-11 years and 12-18 years old).

Although facial approximation is reported to be useful in collecting information related to recognition, Stephen and his team still expressed concern about the relative similarity level. Henneberg et al., published an experimental method to judge the recognition value and question the value for recognition. With the enhancement of information about the relationship between hard and soft facial tissues and more sophisticated computer technology, facial approximation technology is constantly improving. Despite these advances, the facial approximation does not represent a positive scientific identification method. However, the generated image proves to be helpful and assist the public in disseminating the remains of someone with specific visual and demographic characteristics.

Unique Cranial Evidence

Although other methods have led to preliminary identification, the unique features present on the skeleton allow for more definitive classification. Skulls provide anthropological analysis with unique information required for active scientific identification. There are two main reasons: (1) Historically, many studies have
focused on skulls, revealing huge differences in many anatomical features; (2) Front radiographs and related images are available for the head and contain multiple views. As described by Smith et al., skull images can present many unique features useful for recognition. In their case report, they pointed out that the detection of the frontal sinus, sphenoid sinus, ethmoid sinus mastoid air sacs, sagittal sutures, and internal protrusions of the occipital bone by computed tomography (CT) can be used for positive scientific identification. Culbert and his team provided extensive information on the use of the nasal cavity and mastoid system to identify deceased elderly patients in India. Sperry et al. offered further examples of detection using the frontal sinus and intracranial nervous system. Rogers et al. also adopted a cranial suture pattern, claiming that the path they followed for this activity fulfilled the legal requirements of the United States and Canada at that time.

Frontal Sinus Variation

While several features of the human skull show great differences and can be used for individual identification, many researchers have focused their attention on the frontal sinus. The sinus is located above the supraorbital bulge, higher than the nostrils, and shows significant changes, ranging from the smallest presence to the formation of large labia intussusception. Reflecting the environmental and developmental influence, even the same twins show morphological differences in the frontal sinus expression. Schuller specified the significance of the frontal sinus for positive scientific identification. Later, for comparative purposes, Asherson et al. established a method of using outlines of sinus expression. Ubelaker and colleagues in 1984 explained how frontal sinus comparison, combined with sella turcica morphology and other cranial characteristics, was used in a murder trial for positive scientific identification. Radiographs of cranial specimens at the Smithsonian Institution were also used by the team of scientists to show population variation of the frontal sinus. Angyalet al. presented cases from Hungary showing how frontal sinus radiography and features were performed. Though trends were recognized at the earliest, comparative studies on the frontal sinus morphology, metrical, and more complex statistical treatments were also implemented. Kirk et al. introduced a metric approach documenting the vertical and horizontal sinus expression. They declared the corresponding measurements to be less than 5 mm apart. The authors also documented using pattern recognition and metric analysis for positive scientific detection in their retrospective analyses of thirty-nine cases in Ontario’s Chief Coroner’s Office. Furthermore, it was noted that the probability of recognition using this function was not influenced by adult age, sex, and cause of death. Christensen and his team used Elliptic Fourier analysis to determine the individualization of the frontal sinus in the light of the increasing demands of the legal arena for increased quantifying and likelihood assessment of the features of identity. As indicated in the earlier publication, this application indicates a consistent methodology to human positive scientific identification by evaluation of the frontal sinus morphology.

Post Cranial Remains

There are also ample anatomical features used for the identification of skeletal remains from the post-cranial skeleton, where subsequent antemortem radiographs can be sited. Animal scavenging, and other post-mortem factors may influence post-cranial bones. Trabecular general bone patterns and ossic contours, abnormalities, and radiodensities may provide specific identifying features. Clavicle, thorax area, hand and wrist, patella, and foot defects were the key points for post-cranial detection approaches. Unconventional medical conditions are important because radiographs with skeletal anatomical information can be connected to them.

The Anthropometric American method/ tissue depth method

This technique was first introduced by Krogman in 1946. This method uses data from soft tissue depth collected by employing needles, X-rays, or ultra-sonic analysis. Muscles of the face are adequately recorded anatomically. This is not a favoured approach now a few
days because it needs highly skilled professionals\textsuperscript{56}.

\textbf{Conclusion}

Forensic analysis in skull detection and facial reconstructions is highly beneficial and an alternative approach in the identification process in generating images where no other evidence is offered and accessible. Nevertheless, the options taken by the team of investigators such as forensic anthropologists, forensic dentists are centred on the method of facial reconstruction. The facial reconstruction aided by computers has many advantages compared with conventional approaches. It simplifies the process and significantly reduces the time taken to propose a face model. Various models can be shifted in many ways improving the likelihood of individual recognition. Although the techniques employed for skull detection and facial reconstruction are dubious, these techniques also demonstrate to be a significant tool for the team of forensic analysts in detection when the source of substantiation is not available.

Too Blue To Be True”: Indoxacarb Induced Methemoglobinemia- A Rare Case

Jerry Jacob¹, Karthik Reddy C H², Jobin James³, Nijila Janardhanan¹
¹Junior Resident, Emergency Medicine, St. Johns Medical College Hospital, Bengaluru, ²Assistant Professor, Emergency Medicine, St. Johns Medical College Hospital, Bengaluru, ³Senior Resident, Emergency Medicine, St. Johns Medical College Hospital, Bengaluru

Abstract

Indoxacarb is an oxadiazine insecticide, which is a sodium channel blocker in the nervous system of insects and causes mild tremors, cessation of feeding, and death in few hours.

Here we describe a case of novaluron and indoxacarb poisoning in a suicide attempt. The patient presented with cyanosis with saturation – paO2 gap indicating methemoglobinemia and was treated with methylene blue and other supportive measures.

Keywords: insecticide, toxin, indoxacarb, novaluron, methemoglobinemia, cyanosis, methylene blue, tissue hypoxia.

Introduction

Indoxacarb is an oxadiazine [¹] compound and a sodium channel blocker. It is a broad-spectrum insecticide [¹] widely used in commercial and farm planting for the control of certain insects, i.e. moth, leaf hopper and fruit worm. Contact with the substance can take place through ingestion, physical contact, pruning, and rewetting of surfaces.

We report a case of novaluron and indoxacarb toxicity with suicidal intent, presenting as a medical emergency. Acute methemoglobinemia is an emergency requiring prompt diagnosis and treatment with methylene blue.

Case Report: A 55 year old farmer hailing from Andhra Pradesh reported to our emergency department with alleged history of a feud at home and consumption of 100 ml of an unknown insecticide as shown in

The insecticide was identified to be a combination of novaluron (5.25%) and indoxacarb (4.5%) (trade name: SENORA) with no specific antidote as per the leaflet. The patient presented to us 4 hours after the ingestion with no first aid administered. He complained of vomiting, drowsiness, headache and abdominal pain.

On arrival he had a pulse rate of 84/min, blood pressure of 110/80 mm Hg, saturation of 80% on room air and 82% on 15 litres of oxygen via Non-rebreathing mask (NRBM), respiratory rate of 22/min. He was conscious but mildly drowsy with Glasgow Coma Scale of 14/15. His pupils were 3 mm, bilaterally equal and reactive to light.
Figure 1: Insecticide containing indoxacarb and novaluron (trade name: SENORA)

On general physical examination, the patient had central cyanosis involving tongue and mucous membranes as shown in Figure 2:

Figure 2: Central cyanosis involving tongue
On further eliciting history there was no history of congenital heart disease, fever, cough or respiratory distress in the near past or other comorbidities. His only habits were occasional ethanol consumption and smoking approximately amounting to 10 pack-years.

An arterial blood gas was obtained which showed a pH: 7.237, pCO2: 22.9, pO2: 141, Hb: 18.3, sO2: 97.8, Na: 143, K: 2.8, Cl: 109, lac: 18, HCO3: 9.4 interpreted as partially compensated metabolic with lactic acidosis with hypokalaemia.

To identify the cause of spO2 - paO2 gap and co-oximetry was ordered for.

The results came as follows: MetHB (methemoglobin) – 46.4%, COHb (carboxyhemoglobin) – 3.3%, leading us to the diagnosis of methemoglobinemia. Literature review led us to the conclusion of a rare case of methemoglobinemia caused by indoxacarb exposure.

On comparing the patient’s blood gas sample to a normal patient’s sample the characteristic chocolate brown colour of blood was appreciated as shown in Figure 3:

Our final diagnosis was methemoglobinemia secondary to pesticide ingestion: Indoxacarb and novaluron.

The patient was treated with anti-emetics and the antidote methylene blue. The patient’s weight was about 70 kg and he was treated with 70 mg of methylene blue intravenously (1mg/kg with each ml containing 10 mg of methylene blue). Saturation picked up to 94% shortly after and repeat ABG was as follows: pH 7.415, pCO2: 32, pO2: 101, HCO3: 20.1, sO2: 95.8, Na: 137, K: 3.11, Cl: 108, lac: 0.9, MetHb: 1.6.
Table 1 given below shows the comparison between the pre and post treatment blood gas analysis.

CLINICAL DECISION MAKING

The Figure 7 given below illustrates an algorithm to approach a patient with cyanosis.

**ED**

![Algorithm Image]

**Figure 7: Approach to cyanosis in ED**

**Diagnosis**

**Arterial blood gas analysis**

Methemoglobinemia may cause chocolate-brown discoloration of the blood. As a bedside test, if blood is dropped on a piece of white gauze, it will remain brown as it dries (in contrast, normal deoxygenated blood will absorb oxygen and become red). [5]

There is an obvious mis-match between the PaO2 (which is >>100 mm) versus the pulse oximetry (which is typically ~80-90% saturated). This is known as PaO2-saturation gap, and it is indicative of some sort of hemoglobinopathy (most often methemoglobinemia). [5]

Co-oximetry is the gold standard of detecting methemoglobinemia with spectrophotometry. Methemoglobinemia has a peak absorbance of light at 630 nm which is characteristic. [6]

**Discussion**

Methemoglobinemia refers to the oxidation of ferrous iron (Fe++) to ferric iron (Fe+++ within the haemoglobin molecule. [1] This reaction impedes the ability of haemoglobin to transport oxygen, leading to tissue hypoxemia. Methemoglobinemia most commonly results from exposure to an oxidizing chemical, but may also arise from genetic, dietary, or even idiopathic etiologies. [2, 3]

**TREATMENT**

**Methylene blue**

Methylene blue (MB) is a reducing agent. MB exerts its reductive effects by activating the dormant but volatile hexose monophosphate (HMP) shunt to regenerate NADPH. Dextrose should be co-administered in order to increase NADPH formation. If MB therapy is ineffective and life-threatening shock is imminent, exchange transfusion should be initiated.

Methylene blue is provided as a 1% solution (10 mg/mL). The dose is 1 to 2 mg/kg (0.2 mL/kg of a 1% solution) infused intravenously over 3 to 5 minutes. The dose may be repeated at 1 mg/kg if MB does not resolve within 30 minutes. Methylene blue should reduce MB levels significantly in less than an hour. The maximum dose is up to 7 mg/kg within 24 hours. [7]

Dextrose should be co-administered in order to increase NADPH formation. If MB therapy is ineffective, exchange transfusion should be considered. Ascorbic acid, part of the minor reduction pathway of methemoglobin, may be useful in patients in whom MB
therapy is contraindicated. The dose is 1-3 gm every 8th hourly. [8] Hyperbaric oxygen is also effective in MB levels above 50% and in patients with no response to other treatment modalities. Other agents considered were N-acetyl cysteine and high dose cimetidine in dapsone induced methemoglobinemia. [9]

**Conclusion**

To conclude we report a rare case of toxin (indoxacarb) induced methemoglobinemia with a MB level of 46%, treated successfully with methylene blue and ascorbic acid and discharged after 5 days of hospital stay. Early diagnosis and initiation of methylene blue aided in significantly reducing the morbidity and need for mechanical ventilation in this patient. During this pandemic of COVID-19, importance of understanding that other etiologies might present with hypoxemia and ordering for co-oximetry when appropriate is of paramount importance.

Knowledge and Awareness towards Dental Management of Post-Cardio-Thoracic Surgery Patients among Dental Students

Johara Maria Cruz¹, Keerthi Narayan. V², Vasumathi.D³

¹Professor, Department of Prosthodontics, Sathyabama Dental College and Hospital (Deemed University) Jeppiar Nagar, Shollinganallur, Chennai, ²Senior Lecturer, Department of Oral Pathology and Microbiology, Thai Moogambigai Dental College and Hospital, Dr. M. G. R. Educational and Research Institute, Chennai, ³Lecturer, Department of Public Health Dentistry, Thai Moogambigai Dental College and Hospital, Dr. M. G. R. Educational and Research Institute, Chennai

Abstract

Background of the Study: Oral health care professionals must be able to identify various cardiac diseases and its associated post-operative dental emergencies to adopt the appropriate measures to treat them efficiently and effectively. A comprehensive dental treatment plan should be constructed keeping in view all the possible complications related to the post-operative cardio-thoracic surgical factors.

Aim: This study was aimed to determine the knowledge, attitude and awareness towards dental treatment and their management following Cardio-thoracic surgeries among the dental students at undergraduate and postgraduate level.

Methodology: A cross sectional survey was conducted using self-administered questionnaires, through Google forms among 100 dental students from Tamil Nadu India. Statistics has been done and results are tabulated.

Results: The overall knowledge towards various cardio-thoracic surgical procedures carried out and their dental management among dental students was only 65% and 45% for postgraduates and interns group respectively.

Conclusion: The present study showed lack of awareness with limited knowledge and attitude towards various cardiac-thoracic surgical procedures carried out and their corresponding dental management among the dental students especially at the undergraduate level. Hence enlightening and educating the students on several post-surgical management phases at the undergraduate level is essential for effective and efficient treatment outcome and increase the quality of life.

Keywords: Awareness, Cardio-thoracic Surgery, Cardiac Pacemaker, Dental Extraction, Oral Health Problems.

Introduction

Cardiovascular disease is one of the most common medically compromised conditions that can be challenging to manage in terms of oral complications, oral rehabilitation with dental treatment and emergency care. Oral health care professionals play a crucial role in managing this state and are believed to have a sound knowledge, attitude and awareness towards medically compromised condition and treating the same [1].

Several authors recommended that if emergency dental procedure must be performed on a patient who has received a CABG (Coronary Artery Bypass Grafting), pacemaker, or stent before the appropriate time (three to six month) interval has elapsed, that patient should be pre-medicated. After the time interval, no premedication is indicated for those procedures since coronary artery bypass graft surgery is not associated with a long-term risk of infection, antibiotic prophylaxis for dental procedures
is not needed in individuals who have undergone such surgeries. Antibiotic prophylaxis is recommended only for patients with conditions such as Cardiac valvulopathy in a cardiac transplant recipient, congenital heart disease, patients with previous infective endocarditis and Prosthetic cardiac valve who are undergoing dental procedures that involve manipulation of gingival tissues or periapical region of teeth, or perforation of the oral mucosa [2, 3, 4]. Over the years several studies have shown that invasive dental procedures may contribute to the development of infective endocarditis in patients known to present a high incidence of cardiovascular disease and to be at high risk of morbidity and mortality associated with the disease [5].

A multidisciplinary approach while treating medically compromised dental patients is required to reduce complications and to enhance the prognosis. At the same time, the cardio-thoracic surgeon should refer to a dental surgeon preceding any cardiac surgery in view to prevent infection from the Oral and Para-oral region seeding structures within the heart [6]. To the best of our knowledge, there are very few studies initiated with a key emphasis on knowledge about various cardiac surgical procedures carried out and their corresponding dental management among dental students. Hence the present cross-sectional study was performed to determine the knowledge, attitude and awareness towards dental treatment and their management following Cardiac surgeries among the dental students at undergraduate and postgraduate level.

**Methodology**

This survey was done to evidently assess the knowledge, attitude and awareness of undergraduate and postgraduate dental students about dental treatment and their management following Cardiac surgeries. It was randomly done among the dental students residing in Chennai through Google forms. The links of the Google forms were circulated via social media to reach 100 dental students within a time of 3 weeks. This study was based on self-applied questionnaire composed of 10 questions, the questions were based on students own perception hence it helps to assess the actual scenario about the knowledge and behaviour of students. The actual purpose behind the study was well-explained to the participants. The questionnaire covered all the important aspects of oral health problems with special emphasis among post-cardiac surgery patients.

**Results**

Non-probability, convenient sampling technique was employed that yielded information from 100 dental students. The study comprises of 27 male and 73 female participants. Relevant questionnaire was prepared; responses were noted among the selected population group under the study and evaluated for statistical analysis by SPSS software Version 20.0. The level of statistical significance was set at a $P$ value less than 0.05. On statistical evaluation it was observed that all 100 samples were valid for the study with Cronbach’s alpha reliability score being 0.846 (Significant score). On evaluation, 100 participants were distributed category wise comprising of 50 intern (undergraduate) students followed by 50 postgraduate students. The questions were individually subjected to chi square test. The Overall chi-square statistic is 277.985. The $p$-value is .0001. The result is significant at $p < .05$.

On evaluating the responses about knowledge on various cardiac surgical procedures among the undergraduate and postgraduate dental students it was observed only 76.02% of the total study participants were aware, among which 58.4% were postgraduates. About 33.8% of the study population were familiar about dental problems associated with cardiac pacemakers, 24.6% about CABG (Coronary Artery Bypass Graft) and 41.6% were aware of dental problems associated with heart valve replacement (Stent) procedure (Figure 1). On assessing the distribution of responses about knowledge on medications prescribed and their mechanism of action following cardiac surgical procedures it was observed only 46.5% of postgraduates and 31.1% of undergraduates were aware of aspirin given to prevent blood clots (66.4%) followed by beta-blockers (85%) and ACE inhibitors to help lower blood
pressure (57.6%).

On assessing the responses about attitude and awareness on Indications and Contra-indications of various dental procedures following cardiac surgeries it was noted 64.7% of the post-graduates and 52.3% of the under-graduates were aware of the recommended dental procedures, However majority of the study participants (94.3%) prefer referring to physician or cardiac specialist before starting any dental procedures.

On evaluating the responses about knowledge on emergency dental procedures to be followed it was observed 79.4% were aware of role of Local anaesthesia with Vasoconstrictors for extraction procedures (Figure 2) and only 43.3% were aware of guidelines for safe dental practice in this high-risk group such as antibiotic prophylaxis for various cardio-thoracic surgeries (Figure 3), and 57.36% were aware of dental guidelines for minor dental procedures such as use of hand scalers rather than ultrasonic scalers. No significant differences in responses were obtained among the study groups when asked about the oral manifestation of patients following cardiac surgeries.

Descriptive statistics were used to summarize the responses to the questionnaire, with the results being presented as frequencies and percentages. Chi-square tests were used to compare between groups, and the level of significance was set at \( P \leq 0.05 \). In the final analysis, “yes” or correct responses were given a score of 1 and “no” and “maybe” responses were given a score of 0; the scores were summed to obtain the overall scores in each group and they were then converted into percentages for all the questions. These percentages were classified into four levels: ≤ 50 (“poor”), 50-70 (“moderate”), 70- 90 (“good”), and ≥ 90 (“very good”). The overall knowledge towards various cardiac surgical procedures carried out and their dental management among dental students was only 65% and 45% for postgraduates and interns group respectively (Table 1).

Discussion

Patients with cardiovascular disease who had undergone surgeries constitute a high-risk group in dental practice, particularly with a short-span following surgery (Less than six months). It is therefore important for dental surgeons to know their medical condition, cardio-thoracic surgery performed, associated treatments received, dental complication and medicaments, and the possibilities for dental treatment [7]. In the present study on evaluating the responses about knowledge on various cardiac surgical procedures among the undergraduate and postgraduate dental students it was observed only 76.02% of the total study participants were aware, among which 58.4% were postgraduates. About 33.8% of the study population were familiar about dental problems associated with cardiac pacemakers, 24.6% about CABG (Coronal Artery Bypass Graft) and 41.6% were aware of dental problems associated with heart valve replacement (Stent) procedure. Kamath et al [6]. Pacaric et al [8], Cruz-Pamplona et al [9] and Cotti et al [10] suggested modified dental treatment and procedural considerations in cardiac disease patients with recent cardio-thoracic surgeries.

On assessing the distribution of responses about knowledge on medications prescribed and their mechanism of action following cardiac surgical procedures it was observed only 46.5% of postgraduates and 31.1% of undergraduates were aware of aspirin given to prevent blood clots (66.4%) followed by beta-blockers (85%) and ACE inhibitors to help lower blood pressure (57.6%). Chaudhry et al [11] similar to our study also recommended the prerequisite of knowledge about several drugs used in treatment of cardiovascular diseases, mechanism of action and the potential adverse effects of drugs.

On assessing the responses about attitude and awareness on Indications and Contra-indications of various dental procedures following cardiac surgeries it was noted 64.7% of the post-graduates and 52.3% of the under-graduates were aware of the recommended dental procedures. Deppe et al [12]. Singh et al [13] evaluated the long-term need for dental treatment and concluded that non-radical dental treatment modes prior to cardiac valve replacement can only be successful over the long-term if adequate postoperative dental care is provided suggesting the need for emergency dental treatment even after surgery however in the present study majority of the study participants (94.3%) lack confidence in treating emergency cases and prefer referring to physician or cardiac specialist before starting any dental procedures.

On evaluating the responses about knowledge on emergency dental procedures to be followed it was observed 79.4% were aware of role of Local anaesthesia with Vasoconstrictors for extraction procedures. However, different studies have shown that no significant increases in arterial pressure are induced by the use of anaesthesia with a vasoconstrictor in dental treatments. Silvestre et al [14] observed no significant changes in systolic blood pressure before, during or after dental extractions – the lowest pressures being recorded at the end of the procedure, and the highest at the time of extraction. Laragnoit et al [15] in coincidence with other studies in patients with heart diseases, reported that the administration of 2% lidocaine with epinephrine (1: 100,000) induces no significant changes in the hemodynamic parameters during dental treatment suggesting that its use is safe in minor dental operations, provided a good anesthetic technique is performed and the treatment prescribed by the cardiologist is maintained.

Tubiana et al [16] assessed the relation between invasive dental procedures and infective endocarditis in patients with prosthetic heart valves and concluded proper understanding of the various antibiotic regimes is mandatory for effective dental treatment whereas in the present study only 43.3% were aware of guidelines for safe dental practice in this high-risk group such as antibiotic prophylaxis for various cardio-thoracic surgeries and 57.36% were aware of dental guidelines for minor procedures such as use of hand scalers rather than ultrasonic scalers suggesting lack of awareness and knowledge. In dental practice a minimum safety period of 6 months has been established before any oral surgical
procedure can be carried out. In this time, dental treatment should be limited to emergency procedures aimed at pain relieving extractions, the drainage of abscesses and pulpal therapy preferably carried out in the hospital setting \[17\]. After this safety period, the treatment decision should be established on the basis of the condition and medical status of each specific patient. Thus a comprehensive dental treatment plan should be constructed keeping in view all the possible complications related to the post-operative cardio-thoracic surgical factors.

**Conclusion**

The present study showed lack of awareness with limited knowledge and attitude towards various cardio-thoracic surgical procedures carried out and their corresponding dental management among the dental students especially at the undergraduate level. Most of the study participants specified that they would prefer referring to physician before starting any procedures however were unsure and lack confidence to treat in emergency situations. Hence enlightening and educating the students in several post-surgical management phases at the undergraduate level is essential for effective and efficient treatment outcome and increase the quality of life.

Forensic Medical Assessment of Thanatogenesis in the Experience of Gunshot Injuries

Julia V. Zbrueva

1Associate Professor of the Department of Forensic Medicine of the Federal State Budgetary Institution “Astrakhan State Medical University” of the Ministry of Health of the Russian Federation, 414000, Astrakhan, ul. Baku, bld

Abstract

Gunshot injury remains relevant at the present time and requires serious study. During the examination of a gunshot injury, it is necessary to answer the investigator’s questions about the cause of death, the type and rate of thanatogenesis, the distance of the shot, the sequence and mechanism of damage formation, and the severity of the injury. The aim of the study was to determine the type of thanatogenesis in death from various types of gunshot injuries. Standard methods of sectional research, forensic histological methods, morphological and statistical analysis, supplemented with semi-quantitative technologies of thanatogenetic analysis were used in the study. The material for this study was 85 cases of death from gunshot injuries, which was distributed by gender, age, location of the injury, type and rate of thanatogenesis, type of gunshot injury (bullet and shotgun wounds), the distance of the shot and the duration of hospital stay.

Keywords: type of thanatogenesis, gunshot injury, post-traumatic period, momentum of death, cause of death

Introduction

Gunshot injuries account for the smallest proportion of violent deaths. Examination of a gunshot injury has certain features, is complex and not always well studied. Great attention should be paid to the specifics and severity of the gunshot injury.

During the examination of a gunshot injury, it is necessary to answer the investigator’s questions about the cause of death, the type and rate of thanatogenesis, the distance of the shot, the sequence and mechanism of damage formation, and the severity of the injury.

The Aim of the Study is to determine thanatogenesis as a result of death from various types of gunshot injuries.

Materials and Methods

The study used standard methods of sectional research, forensic histological methods, morphological and statistical analysis, supplemented by semi-quantitative technologies of thanatogenetic analysis.

The material for this study was cases of death from gunshot injuries from various types of weapons. This group is made up of 85 observations.

The material was distributed by gender, age, injury localization, type and rate of thanatogenesis, type of gunshot injury (bullet and shotgun wounds), distance of the shot, and duration of hospital stay.

Results and Discussion

We examined the materials of 85 victims who died as a result of gunshot injuries under various circumstances.

By gender, the material was distributed as follows: men – 77 (90.6%), women – 8 (9.4%). In the age aspect, the following indicators were noted: under 19 years – 2 (2.4%), 20-29 years – 21 (24.7%), 30-39 years – 22 (25.9%), 40-49 years – 23 (27.1%), 50-59 years-12 (14.1%), 60-69 years – 5 (5.9%). Alcoholemia was observed in 26 cases, which corresponds to 30.6%. A forensic chemical blood test for the presence of...
ethyl alcohol was not performed in 11 (12.9%) cases, since death occurred in a hospital with a duration of hospitalization of more than 1 day. Out of 26 (30.6%) studies, mild alcohol intoxication was observed in 8 (9.4%) cases, average – 9 (10.6%) cases, high – 4 (4.7%) cases, and severe – 5 (5.9%) cases. Shotguns were used in 37 (43.5%) cases, while bullets were used in 48 (56.5%) cases. When studying the close-range shot following data were obtained when the shot was noted in 30 (35.3%), within the scope of the additional factors of a shot – 48 (56.5%), outside the scope of the additional factors shots – 7 (8.2%). According to the localization of the injury, the material was distributed as follows: isolated gunshot injury was observed in 51 (60.0%) cases, concomitant injury - in 33 (38.8%), combined injury - in 1 (1.2%) case, where a combination of both gunshot and stab injuries was established.

21 victims out of the 85 cases of gunshot cases died in the hospital at various times of the hospital period. We used the following time periods: the period of 1 day, 2-3 days, 4-7 days, more than 7 days. 9 (10.6%) victims were observed during the 1st day, 3 (3.5%) on the 2nd-3rd day, 3 (3.5%) on the 4th – 7th day, and 6 (7.1%) on more than 7 days.

Studying thanatogenesis in gunshot injuries, it was found that the combined type prevailed, which made up 62 observations, corresponding to 72.9%, and the isolated type – 23 (27.1%).

The thanatogenetic analysis revealed the predominance of the combined type of thanatogenesis, which was represented by a combination of three components (cerebral+cardiac+pulmonary), which accounted for 27 (31.8%) of observations. The combination of cerebral, cardiac, and pulmonary components was manifested by the presence of perivascular and recellular edema of the brain, neuronal ischemia, neurocyte lysis, neurocyte karyolysis, neurocyte gliosis, and neuron swelling. The pulmonary component of this type of thanatogenesis was manifested by ARDS (hyaline membranes and fibrin), pulmonary edema, pneumonia, bronchial spasm, atelectasis, and emphysema. The cardiac component of this type was manifested by fragmentation, cytolysis of cardiomyocytes, tortuosity of cardiomyocytes, karyolysis, hypertrophy, and contracture injuries. Among the isolated type of thanatogenesis, the cerebral
component of 20 (23.5%) observations prevailed. The cerebral type of thanatogenesis was accompanied by destructive and recellular edema of the brain, hemorrhages under the membranes and substance of the brain, neuronal ischemia, lysis, karyolysis and gliosis of neurocytes, and swelling of neurons with gross destruction of the brain substance, as well as with damage to the skull bones. The described type of thanatogenesis is explained by localization of injuries or massive blood loss leading to cerebral edema in this group\textsuperscript{10,12,13}.

When studying the momentum of death, we obtained the following distributions, which revealed the prevailing lightning-fast rate of death, which was characterized by an agonal period not exceeding 15-30 minutes, which corresponded to 41 (48.2%) cases \textsuperscript{11}.

As an example, we present the observation of an isolated type of thanatogenesis, which is represented by the brain component.

The body of Mr. H., 43 years old, was found near the cafe “Dream****”. At the time of examination of the scene, the corpse is located on the front surface of the body, arms spread out to the sides, slightly stretched up, legs stretched out. Clothes on the corpse: a cotton jacket, gray, contains brown blots in the upper sections of the item; knitted T-shirt, black, contains similar blots mainly in the collar area; blue jeans; knitted panties, black; knitted socks, black. According to the degree of development of early postmortem changes, death had occurred about 2-4 hours before the start of the examination. In the occipital region of the head, a wound is detected, the skin and hair are contaminated with brain matter and liquid blood. After an examination of the crime scene, the body was sent for medical forensic examination.

An external examination of the corpse found that the postmortem changes correspond to the first day after death. The corpse of a man of the correct constitution, satisfactory nutrition. Body height is 178 cm. The hair on the head, in the occipital region, is profusely stained with dark red liquid blood with an overlay of gray brain detritus. The hair on the head is black with a single gray, straight, up to 4 cm long. In the frontal area on the left, an unevenly expressed abrasion, irregular oval shape, 3x2 cm in size, oriented from bottom to top, from left to right, located 4.5 cm from the conditional median line of the face and 4 cm from the left brow arch. In the frontal area on the left, immediately above the left brow arch, there is an irregular oval abrasion, 1.5x1.0 cm, oriented
longitudinally, located 5 cm from the conditional median line of the face. In the eyelids of the right eye, mainly in the lower eyelid, with a spread to the right half of the nose and the right zygomatic region, on a 6x3 cm section oriented longitudinally, multiple wounds are discernible, with the edges of the linear shape reduced, from 0.2 cm to 0.4 cm long. Their ends are sharp, the edges are relatively smooth, comparable, and have no abrasions. In the inner corner of the right eye wound, when the edges of the linear length of 0.6 cm, focused on the numbers 1 and 7 hours conditional dial in the lower eyelid of the right eye wound, when the edges of the linear length of 1.0 cm, oriented transversely. The ends of the above-described wounds are sharp; the edges are uneven, wavy, have no abrasions; the walls are uneven, soaked in blood. The lumen of these wounds contains soft tissues and damaged skull bones. The remaining wounds are superficial, 0.1 cm deep, and in the nose area, wounds of the type of cracking, up to 0.1 cm deep; in their lumen, deep layers of skin and subcutaneous fat. The lower edge of the above-described area is located 165 cm from the level of the plantar surface of the right foot. In the occipital region of the scalp, in the projection of the top of the occipital protuberance, there is an extensive wound with a defect “minus tissue” of an irregular oval shape, 3, 3x2, 5 cm, oriented longitudinally. The lower pole of the edge of this defect is located 173 cm from the level of the plantar surface of the left foot. The edge of the defect is uneven, wavy, with discernible breaks oriented on numbers 12, 2, 3, 4, 7, 8, 11 conventional watch face, length from 0.2 cm to 0.5 cm. The edge of the defect is unevenly aligned throughout the entire width from 0.1 cm to 0.3 cm. Minor defects are visible around the defect: right 0.4 cm in diameter located at a distance of 0.4 cm; diameter 0.4 cm, located at a distance of 0.3 cm from the large defect; bottom, 0.3 cm in diameter, located at a distance of 0.2 cm from extensive defect; 0.4 cm in diameter, situated at a distance of 1.5 cm from the primary defect; 0.4 cm in diameter, located at a distance of 0.8 cm from extensive defect; left, 0.4 cm in diameter, located at a distance of 0.2 cm from an extensive defect. The properties and nature of these defects resemble those described above, their edges are aligned to a width of 0.2 cm to 0.3 cm, throughout. The bruise described above is bluish-red, with indistinct contours, without soft tissue swelling. The surface of the above-described abrasions is red-brown, dried, sinking, without a characteristic pattern and flaps of detached epidermis. The thickness of the bones on the cut: frontal – 0.9 cm, temporal – 0.5 cm, parietal – 0.6 cm, occipital – 0.6 cm. In the soft tissues of the head in the occipital region, there is an extensive dark red hemorrhage of an irregular oval shape, 10x7 cm, oriented longitudinally. Blood permeates the skin-aponeurotic flap to its entire thickness. In the center of the hemorrhage is the above-described defect on the skin. The walls of this defect is dyed in a light red color. There is a defect of the occipital bone at the top of the occipital protuberance 3.5 cm in diameter, from it there are multiple lines of fractures that spread in different directions, sometimes combine with each other to form many fragments of various shapes and sizes, which are held by the underlying soft tissues. These lines of fractures in their course damage the base of the skull throughout, in all cranial pits. At the bottom of the defect, multiple fragments of the bones of the arch, the base of the skull and the facial skeleton, flaps of the dura mater, fragments of the crushed substance of the brain and partially preserved brain, and foreign objects made of white metal (shot) are detected. There are multiple cracks forming bone fragments of various shapes and sizes. The parietal, occipital, temporal, frontal, sphenoid, and latticed bones are damaged. Intense hemorrhage in the ligaments and muscles of the atlanto-occipital joint. The large occipital foramen is not damaged. There are intense hemorrhages in the fat tissue of the orbits. Multiple fractures of the bones of the facial skull are determined. Bones are damaged, shattered. The right zygomatic bone is fragmented, easily mobile, and sinks into the thickness of soft tissues. The left zygomatic bone is intact. The bones of the nose are shattered. The resulting bone fragments are held by soft tissues, are poorly comparable with each other, and some of them are missing. The soft tissues of the face at the level of fractures are soaked with blood. The maxillary sinuses and other sinuses of the facial skull are filled with blood. The upper jaw is mobile, easily
shifted to the sides. The dura mater is preserved over the preserved part of the brain; pale gray, smooth, shiny, not tense, in places tightly soldered to the bones of the cranial vault, in the sinuses of its dark red liquid blood. The soft brain membranes at the level of crushing are preserved as separate small flaps of gray-red color. The pattern of sulcus and convolutions at the level of crushing is not distinguishable. In the substance of the brain at this level, multiple gray-red, pinpoint hemorrhages are discernible, spreading in the form of a wedge directed by the base to the occipital lobes. In the posterior part of the large hemispheres of the brain, at the level of crushing, the lateral ventricles filled with dark red blood are distinguishable, as well as poorly distinguishable subcortical nuclei. On the preserved part of the brain, the soft meninges are pale gray, translucent, and moderately full-blooded. The wound channel is directed from the back to the front, from left to right and somewhat from top to bottom. This wound channel communicates with the wounds of the right eyelid. A fragment of gray plastic resembling a wad container was found. On the basal surface of the preserved part of the brain, under the soft meninges, there is a dark red hemorrhage of an irregular oval shape, 14x11 cm, oriented longitudinally. The blood spreads to the bottom of the furrows and covers 1/3 of the height of the convolutions. The soft meninges are intact at this level. The pattern of furrows and convolutions is somewhat smoothed and flattened. There are no hemorrhages in the brain substance at this level. For the rest of the length, the pattern of furrows and convolutions is expressed satisfactorily.

During the forensic histological examination of the brain substance, it was found that areas with a lost modified structure with perifocal infiltration by a few red blood cells and the imposition of microparticles of bone fragments are determined. Pronounced perivascular and pericellular edema of the substance. Focal venous paresis, with their fullness with perivascular exudation of red blood cells. Burned-out neurons: cell-shading, shrinkage and loss of neurons, neuronophagia.

During the forensic histological examination of soft tissues from the wound area, it was found that infiltrating hemorrhages consisting of contoured, partially sludged red blood cells with an admixture of single white blood cells, edema of myocytes are detected; vessels are spasmodic, mainly anaemic.

Thus, the death of Mr. H., 43 years old, came from gunshot blast wounds to the head with injuries of bones of vault and base of the skull and right zygomatic, maxilla and nasal bone, shells and substances of the brain, crush the big hemispheres of a brain is accompanied by focal-diffuse subarachnoid hemorrhage to the basal surface preserved brain and hemorrhages in the soft tissue of the occipital region and face.

This morphological picture corresponded to the brain type of thanatogenesis. The momentum of death is lightning fast.

**Conclusion**

The results of the study showed that the largest number of victims of gunshot injuries were men – 77 (90.6%), in the age group of 40-49 years – 23 (27.1%). Alcoholemia was observed in 26 (30.6%) cases. Based on this indicator, the prevalence of the average degree of alcohol intoxication was revealed – 9 (10.6%). Assessing the morphology of the injury, the prevalence of isolated injuries was revealed – 51 (60.0%). Among the types of firearms, the largest number of injuries was caused from a bullet weapon – 48 (56.5%). The highest number of deaths occurred at the scene – 64 (75.3), due to the severity of the victim’s condition. The number of victims who died during the hospital period during various periods of stay was 21 (24.7%), with 10 (11.8%) fatalities prevailing on the first day.

Evaluating the variants of the course of thanatogenesis in gunshot injuries, it was found that the combined type prevailed in 62 (72.9%) cases. The combined type included markers of three components of the cerebral, cardiac and pulmonary, which were manifested by the corresponding morphological features.

Studying the momentum of death, it was found that the predominance of fulminant, which was characterized by an agonal period of no more than 15-30 minutes,
which corresponded to 41 (48.2%).

The data obtained confirm the relevance of the study of forensic medical examination of gunshot injuries. It is important to note that it is promising to use new research methods to analyze such observations2,3,5.

A Study to Assess the Prevalence of Anemia and Knowledge Regarding Anemia among Adolescent Girls of Selected Schools of Gurugram, Haryana

Jyoti¹, Varinder Kaur², Arindam Chatterjee³
¹PG Tutor, SGT University, Gurugram, Faculty of Nursing, SGT University, Budhera, Gurugram, ²Assistant Professor, MM University, Solan, College of Nursing, MM University, Solan, ³Medical Officer, MBBS, MD(FMT) DCH Sonipat

Abstract

Background: Anemia is a major nutritional health problem in developing countries like India because of poor dietary habits and malnutrition. The prevalence of anemia is inordinately higher among adolescents as they are signalized by marked physical activity and rapid growth spurt; therefore they need additional nutritional supplements and are at utmost risk of developing nutritional anemia.

Materials and Methods: A quantitative research approach with descriptive Research design was adopted for the study. A total of 86 adolescent girls studying in Vinay public school, Gurugram, Haryana who met the inclusion criteria were selected using total enumerative sampling technique. The tools consists of demographic variables, knowledge questionnaire and Sahli’s hemoglobinometer to assess the knowledge and prevalence regarding anemia. Reliability of the tool was established by Cronbach’s alpha method and it was found to be 0.84. Ethical permission was obtained from ethical committee SGT University and the written informed consent was taken from each participant before administering the tool.

Results: Findings of the present study revealed that majority 81% adolescent girls have poor level of knowledge followed by 19% adolescent girls have moderate level of knowledge regarding anemia. Overall prevalence and knowledge regarding anemia has range value varied from of 3-16 with mean 9.8 and standard deviation 2.88. The area of residence had significant difference on knowledge score regarding anemia in adolescent girls when P value is ≤ 0.05.

Conclusion: Knowledge level affects the prevalence rate of anemia in adolescent girls. Majority of adolescent girls have poor level of knowledge. Most of adolescent girls fall under moderate category of anemia.

Key Words: prevalence, anemia, knowledge, adolescent girls.

Introduction

Anemia is the condition of having a lower-than-normal number of red blood cells or quantity of haemoglobin. Anemia diminishes the capacity of the blood to carry oxygen. Patients with anemia may feel tired, fatigue easily, appear pale, develop palpitations, and become short of breath. Children with chronic anemia are prone to infections and learning problems.¹

Adolescents are vulnerable to both macro and micro nutrient deficiencies. Iron requirements increase due to growth during adolescence. Adolescent girls are particularly vulnerable group as their requirement of iron...
as well as its loss from the body is high which may be due the blood loss during menstruation and poor dietary habits. The average monthly menstrual blood loss is about 45 ml and causes the loss about 22mg of iron as a result as peak in the prevalence of iron deficiency anemia frequently occurs among females during adolescence.

The world health report of World Health Organization (WHO) states that the world wide mortality rates of iron deficiency anemia is 60,404,000 in 2017. It also states that the world wide morality rate of iron deficiency anemia’s 13,704,953 cases in India 2017 moreover the risk of anemia is further aggravated by poverty illiteracy, ignorance and lack of knowledge.²

According to National Family Health Survey (NFHS)–IV (2015-16), the prevalence of anemia among women aged 15 to 49 years is 53%. According to National Family Health Survey (NFHS)–IV (2015-16), the prevalence of anemia among adolescent girls aged 15-19 years is 54%. The disaggregate data of adolescent girls suffering from anemia in the country, urban and rural-wise is not available. In order to tackle this health problem, some initiative has been launched in the country. The initiative is targeted at all adolescents across the country with the aim for achieving haemoglobin level of 12 gm% by the age of adolescence by 2018. The important element of the initiative are as follows as capacity building, health and nutrition education, Increasing control through periodic, De-worming, Appropriate immunization.³

In India the prevalence of anemia among adolescent girls were 56% and this amount to an average 64 million girls at any point in time. Studies conducted in different regions of India shown that prevalence of anemia was 52.5% in Madhya Pradesh, 37% in Gujarat, 41.4% in Karnataka, 85.4% in Maharashtra, 21.5% in Shimla, 56.3% in Andhra Pradesh, 58.4% in Tamilnadu.

Need of the Study:

Chaudhary SM, DhageVR.(2018) conducted a cross sectional study on anemia among adolescent females in the urban area of Nagpur. Data was collected from 296 adolescent females aged between 10–19 years through simple random sampling method. Results depicted that the prevalence of anemia was found to be 35.1%. A significant association of anemia was found with socio-economic status and literacy status of parents. Mean height and weight of subjects with anemia was significantly less than subjects without anemia. Hence it is concluded that a high prevalence of anemia among adolescent females was found, which was higher in the lower socio-economic strata and among those whose parents were less educated. It was seen that anemia affects the overall nutritional status of adolescent females.⁴

Nutritional problems during Adolescents period are causing impact not only in girl’s quality of life, also affect her family members and community as well. Anemia in adolescent age is one of the important public Health Problem which also increases morbidity significantly. Therefore the investigator thought that Nutritional Anemia is the most frequent among adolescent girls so they thought to do a research on assessment of the prevalence of anemia and knowledge regarding anemia among adolescent girls of selected schools of Gurugram.

Statement of Problem

A study to assess the prevalence of anemia and knowledge regarding anemia among adolescent girls of selected schools of Gurugram

Objectives of the Study

• To assess the prevalence of anemia among adolescent girls.

• To assess the knowledge regarding anemia among adolescent girls.

• To determine the association of knowledge score regarding anemia with selected demographic variables.

Review of Literature

A. noviani, D. Indarto, A. probandari (2017) conducted a cross sectional study on high prevalence
anemia in female adolescents with low intake of vitamins and minerals. Data was collected from 120 female adolescents girls aged between 13-17 years. Results illustrated that 37.5% female adolescents was found anemic and the result of chi-square analysis indicated a positive association between folic acid (OR=1.6), Magnesium (OR=1.17) and Manganese (OR=1.97) and anemia, but it was not significant. Inadequate vitamin B12 intake increased 1.78 times anemia risk. Thus, it is concluded that higher risk of anemia was found in female adolescents with inadequate intake of Vitamin B12 and Magnesium.5

Ahankari A.S, Myles P.R, Fogarty A.W, Dixit J.V, Tata L.J (2017) conducted a cross-sectional study on 13 to 17 years old adolescent girls living in 34 villages of Osmanabad district. Data was collected from 1010 adolescent girls on individual health, dietary, socio demographic factors, and anthropometric measurements were taken. Logistic and linear regressions were used to identify risk factors associated with IDA and Hb levels, respectively. Results demonstrated that 87% had anemia. The prevalence of anemia was 17% were having mild anemia followed by 65% were having moderate while 5% were having severe anemia. Therefore, it is concluded that anemia prevalence was extremely high among adolescent girls in rural area of Maharashtra. There is urgent need of comprehensive preventive intervention for the adolescent girl’s population.6

A.K. Arya, P. Lal, N. Kumar, S. Barman (2017) conducted a cross-sectional study to determine the prevalence of anemia among adolescent girls in an urban slum of Kanpur, Uttar Pradesh. Data was collected from 400 adolescent girls aged between 10-19 years. Results depicted that the prevalence of anemia among adolescent girls was found to be 78.5%, of which 40% had mild followed by 33% had moderate while only 5.5% had severe anemia. Thus it is concluded that anemia was significantly higher among the adolescent girls whose mothers were either illiterate or having only primary education and those belonging to lower socioeconomic status. A special attention is needed to improve their haemoglobin status through proper implementation of intervention programs such as iron and folic acid supplementation and dietary modifications along with special emphasis on health education.7

Material and Methods

The study was conducted from October 2019-December 2020. A quantitative research approach with descriptive Research design was adopted for the study. A total of 86 adolescent girls studying in Vinay public school, Gurugram, Haryana who met the inclusion criteria were selected using total enumerative sampling technique. The conceptual framework of the study is based on General system model. The tools consists of demographic variables, knowledge questionnaire and Sahli’s hemoglobinometer to assess the knowledge and prevalence regarding anemia. Reliability of the tool was established by Cronbach’s alpha method and it was found to be 0.84. Ethical permission was obtained from ethical committee SGT University and the written informed consent was taken from each participant before administering the tool. The data was analyzed and interpreted in terms of objectives of the study. Descriptive and inferential statistics were utilized for the data analysis. A p value ≤ 0.5 was considered as significant for the present study.

</table>
Data presented in table 1 depicted that nearly half (54%) of adolescent girls belongs to age group 15-16 years. 35% of adolescent girls were studying in class 9th. Majority (98%) of adolescent girls belongs to Hindu religion. Most (57%) of adolescent girls were having joint family. Nearly half (45%) of adolescent girl’s mother had secondary education 36% of adolescent girls father were having secondary education. 38% of adolescent girls’ family income per month was Rs.10000-20000. Most (73%) of adolescent girls were from rural area of residence and most (70%) of adolescent girls were having vegetarian diet. Most (74%) of adolescent girls had attained onset of menarche and majority (84%) of adolescent girls had no history of taking iron supplements. Majority (61%) of adolescent girls were having no knowledge regarding anemia.

Findings revealed that majority of the participants (81%) of had inadequate level of knowledge followed by 19% with moderately adequate level of knowledge.

**TABLE 2: Prevalence and severity of anemia among adolescent girls.**

<table>
<thead>
<tr>
<th>Severity of anemia</th>
<th>Percentage %</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Moderate (7-10gm/dl)</td>
<td>55.6</td>
</tr>
<tr>
<td>Severe (&lt;7gm/dl)</td>
<td>6.9</td>
</tr>
</tbody>
</table>

Findings represented that 37 participants had moderate anemia followed by 27 participants with mild and only 5 with severe anemia. Findings also revealed that knowledge score ranged from 3-16. The mean knowledge score & standard deviation was 9.8±2.88. It is also concluded that area of residence had significant difference on knowledge score regarding anemia in adolescent girls. Whereas selected demographic variables of adolescent girls age, education, religion, type of family, mother’s education status, father’s education status, family income per month, type of diet, onset of menarche, history of taking iron supplements, sources of health information were not statistically significant at 0.05 level of significance.

**Discussion**

Findings in the present study revealed that half (54%) of the girls were between the age group 15-16 years. Nearly half (35%) of girls were studying in class 9. Most (73%) of adolescent girls were from rural area of residence. Most (57%) of adolescent girls were having joint family. Most (74%) of adolescent girls had attained onset of menarche while 26% of adolescent girls had not attained onset of menarche. The findings are consistent with the findings of the study conducted by Toppo M, etal\(^8\) where it was found that the most of girls (36.4%) belong to age group 14-16 years. Mostly (80%) of girls had attained menarche.

The result shows that majority (81%) of adolescent girls have poor level of knowledge followed by 19% adolescent girls having moderate level knowledge regarding anemia. Not a single girl had good level of knowledge regarding anemia. The findings are consistent with the findings of R.Sridevi\(^9\) where it was found that the maximum 43 (61.4%) adolescent girls are having inadequate level of knowledge regarding anemia, 26 (37.1%) adolescent girls are having moderate level of knowledge regarding anemia and 1 (1.5%) adolescent girls are having adequate level of knowledge regarding anemia.

**Conclusion**

The following conclusions were drawn from the findings of the study:

- Knowledge level affects the prevalence rate of anemia in adolescent girls.
- Majority of adolescent girls have poor level of knowledge followed by few who had moderate level of knowledge regarding anemia.
- Most of adolescent girls were from rural area of residence while some were from urban area.
Demographic variables mother’s educational status, father educational status, family income per month, had significant difference on knowledge score regarding anemia in adolescent girls.

Mostly of adolescent girls falls under moderate category of anemia.

Implication of The Study

The findings of the study have several implications which are discussed under the following areas.

Nursing Practice

- Nurses are the backbone of every health care set up of any country. The nursing practice has gone under many evolutions in the recent past. The expanded role of professional nurse is to emphasize the activities which include the promotive, preventive, curative and the rehabilitative aspects. The nurse educator has the responsibility to update the knowledge of adolescent girls. They should be able to identify and understand the knowledge regarding prevention of anemia in adolescent girls.

- The nursing personnel working in the community unit must be well acquainted with knowledge regarding the prevention of anemia in adolescent girls of age group 13-18 years.

- The study has an important implication in the nursing education and other fields. Nurse educator has the responsibility to upgrade the knowledge regarding prevention of anemia in the adolescent girls of age group 13-18 years.

- In service and continue education programs needs to be planned and implemented for the health care personnel to upgrade the knowledge regarding prevention of anemia in adolescents’ girls age group 13-18 years.

- The nursing educator/clinical instructor should be encouraged the adolescent’s girls and their parents to improve their knowledge regarding prevention of anemia among the adolescent’s girls age group 13-18 years.

- By adopting the different teaching strategies like lectures, seminars, related video and workshops regarding prevention of anemia can be disseminated effectively.

Nursing Administration

- Administrator should include the questionnaire for the adolescent girls to assess the knowledge regarding prevention of anemia among adolescent girls age group 13-18 years.

- The nurse as an administrator organizes and conducts teaching programs for the adolescent girls regarding prevention of anemia among adolescent girls age group 13-18 years.

- Nurse administrator should be aware about the general problem faced by the adolescent girls regarding prevention of anemia.

- Nurse administrator should ensure that there are adequate facilities of using different types of strategies to conduct the programs on prevention of anemia among adolescent girls age group 13-18 years.

Nursing Research

- Nursing research is a strong foundation for the evidence-based nursing. Hence nursing staffs and students should be encouraged to conduct research. Research provides knowledge regarding the prevention of anemia among adolescent girls age group 13-18 years.

- Research studies need to be explored in the other health care setting to make timely referral of parturient in order to save their lives as women’s health is Nation’s health.

Recommendations

Ø Similar studies can be undertaken on a large sample for making a more valid generalization.

Ø Study can be conducted on different samples.
Ø A comparative study can be conducted to assess effectiveness of structured teaching program with other instructional methods.

Ø A correlation study can be conducted to analysis of knowledge regarding prevention of anemia among adolescent girls age group 13-18 years.

Ø The study can be replicated on large sample size.

Ø A similar study can be done to assess the prevalence and knowledge regarding anemia in adolescent girls of urban population.

Ø A similar study can be performed for various diseases.

Ø A similar study can be done to compare the prevalence and knowledge regarding anemia in adolescent girls of urban and rural population.

Ethical Consideration: Ethical approval to conduct this study was obtained from DRC and the ethical committee of the Faculty of Nursing, SGT University.

Conflict of Interest: There is no conflict of interest among the authors.

Effects of Medical Hand Washing on Hand Flora among Staff Nurses

Kabita Dhami¹, Padmapriya S², Sasi Kumar S³

¹Lecturer, Nobel Medical College Teaching Hospital, Kanchanbari, Biratnagar, Morang, Nepal, ²Associate Professor, ³Professor, Yenepoya Nursing College, Yenepoya Deemed to be University, Mangaluru, Karnataka, India

Abstract

Background: One of the leading causes of hospital associated infection is providing patient care with contaminated hands as a result of transmission of microorganism from health care provider to patients and others. Hand washing is the most important and simple act of reducing the spread of transmission of infectious agent and reducing hand flora. Materials and Methods: The study was done to evaluate the effects of medical hand washing on hand flora among staff nurses working in a selected hospital, Bengaluru. One group time series design was used. Swabs were taken from a randomly selected sample of 25 nurses working in medical ward for hand flora analysis. Results: Study results revealed that before hand washing there were many colonies of hand flora were found. After medical hand washing there was a significant reduction in the number of colonies of the hand floras between the pre-test mean (O₁= 10.02) and post-tests mean (O₂= 4.23, O₃ = 4.02 and O₄ = 2.36) and was found to be statistically significant at H= 83.288 and P value = 0.001. Conclusion: Medical hand washing is an effective technique to reducing the hand flora among the staff nurses working in the different medical wards of hospital.

Key words: Medical hand washing, hand flora, Hand hygiene, Health care providers.

Introduction

Hand hygiene is an important infection control procedure which limits the spread of micro-organism by breaking the transmission. World Health Organisation (WHO) emphasise that inappropriate hand hygiene practices is a leading cause of health care-associated infections (HCAI). It has been recognised as a significant contributor to outbreaks of infectious diseases and is responsible for increase in the cost of treatment, prolong the hospital stay, and increase the cost of healthcare, all over the world¹-⁴. The nurses are the health care providers should learn to adopt hand washing before and after giving patients care as well as after contact with any possible source of contamination⁵. Nursing practices, such as direct touching, contact with bodily fluids, and wound care, can result in high levels of microorganism contamination. Even during relatively clean procedures, such as taking the pulse, measuring arterial blood pressure and taking temperature, nurses’ hands can become contaminated with anywhere from 100–1000 Colony Forming Units (CFU) of Klebsiella, Staphylococcus aureus, Escherichia coli, Pseudomonas aeruginosa, and Enterococcus faecalis after patient contact. Transient flora on the hand is mostly acquired from the hospital environment or poor hygiene and is responsible for cross-infections. The number of microorganisms found on the hands of nurses as they are performing patient care procedures such as providing medication, dressing, sterilization and disinfection. The microorganisms that colonize the external layer of the skin temporarily are eradicated and reduced when hands are washed with soap and alcohol-based agents. But hand washing habits of nurses are thought to be poor.

for many reasons\textsuperscript{6-8}. This study was done to evaluate the extent to which medical hand washing practices are helpful on reduction of hand flora among staff nurses in a selected hospital.

**Materials and Methods**

The study was conducted after getting the written approval from the Institutional Ethics Committee Review Board. Individual permission and consent was obtained. The study was conducted at selected hospital, Whitefield, Bengaluru. The formal and written permissions were obtained from the hospital medical and nursing superintendent before conducting the study. Study used one group time series design based on the study objectives. The sample size was 25 staff nurses selected from different medical ward of the hospital using simple random sampling techniques. The sample size was estimated by use of power analysis with 90% confidence level and 5% significant level. The data was collected using structured questionnaire for demographic profile and observation checklist for assessing the steps of medical hand washing which prepared based on WHO guide lines. The hand floras were collected in a sterile manner using sterile cotton swab from the four different sites of the nurse’s hands that is from nail beds, in between fingers, palm and dorsum before and after hand washing each using different swab. After hand washing the hand floras were collected four times respectively at the interval of one and half hour each in the shift. In which the pre- test swabs were collected at the starting of the shift before which the nurse start their duty with hand washing, where the first non-participant observation was done and swabs were collected and then the procedure of proper medical hand washing was demonstrated by the researcher to the nurses and respectively the other three post-test swabs were collected at the interval of 1 and half hour. The swabs after collection were inoculated in the nutrient agar media in Biosafety cabinet by dividing the Petridis into four quadrants each, and then the media was incubated in an incubator for overnight at 37\textdegree C. Next day, the growth of hand flora was observed and number of colonies of hand floras was counted and each site different slides were prepared by investigator. Then smearing of slides was done using normal saline in biosafety cabinet and Grams staining of slides were done by investigator with the help of microbiologist the slides were observed in microscope to identify the hand floras and if hand floras were found as staphylococcus the further test was done to differentiate whether it was staphylococcus aureus or staphylococcus epidermidis with coagulases test by investigator and at last methicillin-resistant staphylococcus aureus (MRSA) test was done. The sample size estimation, data entering, analyzing, and graph plotting were carried out using SPSS 23.0 Version.

**Results**

Demographic characteristics: Table 1 reveals that frequency and percentage distribution of staff nurse demographic characteristics. Maximum numbers of staff nurses 21 (84%) were in the age group of 20-30 years. In case of sex 23 (92%) were female and 2 (8%) were male. With regard to qualification, majority of staff nurses 16 (64%) were GNM and 9 (36%) with BSc Nursing. The maximum number of years of experience of registered nurses, 21 (84%) were having below 8 years of experience and 4 (16%) were having above 8 years of experience. Majority of the staff nurses that is 19 (76%) have attended in-service education on hand washing. Figure 1 shows that percentage distribution of staff nurses base on following the hospital standard protocol. Out of 25 nurses most of the selected registered nurses follow standard protocols of the hospital that i.e,16 (64%) follows always, 8 (32%) follows sometimes and 1 (4%) never follows the standard protocol of hand washing of hospital.

The frequency distribution of staff nurses according to hand flora analysis: Table 2 shows that in pre-test (O\textsubscript{1}) observations maximum hand floras were Staphylococcus epidermidis 27, Micrococci 18, Gram positive cocci in pairs 9, Gram positive cocci in singles 7, Gram positive bacilli 7, Gram positive cocci in chains 6, Streptococci 3, Spore bearer bacilli 2, Staphylococcus aureus 2, Pneumococci 2, and the least were Diptheroids 1,Acienito bacter 1, and MRSA 1. Similarly in the first
post test (O2) observations the maximum hand floras were Staphylococcus epidermidis 19, Micrococci 18, Gram positive cocci in pairs 9, Streptococci 7, Gram positive cocci in singles 6, Gram positive cocci in chains 6, Entero cocci 4, Diptheroids 2, Gram positive bacilli 2, and the least were Spore bearer bacilli 1 and Gram negative bacilli 1. The second post-test(O3) observations the highest number of hand floras were Staphylococcus epidermidis 13, Gram positive cocci in pairs 7, gram positive cocci in chains 7, Gram positive cocci in singles 6, Gram positive bacilli 5, Spore bearer bacilli 4, Streptococci 4, Pneumococci 2, and the least were Micrococci 1, Diptheroids 1, Entero cocci 1, and Candida 1. Similarly, the third post-test(O4) observations the maximum number of hand floras were Micrococci 16, Staphylococcus epidermidis 13, Gram positive cocci in pairs 7, Gram positive bacilli 7, Gram positive cocci in singles 6, Gram negative bacilli 4, MRSA 3, Entero cocci 2, Staphylococcus aureus 2 and the least were Diptheroids 1 and streptococci 1.

Effectiveness medical hand washing on hand floras Table 3 shows that mean, standard deviation, standard error of the mean and Kruskal wallis test (H) value. It was found that there was a significant reduction in the number of colonies of the hand floras after medical hand washing between the pretest mean (O1= 10.02) and posttest mean (O2= 4.23, O3 = 4.02 and O4 = 2.36) and was found to be statistically significant at H= 83.288 and P value = 0.001. It revealed that medical hand washing was effective to reduce the hand flora.

Conclusion and Discussion

Hand hygiene is an important and simple way to prevent the spread of micro-organism. Proper hand washing reduces the 50% of hospital associated infection by breaking the transmission of infection from one person to other9. According to World Health Organization (WHO) per second 1,400,000 people worldwide suffer from the side effects of hospital infections. In developing countries, the rate of preventable infections induced by healthcare services was estimated 40% higher10. Hand hygiene and hand washing are considered to be a first step to control infections11. Some studies show that various factors such as knowledge, beliefs and attitudes can affect the hand hygiene compliance rates12. The spread of germs between humans can occur directly through hands, or indirectly through an environmental source by having contact with them (e.g. clinical equipment, opening of doors, toys etc.)13 Nurses are often exposed to the risk of coming in contact with biohazards. Even health professionals could also be vehicle for disease transmission. Nurses required hand hygiene as they are part of the health care workforce come into contact with patients14,15. Hand hygiene has now been recognised as one of the most effective intervention to control the transmission of infections in a hospital and education is an important tool to ensure its implementation. The study demonstrates that transient bacteria are present on the hands of health care workers but majority could be removed by proper hand hygiene. Research has shown that may healthcare-acquired infections (HAIs) can be prevented with good hand hygiene. In the present study different types of hand flora were identified in the nurses hands such as staphylococcus epidermidis, spore bearer bacilli, micro cocci, diptheroids, enterococi, gram positive cocci in singles, gram positive cocci in pairs, gram positive cocci in chains, gram positive bacilli, gram negative bacilli, acienitobacter, staphylococcus aureus, candida, pneumonia, streptococci and methicillin resistant staphylococcus aureus. Medical hand washing is performed to removes both transient microorganisms that colonize the superficial layers of the skin and normal flora that is microorganisms that live under the superficial cells of the stratum corneum. The numerous study have reported that hand hygiene was effective on reduction of rates of nosocomial infection in hospital and communities16-18 in which majority were causing both community and hospital acquired infections19. In the present study it was found that there was a significant reduction in the number of colonies of the hand floras after medical hand washing. The finding was also supported by the similar study that hand washing with plain soap and water for 15 seconds reduced transient floral load on the skin by 0.6 - 1.1 log10, whereas washing for 30 seconds reduced counts by 1.8 - 2.8
log_{10} 20. It’s the nurse’s responsibility to ensure that his or her patients receive the best care possible, which includes care provided with clean hands.

Effect of Helichrysum Oil on Toothache

Kamalli.M¹, Gayatri Devi R², Jothi Priya.A², Saravana Kumar.S³

¹Undergraduate Student, ²Assistant Professor, Department of Physiology, Saveetha Dental College & Hospitals, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, ³Assistant Professor, Department of Anatomy, SEGI University, Malaysia

Abstract

Introduction: Toothache is the pain or inflammation in the tooth. A symptom of toothache includes sensitivity, gum bleeding, cavities etc. Toothache can occur due to improper dental care and oral hygiene practice which is one of the commonest reasons. The genus Helichrysum consists of about 600 species which are flowering in the family of sunflower. The other names are Italian strawflower and Immortelle. It grows on dry, rocky and sandy regions in the Mediterranean. It has anti-inflammatory, antispasmodic and analgesic properties. The aim of the study is to determine the effect of helichrysum oil on toothache.

Materials and Methods: The sample size of the study was 15 individuals with toothache who visited the dental clinics. Participants having periodontal problems, cardiovascular problems were excluded from the study. To every 2 drops of helichrysum oil, 1 ml of coconut oil was added. The intensity of the pain was measured by using the pain scale. The participants were given to apply it on the gingival area of the painful tooth. The patients were followed to know the intensity of pain after a few hours. The results were tabulated and then statistically analysed.

Results and Discussion: 27% of the participants have moderate pain after a few hours of application of oil. 26% of them have less pain. 13% of participants have very little pain. 27% of them do not feel any change in the intensity of pain. 7% have high pain.

Conclusion: From this study it was evident that helichrysum oil had an effect in reducing the toothache as helichrysum possess anti-inflammatory properties.

Keywords: Helichrysum oil; toothache; intensity of pain; anti-inflammatory

Introduction

Toothache is the pain or inflammation in the tooth. Symptoms of toothache include sensitivity, gum bleeding, cavities etc. Toothache can occur due to improper dental care and oral hygiene practice which is one of the commonest reasons. Generally, salt water rinsing is preferred as the first treatment for toothache as it is a natural disinfectant and reduces the inflammation followed by using a hot pack. Regular brushing and flossing will reduce the risk of toothache. Root canal treatment is required in case of intense toothache as it affects the nerves. Proper identification of severity of toothache is necessary as the infection may spread to other parts of the face.

The genus Helichrysum consists of about 600 species which are flowering in the family of sunflowers. The other names are Italian strawflower and Immortelle. It grows on dry, rocky and sandy regions in the Mediterranean. It has anti-inflammatory, antispasmodic and analgesic properties. There is a fact that Helichrysum was considered a very complex genus (¹). Antifungal property was exhibited by the species of Helichrysum (²). Helichrysum is an aromatic plant in the Asteraceae family of plants (³). Helichrysum being

DOI Number: 10.37506/ijfmt.v15i4.16927
a traditional medicine, it possessed choleretic, diuretic and expectorant \(^{(4)}\). Helichrysum also showcases the properties of antibacterial activity which can be turned into medicinal usefulness. The Helichrysum decoction which is obtained by heating the roots of the plant can be used for the treatment of asthma \(^{(5)}\). Anti-inflammatory properties of Helichrysum italicum included inhibition of enzymes and scavenging activity \(^{(6)}\). In the genetics study of Helichrysum species aided the discovery of various chemotypes \(^{(7)}\). Anti viral and Anti-oxidant properties of the species were also identified \(^{(8)}\). Other species exhibited properties of a purgative and it can be used as herbal medicine for cold, cough, flu and fever etc \(^{(9,10)}\).

The primary aim of this study is to find the effect of Helichrysum oil on toothache. The analysis is based on different parameters like the effect on tooth ache, ability to reduce the pain and the duration of relief of pain determined by using pain scale.

**Materials and Methods**

The sample size of the study was 30 individuals with toothache who visited dental clinics. They were randomly selected. Participants having toothache only were included. Exclusion criteria which included are participants having periodontal problems, cardiovascular problems, diabetes. The Oil which was used for this study was Helichrysum italicum essential oil. To every 2 drops of helichrysum oil, 1 ml of coconut oil (carrier oil) was added. The intensity of the pain was measured by using the pain scale before the application of the oil. The participants were given to apply it on the gingival area of the painful tooth. The patients were followed to know the intensity of pain after a few hours of application. The results were tabulated and then statistically analysed.

**Pain scale:**

0-Nil, 1-Very mild, 2- mild, 3-Moderate, 4 – severe, 5- Very severe

**Results**

From this study, 27% of the participants have moderate pain after a few hours of application of oil. 26% of them have less pain. 13% of participants have very little pain. 27% of them do not feel any change in the intensity of pain. 7% of the participants have high pain. The time of relief of pain differs from individual to individual (Fig 1).

---

**Figure 1: Pain sensation after usage of Helichrysum oil**

![Effect of Helichrysum oil](image_url)
Discussion

There are many studies done on pharmacological activities of Helichrysum. In the study by the authors Daniel Antunes Viegas et al., they reported that the promising pharmacological activity of Helichrysum italicum can be converted into useful medicines. The pharmacological activities i.e the anti-inflammatory properties and antimicrobial are best studied. The authors mentioned that it has considerable effect on inflammation in skin and gums (1). In the present study, it shows a positive effect in relieving the pain and inflammation in gums as mentioned in the previous study. The authors Angel Rumbero et al., in their study concluded that the results finalized that the co-occurrence of acidic phenolic hydroxyls and lipophilic residues is a significant chemical feature for the expression of antifungal property in Helichrysum species (2). In the present study, the time of relief varies from individuals and there is no constant time of relief that can be reported. In the study by Angioni et al., it was concluded that two chemotypes of the species showed an interesting antifungal activity (7). In the study by J.Mastelic et al., it was reported that there was an exhibition of antimicrobial activities related to the terpene fraction (11). The authors A Bianchini et al. concluded that there was an exhibition of different compositions (12). In the study by JB Hinou et al., it was reported that Helichrysum oil exhibited medicinal usefulness (13). Nostro et al., in their study concluded that Helichrysum showed anti-allergic properties as well (14). In the study by Teodara Jankovic et al., it was reported that Helichrysum can be used as an hepatoprotective agent which is significant for detoxification (15). In the study by Lourens et al., they reported that extracts of helichrysum exhibited promising activity in the anti-microbial tests (16). In the study by Juliano et al., they reported in their results that helichrysum as a therapeutic alternative in the treatment of opportunistic infections and stated that topical application has strong inflammatory action. In the present study, the topical application of oil aids in reduction of inflammation and pain which coincides with the statement of the previous literature (17).

Conclusion

From this study, it was evident that Helichrysum oil had an effect in reducing the toothache as it has anti-inflammatory properties and this study can be utilized as a basis for further studies.

Abstract

The formation of cardiorenal syndrome (CRS) in patients with chronic heart failure (CHF) is a natural manifestation of a functionally interrelated process at the organ level. Moreover, impaired renal function is a common and independent factor in the progression of the disease, a high incidence of cardiovascular events and death in a population of patients with asymptomatic and/or clinically manifested CHF, which is due to the pathogenetic features of the formation of cattle in patients with CHF of ischemic genesis. The article provides an overview of studies on the pathogenesis of kidney damage in CHF, the role of various markers in the early diagnosis of cattle. A decrease in glomerular filtration rate (GFR) and an increase in urinary albumin excretion are currently considered as “renal” markers of a poor prognosis within the cardiorenal continuum. In this regard, for stratification of patients by stages of chronic kidney disease (CKD) and, consequently, for assessing the risks of increased overall and cardiovascular mortality in patients with CHF, the accuracy of calculating GFR, as the main indicator reflecting the severity of formed kidney damage, is of great importance. Microalbuminuria is one of the early signs of CKD, the main cause of which is glomerular capillary endothelial dysfunction that occurs in most patients with CHF. The presence and persistence of subclinical renal dysfunction during treatment, even with the achievement of risk factors (RF) control and regression of organ lesions, can adversely affect the patient’s prognosis. Assessment of the functional state of the kidneys is important for early diagnosis, selection of effective preventive measures and treatment. The therapeutic strategy in patients with CHF in combination with CKD should be based on the nephroprotective effects of drugs.

Keywords: chronic heart failure, renal function, cardiorenal syndrome

Introduction

Chronic heart failure (CHF) due to the significant prevalence, high mortality rate is not only a medical, but also a social problem. Chronic heart failure (CHF) due to the significant prevalence, high mortality rate is not only a medical, but also a social problem. Impaired renal function is the most important predictor of poor prognosis in patients with CHF, even more significant than the severity of CHF and left ventricular ejection fraction (LVEF). The prevalence of impaired renal function in chronic heart failure (CHF), according to various studies, ranges from 25% to 60%.

Proteinuria and decreased glomerular filtration rate (GFR) are seen as a marker of a poor prognosis for cardiovascular disease (CVD), which is in line with the well-established concept of cardiorenal relationships. Proteinuria causes an increase in the synthesis of angiotensin II, endothelin and profibrinogenic growth factors, which participate in the development of renal damage in CHF.

factors, transformed by mesenchymal and tubular cells. With GFR < 60 ml/min/1.73 m², the risk of mortality increases 2.1 times, with reduced left ventricular (LV) systolic function, the risk of death in patients with kidney failure (KF) increases 3.8 times, with unchanged systolic function - 2.9 times. LV ejection fraction in CHF, as the main indicator of LV dysfunction, determining the prognosis of CHF, so the level of creatinine is also an independent predictor of a poor prognosis of LTP.

The formation of cardiorenal syndrome (CRS) in patients with CHF is a natural manifestation of a functionally interrelated process at the organ level. Moreover, impaired renal function is a common and independent factor in the progression of the disease, a high incidence of cardiovascular events and death in a population of patients with asymptomatic and/or clinically manifested CHF, which is due to the pathogenetic features of the formation of CRS in patients with CHF of ischemic origin.

The kidneys are an integral and significant part of the microcirculatory system of the body, an important organ of metabolism and humoral regulation of various processes.

In the formation of CRS, the leading role is played by the activation of SAS, circulating RAAS, and renal tissue RAS, which trigger neurohumoral and microcirculatory mechanisms of damage to the glomeruli, tubules, and tubulointerstitial tissue in the kidneys.

It is known that ATII enhances sodium reabsorption, leads to contraction of smooth muscle cells of the arterioles in and out of the glomeruli and, consequently, to a decrease in renal blood flow. The narrowing of the efferent arterioles prevails over the narrowing of the efferent arterioles; therefore, in the early stages of CHF, despite a decrease in renal blood flow, renal perfusion pressure and filtration fraction increase, and normal GFR values remain.

Hyperfiltration promotes a decrease in hydrostatic pressure, an increase in oncotic pressure in the peritubular capillaries and an even greater increase in water reabsorption in the proximal tubules and the ascending part of Henle's loop. With the progression of CHF and a pronounced decrease in cardiac output, renal blood flow decreases so much that renal perfusion pressure, GFR decrease and the concentration of Cr in the blood serum increases.

In addition to the effect on renal hemodynamics and reabsorption of sodium and water, ATII, as shown in animal experiments, stimulates the production of transforming growth factor P by mesangial cells of the glomeruli, which increases the synthesis of extracellular matrix components such as biglycan, type I collagen and fibronectin. The accumulation of the glomerular matrix can lead to the development of nephrosclerosis, a morphological substrate of chronic kidney failure (CKF). Aldosterone, the synthesis and release of which is enhanced by ATII, like the latter, promotes sodium reabsorption, but works at the level of the distal tubules and collecting ducts. It should be noted that normally high doses of mineralocorticoids first increase renal sodium retention and extracellular fluid volume, but after 3-5 days' renal sodium retention ceases and sodium balance is restored.

This is the so-called mineralocorticoid-mediated sodium retention (escape phenomenon) mechanism, the development of which is due to an increase in sodium delivery to the sites of aldosterone action in the collecting ducts. In patients with CHF, the sodium-sparing action of aldosterone does not escape. This is due to a decrease in sodium intake to the distal tubules and collecting ducts due to an increase in its reabsorption under the action of ATII and adrenergic stimulation.

Microalbuminuria is one of the early signs of chronic kidney disease (CKD), the main cause of which is glomerular capillary endothelial dysfunction that occurs in most patients with CHF II – IV FC NYHA. This is especially true for persons with CHF of ischemic origin, which is accompanied by endothelial dysfunction of large arterial vessels and veins, coronary vessels, pulmonary vessels and vessels of the peripheral microvasculature.
The leading role in its formation is played by systemic oxidative stress, an increase in the content of circulating pro-inflammatory cytokines, which cause a loss of negative charges of the endothelium of glomerular capillaries and an increase in the permeability of the glomerular filter.

Another cause of kidney dysfunction (KD) is glomerular hypertension, which is detected at an early stage of HF progression and is associated with impaired renal hemodynamics. The resulting increase in pressure in the glomerular capillaries causes mechanical damage to the endothelium, glomerular basement membrane and podocytes, leading to an additional increase in the permeability of the glomerular filter.

A large number of works are devoted to the diagnostic role of β2-microglobulin and microalbuminuria in various diseases. The greatest value of β2-microglobulin has been proven in nephrology. With the help of this marker, it became possible to early detection and determination of the localization of damage, selective assessment of filtration, resorptive function, and determination of the degree of damage to the glomeruli and tubules. According to the literature, microalbuminuria is an indispensable criterion for early diagnosis of diabetic nephropathy.

The influence of CKD on the prognosis of CHF patients is closely related to the severity of renal function damage, which is manifested by the degree of decrease in the level of the calculated GFR. According to current recommendations, the group of persons with mild KD includes patients with a GFR level of 60–70 ml / min / 1.73 m², a serum creatinine content of 115–133 μmol / L (1.3–1.5 mg / dL) and 107–124 μmol / L (1.2–1.4 mg / dL) for men and women, respectively. The observation period was at least one year. During this period, 38% of patients died in the first group and 51% of patients in the second. The relative risk of total mortality in the group of people with mild KD increased 1.56 times (p <0.001) and 2.31 times in the second group. The results of the study showed that mortality in the general population of patients with CHF increases by 15% with each subsequent increase in serum creatinine by 44.3 μmol / L (0.5 mg / dL), starting from 88.6 μmol / L, and by 7% with another decrease in the level of the calculated GFR by 10 ml / min / 1.73 m².

In recent years, biomarkers of renal tubular damage have been used to detect renal dysfunction. A retrospective analysis of data obtained in 85 controlled studies, which included about 550 thousand patients with CKD of various origins, showed that GFR is critical for damage to the heart and blood vessels at about 75 ml / min / 1.73 m², below which an increasing increase in cardiovascular vascular morbidity and mortality. In this regard, for stratification of patients by stages of CKD and, therefore, for assessing the risks of increased overall and cardiovascular mortality in patients with CHF, the accuracy of calculating GFR, as the main indicator reflecting the severity of the formed kidney damage, is of great importance. Previously, for this purpose, the Cockcroft – Gault and MDRD formulas were used.

A decrease in GFR and an increase in urinary albumin excretion are currently considered as “renal” markers of a poor prognosis within the cardiorenal continuum. Microalbuminuria is one of the early signs of CKD, the main cause of which is glomerular capillary endothelial
dysfunction that occurs in most patients with CHF II – IV FC NYHA. This is especially true for persons with CHF of ischemic origin, which is accompanied by endothelial dysfunction of large arterial vessels and veins, coronary vessels, pulmonary vessels and vessels of the peripheral microvasculature. The leading role in its formation is played by systemic oxidative stress, an increase in the content of circulating pro-inflammatory cytokines, which cause a loss of negative charges of the endothelium of glomerular capillaries and an increase in the permeability of the glomerular filter.

Another cause of KD is glomerular hypertension, which is detected at an early stage of HF progression and is associated with impaired renal hemodynamics. The resulting increase in pressure in the glomerular capillaries causes mechanical damage to the endothelium, glomerular basement membrane and podocytes, leading to an additional increase in the permeability of the glomerular filter. A large number of works are devoted to the diagnostic role of β2-microglobulin and microalbuminuria in various diseases. The greatest value of β2-microglobulin has been proven in nephrology. With the help of this marker, it became possible to early detection and determination of the localization of damage, selective assessment of filtration, resorptive function, and determination of the degree of damage to the glomeruli and tubules.

According to the literature, microalbuminuria is an indispensable criterion for early diagnosis of diabetic nephropathy. The CHARMS sub-study (n = 2310) showed a significant independent worsening of prognosis for the combined endpoint (overall mortality, cardiovascular mortality, and hospitalizations for acute decompensated heart failure (ADHF)) in patients with heart failure and microalbuminuria (risk ratio (RR) was 1.43 (1.21-1.69); p <0.0001 and 1.75 (1.39-2.20); p <0.0001, respectively) 28. The GISSI-HF study (n = 2131) also confirmed the role of micro- and macroalbuminuria as a predictor of overall mortality in patients with CHF with LVEF 33 ± 9% (RR = 1.42 (1.11-1.81); p = 0.005) and RR = 1.70 (1.16-2.50); p = 0.006) 9, 22.

In recent years, there is also more and more data on the importance of assessing the state and tubulointerstitial tissue of the kidneys, which, according to some researchers, is involved in the pathological process in cardiovascular diseases often before the glomerular apparatus 15. It is known that the cause of proteinuria can be not only increased glomerular protein filtration, but also impaired tubular reabsorption of the filtered protein. There is evidence that in the absence of proteinuria in 75% of diabetic patients, antibodies to the antigen of the nephritogenic fraction of the epithelium of the brush border of the proximal tubules are found in the serum25, 29.

Thus, the presence and persistence of subclinical renal dysfunctions during treatment, even when risk factors (RF) control is achieved and organ lesions regress, may adversely affect the patient’s prognosis. Assessment of the functional state of the kidneys is important for early diagnosis, selection of effective preventive measures and treatment. The therapeutic strategy in patients with CHF in combination with CKD should be based on the nephroprotective effects of drugs.

A Review of Environmental Screening on Strategic Formulation in Health Care Sector

Kasih Puji Utami¹, Nur Wening²

¹Doctoral Student, ²Associate Professor, Post Graduate Program of Management, University of Technology Yogyakarta

Abstract

This paper is a literature review that discusses the screening of the business environment in strategy formulation. The purpose of the review is to explore and connecting theories from various research. This paper identified 22 articles with related topics published the last decade. The results of this study show that screening of the external environment that is important to do is the general environment (politics, economy, socio-culture, technology, demography, and epidemiology) which plays a role of 66.66%. While internal environmental analysis that is important to do is resources (finance, physical, technology, human resources, innovation and reputation) and value chain management (infrastructure, HRM, technology development, purchasing, inbound logistics, operations, outbound logistics, sales and marketing, and services) played a role of 33.33%. Based on a summary related to research on internal and external factors that have been carried out in health facilities, it is known that industrial environmental factors and environmental factors of competitors are still minimally studied so that they can become opportunities for future research.

Keywords: Screening Business environment, internal environmental, external environmental

Introduction

High market competition and strict regulations related to the health sector make the implementation of strategic management important¹. There are many problems faced by health services such as patient dissatisfaction with the health sector to implement the best strategy in ensuring the quality of services². Changes in the business environment that take place very quickly in the health sector require the health sector to carry out environmental screening properly to create the right strategy formulation to achieve company targets³,⁴. Previous research has shown that environmental screening is important in supporting the formulation of strategies in the health sector. Previous research also shows that most health facilities have not implemented strategic management in their companies, namely 71.4% who have not implemented strategic formulations so that this research can help health facilities in examining what matters are important in screening the business environment⁵. However, there are not many studies that discuss environmental factors that are important to be analyzed in the strategy formulation process. His article contains a review of research that discussed environmental screening in the strategy formulation process. Article searches were carried out using the google, google scholar and mandeley databases. The review process was carried out on articles that discussed environmental screening in the strategy formulation process. The articles reviewed are articles published in the last 10 years. This review identified approximately 51 articles that fit the topic and were published in the last 10 years for further analysis and conclusion in this paper.
Literature Review

Freed David formulated that the process of creating a business plan was carried out in several stages, namely environmental screening in strategy formulation, strategy implementation and evaluation. Environmental screening includes internal and external environmental screening. The organization must continuously observe changes in the internal and external environment because changes in the internal and external environment will change the formulation of the company’s strategy, so the company must be adaptive to environmental changes. The development of increasingly advanced technology makes the process of screening the business environment easier, among others, by using Decision Support Systems which enables a company to achieve a competitive advantage. Health facilities are very complex and pluralistic organizations so that organizational knowledge, legitimacy and social capacities greatly influence the screening of the internal and external environment in health facilities. Besides, political influence also plays an important role in environmental screening at the stage of strategy formulation in health facilities.

Previous research has shown that there are several factors that are important in screening the business environment, including political factors, economic factors, socio-cultural factors, technological factors and epidemiological factors. Internal environmental factors that are important to be studied in business processes include resources (financial, physical, technology, human resources, innovation and reputation) and value chain analysis (infrastructure, HRM, technology development, purchasing, inbound logistics, operations and bound logistics, sales and marketing, and service). While the external environment that is important in screening the business environment includes the general environment (political, economic, socio-cultural, technological, demographic, epidemiological), industrial environment (threat of new entrants, bargaining power of suppliers, bargaining power of buyers, threats of substituted products), and the environment of competitors. These factors in the business environment are important to analyze in order to make sound and wise strategic decisions and solutions. The company must be able to analyze and control both internal and external factors to make strategic management successful.

The organization’s ability to conduct internal and external environmental screening will enable the organization to quickly extract information that is important for strategic management for the company. In the management of internal and external factors, the existence of external factors is the most difficult to predict and control by a company because they are outside the company, while internal factors are easier to screen, predict and control because they are in the company’s internal environment. Several studies have shown that screening of the company’s internal and external environment can have a positive impact on the performance of health facilities.

Method

This paper is a literature review that discusses the screening of the business environment in strategy formulation. The articles collecting by the google database, google scholar and mendeley. A review was conducted on articles with topic. Screening of the business environment in strategy formulation. We identified approximately 22 articles that were published in the last decade then analysis and drawing conclusions.

Results and Discussion

Based on a summary of various studies, it shows that the internal and external environments that are important to be screened for strategy formulation include the internal environment, namely resources and value chain management. Resources include finance, physical, technology, human resources, innovation and reputation. While value chain management includes infrastructure, HRM, technology development, purchasing, inbound logistics, operations, outbound logistics, sales and marketing, and services. If it is made in the form of a description of the composition of the internal and external environment in the formulation of a strategy based on research that has been done previously, it is as
follows

**Table 1. Summary of percentage of internal and external environmental factors that have been studied in health facilities.**

<table>
<thead>
<tr>
<th>Type of Environment</th>
<th>Type of analysis</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

Source 5,12,15,17–22

Based on table 1, it is known that the external environment has a greater composition than the internal environment in the environmental screening process for the formulation of process strategies in health facilities. External environmental screening (politics, economy, socio-culture, technology, demography, and epidemiology) holds a composition of 66.66% while internal environmental screening (finance, physical, technology, human resources, innovation and reputation, infrastructure, HRM, technology development, purchasing, inbound logistics, operations, outbound logistics, sales and marketing, and services) is only 33.33%. External environmental factors are the environment outside the company that continues to change rapidly, is unpredictable and difficult to control so that it plays a bigger role and is more difficult to analyze than the internal business environment within the company.

**Conclusion**

The internal and external environmental screening stage is an important stage in the strategy formulation process. Internal environmental factors consist of resources (finance, physical, technology, human resources, innovation and reputation) and value chain management (infrastructure, HRM, technology development, purchasing, inbound logistics, operations, outbound logistics, sales and marketing, and services). While external environmental factors consist of general environment (politics, economy, socio-culture, technology, demography, epidemiology), industrial Environment (threat of new entrants, bargaining power of suppliers, bargaining power of buyers, threat of substitute products), competitor Environment. Based on this review paper, it is known that external environmental screening has a more role in the strategy formulation process which has a 66.66% share, while internal environmental analysis has a 33.33% portion, this happens because the external environment is an environment outside the company that changes rapidly, not predictable and controlled so that the external environment screening while the internal environment of the company is in the company. In the end, the process of screening the external and internal business environment is a very important process for the formulation of strategies in achieving company goals, including in health facilities.

Basal Cell Adenoma – A Report of a Rarity in a Relatively Rare Site

1Reader, 2Senior Lecturer, Department of Oral Medicine and Radiology, Madha Dental College and Hospital, Kundrathur, Chennai, Tamil Nadu, India, 3Senior Lecturer, Department of Oral Medicine and Radiology, Tham Moogambigai Dental College and Hospital, Dr.M.G.R Educational and Research Institute, Chennai, Tamil Nadu, India, 4Senior Lecturer, Department of Oral Medicine and Radiology, Ragas Dental College and Hospital, Chennai, Tamil Nadu, India

Abstract

Basal cell adenoma is a rare benign neoplasm of the salivary gland. It preferentially occurs in the parotid gland and upper lip during the sixth and seventh decades of life. The clinical presentation most frequently seen is a slow-growing, asymptomatic, movable, round or oval, normally coloured submucosal mass measuring less than 3.0 cm in diameter, encapsulated and well circumscribed. Histologically, the tumor consists of a proliferation of the terminal duct epithelial cells forming islands and sheets supported by a fibrous stroma, and also the presence of myoepithelial cells. There are 3 subtypes of basal cell adenoma: solid, tubulo-trabecular, and membranous. Although recurrence is rare, the membranous subtype, which is a hereditary variety of basal cell adenoma, has a 25% to 37% recurrence rate, possibly related to its multifocal nature, which impairs complete removal. [5]

Keywords: Basal cell adenoma, Monomorphic adenoma, Palate

Introduction

Basal cell adenoma is a very rare benign neoplasm of the salivary glands and name derives from the basaloïd appearance of tumor cells. It represents 54% of monomorphous adenomas and 1-3% of major salivary gland tumors and has an incidence of 7.5% among primary epithelial parotid gland tumors. [1] It occurs more common in the parotid gland and upper lip during the sixth and seventh decades of life, with female predilection (1:1.02). Palate is a rare site of occurrence. [2,3,4] Clinically, it presents as slow-growing, asymptomatic, round or oval, normally coloured well circumscribed submucosal mass. [1] Histologically, the tumor consists of a proliferation of the terminal duct epithelial cells forming islands and sheets supported by a fibrous stroma, and also the presence of myoepithelial cells. There are 3 subtypes of basal cell adenoma: solid, tubulo-trabecular, and membranous. [5] Although recurrence is rare, the membranous subtype, which is a hereditary variety of basal cell adenoma, has a 25% to

Report of a Case:

A 52 yrs old female patient reported with a chief complaint of slow growing asymptomatic swelling in the left side of the palate of 3 months duration. On General examination, patient was healthy. There was no abnormalities of TMJ and lymph nodes. No abnormalities on extra-oral examination. Intraoral examination (Fig 1) revealed a well-defined oval shaped smooth surfaced swelling on the left posterior hard palate, extending antero-posteriorly from the mesial aspect of 25 to the soft palate, Medio-laterally from palatal gingiva of 25-28 to 0.5 cm away from the midline, measuring approximately about 5x3 cms with no secondary changes and no surface pulsations. On palpation, the swelling was non tender, uniformly soft to firm in consistency, smooth, non-fluctuant, non-compressible, no blanching and does not yields on pressure, fixed to
the underlying tissues with well-defined borders with no discharge. Associated teeth 25, 27 were non-tender and vital. On aspiration, hemorrhagic tissue smear showed small clumps of plump spindle cells over a background of hemorrhage. Provisional diagnosis of **benign minor salivary gland tumor** in relation to the left posterior hard palate were considered. Differential diagnosis of Pleomorphic adenoma, monomorphic adenoma, Warthin’s tumour, Palatal abscess in relation to 27, Palatal mucocele were included.

![Image](image1.png)

**Fig 1.** Intra oral Picture showing swelling in the left side of the palate

On radiological investigations, IOPAR, Maxillary cross sectional occlusal view (Fig.2), OPG (Fig.3) and PNS (Fig.4) showed no radiographic abnormalities.

![Image](image2.png)

**Fig 2.** IOPA-24, 25, 26 region and Maxillary cross sectional occlusal view showing no abnormalities.
All laboratory findings were found to be within normal limits. Incisional biopsy of the lesion revealed relatively uniform, small, dark basaloid epithelial cells in the stroma, and is surrounded by a fibrous connective tissue capsule. Palisading at the periphery of the epithelial nests result in a ‘basaloid’ appearance (Fig. 5) and is diagnosed as Basal cell adenoma in the minor salivary gland of hard palate.
Discussion

Basal cell adenoma is a type of monomorphic adenomas. The salivary gland tumours are uncommon, which constitutes less than 3% of all neoplasms of head and neck. Although basal cell adenoma is the most common variant in the group of “monomorphic adenomas,” it represents only 1% of all salivary tumors. It is most prevalent in the sixth and seventh decades of life [6,7,8,9], however, in our case, the patient was in the fourth decade of life, in contrast to the literature and has...
female predilection. The basal cell adenoma occurs more frequently in the parotid gland, followed by upper lip. The development of these tumors in the buccal mucosa, palate, or lower lip is unusual. [2, 6, 7, 8] in the current case; the palatal location of the tumor did not fit the more frequent sites. Clinically, it presents as painless mass, enlarging slowly and frequently measures about 3-8 cms [10]

Malignant transformation to basal cell adenocarcinoma is rare but is suggested by some authors. Recurrence is rare, with the membranous subtype has a recurrence rate of 25% to 37% due to its multifocal nature, which impairs complete removal.[11] The treatment used in this case is the same proposed in the literature, consisting of complete surgical removal with an extra capsular limit. The patient had a satisfactory postoperative period, with complete healing of the operated area, and presents no signs of local recurrence 18 months after surgery

**Conclusion**

The present case, Basal cell adenoma is an uncommon salivary gland tumour presented in a relatively rare site. These rare cases should provide us an insight to the biologic behaviour and clinical course of the tumours and should be correlated with radiological & histopathological findings which help in accurate and timely diagnosis that can go a long way in the overall meticulous rehabilitation of the patient.

Molecular Characteristics of Iraqi *Lactobacillus plantarum* Isolates and Evaluate its Natural Bacteriocin (plantaricins) Antimicrobial Activity against Pathogenic Bacteria

Khadeeja S. Madhi¹, Mohammed H. Khudr¹, Rasha M. Othman¹

¹College of Veterinary Medicine, University of Basrah, Basrah, Iraq

Abstract

In this study, local strains of *Lactobacillus plantarum* bacteria were isolated from traditional Iraqi raw milk and milk products. The present study was aimed to study the molecular aspects of Iraqi *Lactobacillus plantarum* isolates and to evaluate its natural plantaricins antimicrobial activity against pathogenic bacteria. For complete detection for *Lactobacillus* spp., the partial sequencing of 16S rDNA gene result was analyzed and compared with those in GenBank to find out the different in the sequence using the BLAST program (http://www.ncbi.nlm.nih). The result was 17 samples diagnosed as *Lactobacillus plantarum*. Moreover, 14 isolates of local *Lactobacillus plantarum* bacteria were show 100% similarity with those previously recorded in GenBank, while 3 isolates were found to display more than 99% similarity with *L. plantarum* strains were previously listed in GenBank. Moreover, the study also reveals that all *L. plantarum* strains showed antibacterial activity against three studied indicators bacteria and the *plnEF* gene (530bp) was detected in all 17 isolates of *L. plantarum*.

**Key words:** *Lactobacillus plantarum*, molecular, bacteriocin, antimicrobial, pathogenic bacteria

Introduction

Bacteria in their life produce a different types of substances some of these substance have antibacterial activity. Plantaricins is a bacteriocin which is a unique group of substances, which contains of aminopoly-peptides with a bactericidal and moderately narrow anti-bacterial spectrum ¹ ². Currently, the newly purified bacteriocins have a wide range of anti-microbial uses particularly in food preservation besides the fields of medication ³ ⁴. Moreover, the lactobacilli are consider a common microorganisms which have been applied in manufacturing and human health, including food preservation and probiotics ⁵ ⁶. Additionally, the Lactic Acid Bacteria (LAB), are broadly used in the food production, especially in the fermented foods manufacture. Lactic acid bacteria are Gram positive bacteria, non-sporulating, anaerobic fermentative bacteria ⁷. In addition to the previous application of antimicrobial bacteriocin and bacteriocin-like inhibitory substances (BLIS), that produced by lactic acid bacteria, they also show a good health promoting, for enhancing the nutrition rate, regulator the infection of intestinal, and reduce of pathogenic microorganisms ⁸. Among the best significant LAB which are applied for making of fermented food products for example (meat, grass, and vegetable) is *Lactobacillus plantarum*. Several types of bacteriocins substances which produce by *L. plantarum*, was already described, as plantaricin (A), plantaricin (B), plantaricin (C), plantaricin (F), plantaricin (S) and plantaricin T ⁹.

*Lactobacillus plantarum* strains are produced plantaricin belong to class (IIb). These include two-peptide of bacteriocins, where in corresponding peptides for instance, PlnE/F and PlnJ/K which have a
synergistic influence in contrast to the target bacteria. The majority of antibiotics have specific targets at the site of the bacteria. The bacteriocins, by destructive the cytoplasmic membrane or inhibition of bacterial cell wall, or by both actions. The bacteriocins have a complex mode of action, development of resistance against bacteriocins is mostly not reportable. One of the significant limits within the widespread usage of most of the bacteriocins from Gram positive microorganisms is their incapability to eradicate the Gram-negative pathogens. On the other hand, many previous studies attempt to isolate the Lactobacillus plantarum from worldwide a variety of traditional cheese products, such as several Iranian, Italian cheese varieties, etc. on the basis of antimicrobial substances production and harmless characteristics, L. plantarum could be the suitable applicants for natural antimicrobial agent. Therefore, the present study was aimed to study the molecular aspects of Iraqi Lactobacillus plantarum isolates and to evaluate its natural plantaricins antimicrobial activity against pathogenic bacteria.

**Materials and Methods**

**Samples collection and isolation Lactic Acid Bacteria (LAB)**

One hundred twenty-three samples of raw milk and traditional milk products (cheese and yogurt) were used in this study. The samples of milks from cows and goats’ milk were collected from farms located at the local north of Basrah province, while the cheese and yogurt samples were collected from local markets. The samples have been collected under aspect condition in sterile bottles and kept in an ice-box and instantly transported to the laboratory of Microbiology. About 1 ml of milk sample was mixed thoroughly with 9 ml of sterilizedringer’s solution (1:4) for 60 s. A serial dilution has been made, then 100 µl from each diluteness were spreading on duplicate plated of MRS agar (HiMedia, India). The MRS inoculated culture were incubated under anaerobic conditions at 37°C for 48 h. Then ten colonies from inoculated plates which analogous to the maximum diluting were picked and subculturing for further tests.

On the other hand, cheese and yogurt samples were collected from different local markets in which 1 gm. of sample was inoculated into 9 ml of MRS broth (HiMedia, India) and incubated at 37°C for 48 h. under anaerobic conditions. Then 1 loopful of broth culture was spread on MRS agar plates and incubated at 37°C for 48 h. under anaerobic conditions at 37°C.

For further characterization of LAB, both Gram staining and catalase test were applied on all suspected isolates from raw milk, cheese, yogurt samples. Only Gram-positive and catalase-negative isolates were taken as presumptive LAB and stored at 4°C in MRS agar plates.

**DNA extraction and PCR analysis**

All suspect LAB isolates were initially cultured in MRS broth at 37°C for 48 h. Three ml of overnight culture were centrifuged at 14000 × g for 2 min., the supernatant was discarded and the pellet cells were collected. The bacterial DNA were extracted by using the Geneaid microbial DNA isolation Kit (Geneaid Biotech Ltd, China), following the instructions of the manufacturer.

For confirmation and identification of L. plantarum, the PCR was used on previously extracted DNA samples. The PCR reaction was completed in 20 µl reaction mixtures with 1 µl (10 pmol/µl) for each primer, 5 µl ready to use master mix (Bioneer/Korea) and the 5 µl of DNA template. The final volume was adjusted by adding 8 µl of sterile water to each reaction tube. The PCR conditions were initial denaturation of 95°C for 5 min. followed by 34 cycle of denaturation of 95°C for 30 s, annealing of 45°C for 45 s, and final extension at 72°C for 10 min. The PCR amplicons were then run on 1.5% agarose gel staining with ethidium bromide to check the successful of amplification. Agarose gel was used and visualized using a gel documentation system (E - graph – ATTO -Japan). Fragment size of approximately
319bp. positive gene was verified as positive for *L. plantarum* bacteria.

16S rRNA gene sequencing and phylogenetic analysis

The 5′ end variable region of the 16S rDNA was PCR amplified using 27F and 1525R primers (table 1). The PCR amplification reaction was performed in a total volume of 50μl, contains of 10μl master mix supplied from Bioneer /Korea and 10μl of genomic DNA, then 1μl of each primer was added to the reaction and the final volume was adjustment by adding the nucleus free water. Amplifications steps were carried out in a Thermal Cycler (Thermal Cycler, MJR), using the following program:

ThePCR condition was achieved with first denaturing phase of 95 °C for (5min) then 30 PCR cycles of 94°C (15s); 52°C(30s) and 72°C (2min). The final elongation cycle was conduct at 72 °C for (5min). The PCR amplification products then electrophoresis using 1.5% agarose gel already staining with ethidium bromide and subsequently visualize using gel documentation system. The DNA ladder was used as a molecular mass marker. The PCR product then sequenced by (Macrogen Inc./Seoul,South Korea Korea).The blast analysis are used then to distinguish comparable sequences in the https://www.ncbi.nlm.nih.gov (NCBI) database. The phylogenetic tree were constructed by the neighbor -joining method using the software MEGA (Version 10).

Identification of genes encoding bacteriocin production

The oligonucleotides primers used in the current study are mentioned in table 1. The PCR was achieved on17 DNA samples using a master mix from Bioneer /Korea under the following conditions: the initial denaturation at 94°C for 3 min, then 35 cycles of another denaturation step at 94°C (1 min.); annealing step at 58.5°C(1 min) and elongation step at 72 °C.(90 s.) and final elongation at 72°C (6 min.). The amplicons of PCR were electrophoresed on 1.5% agarose gel.

**Evaluation the ability of identified strains to produced active bacteriocin**

All 17 isolated were showed a significant bacteriocin producing, we select only one strain for further studies related to antibacterial activity and bacteriocin producing. Production of crude bacteriocin from isolated strain was tested according to method described previously 33.
The antibacterial effect of bacteriocin were screened in vitro for their antibacterial activity against: *Escherichia coli*, *Staphylococcus aureus* and *Pseudomonas aeruginosa* using the paper disc-agar diffusion technique on Muller Hinton agar as a culture medium for antibacterial activity. The filter paper disks (6 mm in diameter) impregnated with different volume of crude bacteriocin (20, 40, 60 μl) and placed on the Petri plates. The plates were incubated for 24 hrs. at 37 °C. The inhibition zone diameters were measured in millimeters of inhibition zone around the disc. The pathogenic bacteria was supplied from Department of Microbiology, College of Veterinary Medicine, University of Basrah, Iraq. The percent bacteriocin activity was calculated using the following formula:

\[
\frac{B-A}{A} \times 100
\]

Bacteriocin activity (%) =

A = Disc diameter

B = Inhibition zone diameter

**Results**

A total of 28 Lactic Acid Bacteria (LAB) were isolated from the 123 collected samples of locally produced raw milk and traditional milk products (cheese and yogurt). These samples originated from different animal sources, including cows and goats. All of the isolates were Gram positive and catalase negative (table 2). On the other hand the PCR technique was done for these samples. The PCR results of 16rRNA specific primers revealed that out of 28 only 23 isolates were diagnosed as *Lactobacillus plantarum* (figure 1) which reveals the bands of 319bp.s was clear observed on the 1.5% agarose gel analysis. Moreover the DNA of the 23 isolates were sent to Macrogen (Seoul, South Korea) with the primer (27F-1525R), Averagely 1525bp was obtained per sequence, which was then compared with those in GenBank using the BLAST program (http://www.ncbi.nlm.nih.gov). The result was 17 sample diagnosed as *lactobacillus plantarum* (table 2). In this table 14 isolates of local *Lactobacillus plantarum* bacteria were show 100% similarity with those previously recorded in GenBank, while 3 isolates were found to display more than 99% similarity with *L. plantarum* strains were previously listed in GenBank (table 3). The 16S rDNA gene sequences results of 17 isolates were used to construct the phylogenetic tree using MEGA10 software. The Neighbor -Joining method was used for tree constructed and for confirmed the results of the homology analysis with the higher query cover (above 99%) of national samples as shown in figure (2). For recognize between Iraqi samples and national sample from NCBI information a recording code was put before national sample with the country were it isolate. Finally the PCR results of plnEF gene specific primers revealed that all of the 17 isolates of *Lactobacillus plantarum* were have the plantaricin gene (figure 3). According to this figure the bands of 530bp was observed on the gel and represented the plnEF gene.

Discussion

The raw cows and goats milk and their derivative products are considered a good source for isolation of lactic acid bacteria (LAB) which having the probiotic properties and have the ability to produce a novel bacteriocinogenic materials like plantaricins. In this context, there is a several previous studies were focused on isolation and molecular characterization of lactic
acid bacteria and study their activity against other pathogenic bacteria \(^{34-36}\). In the present study we try to isolate the local strain of *Lactobacillus plantarum*, and study their potential antibacterial activity. The results of primary isolation indicated that 28 out of 123 were isolated based on culturing De Man Rogosa Sharpe (MRS) medium and catalase test, and 23 isolated on the bases of PCR. This results were in line with the results of \(^{37,38}\). They reported that MRS agar was used as routinely medium for isolation of LAB and suitable for lactobacilli bacteriocin assay.

On the other hand the final diagnosis were based on sequencing results in which 17 isolates were confirmed as *L. plantarum*. Since the genome sequencing plays an important role in the accurate identification of bacteriocinogenic LAB \(^{39}\). The phylogenetic tree was constructed based on 16S rDNA gene of local bacterial isolated and the results of sequences analysis were closely linked to those previously registered on the NCBI (National Centre of Biotechnology Information) from Slovakia, China, India and Egypt (figure.3). The phylogenetic analysis categorized all isolates into two main roots and each roots have different sub-roots or branching. In the figure (3) the first branch have shown the distribution of the national samples among with the Iraqi samples S9 and S2 in which S9 show extreme similarity with sample from Slovakia, while S2 share the same ancestor but it has a special branch. On the other hand the *Lactobacillus plantarum* local strain (S7 and S8) show more nearby with sample from Egypt. While *Lactobacillus plantarum* local strain S14 also share the same ancestor but it has the special branch. While the *lactobacillus plantarum* local strain (S5,S12,S3) were lacks to the national samples lead to distributed in special branch. Moreover, figure (3) also reveals that most *lactobacillus plantarum* local strain (S17,S16,S6,S4, S13 ,S10, S15,S11,S1) show similarity with sample from China and this result was in line with \(^{40}\).

In all genetics and molecular studies the phylogenetic tree was consider a good tool to see the kinship between species based on similarities or differences in physical properties such as sequence or genetic sequence of DNA or amino acid and protein \(^{41}\). So the differences in the distribution of *lactobacillus plantarum* local strain could be attributed to the mutation in 16S rDNA gene that led to some variation in the Iraqi isolates. This mean the Iraqi isolates of *lactobacillus plantarum* were extreme similar to the national strains and share the same sequence of (16S rDNA) gene because this gene is more constant and have a slight mutation rate and evolution and need very long time to change so it is used in the classification of the microorganisms in the world. Detection based on 16S rDNA is consider a reference means for bacterial identification and taxonomic studies. Additionally the using of 16S rRNA gene as housekeeping genetic marker for taxonomic and bacterial phylogeny analysis could be attributed to the exist of 16S rRNA gene in almost all bacteria, moreover the 16S rRNA genes (1500 bp) are huge enough for informatics and genetic analysis purposes \(^{43}\).

In the present study the primary screening for the ability of local *L. plantarum* isolates to produce antimicrobial activity (crude plantaricins) was assessed against three studied indicators *S.aureus*, *E.coli* and *P.aeruginosa* (table 4,5,6). In these tables the highest inhibitory activity was observed at 40μl and 60μl concentrations against *S. aureus* (166.66%, 219.33%) followed by *P. aeruginosa* (191.66% and 252.66%) while inhibitory activity reported against *E. coli* was (166.66% , 219.33%) for 40μl and 60μl respectively. The antimicrobial activity of crude bacteriocins have been reported to be inhibitory against several other bacteria \(^{44-46}\) and \(^{33}\). The results described in the present study are in agreement with the observations of \(^{20,21}\) who reported a highest inhibitory activity of bacteriocin producing *Lactobacillus* spp. against *S. aureus*, \(^{33}\) and against*S.aureus, E.coli* \(^{47}\). Furthermore, \(^{35}\) was observed that *L.plantarum* isolates from raw cow milk samples had a powerful antimicrobial activity against a set of indicator microorganisms.

Moreover, the plantaricins-encoding genes was detected in all *L.plantarum* isolates by polymerase chain reaction (PCR). The results were revealed that all
tested *Lactobacillus plantarum* strains (no = 17) hold plnEF genes. The results were agree with the results of 48 based on the observation of the PCR product by using specific primers for amplified the plnEF in *Lactobacillus plantarum* bacteria.

**Conclusion**

We concluded that *lactobacillus plantarum* local strains have share the same DNA sequences similarity with samples from Slovakia, China, India and Egypt. Moreover all *L.plantarum* isolates were have the genes responsible for production of bacteriocins which a provide a natural substitute for antibiotics. However, more further studies are necessary to improve quality and safety of these bacteriocins.

Outcomes of Fissurectomy and Advancement Flap in Management of Chronic Anal Fissure

Khairallah Muzhir Gabash1, Saleh Omair2, SarabMuhammed Zeki Radhi3

1Assist. Prof. Department of Surgery / College of Medicine / Wasit University, 2Lect., Department of Anatomy and Biology / College of Medicine / Wasit University, 3B.D.S.MSc Oral and Maxillofacial Radiology Wasit health Directorate

Abstract

Chronic anal fissure is a painful linear tear in the mucocutaneous junction of the distal part of the anal canal and involves the full thickness of mucosa, causing severe pain may last even hours after defecation. Usually, it occurs along the midline either anterior or posterior; if it presents off the midline, other pathology might be associated with. Unhealed anal fissure after 6-8 weeks is defined chronic, with the presence of other criteria, it unlikely heals with medical treatment, and surgery is mandatory after pharmacological treatment failure. Lateral internal sphincterotomy had high healing rate, but unfortunately, with risk of incontinence. Fissurectomy with complete excision of the fissure keeping the internal anal sphincter intact, and an advancement flap of well vascularized tissue is transferred to cover the base of fissure and improve healing. This study mainly aiming to analyze the outcome of fissurectomy with advancement flap procedure in the treatment of chronic anal fissure and highlight its advantage in terms of healing rate and complications especially anal incontinence. During a period of about 5 years 345 patients (260 males and 85 females), have been included in this study and were diagnosed as cases of chronic anal fissure. After administration of local anesthetic, fissurectomy with advanced flap was performed. Patients had been followed up regularly for 6-24 months. Data collected and statistical analyses by using SPSS. About 75% of patients were males while, 25% were females, their ages were between 20-59 year, most of the patients were in thirties, nevertheless most of the females were in twenties. Mean time for wound healing was 10 days. Whilst complete fissure healing process lasting approximately one month. About 11.9% of the patients take more than one month to complete healing process. Healing rate was 100% after the follow up period of 6-24 months. Recurrence developed only in 2% of the patients. None of the patients developed incontinence, anal stenosis, key hole deformity, necrosis or urine retention. From this study concluded Fissurectomy with advancement flap in the treatment of chronic anal fissure is cost effective procedure, can be done under LA with least time-off work, with low complication, low recurrence, and no incontinence.

Key words: Fissurectomy, Chronic, Anal canal, Fissure, Tissue and Flap

Introduction

Fissure has been known as a painful, linear tear in the mucocutaneous junction of the distal part of the anal canal, which usually involves the epithelial layer only in acute stage and involves the full thickness of mucosa in chronic stage1. It develops with equal frequency in both males and females, but it tends to have predilection for younger and middle age group1,2. Anal fissure causing severe pain may last even hours after defecation and it is accompanied either with constipation or diarrhea1. The exact etiology is not understood, yet, but physical trauma stands at the top list(2,3). Anal fissure mainly occurs in the midline either posteriorly or anteriorly, if it presents off the midline, other pathology might be associated such as crohn’s disease, sexually transmitted disease, granulomatous disease and neoplasms4,5. Unhealed anal fissure after 6-8 weeks is considered chronic, with the presence of other criterialike skin tag, hypertrophied papilla, raised margin and exposed internal sphincter.
muscle fibers\textsuperscript{4,5,6}.

Chronic anal fissure was unlikely healed with medical treatment and surgery is mandatory after pharmacological treatment failure \textsuperscript{5}. Lateral internal sphincterotomy was first described in 1835, it was the treatment of choice, with high healing rate, but unfortunately risk of incontinence may reach to 30\% based on previous studies\textsuperscript{7,8}. In fact, this increased the need for new surgical procedure that preserve the anal sphincter integrity. Notably, Fissurectomy is the most commonly practiced procedure, however a possible drawback is keyhole defect and guttering that may lead to fecal soiling\textsuperscript{4}. So, Fissurectomy either with pharmacological agent like botulinum or with advancement flap introduced to overcome this complication\textsuperscript{6}. Fissurectomy has been defined as a complete excision of the fissure keeping the internal anal sphincter (IAS) intact, while anal advancement flap (AAF) is the transfer of well vascularized tissue to cover the base of fissure to improve healing. These procedures when combined together give high healing rate with less complication specially incontinence\textsuperscript{9}. Island advancement flap, V-Y flap, rotational flap, sliding skin flap and house advancement flap different in shape but, all induce and accelerate healing process\textsuperscript{9,10}. Other option is Fissurectomy with injection of 25U of botulinum toxin into IAS, to avoid lateral internal sphincterotomy (LIS), this combination had good healing with low incontinence\textsuperscript{11}. Patient who doesn’t heal or has recurrent anal fissure should be evaluated using anoscope and rigid proctosigmoidoscopy to exclude other pathology. Current study aiming to extensively analyze the outcomes of Fissurectomy with advancement flap procedure in the treatment of chronic anal fissure and highlight its advantage in terms of healing rate and complications especially anal incontinence.

**Methods**

From Sep. 1\textsuperscript{st}, 2015 to Aug. 31\textsuperscript{st} 2020, 395 patients (305 males and 90 females) were attending to private clinic in Al-Kut city /Wasit province/ Iraq. They were complaining of variable symptoms mainly: anal pain during and after defecation, passage streak of blood, constipation, itching, and were diagnosed as cases of chronic anal fissure.

During this period of about 5 years only 345 patients; 260 males and 85 females, were included in this study, while the others were excluded on the base of the following criteria:

**Exclusion criteria:**

* Patient’s age less than 20 years and older than 59 years.
* Patients with associated pathological conditions with fissure like piles, anal fistula and anal wart.
* Multiple or lateral fissures.

Following history taking, general and local clinical examination of patients’ perianal and anal region by putting the patient in left lateral position with good light illumination and gentle inspection of the anal region they found to have signs of chronic anal fissure mainly posterior and anterior midline of variable duration which were more than 6 weeks and they were tried conservative medical treatment but, they didn’t respond for this type of medical treatment.

Explanation of the disease process for the patients, decision and consent were taken for surgical interference for those patients. Then preparation by positioning the patient in left lateral position, shaving the operative area, using plastering strap on the both buttocks for separation to get good access, scrub by povidone iodine, draping, administration of local anaesthesia; lidocaine with adrenaline 1:100000, has been performed. After good infiltration we use electro cautery for excision of the fissure edges and its skin tag up to anal papilla, proximal to the chronic anal fissure providing a fresh mucocutanous edges, meticulous hemostasis was done from the base, limited undermining of skin and mucosal side were practiced to achieve tension free flaps on both sides, advancing and suturing the 2 flaps transversely to avoid anal narrowing and decrease jeopardizing the circulation and covering the row area.
by the 2 mucocutaneous flaps. The suturing is done by using 40 vicryl suture ininterrupted manner, dressing the operative area and discharging the patient on antibiotic cover, analgesia, sometimes laxative and special advice regarding personal hygiene; using salty water for washing the area to decrease congestion and pain. In addition, dietary advices concerning high fiber diet, and avoiding pepper and spicy food, then to be seen 10 days later followed by regular visit until complete healing take place. This was done in outpatient clinic. Period of following up range from 6 to 24 months, depending on the presence or absence of postoperative complications. Data analyzing has been performed using SPSS version 13.0, and described in terms of frequency and percentage.

**Results**

About 345 patients out of 395 attending the private clinic were included in this study 75.37% (260) of them were males while, 24.63% (85) were females. Their ages ranged 20-59 year with a mean of 36.06 (St=±0.037), their age distribution is shown in table no. 1, which shows that most of the patients were in thirties, nevertheless most of the females were in twenties (table 1).

Concerning clinical characteristics of CAF, it sites were along the midline, anteriorly in 18.55% and posteriorly in 81.45%, this after the exclusion of patients with multiple fissures and those with fissures outside the midline. (Table 2). Presence of other signs of chronicity like skin tag and papilla were frequent, about 36% of patients had hypertrophied papilla, 48% had skin tag and both signs were present in 15% of patients (Table 3).

Mean time for wound healing was 10 days. Whilst complete fissure healing process took about one month. About 11.9% (41) of the patients take more than one month for complete healing process due to either infection or wound dehiscence. Interestingly, healing rate was 100% after the follow up period of 6-24 months.

Nearly 14.49% (50) of patients underwent surgery have developed complications like infection, partial breakdown or recurrence as shown in (Table 4). Importantly, none of the patients developed incontinence, anal stenosis, key hole deformity, necrosis or urine retention.

Recurrence developed in 7 patients (2%), all of the new fissures developed after one year and in another site. None of them need surgical intervention. Wound dehiscence or partial breakdown in the flap arises in 23 patients comprises 6.67% of the sample, however all patients healed without surgical intervention.

Discussion

In a period of five years 345 patients were included in the current study. Patients were diagnosed as chronic anal fissure (CAF), most of them 75.37% were males and only 24.63% were females. Nevertheless, Mapel et al in their cohort study (2014) calculated more percentage in female which was 55.8%. This controversy may be due to social and religious factors that made females in our society hide their medical problems or seek for a female surgeon. But in both studies the higher number of females was in twenties and for males was in middle aged groups12.

Notably, observations of present study illustrate that Fissurectomy with advancement flap in patients with CAF regardless of internal anal sphincter (IAS) tone has a good outcome with minimum postoperative complications, low recurrence rate and no incontinence.

Wound dehiscence is a known complication of Fissurectomy with advancement flap. In this study partial breakdown of the wound was the major complication 6.67%, that is near to the percent of Patti et.al.(2012), Pateland Aarakiet.al. which were (5.1%), (8%) and (5.9) respectively13. We suppose that this type of complication could be attributed to abuse of topical steroid-containing drugs by the patient him/herself before surgery. However, none of these patients needed repeated surgical intervention. Infection is a minor complication of any wound healing especially after Fissurectomy. We found that infection rate was mild and responded to antibiotic therapy in 5.79% of patients involved in the current study in contrast to Patti et.al study, where infection was developed in 5 per each 48 patients(10.4%) involved in the study6. Patti et al recorded 8% recurrence rate, all of them responded to medical treatment and didn’t need surgery6. Giordano et.al. reported new fissure development in 3 patients (5.9%) one of them need surgical treatment and the others treated medically10. While in this study the recurrence rate was only 2%. All recurrences developed after 12 months and treated medically. Our data demonstrate that the complete healing was achieved in a mean period time of 30 days.

Delayed healing process was observed only in about 12% of the patients, it took about 40-45 days for healing. Based on study done by Patti et. al.2012 and another study in the same year, refer that all their patients healed within 30 days 6,14.

Furthermore, Fissurectomy with advancement flap is known as sphincter saving procedure, since the sphincter remains intact14. Consistently, Fissurectomy alone without flap might raise the risk of keyhole deformity that leads to stool soiling. As mentioned previously in this study we excised fissure completely and apply a mucocutaneous flap to substitute the defective anal canal, this provides good blood nourishment, thus facilitate healing and minimize or prevent complications like fecal incontinence, keyhole deformity, stenosis and flap necrosis. Sahebally et.al. in his review and analysis of 4 studies’ results, compared between AAF and LIS and conclude that AAF had less incontinence than LIS but, same other complications associated with healing process9. It is worth to mention that in addition to low wound complication and nil incontinence rate, the surgery in this study was done under LA, in outpatient clinic and with short resting time.

Conclusion

Fissurectomy with advancement flap in the treatment of CAF has the advantages of:

1. It’s done under LA.
2. Least time-off work
3. Cost effective method.
4. Low complication and nil incontinence since it preserves the IAS.
5. Low recurrence rate.

Abstract

Objective: This study aims to evaluate the quality of landfill leachate that has been treated in a wastewater treatment plant.

Methods: Leachate samples were taken for 12 months (January-December) in 2018. The leachate quality parameters studied were: BOD 5, COD, TSS, total N, and heavy metals (Hg and Cd).

Results: The results showed that the BOD 5 quality met environmental quality standards in May, June, July, September, October and December, COD exceeded environmental quality standards, TSS met environmental quality standards in February, March, August, and December, N total met quality standards environment for 11 months, only December did not meet environmental quality standards, heavy metals (Cd and Hg) were below environmental quality standards.

Conclusion: The Sliwunglandfill to conduct an approach study that can reduce the BOD 5, COD, and TSS values so that they do not exceed the specified quality standards.

Keywords: leachate, coagulation, landfill, municipal solid waste

Introduction

Waste is a on of the world problem and not only in Indonesia, in several developed countries waste is a complex problem that causes environmental pollution. Symptoms of population growth correlate with waste production 1. In Indonesia, plastic waste is a kind of waste that is often found in several areas, especially in big cities. The most of plastic waste is produced by urban areas. The excess waste capacity and the lack of optimal waste management causes the waste to be carried by the river to the ocean.

The government in conducting management and processing efforts, forms a shelter known as a final disposal site (landfill). The garbage that has accumulated and is not immediately handled will produce looking waste which is called leachate. Leachate is liquid waste that contains harmful organic and inorganic materials 2,3. The leachate with high concentrations also has the potential to contain heavy metals Fe, Cr, Hg, Pb, and Cl 1. In Indonesia, the leachate management has been regulated in the Regulation of the Minister of Environment and Forestry of the Republic of Indonesia Number P.59/Menlhk/Setjen/Kum.1/ 7/2016 concerning the quality standard of leachate. In this regulation, the government can assess and evaluate the management of leachate in each landfill which is spread throughout Indonesia.
The process of leachate formation occurs when large amounts of buried waste are wetted by rainfall, causing sediment to occur in the soil\textsuperscript{2,5}. The leachate leaks will cause dangerous impacts ranging from environmental pollution and health problems\textsuperscript{6,7}. The pathogenic bacteria produced exceeds the ferocity of \textit{Escheria coli}. The contamination of soil and water will cause a decrease in the biodiversity of biota components and a decrease in environmental quality.

Landfill of Sliwung is the final waste management sites in Situbondo Regency, East Java, Indonesia. The purpose of this study is to evaluate the feasibility of a waste management site based on the quality standards set by the government. This assessment can be a recommendation and study in increasing efforts to improve the quality of waste management to maintain environmental sustainability and safety.

\textbf{Methods}

\textbf{Research Sites.} This research was conducted in January - December 2018. The Landfill Sliwung is located in Situbondo Regency, East Java, Indonesia with a coordinate point of 7°45’16.16”S South Latitude and 114° 1’8.51”E East Longitude. Situbondo Regency has an area of 1,638.5 KM\textsuperscript{2}.

\textbf{Kind of Study.} This study was included in quantitative descriptive. The data obtained will be analyzed descriptively using literature references. Scientific studies will be a method of comprehensive discussion analysis by referring to several sources of research.

\textbf{Research procedure.} Leachate samples were taken 12 times each month from January to December 2018. At the time of sampling, the research also recorded whether it was rainy or dry. Sampling is located at a single location. This is because the sampling based on the source of pollution is included in the point sources discharges\textsuperscript{8}. The collected samples were then analyzed in an accredited laboratory, namely PT. JasaTirta I. The parameters observed in this study refer to the provisions of the Regulation of the Minister of Environment and Forestry of the Republic of Indonesia Number P.59/ Menlhk/Setjen/Kum.1/7/2016. The methods used in the analysis of leachate can be seen in table 1 below.

The existence of the quantity of leachate is influenced by the season in a region. So that environmental conditions affect the concentration level of the leachate produced. The seasons in Indonesia consist of the dry and rainy seasons. So table 2 shows the recording of the sampling process based on season conditions and the date of collection.

**Results and Discussion**

The management of leachate in Indonesia is regulated in accordance with the Regulation of the Minister of Environment and Forestry of the Republic of Indonesia Number P.59/Menlhk/Setjen/Kum.1/7/2016 concerning leachate quality standards (Table 3). Efforts to manage and treat leachate are very important to minimize the pollution load they cause. Table 3 shows some of the specific observational parameters of leachate. The presence of leachate becomes a pollutant when it exceeds the specified quality standards. The presence of leachate is influenced by several factors such as the type of waste buried, the influence of the microclimate, namely the intensity of rainfall, and the condition of the garbage collection."
Based on primary data from sliwung processing, periodically in each month of the year the amount of waste that enters for processing is recorded (Table 4). The characteristics of the waste produced consist of organic and inorganic waste such as household waste, plastics, and market waste. The amount of waste that comes in every year is getting higher. This is similar to the research results that the composition of the type of waste affects the quality of leachate produced\textsuperscript{10}. Organic waste is the dominant waste produced in Nepal and affects the amount of BOD\textsubscript{5} and COD. Organic waste is easier to break down by microbes than plastic waste.

</table>
Based on Figure 1 shows the results of pH, BOD$_5$, and COD in leachate. Every month the pH value is relatively stable. The pH value of the measurement results was still below the quality standard set by the government in accordance with Table 3. The average pH value every month reaches 7.9. However, in July the pH value reached 4.1 (in Figure 1). Such conditions can be caused by activities from the ecological conditions of the final processing plant. Then it is assumed that there are buried garbage that is difficult to oxidize so that it is confirmed that the waste experiences inhibition of decomposition. In contrast to BOD$_5$, the graph shows that in May to November the BOD$_5$ value was just below the specified quality standard. This is influenced by the intensity of rainfall. In Indonesia, this month enters the dry season. This is similar to research conducted that stated that rainfall has a correlation with the quality of leachate produced$^{11,12}$. The highest BOD$_5$ value occurred in December, this is due to the fact that Indonesia is entering the beginning of the rainy season in this month (Figure 1). Delays in waste processing can increase humidity and temperature in the decomposition process. BOD$_5$ and COD are parameters related to pollutants. The existence of BOD$_5$ and COD is very dynamic. Therefore COD in every month exceeds the quality standard limit set. The highest COD value occurred in December with a value of 3,840 mgL$^{-1}$. There are several ways that can be done to reduce COD in leachate, namely using the coagulation flocculation technique$^{13,12,14}$.

![Figure 1.PH, temperature, BOD$_5$, and COD parameters from leachate in Sliwung.](image)

TSS is one of the leachate quality parameters that can pollute the environment. TSS by definition is part of the solid residue left behind, one of which can produce sludge. TSS can be observed physically because it can increase the turbidity level of leachate. In Figure 3, the TSS value in several months reaches a value that exceeds the quality standard. The quality standard value set by the government is 100 mgL$^{-1}$. However, the graph in Figure 2 shows that the highest TSS value was in June at 343.3 mgL$^{-1}$. TSS value affects the presence of aerobic bacteria so that the respiration process decreases. The oxygen level in waste with high TSS will reduce cellular metabolic processes in aerobic microorganisms. Then it has an effect on the digestibility of the amount of solids
produced. The use of FeCl$_2$ can reduce the amount of TSS by 95%, COD by 95% and the level of turbidity $^{13,15}$ Meanwhile, the parameter N Total per month is still in safe conditions the average value is below 60 mgL$^{-1}$. In December, the total N value was 223.9 mgL$^{-1}$ (Figure 2). The increase in this condition is proportional to the increase in COD values related to the amount of organic matter available in leachate.

![Graph showing TSS and N Total parameters of leachate in landfill Sliwung for one year.](image1)

The heavy metals Hg and Cd are non-essential heavy metals which can have a very dangerous impact if there is contamination. Both metals have toxic properties despite their presence in limited quantities. So based on the Regulation of the Minister of Environment and Forestry of the Republic of Indonesia Number P.59/Menhik/Setjen/Kum.1/7/2016 concerning the standard of leachate, the amount of heavy metals Cd and Hg is strictly limited to not more than 0.1 mgL$^{-1}$ and 0.005 mgL$^{-1}$. In Figure 3, the parameter of heavy metals, the number of results of the analysis, shows that the waste processing location in Sliwung is still in accordance with the quality standards applied by the government. Based on the analysis results, the Cd and Hg values in leachate reached an average value of 0.00025 mgL$^{-1}$ and 0.0000159 mgL$^{-1}$. The presence of essential heavy metals in waste can cause extraordinary pollution events. The contamination is not only in the environment but can also occur in human health. The essential heavy metals such as Hg and Cd have a very difficult breakdown rate, so an integrated management effort is required.

![Graph showing Hg and Cd parameters from leachate in landfill Sliwung while one year.](image2)
Conclusions

Based on the results of the analysis on several parameters BOD\textsubscript{5}, COD, and TSS still require special handling to meet the environmental quality standards set by the government in accordance with the Regulation of the Minister of Environment and Forestry of the Republic of Indonesia Number P.59/Menhk/Setjen/Kum./7/2016 concerning the quality standard of leachate. This evaluation aims to assess the feasibility of processing waste to improve its management in maintaining environmental balance. So that the results of this study can be a recommendation for the Sliwung landfill to conduct an approach study that can reduce the BOD\textsubscript{5}, COD, and TSS values so that they do not exceed the specified quality standards.

A Study to Assess the Effectiveness of Planned Teaching Program on Knowledge Regarding Electro Convulsive Therapy among Patient’s Relatives Undergoing ECT in Selected Hospitals in Vadodara

Kiran Patel¹, Seema Boresa², Mural Christian³
¹Assistant Professor, ²M.sc Nursing Tutor, Dinsha Patel College of Nursing, Nadiad

Abstract

Background of Study: Electroconvulsive therapy (ECT) is a safe and efficacious treatment; there is a widespread negative view of electroconvulsive therapy in public and professional circles. Clinical experience and research have resulted in continued improvements to the efficacy and safety of electroconvulsive therapy. It is necessary to conduct research on this basis to modify the misconceptions and prejudices about the electroconvulsive therapy¹.

Objectives: 1. To assesses the existing level of knowledge regarding electro convulsive therapy among patient’s relatives undergoing ECT.2. To determine the effectiveness of planned teaching on knowledge regarding electro convulsive therapy among patient’s relatives undergoing ECT.3. To find out association between pre test knowledge scores of patients relatives with their selected demographic variables.

Methodology: Quantitative Research Approach was use with 2 Group pre test & Post test Design. The investigator used pre-experimental one group pre-test post-test research design. Purposive sampling technique used for Selecting 30 Samples. The Structural questioners Used Check knowledge of ECT before & after administration of planned teaching program.

Results: Analysis of paired t test is done to assess the effectiveness of planned teaching on knowledge regarding electroconvulsive therapy. Researcher has found t value= 24.853 thus the obtained t value in this study is more than the table value of t test at 0.05 level of significance. Hence the obtained t value is significant. So it reveals that planned teaching on knowledge regarding electroconvulsive therapy is improved in knowledge among patient’s relatives.

Key words: Effectiveness, Planned Teaching Program, Knowledge, Electro Convulsive Therapy

Introduction

Mental illness is shrouded in the gloom of ignorance, superstition, feeling of mystery and fear among the public. Many mental ill patients are taken to different healers and religious places where they usually undergo torturous procedures. Often the family spends most of its income in seeking relief from various other sources before coming to mental hospital; by this time mental illness would have reached an advanced stage and the family members have lost all their hopes. With the emergence of biological psychiatry and the growing knowledge bases in the neurosciences, interest has increased in treatment resistant psychiatric disorders and refinement in treatment techniques have placed greater emphasis on evaluating the indications for and efficacy of somatic therapeutic interventions.

Electroconvulsive therapy is a type of somatic treatment in which electric current is applied to the brain through the electrodes placed on the temples of the patient. 200-1600mA of electric current is passed for 0.7-1.5 seconds.²

Electroconvulsive treatment (ECT) is a powerful non-pharmacological mediation utilized for treatment in psychiatry. It offers a helpful, safe, and sometimes, life-sparing intercession, during which a minuscule electrical flow is applied to the patient’s cerebrum through terminals. The current delivers a seizure enduring from 30 s to 1 min. The actuated convulsive seizures in neurons in the whole mind mitigate indications of issues, for example, significant discouragement, intense hyper scenes, schizophrenia, or schizoaffective problem.³

Methodology

Research Approach: - Quantitative research approach

Research Design: - Pre-experimental, one group pre-test and post-test.

Sampling method: - Purposive sampling technique

Study population: - Relatives of patients are undergoing ECT in selected mental hospitals in Vadodara.

Study Setting: Selected mental hospital in Vadodara.

Study Size: - The sample size of the study was 30 relatives of the patients undergoing ECT

Results

Association of age in years with the patients relatives score the calculated value of chi-square is 1.45 less than the table value of chi-square 3.18 , at the 3 degree of freedom and P<0.05 level of significance. Therefore, age is non-significant with the score of patient’s relatives.

Association of sex (Gender) the patients relatives score, calculated value of chi-square is 1.152 less than the table value of chi-square 12.71, at the 1 degree of freedom and P<0.05 level of significance. Therefore, gender is non-significant with the patients relatives score.

Association of patients relatives score, calculated value of chi-square is 6.11 more than the table value of chi-square 3.18, at the 3 degree of freedom and P<0.05 level of significance. Therefore, patient’s relatives’ education score is significant.

Association of occupation of the family, calculated value of chi-square is 2.49 less than the table value of chi-square 12.71, at the 1 degree of freedom and P<0.05 level of significance. Therefore, Occupation of family is Non significant with the patients relatives score.

Association of type of family with the patients relatives score, calculated value of chi-square is 0.000 less than the table value of chi-square 12.71, at the 1 degree of freedom and P<0.05 level of significance. Therefore, type of family is no significant with the patients relatives score.

Association of relation with the patients relatives score, calculated value of chi-square is 0.67 less than the table value of chi-square 3.18, at the 3 degree of freedom and P<0.05 level of significance. Therefore, relation with patient non-significant with the patients relatives score.

The mean post-test knowledge score regarding electroconvulsive therapy among patients relatives significant higher than there mean pre-test score.

Conclusion

The present study was done to find out the effectiveness of planned-teaching program on knowledge regarding electroconvulsive therapy among patient’s relatives undergoing ECT in selected hospitals in Vadodara.
Conclusion drawn based on the finding of the study revealed the Pre – test knowledge score of patient’s relatives regarding “electroconvulsive therapy” undergoing ECT was poor. Planned-teaching program by the investigator was found to be effective in improving the knowledge of patient’s relatives.

Planned-teaching program is effective method. There was no significant relationship between pre test knowledge score and selected variable like age, gender, occupation, Types of family, relation with patients there is only significant with education of the patient’s relatives. Therefore it could be concluded that planned-teaching program can help in improving the knowledge of patient’s relatives and could be used in various settings. It can be concluded that there is no significant association between knowledge and selected demographic variable.

The analysis has been organized and presented under various sections like description of demographic variables, description of pre-test knowledge score, comparison of pre-test and post-test knowledge score and association between the post-test knowledge score and selected demographic variables. It is found that post-test knowledge score is higher than the pre-test knowledge score so it indicate planned teaching program was effective.

Conflict of Interest: Nil

Source of Funding: College Management

Ethical Clearance: The study was approved by the research committee, IEC – DPCN/1st IEC/2018-19/09 and a formal written permission was gathered from the hospital, Vadodara.

Statement of Informed consent: Informed consent was acquired from the participants

Abstract

Objective: Postmortem CT (PMCT) can help conventional autopsy in determining the cause of death and finding injury to various organs. Since injuries among several vital organs in the thorax can cause death, this research aims to assess the performance of PMCT in detecting injuries of the thoracic cavity organs.

Materials and Method: A total of 56 dead bodies by unnatural traumatic death who underwent PMCT before autopsy were collected. Thoracic traumatic findings from PMCT were compared with data obtained from conventional autopsy where the autopsy was the reference standard and calculated for sensitivity, specificity, PPV, NPV, and accuracy.

Results: Findings in which PMCT showed high sensitivity included air (100%) and fluid (86.67%). In terms of bone fracture, sensitivity and accuracy were 79.18% and 88.69%, respectively, especially for T-spine fractures (sensitivity 92.31%, accuracy 87.50%) and clavicle fractures (sensitivity 90%, accuracy 89.29%). For rib fractures, PMCT exhibited moderate to high sensitivity (68.18-91.67%) and high accuracy (78.57-98.21%). For soft tissue injuries, PMCT had high specificity (99.21%), but low sensitivity (34.94%).

Conclusion: PMCT is useful in detecting thoracic injuries in conjunction with the conventional autopsy by helping to diagnose bone fractures, abnormal air, and fluid with high sensitivity and specificity.

Keywords: Postmortem CT; Virtual autopsy; Chest injury; Trauma; Forensic Imaging; Forensic Pathology.

Introduction

Imaging is useful for diagnosing pathologies in the body, making it useful in postmortem inquest. This is especially true for postmortem CT (PMCT), which plays a role in enhancing conventional autopsy to determine the cause of death¹⁻⁹, detect organ injury, and some internal organ pathologies. The conventional autopsy had limited access to some internal injuries¹⁰⁻¹² such as facial bone fractures⁷,¹³, spinal fractures⁷,⁹,¹³,¹⁴, etc, and had limitations in its methods to detect pathologies caused by abnormal air, such as pneumothorax and air embolism¹⁵⁻¹⁸. Air generated within the body after death is something that is difficult to prove with conventional autopsy and requires additional techniques. In our experience, there were cases where this could not be proven, or if it was present in small quantities, may not have been possible to verify¹⁹. With these types of injuries, PMCT can be helpful for detection and in the detection of multiple injuries³,¹⁰,¹⁸,²⁰,²¹.
The thoracic region contains many vital organs, such as the heart, lungs, aorta, etc. Injury to the thoracic organs can be a common cause of death. For example, tension pneumothorax had a death rate of 40%\textsuperscript{22}, flail chest had a death rate of 18%\textsuperscript{23}, and cardiac tamponade\textsuperscript{24} can come from injury to the heart or the aorta. These are all possible causes of death. Injury to the chest is the fourth most common cause of death with a death rate of 18.7%\textsuperscript{25}.

PMCT is effective in detecting trauma to the pleura, thoracic bony structures, with high sensitivity and specificity of 100%\textsuperscript{7,26} but it has a lower sensitivity of 50-94% and specificity of 85-94% for soft tissue injuries\textsuperscript{26}. It could be seen that thoracic PMCT showed differences in performance between bone, soft tissue, fluid, and air. In addition, the researcher observed that there were several times when the autopsy revealed injuries that did not match the PMCT results. The researcher, therefore, would like to study the sensitivity and specificity of PMCT in the detection of thoracic injuries.

**Material and Methods**

**Sample**

The sample was comprised of unnaturally dead bodies that were fully autopsied between 2012 and 2020 and underwent PMCT before the autopsy. The exclusion criteria were the dead bodies without a history of injury prior to death, or with signs of decomposition on external examination.

**Data Collection**

Data collected were gender, age, incident history, cause of death, circumstances of death, and the time period from deceased to autopsy (postmortem interval: PMI). The cause of death was divided into 6 groups: 1) head injury, 2) neck injury, 3) chest injury, 4) abdominal injury, 5) multiple injuries (when more than one fatal injury group was involved) and, 6) others.

**Postmortem CT**

PMCT was performed on a 128-slice Aquilion CX scanner (Toshiba Medical Systems Corporation, Tokyo, Japan) or a GE revolution HD (GE Healthcare, Chicago, IL, USA). Scan parameters were as follows: slice thickness 2.0-2.5 mm, rotation time 0.5-0.6 s, tube voltage 120-140kVp, and tube current 200-300mAs without IV contrast. The examination was performed from the head to the halfway point of the upper leg or below, depending on the height of the body. Images were collected for analysis in the Picture Archiving and Communication Systems (PACS) and results were formally reported in the reporting system. The images were interpreted by emergency radiologists who had some experiences in postmortem imaging. The radiologists who interpreted the images knew the trauma history of the corpses but did not know the results of the autopsy.

**Conventional autopsy**

The autopsy was performed by forensic pathologists who were aware of the PMCT results using standard methods. The body was dissected throughout the body with the removal of all internal organs, including the brain, heart, lungs, liver, pancreas, spleen, kidneys, adrenal glands, and uterus (in the case of female corpses) for a thorough examination. The cause of death was recorded in the report.

**Definitions**

The definitions of each type of injury were described below.

1. Bone injuries included rib fracture, sternum fracture, clavicle fracture, and thoracic spine fracture. Rib fractures were described according to each rib separately, as 1\textsuperscript{st}-12\textsuperscript{th} ribs, right and left. The scapular fracture was not included in this study because of technical limitation of the conventional autopsy.

2. Pleura injury included hemothorax or pneumothorax.

3. Lung injury included lung contusion or lung laceration.

4. Heart injury included heart contusion or heart...
laceration.

5. Aorta injury included aortic tear or periaortic hemorrhage.

6. Superior vena cava (SVC) and inferior vena cava (IVC) injuries included hemorrhage or tear of the SVC or IVC.

7. Diaphragm injury included diaphragm contusion, diaphragm laceration, or traumatic diaphragmatic hernia.

8. Thoracic spinal cord injury included spinal cord hemorrhage (epidural hemorrhage or subdural hemorrhage), spinal cord contusion, or spinal cord laceration.

The definitions of the injury groups are divided into four groups of injuries:

2. Soft tissue and organ injury: heart, lung, diaphragm, and thoracic spinal cord injuries.

**Statistical Analysis**

Injury data of chest organs and parts from conventional autopsy and PMCT were compared and calculated to determine sensitivity, specificity, PPV, NPV, and accuracy using conventional autopsy as the reference standard.

**Results**

Data were collected from 2012 - 2020 for corpses that were PMCT tested. From a total of 63 cases, 7 cases were non-trauma and were excluded. Thus, a total of 56 cases were included in the study, 47 were men and 9 were women, ranging from 15-81 years of age, with a median age of 33 years. There was one case with no age identified. For the cause of death, the manner of death, and the postmortem interval (PMI), the data are shown in Table 1.

*Rib fractures were counted from each rib

The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy of PMCT when the conventional autopsy was the reference standard, are shown in Table 3. For heart injury and aorta injury, values could not be calculated except for the negative predictive value, because either the PMCT results were all negative or the number of pathologies was very low.

</tbody>
</table>
For main venous injuries (SVC, IVC injury), PMCT results and autopsy were all negative, so values could not be calculated. The conventional autopsy could not detect pneumothorax in some cases and therefore could not be used as a reference standard.

Thoracic injuries with the highest sensitivity of PMCT were T-spine fractures (92.31%), followed by clavicle fractures (90%), and hemothorax (86.67%). The injuries with the highest specificity included diaphragm injury and thoracic cord injury (100%), followed by lung contusion (95.45%), though the latter two had low sensitivity of 20-47%.

Detecting rib fractures with PMCT resulted in an overall sensitivity of 78.63% and specificity of 93.06%.

Sensitivity ranged from 63.64% to 91.67%, with the highest sensitivity being recorded at the right 10th rib, left 9th rib, left 10th rib, and left 12th rib, respectively. Specificity ranged from 85.29% to 100%, with the highest being at the left 12th rib, left 10th rib, and right 8th rib, respectively. PPV ranged from 55.56% to 100%, with the maximum found at the left 12th rib, right 4th rib, right 3rd rib, respectively. NPV ranged from 79.49% to 97.87%, with the highest being the left 12th rib, left 10th rib, and right 12th rib, and left 9th rib, respectively. Accuracy ranged from 80.36% to 98.21%, with the highest being the left 12th rib, left 10th rib, right 8th rib, and right 10th rib, respectively. The details were shown in Table 4.

When the trauma pathology was grouped into four groups to calculate the diagnostic performance of PMCT compared to conventional autopsy (Table 5), PMCT was found to have relatively high accuracy (78.13% - 88.69%), with the highest value indicated for bone injuries. For abnormal air detection, PMCT had the highest sensitivity, detecting NPV at 100%, but its specificity, PPV, and accuracy could not be determined because it could not be detected in conventional autopsy in many cases due to the technical limitations.

### Discussion

This research shows that PMCT is highly accurate for the diagnosis of fluid and air, as well as injuries to soft tissue and organs in the thoracic cavity, with the highest sensitivity for pneumothorax diagnosis and the highest accuracy for bone fractures (especially T-spine fracture and clavicle fracture). It is also superior to conventional autopsy in the diagnosis of pneumothorax.

**Bone fracture**

This research is consistent with previous research findings proclaiming PMCT to be very accurate for bone injuries, with accuracy levels up to 88.69%. Clavicle fractures display the highest accuracy of 89.29%, as shown in research by Moskala A. et al.\(^{27}\), where PMCT can detect clavicle injuries better than any other bones in the thorax. Overall sensitivity, specificity, and accuracy in this study were lower than that found by Sifaoui I. et al.\(^{26}\), who showed the sensitivity of 100% and specificity of 100%, but similar to a study by Ampanozi G. et al.\(^{28}\), which had a sensitivity of 86%.

For rib fractures, PMCT was found to have a sensitivity of 78.63% and specificity of 93.06%. Research by Schulze C. et al.\(^{29}\) obtained lower sensitivity rates, but slightly higher specificity. In the area of rib fractures, some differences from past research were found. In research by Hamanaka K. et al.\(^{30}\), it was shown that PMCT detected fractures of the 2nd, 5th and 6th ribs very well. As for the Schulze C. et al.\(^{29}\) research, PMCT presented better detection at the 1st rib. In this research, the rib fracture sites where PMCT showed the highest accuracy were the left 10th rib, left 12th rib, right 8th rib, and right 10th rib, which are false ribs, as well as floating ribs.

As for scapular fractures, it was found that PMCT revealed a certain number of positive results, whereas conventional autopsy could not reach the scapula during the examination in many cases because of technical limitation. Therefore, we did not include the scapular fracture in this study.

**Soft tissue and organ injury**

For injuries to soft tissue and organs, PMCT exhibited high specificity (99.21%), comparable with Aghayev E. et al.\(^{31}\), but showed lower sensitivity (34.94%) than the study of Ampanozi G. et al.\(^{28}\).
In lung injuries, PMCT was higher in specificity than Aghayev E. et al.\textsuperscript{31} for both lung contusion and lung lacerations. Diaphragm injury was the best soft tissue and organ injury to be detected by PMCT, with a sensitivity of 80\%, a specificity of 100\%, and an accuracy of 98.21\%. This is similar to research by Sifaoui I. et al.\textsuperscript{26} with 94\% sensitivity, 94\% specificity, and 97\% accuracy. Three-quarters of the four true positive cases were detected for diaphragmatic herniation. These values were higher than those found in research by Aghayev E. et al.\textsuperscript{31} (sensitivity 50\% and specificity 100\%), and that of Christe A. et al.\textsuperscript{32} (sensitivity 0\% and specificity 94\%).

\textit{Pneumothorax}

Pneumothorax was the most common condition, presenting in 28 out of 56 cases (50\%) in PMCT images, but not in the conventional autopsy. Only 5 cases were found in both conventional autopsy and PMCT. No cases were found only in the autopsy but not by PMCT. This is consistent with other studies, as well, showing that PMCT was able to detect pneumothorax\textsuperscript{3,31,33}. This is the unique property of PMCT allowing abnormal air collection to be detected even in small amounts, while a conventional autopsy is not able to confirm pneumothorax in those cases.

\textit{Hemothorax}

In this study, PMCT had a sensitivity of 86.67\% in the diagnosis of hemothorax, which was 76\% higher than that of the research of Ampanozi G. et al.\textsuperscript{28}

* Calculated from data provided within the article
Limitations

The limitations of this research are its retrospective nature with a relatively small number of cases, and some of the findings were infrequent that the statistical values could not be calculated. Our results were obtained from PMCT results without re-reviewing images. Although this reflects a real clinical practice it does not allow an evaluation of the most optimal performance of PMCT. The study period was quite long and may influence the experience of the radiologists who interpreted the results. The PMCT technique did not use a contrast agent injection, making it limited in the diagnosis of vascular injury. The conventional autopsy had limitations, as well, as some areas were inaccessible, difficult to reach, or some techniques were difficult to perform, making it impossible to use as a reference standard for certain pathologies.

Conclusion

PMCT is highly accurate in the diagnosis of bone fractures, abnormal fluid, and air in the thoracic cavity, and can be used as a complement to autopsy, particularly in the diagnosis of pneumothorax and some fractures. This test has a high specificity for diaphragm injury, but is not very good on other soft tissue injuries.

Medical Coercive Measures Under the Albanian Legislation and their Application to Criminally Irresponsible Individuals

Abstract

Individuals, who are characterized by mental disorders and manifest them in a criminal behavior, cannot be subjects to the same punitive regime provided for other subjects of criminal offenses. Neither penitentiary institutions nor civilian psychiatric hospitals are suitable for these individuals; the former, because they are conceived only for that category of subjects who culpably violate criminal norms; second, because, since psychiatric hospitals have therapeutic purposes, they are not suitable for controlling the social risk of irresponsible subjects.

Any decision of irresponsibility due to mental state brings a certain consequence, namely the dismissal of the case and the imposition of coercive measure. The defendant, due to his social danger, may undergo outpatient treatment or compulsory treatment in a medical institution.

The following manuscript analyzes the importance of medical coercive measures provided by the criminal legislation and at the same time, their importance in the treatment of irresponsible persons, perpetrators of criminal offenses. It tries to give an overview of the different orientations that characterize the issue in question, to underline the conclusions reached by jurisprudence and at the same time to reason not only on the basis of applicable norms, but also on the basis of perspective and opportunity for reform, seeking to develop points of reflection and avoid unreasonable discussions.

Keywords: medical coercive measures, compulsory outpatient treatment, compulsory treatment in a medical institution, psycho-social care, psychiatric hospital.

Introduction

The problem of social risk, rather than an indisputable problem related to the category of socially dangerous individuals, essentially constitutes a problem that has to do with guaranteeing social protection, specifically for the treatment of these individuals.¹

Through coercive measures, the socially dangerous subject is prohibited or prevented from committing criminal offenses. It is necessary to distinguish the coercive measures that are applied after the commission of a criminal offense from an irresponsible person, in the sense of article 46 of the Albanian Criminal Code and article 239 of the Albanian Code of Criminal Procedure from involuntary treatment given pursuant to law no. 44/2012 “On mental health”, in order to prevent persons suffering from a mental illness to have aggressive behavior before they commit a criminal offense.

Medical measures are different from punishments² because they are not a consequence of a punitive trial, but a consequence of a judgment on dangerousness, not on criminal responsibility but on the probability of recidivism in the future.³ Since they provide for a

reduction of the rights or personal freedom of the subject, their implementation is not conceived in the function of punishment, but it is an inalienable consequence of a measure with another purpose. Consequently, if the punishment is stipulated and placed in proportion to the fact that occurred, the coercive measure is logically indefinite, but in proportion to the social danger, as such it ends when the social danger ends.

Compulsory outpatient treatment as a medical coercive measure

Compulsory outpatient treatment intends to leave the person free under the care of the family or the respective guardian, who undertakes to treat him/her in an ambulatory or hospital condition. This type of measure is given mainly for criminal misdemeanor or for those criminal offenses that are not characterized by social danger, or when the latter has disappeared.

Compulsory outpatient treatment should always be based on the current state of mind and as long as no other more severe measures are needed.\(^4\)

In imposing the measure of compulsory outpatient treatment, the court must be very careful, so that the treatment is not neglected, since in this case the person is not deprived from liberty and his treatment is carried out in a free state.

In other words, the person to whom has been given such a measure must be assigned a family caregiver in order to follow him continuously and make sure that the subject undergoes medical therapy correctly. In any case the appointment of compulsory outpatient treatment cannot be given if the person does not have proper care from a family member. Other circumstances that the court must take into account in addition to the appointment of a guardian, are both economic and physical opportunity, proven and guaranteed before the court. In the absence of family members,\(^5\) as a guardian to follow at the same time the person himself and the treatment, the court cannot decide otherwise than the hospitalization in a psychiatric hospital, especially in cases of a temporary stabilized condition. Thus the main difference between outpatient treatment and hospitalization in a psychiatric hospital lies in the fact that the mental state of the irresponsible individual is permanently stabilized. In this way there is no reason why a person should be “deprived from his liberty”, but it is sufficient only the existence of treatment and its non-discontinuation.

In revoking and changing the medical measure of compulsory treatment in a medical institution to the measure of compulsory outpatient treatment, the courts often reject the request of the person on the grounds that in some cases he is not an integral part of the family tree. From this point of view the law has not made any provision for the appointment of a guardian, who will supervise the person who undergoes treatment as determined by psychiatric experts. Some courts also accept persons outside the family tree as guardians. In other decisions, the court requires the existence of economic opportunity to be proven and not only declared by the family members, but without determining the concrete evidence that the court needs to consider the request.

It is a mistake to think that in order to impose the most appropriate medical measure, the court should suffice with the act of expertise, but it should also take into consideration other evidence which sheds light on mental health, which is reflected in the behavior of the person in the community where he lives.\(^6\) An exception is made only in the case when the act of expertise stands as the only evidence, a case in which the court must accept it without any doubt.

The decision of the court to change the medical measure from hospitalization in a medical institution to compulsory outpatient treatment must in any case be justified, with the relevant arguments, why the conditions of treatment in a medical institution have ended and the person must be treated in outpatient treatment. The court should also refer to the act of expertise and in no case should decide differently from what the psychiatrists have prescribed.\(^7\)
The medical measure should be revoked in any case when the conditions and the need for safety are absent, being replaced by the measure of compulsory outpatient treatment. These conditions are always based on the assessments and statements of experts, specifically on improving the mental state of the person.8

Outpatient treatment, as a coercive measure is executed in the residence of the irresponsible person due to mental state who has committed the criminal offense. When the relevant specialists or a relevant institution are missing near the place of residence, he is accompanied in any case to the institutions of the nearest district, according to article 45 of law no. 8331, dated 21.04.1998 “On the execution of criminal decisions”, as amended. When there are obstacles in the execution of the compulsory outpatient medical measure, the prosecutor orders the compulsory execution by the state police and, if there’s the case, submits a request to the court to change the outpatient medical measure to a more severe measure, hospitalization in a medical institution.

Compulsory treatment in a medical institution as a coercive measure

This medical coercive measure is given by the court for persons declared irresponsible, against whom the criminal prosecution has not started or the trial has been terminated under article 387 of the Albanian Code of Criminal Procedure. It is thought that this measure does not apply to persons who have lost the ability to understand and control actions as a result of a transient illness, because at the moment of recovery from this disorder, the subject regains mental abilities and no longer poses a risk to society.

Compulsory treatment in a medical institution is applied to persons who due to their mental condition have not been aware of the importance of the criminal offense they have committed and have not been able to control their actions or omissions.9 The implementation of these measures by the court is an important tool of the Criminal Code and aims to prevent the commission of other criminal offenses by the mentally ill.

In case of dismissal of the litigation because of the irresponsibility due to mental condition, it is always given the medical measure of compulsory hospitalization in a psychiatric hospital for a period of not less than 2 years according to the Italian Criminal Code. According to this code, the minimum duration of hospitalization in a medical institution is not less than 10 years for offenses punishable by life imprisonment.10

On one hand, compulsory treatment in a medical institution, is considered as an opportunity to keep irresponsible and dangerous persons under control, and on the other hand, there is a discussion regarding the real possibility of imposing this measure.11 The Code defines the treatment of a completely irresponsible perpetrator in the form of compulsory isolation in a specialized institute in accordance with the vision that the irresponsible person is seen as a necessarily dangerous subject and that the only medical treatment is isolation from the rest of society.12

The Albanian judicial practice, has encountered a problem regarding the conditions of imposing medical measures, specifically that of compulsory treatment in a psychiatric hospital. The persons declared by the court as irresponsible in the absence of medical institutions, were sent for treatment to the prison hospital. Taking into account law no. 8331, dated 21.04.1998 “On the execution of criminal decisions” and the order of the Minister of Justice no. 329, dated 15.01.2009 “On the categorization of institutions for the execution of criminal decisions”, as amended, the prison hospital is considered a security prison and not a medical institution.

Therefore, the Albanian High Court13 has ruled that the law has been wrongly applied and the person has been unjustly deprived of his liberty, living in the conditions of a prisoner even though he is not such. In the same decision, the court expresses the opinion of the expert for imposing the most appropriate medical measure, emphasizing that according to article 46 of the Criminal Code, the only condition for the application of the medical measure is the irresponsibility of the person who committed a criminal act. The article in question
has not made any determination whether these measures are given to persons who are of great social danger or for any kind of offense.

Courts go beyond the content of the article when placing the emphasis on social danger, which is not required by article 46 of the Criminal Code. The court on itself does not have the means to determine the mental state of the person and necessarily seeks the help of psychiatric experts, who in addition to the mental state determine the need for treatment or isolation. The opinions of the expert often constitute a decisive evidence for the resolution of the case, but like all other evidence they are subject to judicial review, especially in cases where they must be analyzed within all of the evidence administered by the court. The court cannot take over and cannot play the role of the expert nor give it a predetermined value.

The medical measure of treatment in a medical institution must be reviewed by the court in any case after the expiration of the one-year period, as per article 46, paragraph 2 of the Criminal Code. In the review session, the court, with the help of experts, once again re-evaluates the mental state of the person, the progress of the disease, but above all the conditions of the existence of social danger. This reassessment is done for the sole reason that if the situation is improved and the person no longer shows danger, the need of this measure no longer exists and therefore the court is obliged, in accordance with the law, to apply another more lenient measure. The re-evaluation is done on the basis of the appeal of the party, but also mainly by the court where the acts are found.

The execution of the medical measure is done upon the request of the prosecutor. In case the person is locked up in a penitentiary institution, the execution of the medical measure is done by the body where the person is convicted. While in cases when the person is free the execution is carried out by the state police.14

**Psycho-social type custody measures**

An institution that needs special attention and that in many countries of the world is in itself a coercive measure imposed by the court in the full sense of the word, is the placement in custody in psycho-social centers.15

In itself this measure has all the effects of the coercive measure and is imposed by the court in the following cases:

1. as an initial measure for persons who have committed not very serious criminal offenses that present a controllable social danger without the need for enclosure in a medical institution;

2. to persons who have stayed for a certain period of time in a closed structure, when the social danger enters the limits defined in point 1, while waiting for the extension or revocation of the measure.16

The implementation of the psycho-social custody measure must be supervised by the court and as such can be no other than temporary. In this type of measure, the personality of the irresponsible person is monitored with special care, despite the importance of the criminal offense and the fact that the perpetrator is free. Here we are faced with the fact that these irresponsible sick subjects need appropriate therapy and a preventive measure for not committing other acts in the future. Psycho-social type of custody is not a coercive measure, but a complexity of mandatory psychotherapeutic interventions of a preventive nature.

Supervision of the irresponsible subject is closely related to a disease condition that necessarily requires medical intervention. Otherwise stands the supervision of the mentally responsible author on parole, who is free and mostly agrees to cooperate with the guardian. Irresponsible persons in custody are difficult persons who undergo treatment and in this sense it is not only necessary the need of a guardian, but also the existence of a medical observation.17

Another model of the Nordic countries is that of placing these persons in private institutions authorized and controlled by the state.18
Actually psycho-social custody measures are not provided in our Criminal Code, but referring to the practice of other countries, they have resulted to be quite effective in dealing with the above-mentioned subjects. Currently, these subjects, i.e. those who have committed a criminal offense under the conditions of intoxication or use of narcotic and psychotropic substances, are not subject to any kind of rehabilitative measures, but only to imprisonment, the same as other subjects. In these types of persons, quite vulnerable, manifestations of mental disorders have been observed during the execution of the sentence, precisely because of the lack of specialized treatment.

**Reasons for the closure of the judicial psychiatric hospitals in western countries**

In Italy and other countries of Western Europe, the psychiatric hospitals, where mentally ill individuals who have committed crimes, but are legally irresponsible for their actions, are kept under medical measures, or individuals with lower mental balance who need medical treatment, are moving towards closure. In order to have a clear picture on the reasons why these institutions are closing, we should list a number of weak points of the application of this system in practice. Anyway, what results to be the main reason of closure has to do with the fact that this particular type of treatment of this category of subjects, in itself, lost its remedial and rehabilitative function.

First of all, the forced closure in a psychiatric hospital is contrary to constitutional principles, such as the right to health and the respect for human dignity.19

Secondly, the forced closure in a psychiatric hospital is linked with the principle of flexibility that leads the restrictive measures, so that a certain measure can be appropriate for the therapeutic needs of the subject, in other words to the medical treatment which the latter must undergo.

Also, the forced closure in a psychiatric hospital does not respect the principle of proportionality, considering the specific circumstances of each case in respect of freedoms and human rights. The importance of this principle has been emphasized many times by the European Court of Human rights, in the interpretation of the provisions of the European Convention on Human Rights.

This measure in the same time violates the principle of distinctness between the sentence as a punishment and restrictive measures.

This enumeration can’t be claimed to be exhaustive. It is limited in the appearance of the main indicators and rules to which any reform of criminal law have to undergo.

Year 2015 marked in most European countries the end of psychiatric hospitals.20 The completion of this stage should be accompanied with the construction of suitable structures to hold this category of subjects, who were at the stage of execution of these measures. In principle, it was estimated that these new structures should totally be under medical management.

This category of subjects should be admitted to these institutions under the criterion of territoriality, in other words, the institutions closer to the place of residence or stay.

Another condition regarding these new structures was the inclusion of the professional staff made up of psychiatrists, psychologists, nurses and educators. On the other hand, persons who are not characterized by social dangerousness would receive mandatory outpatient treatment, while being nearby their families.

**Conclusions**

The Albanian penitentiary system needs a profound reform and restructuring of institutions that house irresponsible individuals. Currently in Albania there is no institution of the type of forensic psychiatric hospital, leaving the treatment of this category in the prison hospital or in the hospital of Kruja, based on social risk. These two institutions are conceived as penitentiary institutions and accommodation of these subjects constitutes another constitutional violation.
These subjects are not considered convicted and in the conditions of the impossibility of the state to provide service according to the provisions of the law, they have the right to request outpatient treatment. Practically, this cannot happen, as many of them have committed extremely serious crimes such as those against life, health or sexual freedom.

We are of the opinion that it is the time to provide in the Criminal Code a new coercive measure, in addition to compulsory outpatient treatment and compulsory treatment in a medical institution, that of psycho-social type of care. The provision of this measure would be particularly effective in treating those subjects who have committed a criminal offense under the conditions of intoxication or use of narcotic and psychotropic substances, as has resulted from the practice of other countries.

Currently, these subjects, i.e. those who have committed a criminal offense under the conditions of intoxication or use of narcotic and psychotropic substances, are not subject to any kind of rehabilitative measures, but only to imprisonment, the same as other subjects. In these types of persons, very vulnerable, manifestations of mental disorders have been observed during the execution of the sentence, precisely because of the lack of specialized treatment.

**Recommendations**

The definitive closure of psychiatric hospitals will set lawyers and politicians facing each other, in order to overpass the complexity of criminal system and of medical intervention in full respect of human rights and fundamental freedoms.

For a full analysis of this issue associated to irresponsibility because of mental state, it’s important to examine the penalties to which undergo the irresponsible individuals.

Although at the time of their creation, medical measures were presented as a model of progress and openness to human sciences, in a short time they showed their authoritative nature and resulted in a failure.

**This happened for many different reasons.**

First of all, in legislator’s point of view, while the punishment should have a retributive and preventive function, the medical measures were intended to have a specific preventive function (at least theoretically), as they were finalized by the treatment and rehabilitation of a socially dangerous subject. Medical measures, given to irresponsible individuals, or half responsible, but socially dangerous, were applied individually or uphold the sentence, giving rise to a dual sanctioning system. The doctrine of criminal law considers medical measures more severe than the authentic imprisonment sentence.

Medical measures are contrary to the principle of lawfulness in defense of the personal freedom, because of the fact that they are indeterminate in term, being on time for as long as lasts the social dangerousness, as well as of the fact that they are exposed to a great degree of uncertainty.

In practical terms, it is important to note that medical measures cannot be simply implemented because of the current lack of specialized institutions, such as the psychiatric hospital of Elbasan, but also because of the fact that outpatient treatment in many districts is almost impossible.

Abstract

Inflammation in the tumor microenvironment is an essential aspect of tumor biological activity. Interferon γ and IL-10 are pro-inflammatory and anti-inflammatory cytokines that play a crucial role in regulating the host’s immune response to cancer cells. IFN-γ and IL-10 expression are associated with poor prognosis and low survival rate in breast carcinoma patients. This cross-sectional study was performed on the 60 paraffin-embedded samples of radical mastectomy during January 2016-December 2019 at Anatomical Pathology Laboratory of Dr. Soetomo General Academic Hospital Surabaya. The samples were divided based on tumor size into four groups (T1, T2, T3, T4). The analysis was using Kruskal Wallistest. Immunohistochemical staining was performed to detect the expression of IFN-γ and IL-10. There was a significant difference in IFN-γ expression in the four groups (p=0.005) and no significant difference in IL-10 expression in the four groups (p=0.191). Interferon gamma and IL-10 were important in determining prognosis and targeted therapy in breast cancer patients. These results may contribute to the development of breast cancer research.

Keywords: Breast cancer, IFN-γ, IL-10, T stage.

Introduction

Inflammation in the tumor microenvironment is an essential aspect of tumor biological activity because it is associated with tumor initiation, tumor development, response to therapy, and prognosis. Most cancers arise associated with inflammation that occurs continuously.1,2

The incidence of breast cancer increases with age; 80% of breast cancers appear in women over 50 years. Breast cancer is rare in young women, but it becomes more aggressive, with 5-years survival rates reaching 81% at less than 45 years. Early detection with immunoregulatory cytokines including interferon-alpha, beta, gamma, interleukins 2, 6, and 10, and alpha tumor necrosis factor (TNF), which is often associated with breast cancer and can help determine the patient’s prognosis.3

Interferon-gamma and interleukin 10 are pro-inflammatory and anti-inflammatory cytokines that regulate immune responses and inhibit pro-inflammatory function to antigen-presenting cells (APCs) through the expression of antagonist molecules. Interferon-gamma and interleukin expression are associated with poor prognosis and low survival rates4. IFN-γ has an antitumor function, and a reduced amount of IFN-gamma in the tumor environment is associated with a worse prognosis in breast cancer patients.3

IL-10 overexpression triggers a pro-inflammatory effect by increasing IFN-γ, IL-10, and other IFN-γ-induced releases of monokines. Therefore, giving IL-10 antagonists is expected to be a more effective targeted therapy.5
This research aimed to analyze the expression of IFN-γ and IL-10 and investigate differences in expression at various stages of breast cancer.

**Materials and Methods**

This study was analytic observational research with a cross-sectional approach performed on the 60 paraffin-embedded samples of radical mastectomy during January 2016-December 2019 at Anatomical Pathology Laboratory of Dr. Soetomo General Hospital Surabaya. The samples were grouped based on tumor size into four groups (T1, T2, T3, and T4); each group was 15 samples.

Immunohistochemistry staining was performed to detect the expression of IFN-γ and IL-10. The tissues were cut into four mm sections, deparaffinized three times with xylol for five minutes each, and rehydrated through graded alcohol. Antigen retrieval was achieved by microwave treatment in sodium citrate buffer (pH 6.0) for ten minutes. The tissue sections were then incubated with monoclonal antibodies for IFN-γ (LLO6Z: sc-74108; dilution 1:200; Santa Cruz Biotechnology) and IL-10 (GT5111; dilution 1:100; GeneTex) overnight, followed by the secondary antibody for 10 minutes at room temperature. Sections were then counterstained with hematoxylin and dehydrated with alcohol.

Cytoplasmic staining for IFN-γ and IL-10 were evaluated on tumor cells. IFN-γ and IL-10 are considered positive if expressed in tumor cells’ cytoplasm.5

Two pathologists evaluated all samples in a blinded fashion. Any discordant was solved by interobserver agreement. The expression and comparison of IFN-γ and IL-10 expression in any T stages of breast carcinoma was tested using Kruskal- Wallis and Mann-Whitney U test.

**Results and Discussion**

Kruskal-Wallis test showed difference IFN-γ expression in any T stage breast carcinoma \( (p=0.005) \) (Figure 1), and the Mann-Whitney U test found a significant difference in IFN-γ expression between T1 - T2 and T2 - T3 \( (p=0.03; p=0.04) \) meanwhile there is no considerable difference IFN-γ expression in T3 - T4 \( (p=0.2) \) or other T stages. Interferon-gamma and IL-10 expressed at cytoplasm (Figure 2 and 3). Kruskal-Wallis test showed no difference in IL-10 expression in any T stages breast carcinoma \( (p=0.191) \) (Figure 3). Interleukin-10 is expressed in the cytoplasm (Figure 1).
Interferon-γ (IFNγ) has a vital role in activating cellular immunity and stimulation of the antitumor immune response. Based on its cytostatic, proapoptotic, and antiproliferative functions, IFNγ is considered potential adjuvant immunotherapy for various cancer types. IFNγ may inhibit angiogenesis in tumor tissue, induce regulatory T-cell apoptosis, and stimulate pro-inflammatory M1 macrophage activity to support tumor cells proliferation.6

The statistical analysis results showed a significant difference between IFNγ expression in any T stages breast carcinoma ($p = 0.005$). The most significant
difference between each group on the IFNγ expression was performed using the Mann-Whitney U statistical test. This test shows that the T1 and T2 groups are the groups that have the most significant difference \((p = 0.03)\), and the T2 and T3 groups \((p = 0.04)\) while the T3 and T4 groups did not have a substantial difference with \(p = 0.203\) as well as other groups.

High IFNγ expression was found at stage T1, then decreased at stage T2 and increased again at T3 and T4. In T1 tumors, IFNγ will be secreted in large quantities by pro-inflammatory cytokines to support tumor cell proliferation; at this early stage, the body is still able to adapt to inhibit tumor cell proliferation so that IFNγ levels can be suppressed in T2 tumors, hence inflammatory agents are not eliminated (tumor). The inflammatory process continues, causing an increase in pro-inflammatory cytokines and an accelerated proliferation of tumor cells; as a result, the body cannot keep up with the speed of tumor cell proliferation and loses its homeostasis ability, the tumor size increases, and IFNγ levels increase again at stages T3 and T4.\(^{2,7,8}\)

These results were consistent with the study by Tuñón et al., who found differences in IFNγ expression at various T stages of breast carcinoma, and the highest expression was found at stages T1 and T2.\(^9\) He et al. stated that continuous exposure to IFN-γ had been shown to increase the growth of hepatoma tumors, breast tumors, adenocarcinoma, and melanoma.\(^{10}\) These results indicate that the higher levels of IFN-γ in the tumor microenvironment can increase tumor cell growth and proliferation.

Interleukin-10 is known to have an inhibitory effect on T-cell function and proliferation. Interleukin-10 has also been shown to inhibit antigen presentation by macrophages and Langerhan cells and manifest tumor-related antigens by tumor cells. IL-10 production is associated with the induction of anergy in T lymphocytes so that the tumor utilizes IL-10 production in the tumor microenvironment to escape from the immune system.\(^{11}\)

The statistical analysis results showed no difference in IL-10 expression at various stages of T breast carcinoma with a \(p\)-value = 0.191. Expression of IL-10 tends to be high in all T stages, and the highest is found in staging T4 of breast carcinoma. This can occur because tumor cells naturally produce large amounts of IL-10 themselves. Many human cancer cell lines have been shown to secrete IL-10 into their supernatants. Breast tumor cells have been shown to express high levels of IL-10 mRNA. This elevated expression causes high levels of IL-10 to be expressed in the tumor microenvironment and breast tumor cells.\(^2\) These results are in line with Bhattacharjee et al., which stated that there was no correlation between IL-10 expression and patient age, tumor size (T), and ER status, PR.\(^5\)

Gonzalez-Garza et al. Examined samples from breast cancer patients and normal peritumoral breast tissue. Found a correlation between IL-10 expression and a worse prognosis in breast carcinoma patients, and no IL-10 was expressed in normal breast tissue samples. The determination of IL-10 expression in breast cancer patients suggests that IL-10 can be used as a biological marker to differentiate between advanced cancer.\(^{13}\)

Lianes-Fernandez et al. obtained strong IL-10 expression in 23 of 27 breast cancer patients based on immunohistochemical examination. In another study of 105 samples of breast cancer patients and 13 samples of healthy breast tissue, IL10 expression was only seen in breast cancer tissue and no normal healthy tissue.\(^{11,14}\)

The high concentration of IL-10 in the serum of cancer patients does not appear to be related only to the expression of this protein by the immune system. Evidence suggests that cancer cells can synthesize themselves, thereby causing an imbalance in the homeostasis of the immune system and causing tumors to escape.\(^{13}\)

**Conclusion**

There were differences of IFNγ expression in any T stages of breast carcinoma, and there was no difference of IL-10 expression in any T stages of breast carcinoma.

Abstract

Thyroid crisis is a rare complication of hyperthyroidism, with a greater risk about 10 times during pregnancy, also clinical manifestations and significant increasing of level of thyroxine (T4) and tri-iodothyronine (T3). Thyroid crisis could cause mortality in >10%. A 58-year-old female was referred from Bangkalan Hospital, presented with palpitation, shortness of breath, diarrhea 2-3×/day, vaginal bleeding, fever for 1 day before admittance. Hyperthyroid for 3 years ago and routinely consumed thyrozol (1×2tab) in 2 years but did not take the medicine for 1 year ago. Physical examination: BP 147/100 mmHg, pulse rate 124×/minute, temperature 38.4 ºC, RR 30/minute, conjunctiva anemia, thyroid palpable, exopthalmus. ECG results: presence of sinus tachycardia, Chest X-Ray: cardiomegaly. Burch Wartofsky Score obtained a total score of 45, (temperature 38.5 C=15, diarrhea=10, tachycardia=15, CHF=5). Laboratory results: TSH <0.004 IU/mL, FT4 5.31 ng/dl. Thyroid crisis is a rare case of hyperthyroidism, a greater risk during pregnancy which could lead to death. Many symptoms arise in hyperthyroidism which could lead to thyroid crisis. The criteria which used to assess thyroid analysis is the Burch Wartofsky Score, FT4 levels increased 5.31 ng/dl. This patient was diagnosed as thyroid storm in post-partum, based on Burch Wartofsky Score, low TSH level and an elevated FT4 level and not taking medicine for 1 year ago.

Keywords: Thyroid storm, maternal hyperthyroidism, thyroid function, hyperthyroid.

Introduction

Thyroid crisis is a rare complication of hyperthyroidism, with a 10 times greater risk of occurring during pregnancy1. The term “storm” describes the intensity of clinical manifestations and the significant increase in levels of thyroxine (T4) and tri-iodothyronine (T3)2,3. The incidence of hyperthyroidism during pregnancy is relatively rare and usually treated medically with the drug thioamide. One of the most dreaded symptoms of hyperthyroidism is thyroid crisis/thyroid storm, with a mortality rate of >10%1,2,4,5. In the United States survey, the incidence of thyroid storm ranged from 0.57 to 0.76 cases per 100,000 per year in the normal population. According to the Japanese National Survey, the incidence of thyroid storm is 0.2 per 100,000 population per year, approximately 0.22% of all thyrotoxicosis patients3. Poor control of hyperthyroidism during pregnancy is associated with number of problems, including Intrauterine Fetal Death (IUFD), hypertension in pregnancy, preterm birth, low birth weight, intrauterine growth restriction and maternal congestive heart failure6. Diagnosing a thyroid crisis is not easy, therefore an approach is needed to expedite a thyroid crisis diagnose by using the Burch Wartofsky Point Scale with a value of ≥45 to diagnose a thyroid crisis. The principles of management of thyroid crisis in pregnancy reduce the synthesis and secretion of thyroid hormones, decrease the peripheral effects of thyroid hormones, inhibit the conversion of T4 to T3, therapy to prevent systemic decompensation, therapy of precipitating diseases, pregnancy management and supportive therapy7,8,9,10.
Case

Patient Mrs. H, 25 years, referral from Bangkalan Hospital, 7 hours post-partum, came with complaints of palpitations, shortness of breath (+) and diarrhea 2-3 times/day and fever for 1 day before admittance to the hospital, as well as vaginal bleeding (+). The patient suffered from hyperthyroidism for 3 years, had routine treatment for 2 years, and the last 1 year did not take PTU drugs. Physical examination: Blood pressure: 147/100, pulse 124×/m, temperature 38.5°C, RR 30×/m, anemia, palpable enlargement of the thyroid, exophthalmus with a stell wag’s sign (+). ECG results: sinus tachycardia, chest X-ray results: cardiomegaly. The Burch Wartofsky Score got a total score of 45, (temperature 38.5 °C=15, diarrhea=10, tachycardia=15, CHF=5). Laboratory results TSH values <0.004uIU/mL, FT4 5.31 ng/dl.

Pulmo did not appear abnormal.

**Discussion**

Thyroid crisis is a rare complication of hyperthyroidism, with a 10 times greater risk of occurring during pregnancy. Patients with hyperthyroidism during pregnancy with poor control could precipitate a thyroid crisis.\(^1\) In this case, there was poor control during pregnancy where patient stopped taking the drug for a year. The patient was referred from Bangkalan Hospital, 7 hours after post-partum, with complaints of palpitations, shortness of breath, and diarrhea 2-3 times a day for 1 day before admittance to the hospital, vaginal bleeding and fever was also complained of. Theoretically, pregnancy will cause an increase in Thyroid Binding Globulin (TBG) levels which result in an increase in total T4 and T3.\(^5\) Pregnancy could worsen the state of hypertiroidism, resulting in various symptoms. Clinical symptoms which arise such as fever, tachycardia, heart failure, decreased consciousness, seizures, gastrointestinal disorders.\(^2,4,6\)

The patient had a 3-year history of taking the drug and stopped taking the drug for the last 1 year. There were clinical symptoms of fever, diarrhea, tachycardia, rapid breathing and shortness of breath, therefore the patient was referred to the hospital. Cardiomegaly was found on the chest X-ray and to diagnose a thyroid crisis is not easy using the Burch-Wartofsky Point Scale (Table 6).

Through this patient’s case was found a Burch-Wartofsky Score 45, fever with a temperature of 38.50°C=15, diarrhea=10, tachycardia=15, CHF=5, where with a score of ≥45 a thyroid crisis was concluded. Patients who are suspected to have a thyroid crisis based on criteria should be treated intensively. The flow of thyroid crisis management is according to the Japan thyroid storm guidelines (Figure 1). Patients with a history of medication and stopping medication are more likely to develop a thyroid crisis. Patients were evaluated for A, B, C, D, E, treatment and referred to the thyroid crisis diagnosis algorithm. Laboratory results TSH value <0.004uIU/mL, FT4 5.31 ng/dl, anemia, also low albumin in the presence of laboratory results which support a thyroid crisis2,4,5,6. When patients are diagnosed by thyroid crisis should be suggested with PTU 600 mg/day4,7,8.

**Conclusion**

Thyroid crisis is an emergency characterized by acute hypermetabolic rapid deterioration of a life-threatening condition. Early suspicion, prompt to diagnosis and intensive treatment which will improve survival in patients with thyroid crisis. The diagnosis criteria for thyroid crisis using the Burch Wartofsky Score, this patient obtained a score of ≥45 and with a history of stopping taking PTU drugs for 1 year.

1Scholar Researcher, Msc, Clinical Biochemistry, Nahrain University College of Medicine, Iraq, 2Scholar Researcher, PH.D Clinical Chemistry, Department of Biochemistry, College of Medicine, University of Baghdad, Iraq, 3Scholar Researcher, Prof.Dr (Consultant) Urologist, Department of Urology, College of Medicine, University of Baghdad, Iraq, 4Scholar Researcher, Consultant Urologist, Center of Urology, Al-Yarmouk hospital, Iraq

Abstract

Background: Both benign prostatic (BPH) and prostate (Pca) hyperplasia include prostate enlargement. The distinction between benign prostatic hyperplasia and prostate cancer is a major challenge, since the prostatic specific antigen (PSA) cannot be considered a reliable predictor of prostate cancer. Aims: Efficiency of serum thymidine kinase 1 and PSA-related biomarkers in prostate tumor, BPH and PCa diagnosis and differentiation, especially when serum PSA is in the gray (4-10 ng/ml) region and in the pronostic of these patients after surgical therapy. Subjects and Methods: A case control and cross-sectional review. There were 110 elderly patients (45-81 years) and 45 controle. Serum experiments involved the use of ELISA technologies to measure tPSA, fPSA, and TK1. Result: In comparison to both of the BPH and controls, the mean (±S D) of serum tPSA and fPSA in Pca were significantly improved (all p =0,001) while the mean value of f PCa in comparison with BPH and control was dramatically decreased (p = 0,001) for fPSA/tPSA. There was no difference between BPH and controls in these parameters. In both of the Pca and Controls (P<0.001) the mean TC1 was slightly higher (P<0.001). This serum TK1 has the most receptive and specific diagnostic and differentiating potency in the gray zone of tPSA (4-10 ng/ml), which has tPSA in the gray zone with AUC=1 in the 924 pg/ml cut-off zone.

Conclusion: Serum level of TK1 was superior of tPSA in diagnosis of prostate tumor and differentiating between BPH and PCa.

Keywords: Serum, Thymidine Kinase 1, prostatic tumor

Introduction

Prostatic Cancer (PCa) is a complex and heterogeneous disease and the most common malignancy in males worldwide, and the second-leading cause of cancer-associated mortality. While the prevalence of PCa in Arab countries is lower than that in Western countries (1). The majority of PCa cases are indolent and localized at diagnosis, localized tumors can develop into aggressive tumors in the long term (2). A major clinical challenge in prostate cancer clinical management is posed by the inability of current diagnostic tests, such as serum PSA testing, digital rectal examination, and histopathologic grading of tissues, to discern between indolent and aggressive disease (3). Prostate enlargement, is a condition that affects the prostate gland in men. The incidence of occurrence of BPH has recently been estimated at 42% in males aged 51–60, 70% in those aged 61–70 and 90% in males between 81–90 years (4). A homo dimer with an underunit size of 25 kDa is the essential intracellular shape of TK1. In the event of DNA disruption in advance of a new synthesis, intracellular TK1 dimers may be easily transformed into active tetramer (5). TK1 is released from cell death through proliferation; an indicator of cell disruption is the concentration of TK1 in extracellular fluid. Regular cells rarely disintegrate during proliferation and normally, like malignancies, only occur during rapid or non-regulated proliferation. Following its release, TK1 forms
complexes of various molecular weights and enzymes, which is an important element in developing tests (6). TK1 moves the phosphate from ATP and transforms deoxythymidine (dT) to deoxythymidine (dTMP). Monophosphate is exposed to additional phosphorylation of DNA-incorporated deoxidation thymidin triphosphate (dTTP). dTTP self-regulates TK1’s negative feedback DNA precursor synthesis (7). TK1 activity is regulated by the cell cycle and has a distinct pattern of activity compared with tumor cells in normal proliferating cells (2,8).

**Material and Method**

This case-control study took place at the University of Baghdad, the Department of Biochemistry, the University and the Ghazi Al-Hariri Hospital for Specialized Surgery/Medical City in September 2019 to March 2020. During this period the study was conducted. The range of patients (45-81 years) included 110 patients; BPH (n=55) and prostatic cancer (n=55) and controls were 45. The consultant Urologist and Oncology Group was able to obtain diagnosis of BPH and PCa. Each individual obtained formal consent. The Scientific Committee of the department of Biochemistry, University of Baghdad (Iraq), accepted our ethics in this regard. Exclusion criteria is any other conditions such as prostatic intraepithelial neoplasia and other non-malignant diseases of the prostate are excluded in this study and Chronic disease cases like renal failure. The peripheral vein venipuncture of each patient and healthy control woman was extracted by five milliliters of blood, transferred to the simple tube and allowed to coagulate over 15-30 minutes and the serum had been isolated by centrifugation over 10 minutes at 2500-3000 rpm, and stored at 20°C, until the day of the assessment of the TPSA, PSA, and Thymidine (TK1). TK1 kits were provided from My BioSource, Inc., USA.

**Result**

The mean (±SD) values of serum TK1, TPSA, FPSA and fPSA/tPSA ratios of the groups studied are shown in Table 1. Compared to BPH and controls (for all; P<0.001), and Pca serum TK1 levels was significantly higher. The mean value of BPH serum TK1 was significantly higher than that of the controls (P<0.001). Compared to BPH and controls (both P=0.001), the mean (±SD) value of Pca serum tPSA levels was significantly higher. After all, there was no significant difference in tPSA between BPH and controls. In Pca the mean (±SD) value of serum fPSA was slightly higher than in BPH (P=0.001) and controls (P=0.001), respectively. Variance between BPH and controls is also not significant. The mean (±SD) of the fPSA/tPSA ratio of BPH (P=0.001) is also seen in the same table and the controls (P=0.003) is slightly higher than the Pca ratio with no other significant difference.

In the gray zone, tPSA was 69 patients (4-10 ng/ml). Fifty-three (73 percent) of them were with PBH and 16 (22 percent) were with Pca, indicating that those with BHT are the largest patients with tPSA gray zone. In PBH and Pca patients in Gray Zone, Table (3) indicates the mean value (±SD) of tPSA, fPSA, fPSA/tPSA, and TK1. The mean value of serum tPSA between Pca and BPH was not substantially different. In Pca, the mean value of serum fPSA in comparison with BPH was significantly lower (P=0.01). The mean fPSA/tPSA ratio value was also considerably lower at Pca than at the BPH stage (P=0.01). In Pca patients, the mean value of serum TK1 was slightly higher than in BPH patients (P<0.0001).

Discussion

The findings of this study showed that tPSA and Pca values in Pca were substantially higher in average values than patients with BPH and stable controls (Table 1) (1; 9;10). Furthermore, the present research finding that the mean fPSA/tPSA ratio in Pca patients has been considerably reduced to those of BPH that is consistent in the fPSA/tPSA ratio (11,12) finds that fPSA/tPSA is significantly lower in Pca than in BPH.

The current study has shown that the best cutoff of tPSA was 10.1 ng/ml for the differentiation of Pca from BPH patients, with 100%, 71% for sensitivity, and AUC 0.85, with 98% for specificity 4.30 ng/ml for Pca and for healthy individuals. In patients with BPH and healthy persons, the optimal cut for tPSA was 4.20 ng/mL with AUC=1.00, respectively (table 2), indicating that tPSA level of 4.25 ng/ml is useful in discriminating prostate diseases from healthy individuals. Razzaghi et al. observed in the evaluation of Cancer of the Prostate Strategic Urologic Research (CAPSURE) cohort in the United States that median of tPSA at diagnosis in the higher screened Swedish counties was 10.80 ng/ml (13).

Erdogan et al. found that PCa was diagnosed in 35.1% of their patients and clinically significant variations in f/t PSA were found in patients with and without PCa (14). The current study bought a significant increase in the mean value of TK1 serum levels in the Pca group relative to the BPH group and healthy controls and in the BPH patients compared to experiments that had previous studies agreed to (15;6). The results showed that the serum TK1 evaluation was an excellent biochemical marker for differentiating Pca patients from healthy individuals. Razzaghi et al. observed in the evaluation of Cancer of the Prostate Strategic Urologic Research (CAPSURE) cohort in the United States that median of tPSA at diagnosis in the higher screened Swedish counties was 10.80 ng/ml (13).

The current study bought a significant increase in the mean value of TK1 serum levels in the Pca group relative to the BPH group and healthy controls and in the BPH patients compared to experiments that had previous studies agreed to (15;6). The results showed that the serum TK1 evaluation was an excellent biochemical marker for differentiating Pca patients from healthy individuals with a cut-off of 924 pg/ml (AUC=1.00). Serum TK1 is also outstanding for differentiating BPH from healthy controls at 412 pg/ml (AUC =1) (table 2).

TK1 levels are high in all prostate cancer patients and even higher in patients with severe prostate cancer (16). It is indicated that serum TK1 can be used in the screening of BPH or PC patients and that tPSA is a less reliable prostate screening method compared to STK1.

The gray zone The Bewildering outcome is characterized by serum tPSA level between 4-10 ng/ml; whether BPH or PCa is the condition, resulting in unnecessary prostate biopsies. Out of a total of 235 patients with tPSA level, Psa2 Liu et al. found that the results of the gray zone biopsy were negative for 179 (76.2%) patients (non-PCa group) and positive for 56 (23.8%) patients (PCa group) (14). The result found that the serum TK1 level at a cutoff value of 924 pg/ml (AUC=1, Table 4) was the most sensitive and specific biochemical marker for differentiating between PCa and BPH patients with gray-zone tPSA. However, the tPSA, fPSA, fPSA/tPSA ratio serum measurements were poor biochemical markers for differentiating prostatic origin in the gray zone (table 3). It was concluded that serum TK1 concentrations in patients with BPH and PCa were considerably higher relative to healthy people, suggesting that the serum TK1 concentration could be used to monitor for prostate complications. The individual serum TK1 values between BPH patients and PCa patients, it can be impractical to differentiate between these two categories by measuring STK1 concentration alone. BPH patients with elevated STK1 concentrations are expected to have an increased chance of progression of malignancy (15). Hanousková et al. observed that TK-1 serum levels were dramatically elevated in prostate cancer patients relative to healthy individuals and concluded that the determination of TK-1 serum concentration may be a valuable measure also for prostate cancer risk screening in individuals (16). TPSA levels above 4 ng/mL and below 10 ng/mL have a ~25 percent risk of PCa occurrence, according to the American Cancer Society, and tPSA levels above 10 ng/mL increase the probability of PCa occurrence by more than 50 percent (17).

Conclusion

In the diagnosis of prostate tumor and differentiating between BPH and PCa, the serum level of TK1 was superior to tPSA, particularly when tPSA was present in the gray zone, which could prevent the need for invasive
prostatic biopsy in such a distinction.

Stigma and Mental Health during COVID-19 New Normal Transition in Indonesia

Leny Latifah¹, Yusi Dwi Nurcahyani¹, Diah Yunitawati¹, Marizka Khairunnisa¹, Cati Martiyana¹
¹Magelang Health Research and Development Center, Ministry of Health, Indonesia

Abstract

Background: Social isolation and economic catastrophic became the main characters of the current pandemic. Historically, the strongest stigmas related to diseases were characterized as highly transmittable, potentially lethal, and without remedy. All represented COVID-19 during the early transition into the new normal. We aimed to analyzed stigma and economic stressors concerning mental health. Method: We conducted a cross-sectional online survey of 1375 participants in Java, Indonesia. Mental health status evaluated with DASS-21. The presence of social and self-stigma related to Covid-19 assessed with a questionnaire developed based on seven domains of public stigma. Demographics and other psychosocial stressors were assessed with an online questionnaire. Descriptive analyses and logistic regression had carried out. Result: A very high percentage of perceived and anticipated self-stigma and social stigma revealed. Controlling demographics factors, clear self-stigma increased the risk for depression (2.323 (1.241-4.346), p<0.05), anxiety (2.134 (1.205-3.777), p<0.05) and stress 3.931 (1.779-8.685), P<0.001). Clear social stigma increased the risk for anxiety (2.000 (1.066-3.756), p<0.05) but not on depression and stress. Conclusion: Ensuring basic needs fulfilment and eliminating stigma is critical for supporting mental health in the Covid-19 pandemic. Further research into the stigma-related risks is necessary because it represents an important need for intervention in public health.

Keywords: stigma, mental health, COVID-19

Introduction

Awareness, anxiety, and distress due to rapid changes and uncertainty, according to the World Health Organization (WHO) are natural psychological responses¹. But beyond natural responses, COVID-19 stated as the perfect vector for psychological distress pandemic. Mitigation measures of COVID-19 forced people to isolate themselves from one another when social support and togetherness were most needed²,³. Rising concern on the importance of understanding mental health problems during the COVID-19 pandemic proved by extended researches on the general population and/or health workers’ mental health condition during the COVID-19 pandemic⁴. Every phase of a pandemic had its characteristics, therefore understanding mental health dynamics in each unique phase is important.

WHO declared the crisis of COVID-19 global outbreak as a pandemic on 11th March 2020⁵. Indonesia announces first and second patients with positive COVID-19 virus on 1st March 2020⁶. To contain COVID-19 transmission, mass social and physical distancing was declared. If it is essential to go outside their home, face masks wearing, avoid gathering, and maintain physical distance is emphasized⁷. After almost three months of mass social distancing, on 1st June 2020, the Indonesian government declared the new phase of “transition into new normal” which later changed the term into “new habit adaptation”⁸. New normal phase marked by gradually lifting stay-at-home measures and
reviving the economic activities. Indonesia enters the new normal phase in the still steep rising confirmatory person contracting COVID-19 situation, and the effective medicine and vaccine to inhibit COVID-19 infection had not been available. It leads to a heightened risk of infection and possibly psychological distress.

Historically and nowadays, the strongest stigmas related to diseases are characterized as highly transmittable, potentially lethal, and without an acknowledged remedy, all could find in COVID-19 during the transition into the new normal. Studies relating to stigma and mental health in COVID-19 mostly came in a conceptual study or qualitative research. There still limited study relating mental health to stigma COVID-19 in quantitative research with a representative sample, and no scientific manuscript found in an Indonesian context. Research on Vietnamese health workers and the Canadian general population found stigma worsen mental health condition. To fill the gap, this research aimed to assess health workers and general population stigma and mental health during the transition into the new normal. Finding from this research could potentially support policymakers in formulating comprehensive interventions.

**Material and Methods**

**Participants**

We adopted a cross-sectional survey design by using an online questionnaire. A snowball sampling strategy focused on recruiting the general population and health workers living in 5 provinces of Java Island (Central Java, East Java, West Java, Special Capital Region of Jakarta, Special Region of Yogyakarta, and Banten), Indonesia was utilized. Participants were recruited by sending the survey through various social network channels. The final sample obtained with the snowball method was 1,385 people. Inclusion criteria were a participant aged 15-64 years to ensure the understanding of questions based on their knowledge and attitudes.

**Variables and Instruments**

Stigma about COVID-19 was measured using seven-domain public stigma from Pescosolido and Martin. Stigma domains measured including social distance, traditional prejudice, exclusionary sentiments, negative affect, dangerousness perceptions, also carryover in treatment and disclosure. A social and self-stigma scale was developed for this research. Social stigma included peoples’ beliefs and negative behavior related to COVID-19. Self-stigma covered perceived and anticipated stigma, covering personal concerns about negative judgment and behavior when diagnosed as COVID-19 positive, and actual and anticipated stigma in participants with the experience of COVID-19 positive diagnosed. The stigma scale uses a 4-point Likert scale (1: strongly agree; 2: agree; 3: disagree; 4: strongly disagree) to measure agreement with statements about each domain. The score was calculated by adding responses from items and dividing by the total number of items in the domain. A mean score above the midpoint (2.0) indicated a stigmatizing attitude, with higher scores indicating more severe stigma. In this research the score further divided into: 0-2 non stigma; >2 - <3: suggestive for stigma; >3 clear stigma. The reliability of social and self-stigma was 0.795 and 0.800 (Alpha Cronbach). Social and self-stigma had 14 and 10 items. The self and social-stigma items are carefully structured with several tryouts to ensure the balancing concern of COVID-19 precautionary measures with stigma mitigation.

Mental health status was measured using the Depression, Anxiety, and Stress Scale (DASS-21). The DASS-21 is a self-reported tool containing 21 items (7 per scale) that assess three constructs: depression, anxiety, and stress. Participants read statements about the constructs and picked their answers using a 4-point Likert scale ranging from 0 (Did not apply to me at all) to 3 (Applied to me very much or most of the time). Items comprising the scales are summed and doubled to be equivalent to the longer DASS-42 version. The cut-off was using normative DASS-42 data, divided into normal, mild, moderate, severe, and very severe.
Several studies of DASS-21 showed good psychometric results. Demographic data had collected on age, gender, education level, employment status, monthly income, and marital status.

**Statistical Analysis**

Descriptive statistics had used for continuous and categorical variables. Logistic regression analysis had done to determine the relationship between stigma and mental health status. All the analyzes had conducted using IBM SPSS Statistics v.21. The level of significance had set at 5%.

The study has approval from The National Institute of Health Research and Development Ethics Committee, Indonesia (LB.02.01/KE.386/2020). Research information is given in the first section of the online questionnaire. Respondents stated informed consent before starting to fill the data.

**Result**

Participant characteristics are described in Table 1. The sample (N = 1385) were mostly women (74%), with university studies (86.2%), married status (70.5%), and non-health workers (65.8%). The average age was 36.8, reflecting a majority of persons aged between 26-45 years old (63.2%). Being younger (OR 2.426 95% CI 1.601-3.674, p<0.000; OR 3.661 95% CI 2.490-5.383, p<0.000; OR 3.814 95% CI 2.123-6.852, p<0.000), lower education (OR 1.871 95% CI 1.340-2.613, p<0.000; OR 2.085 95% CI 1.528-2.845, p<0.000; OR 2.454 95% CI 1.613-3.736, p<0.000), and no married status (OR 2.052 95% CI 1.575-2.674, p<0.000; OR 2.201 95% CI 1.728-2.804, p<0.000; OR 2.540 95% CI 1.772-3.639, p<0.000) correlated with higher risk of depression, anxiety, and stress. Being health workers lower the risks for anxiety (OR 1.396 95% CI 1.092-1.784, p < 0.05).

Self-stigma (perceived and anticipated stigma) and social stigma were reported by 84.1% and 93.4% of the participants. Clear self-stigma (score > 3) increased the risk for depression (2.323 (1.241-4.346), p<0.05), anxiety (1.512 (1.081-2.117), p<0.05) and stress (OR 2.717 (1.515-4.873)**, p<0.05). Higher mental health problems reported among participants who had a clear social stigma (32.0% vs 16.8% in depression, 43.5% vs 22.1% in anxiety, 14.3% vs 8.4% in stress). Participants suggestive for social stigma could lead to

statistically significant results on anxiety (OR 2.000 95% CI 1.066-3.756, p<0.05), but not on depression (OR 1.618 95% CI 0.820-3.193, p>0.05) and stress (OR 1.052 95% CI 0.417-2.655, p>0.05).

**Discussion**

Our research revealed that 22% of respondents depressive, 31.3% anxiety, and 9.6% stress symptoms, 14.2%, 18.8%, and 4.4% of the respondents revealed moderate to severe degrees of depression, anxiety, and stress. Compared to the general population with the same measure of DASS-21 in the earlier phase of the pandemic\textsuperscript{20,21}, our result shows a lower prevalence of depression, anxiety, and stress. Even lower when compared to research in a specific population of psychiatric patients\textsuperscript{22}, doctors\textsuperscript{23}, and health workers in Indonesia in the earlier phase of pandemic\textsuperscript{24}. The general population had a higher risk of anxiety compared to health workers in transition into the new normal. It contradicts research in Saudi Arabia and China that showed medical field workers had higher scores on sleep deprivation, stress, and depression\textsuperscript{21,25}. Better access to medical and health facilities of health workers also may serve as protecting factors.

While there is a tendency towards a lower prevalence of psychosocial distress in the general population and health workers in this research compare to the previous phase, a very high prevalence of stigma was found. Stigma towards self and others both increased the risk of depression, anxiety, and stress. This study, encompassing health workers and the general population, strengthen several previous research on COVID-19 related stigma in a more specific group. Internalized stigma, shame, and guilty feeling in hospitalized COVID-19 patients triggered by the fear of virus infections, and worry about community acceptance\textsuperscript{26}. Research on health care providers in Lebanon had found symptoms of stress, frustration, fear to contract the virus, and stigma of being infected\textsuperscript{13}. Historically and nowadays, the strongest stigmas related to diseases are characterized as highly transmittable, potentially lethal, and no acknowledged remedy\textsuperscript{12}, all could find in COVID-19 during the transition into the new normal. It could explain the very high percentage of participants considered having self and social stigma. Accurate discernment is necessary between optimizing the effort to contain the risk of infection and reducing the fear, stigma, and blaming others\textsuperscript{27}. Educating the public about COVID-19, reasons for isolation, and providing adequate health information can contribute to reducing stigmatization in the community. It serves as early identification and treatment to reduce the development of mental health problems\textsuperscript{28}. Training is needed for health workers and professionals to improve the mental health and knowledge of COVID-19 of the community\textsuperscript{29}. The role of the government and community leaders in COVID-19 education to the public can contribute to increase health literacy at the community level to prevent stigma related to COVID-19.

The current study presents several limitations. Firstly, we used online convenience sampling that may not represent the Javanese population. The use of online tools has limitations and challenges. The digital divide (people who do not access the internet, such as the lower education are lower in scope compared to participants with high education, with these groups being underrepresented) and validity concern (for example whether the participant is as they say). Our protocol strives to carry out rigorous validity checks to reduce some of these inherent problems.

**Conclusion**

The very high prevalence of stigma during early transition into new normal in Indonesia became important note. Once a pandemic with unknown cure could cause widespread stigma. Clear self and social stigma related to worsening mental health condition in early transition into new normal. Several demographic characters as young people (<25 years old), having non-marital status, and lower education related to worsening mental health condition. Healthcare workers had better mental health status than the general population. This research provides several directions for future research. Eliminating stigma is critical for supporting mental health in the Covid-19
pandemic. The anxiety towards higher risk of infection due to new normal transition conceivably manifested in stigma towards self and others. Intervention to enhance mental health conditions should also be considered a vulnerable group identified like young people and lower education group.

Acknowledgment: The authors would like to thank the Head of National Institute of Health Research and Development and the Magelang Health Research and Development Center. The supports was important for this research. We also thank the cooperation and support of all the participants. The time and effort devoted to this research were valuable.

Funding acknowledgement: This research supported by National Health Institution for Research and Development, Ministry of Health, Indonesia.

Abstract

Background: WHO declared COVID-19 as a global pandemic due to its rapid spread and has been confirmed worldwide. Preventive efforts are made to minimize the virus spread among the community. Sociodemographic factors play an integral role in determining the community’s knowledge, perception, attitudes, and practice towards COVID-19 prevention protocols.

Methods: This review was conducted on various journal articles to see the sociodemographic factors that influence the levels of knowledge, perceptions, attitudes, and practices of the community towards COVID-19 prevention protocols. Journal articles were selected under the PRISMA guidelines, from which 28 articles were found to meet the predetermined criteria.

Result: Several sociodemographic factors found to affect the levels of knowledge, attitudes, practices, and perceptions of respondents towards the COVID-19 prevention protocols were age, gender, education, marital status, occupation, socio economic status, area of residence, and nationality.

Conclusion: Education and socio economic status/monthly income were found to be the main factors that influenced the respondents’ level of knowledge. Individuals with higher education tended to take health problems more seriously, as shown by their better scores of compliance with the COVID-19 prevention protocols, compared to the scores shown by other groups.

Keywords: Sociodemographic factors, knowledge, perception, attitudes, and practice, COVID-19

Introduction

World Health Organization declared COVID-19 as a global pandemic due to its rapid spread and has been confirmed worldwide. Preventive efforts are made by many countries to minimize the virus spread among the community. The effectiveness of these mitigation steps highly relies upon the cooperation and compliance of all community members. Knowledge, perceptions, attitudes, and practices towards COVID-19 play an integral role in determining the community’s readiness to accept behavioral change and health authority actions. Some research works indicate that public knowledge is important in dealing with the pandemic.

People around the world have varied levels of knowledge, perceptions, attitudes, and practices towards the COVID-19 pandemic. They are influenced...
by various factors to form new habits as encouraged by policymakers. In the concept of health behavior, socio-demographic factors have a strong influence on the levels of knowledge, attitudes, and practices. Assessing various socio-demographic factors inherent in society and influencing public awareness and knowledge about COVID-19 can provide deeper insights into community perceptions and practices in implementing the established prevention protocols.

**Research Objectives**

The aim of this scoping review was to critically synthesize scientific proofs of sociodemographic factors that affect the level of knowledge, perceptions, attitudes and practice of community towards COVID-19 prevention protocols. During the pandemic, information related to socio-demographic factors that affect knowledge, perceptions, attitudes, and practices is necessary. It is related to efforts to understand matters that affect the level of public awareness towards COVID-19 and the health protocols established by the authorities.

**Methods and Analysis**

**Search Strategy**

A systematic search following the PRISMA guidelines (Fig. 1). The authors conducted a scoping review of journal articles with a focus on community knowledge, perceptions, attitudes, and practices towards COVID-19 prevention protocols. This study was conducted to determine the extent to which the factors influence the level of public knowledge, perceptions, attitudes, and practices towards the COVID-19 prevention protocol. Articles were derived from four electronic bibliography databases—PubMed, Science Direct, ProQuest, Scopus, EBSCO, and DOAJ—using the keywords “knowledge” OR “attitude” OR “practice”, “public perception”, AND “COVID 19”. The authors also searched extra articles with search engine Google Scholar by manually checking out the references of the review articles identified. Literature search was commenced in July 2020 and ended in October 2020. There was no limit as to the dates and years of publications given that the COVID-19 pandemic was first confirmed at the end of 2019.

**Articles Selection and Restrictive Criteria**

The title and abstract of every publication were to be screened to obtain a relevant article. The restrictive criteria in this scoping review consisted of inclusion and exclusion criteria. The inclusion and exclusion criteria were developed based on the PICOS (Population, Intervention, Comparison, Outcome, and Study Design) standard to include the following: 1) the populations and samples extracted were community groups in general during the COVID-19 pandemic; 2) the publications’ interventions took the form of questionnaires related to community knowledge, attitudes, practices, and perceptions on COVID-19, include sociodemography characteristics of the respondent; 3) the results were in the form of measurements articles on sociodemographic factors that affect the variables of knowledge, attitude, practice, and perception to the pandemic; and 4) the studies used the observational research design with a cross-sectional approach. Articles would not be considered meeting the criteria if they used focused on a specific group of populations (e.g., health service providers, health personnel, students, age groups, or patients with particular comorbidities).

**Screening and Data Extraction**

The manuscripts filtering and extraction to retrieve information covered the following six domains: 1) Lead authors; 2) Country/region. 3.) Methodological characteristics (study design, study objectives, research questions or hypotheses, sample characteristics, sampling method, and statistical analysis); 4) Sample size;5) Main findings, relationships between variables (e.g., the ratio at 95% confidence interval and p<0.05); 6) Conclusion. The data from all journal articles were summarized by category and conceptual framework. This process involved synthesis, analysis, and interpretation of the data from the studies to understand the mechanism of identified sociodemographic factors.
Measurement Instruments

The majority of the studies measured sociodemographic factors and the level of knowledge, perceptions, attitudes, and practices on COVID-19 using online questionnaires. The questionnaires used Google Forms, Survey Monkey, Alphabet Inc, and Wenjuanxing links. The questionnaire links were spread via social media platforms such as Facebook, WhatsApp, Twitter, and WeChat app. Two articles distributed questionnaires directly to willing respondents. The research was conducted by spreading questionnaires to pedestrians and from door to door or at gathering points. Questionnaires were given to people who were willing to participate.7,8

Results

Articles Selection

Initial search gained a total of 945 studies from 4 databases, namely: PubMed, ProQuest, ScienceDirect, and DOAJ. The authors also searched via search engine Google Scholar and found 10 additional articles. Before conducting a review on the articles, a duplication extraction process was completed. The selected duplication-free papers review process was performed in three stages: a review of the title, abstract, and the entire article. Out of 945 papers, 481 were excluded due to duplication. Upon complete screening, a total of 28 articles were found to meet the criteria for review.

Research Characteristics

Study characteristics from 28 articles are presented in Table 1. The 28 journal articles averaged the sample sizes at 201, with the highest number of respondents being 6,910. The total number of participants in all articles was 48,338. The participants’ average age was 12 years to 65 years old. Female participants (n: 26,994) outnumbered male participants (n: 21,344). The 28 articles were based in 18 different countries, namely Egypt (1 article), Pakistan (1 article), Saudi Arabia (3 articles), Nepal (2 articles), Malaysia (1 article), Ecuador (1 article), Lebanon (1 article), Jordan (1 article), Bangladesh (3 articles), India (3 articles), Sudan (1 article), Iran (1 article), China (3 articles), Cameroon (1 article), Vietnam (1 article), Nigeria (1 article), Indonesia (1 article), and Ghana (1 article).

Sociodemographic factors in journal articles focus on age, gender, education, occupation, socio-economic status/monthly income, marital status, and region/area of residence. Some journals involving more than 1 country, or involving foreigner in data collection, also study the nationality factor of the respondents.

Measurement Instrument

The majority of the studies measured using online questionnaires. The questionnaires were shared via Google Forms, Survey Monkey, Alphabet Inc, and Wenjuanxing links. The questionnaire links were spread via social media platforms such as Facebook, WhatsApp, Twitter, and WeChat. Two articles distributed questionnaires directly to willing respondents. Questionnaires were given to people who were willing to participate while still obeying the health protocols.7,8

Sociodemographic Factors

Age

Age can be a determining factor in taking health measures. Younger age is associated with higher access to social media, as a source of information, than older age.9,10 Respondents from the older adult group who were over 50 years old had a lower level of knowledge, compared to the other age groups.8,11 However, other studies found that those aged 30-50 years had a higher level of knowledge, compared to those in the 18-29 years age group.3,6,12,13 The higher the age, the better the attitude shown towards the COVID-19.13 This was in line with the practice shown by respondents aged over 30 years who tended to show higher prevention practices, compared to those in younger age groups.8,9,13

Gender

In some articles, there was no significant difference in the level of knowledge possessed by men and women.7,9,12 However, other research stated that women had a better level of knowledge and attitudes than men.
The majority of female respondents, compared to the male ones, paid more attention when filling out the questionnaire. This condition might affect their COVID-19-related attitude scores. Female respondents also tended to have a positive attitude 1.9 times higher than that of the men. This was related to the habit of women to be responsible for maintaining family hygiene and teaching their children. Men had a significant relationship to dangerous practices in dealing with COVID-19.

**Education**

Respondents’ education level is affected their levels of knowledge. The study found that respondents with a bachelor’s degree or higher education had a significantly higher level of knowledge, compared to those with less education. The knowledge of respondents, towards COVID-19, with high school education was at least 4.7 times higher than that of those who did not have formal education. Educational status was the strongest predictor of the levels of knowledge and perceptions of participants.

**Marital Status**

Respondents who were not married had a better level of knowledge than those who were married. This could be related to their education level. Unmarried respondents tended to be young and have a higher educational background. In other studies, it was found that married respondents showed better prevention practices than those unmarried. Young and unmarried men showed lower prevention practices, compared to the other groups. An optimistic attitude regarding the handling of COVID-19 was also shown by married respondents.

**Occupation**

Respondents with a scientific background or working in the health sector showed a better level of knowledge, perceptions, and attitudes than those without a background in the health sector. There were surprising results regarding the occupation and the level of attitude shown. The attitude score for respondents who worked as government staff was low, compared to that of domestic workers.

**Socio Economic Status/Monthly Income**

The respondents’ levels of knowledge increased along with their income levels. Likewise, an increase in positive attitudes and practices occurred in line with the increasing level of income.

**Region/Area of Residence**

Several articles in this review examined the area of residence as one of the sociodemographic aspects of the respondents. The area where the respondent lived had a significant effect on knowledge, perceptions, and attitudes towards the risk factors for COVID-19. People who lived in urban areas tended to have a higher level of knowledge than those who lived in villages. Low levels of knowledge and perceptions occurred in the general public, especially those in rural areas and without internet access. The compliance with the instruction to wear masks was lower by residents in areas with less serious cases of COVID-19, compared to residents in areas with high case rates. Residents living in areas with a low incidence of COVID-19 believed that they were at lower risk of contracting the COVID-19 virus. The low incidence of transmission in the area at the time of the survey affected the level of community compliance with the COVID-19 prevention protocols.

**Nationality**

Studies involving two countries that also included respondents with other nationalities considered nationality as one of the sociodemographic aspects of respondents that can affect the levels of knowledge, perceptions, attitudes, and practices of society towards COVID-19. In a study involving 2 countries, namely Nigeria and Egypt, it was found that the Nigerian population had a positive attitude which was 11x higher than that of the Egyptian population. In a study that included respondents with foreign citizenship status, it was found that those who were native to that country...
had more positive levels of knowledge and attitudes, compared to foreigners 5.

**Discussion**

*Sociodemographic Factors towards Knowledge*

Several sociodemographic factors also influenced the level of public knowledge about COVID-19. Several articles showed that women were more knowledgeable and aware than male participants. This condition was linked to their innate concern for the condition of their children and their families, which prompted female participants to read and learn more about COVID-1930.

Low socioeconomic status was closely related to an individual’s level of education. Individuals lacking formal education were more likely to be unemployed, which resulted in reduced income, resulting in poor health quality 31. One of the articles reviewed revealed that the level of individual knowledge increased with their high income. Low scores of participants were known to come from those with low income, and the highest scores were obtained from those categorized obtaining high income 6. The percentage of the high level of knowledge was also influenced by the level of education of the respondents; those who were university graduates and aged over 30 years had a good level of knowledge towards COVID-19 16.

Low knowledge scores are associated with older respondents, who live in rural areas, with low levels of education and monthly income 16. Most of the studies showed that the level of respondents’ knowledge of COVID-19 was related to their access to social media as a source of information at a younger age 30. A high level of knowledge also shows a positive relationship between respondents and their works, as a health worker, with high social status23. Respondents with non-working backgrounds have low scores on knowledge related to COVID-19 23.

*Sociodemographic Factorstowards Perception*

The education level and nationality of respondents influenced their perceptions of global and community responses to reduce the transmission of COVID-19 through various policies. Respondents with higher education and medical background showed positive perceptions of global responses 10. Correct perceptions towards COVID-19 transmission, treatment, and prevention measures were shown by those with higher education. Besides, older age groups were associated with better perceptions 13. Regarding the perception of prevention, women indicated that they were more committed to looking after their families through preventive measures 9. Male respondents had perceptions related to higher barriers in implementing compliance with the COVID-19 protocols established by the government9. This might be related to men doing works outside the home.

*Sociodemographic Factors towards Attitudes*

Several articles also examined respondents’ attitudes to government actions to deal with the COVID-19 pandemic that affected their confidence that this pandemic could be passed successfully 20. Confidence in
the success of COVID-19 control increases with the age of respondents. The group with a medical background also showed a high attitude of trust compared to the non-medical group. It was related to a better level of knowledge about COVID-19.

A positive attitude towards the COVID-19 prevention protocols was shown by women. Respondents who were married also showed better attitudes, compared to other groups. Women and married individuals felt more responsible for maintaining family hygiene and teaching their children. Respondents assumed that measures to prevent COVID-19 were a shared responsibility and commitment. A better sense of responsibility was found in older adult respondents.

Sociodemographic Factors towards Practices

Practices are defined as individual behavior, which is influenced by individual attitudes and knowledge. Knowledge of COVID-19 relates to preventive practices carried out by respondents, such as reducing the intensity of going out and wearing masks. However, in some articles observed, there was a gap in translating individual attitudes and knowledge into the practice of preventing COVID-19. This might be due to the economic issues experienced by those who need daily wages.

Practices against COVID-19 prevention were also linked to the area where respondents lived. The inability of various states and local governments to implement strict preventive measures including lockdowns, banning public gatherings, physical distancing, and wearing masks is a risky practice against COVID-19. Visiting the crowd, which is risky, was recorded as being carried out by respondents below 40 years of age. It was related to the work done by the respondents. Most of the young people had to work outside the home for their daily survival even during the pandemic.

Married individuals and those with higher education tended to engage in high-risk practices with the potential to contract COVID-19. Men were more likely to underestimate the severity of the virus’s potential harm to them.

The higher the education level of the respondents, the better the results of the practice carried out on the prevention of COVID-19. Basic educational skills, including knowledge, reasoning skills, emotional self-regulation, and interaction skills, are essential components of health practice. Education is an essential component of health, and a major determinant of long-term health.

Limitations of the Study

The main limitation in writing this review was related to the scope of the discussion. Given the very wide range of factors that may affect the level of knowledge, perceptions, attitudes, and especially the practices of preventing COVID-19, the author only took merely sociodemographic factors. In this review, the author could not include other aspects that might be relevant to the participants’ concepts of knowledge, perceptions, attitudes, and practices such as framework (regulation and policies, health care facilities, health promotion), interpersonal influence (social norms, source of information), public health (respondent or family comorbidity), and self-efficacy.

Conclusion

This review revealed that the education level of respondents is the most influential sociodemographic factor in all articles addressing the concept of knowledge, perceptions, attitudes, and community practices. It was found that individuals with higher education tended to take health problems more seriously than those with less education; individuals with higher education had higher scores in practicing the COVID-19 protocols, compared to other groups. The results of this study are expected to be used in making appropriate interventions to reduce the COVID-19 transmission and face health problems in the future.
Acknowledgement

This research did not receive any specific grant from funding agencies in the public, commercial, or non-profit sectors. The authors are thankful for the support from Master of Nursing Program, School of Nursing, Faculty of Medicine, Brawijaya University, Indonesia.

Declaration of Interest: All authors declare that we have no conflict of interest.

Ethical Clearance

Due to the characteristic of this research design is a systematic review (use of secondary data) the ethical evaluation was not required. However, statement of research ethics in the journal articles would serve as a consideration of the use of the publication for this review.

Abstract

Indonesia’s swimming achievements are still far from that of other countries. Among other things, at the 2018 Asian Games, Indonesia did not succeed in getting a single medal. If not improved, Indonesia’s swimming performance will get worse. One of the innovations is to identify the physical abilities and physiological responses of an athlete through a physical loading test. This study aims to analyze the differences in acute physiological responses between short and middle distance swimming athletes through continuous and interval high intensity physical test. The sample of males aged 14-18 years consisted of the short distance (n=12) and middle distance (n=12) swimmers. Participants did a high intensity physical test with an ergocycle for 21 minutes with a 7-minute warm-up and 3-minute cool down, intervally, and without resting for continuous test. The variables studied included resting pulse rate, blood lactate, leg and shoulder muscle strength, arm and leg power. Data collected inbefore (pre) and after(post) physical test. The results showed that the short distance swimmers had greater increase in lactate level and pulse rate in both physical tests. The leg power decreased significantly in the short distance swimmer when performed continue physical test, whereas the middle distance swimmer when performed interval physical test. The conclusion of this study was to differ the leg power as acute physiology response for swimmers is more appropriate using continuous or interval high intensity physical test. Based on these results, training program for swimmer type can be developed. However, further research is still needed to enhance the swimmers performance.

Keywords: Swimming; Athletes; Pulse; Lactate; Power; Health

Introduction

The achievements of Indonesian swimming athletes are still far from that of other countries (¹). It was proven at the 2018 Asian Games, Indonesia failed to get a single medal (²). In fact, some Indonesian swimmers are predicted to win medals because they managed to be the best in the qualifying rounds several times. Swimming sports tend to use high intensity and good physicality is needed to win. Sports activity is one of the physical stressors that affect the homeostatic system, because it has an impact on physiological responses which are marked by an increase in stimulation of the body’s physical performance in the cardiorespiratory system (³).

The swimming race from 50 m to 1,500 m is divided into 3, namely short distance 50-100 m, middle distance 200-400 m, and long distance 800-1,500 m (⁴). To win in swimming, it takes practice, anthropometry, and strong physical abilities (⁵).

Various attempts have been made to improve the performance of swimming athletes, one of which is the right training program that can improve the performance of swimming athletes. However, the efforts that have been made are still not getting maximum results, to
achieve glorious swimming sports. One of the reasons is that there is no known identification of physical ability which is a physiological response in short and middle distance swimming athletes. Therefore, this study was conducted with the aim of analyzing the differences in physiological responses between short and middle distance swimming athletes through continuous and interval high intensity physical loading tests. Physiological responses measured were variables which included lactate, leg muscle strength, shoulder muscle strength, arm power, leg power, and resting pulse rate.

**Materials and Methods**

This study has received approval from the Research Ethics Commission from the Faculty of Medicine, Airlangga University (No.90/EC/KEPI/T’KUA/2020), and was declared ethical in accordance with 7 WHO 2011 standards which refer to the 2016 CIOMS guidelines.

**Research subject**

This study was analytic observational design and cross sectional. The subjects in this study were athletes of short and middle distance swimming aged 14-18 years. The selected subjects were determined according to their specialization and swimming competition numbers which were grouped into the middle and short distance swimming groups. The middle distance swimming group was 12 person and the short distance swimming group was 12 person.

**Physical Loading Test Protocol**

All groups of short and middle-distance swimmers performed a continuous and interval high-intensity test in 31-minute using an ergocycle. The pattern of interval was a 7-minute warm-up, 21-minute core and 3-minute cool down.

All athletes in short and middle distance swim was fasting for ± 8-10 hours (drinking water was still allowed), before the physical test was carried out, resting pulse rate, blood lactate, leg muscle strength, shoulder muscle strength, arm power, and leg power were measured, and Leg Power as a pre-test. Then, the subject were given a sweet solution and rest for 30 minutes. Subsequently, continuous and interval physical tests were accomplished. Afterward, blood lactate, leg muscle strength, shoulder muscle strength, arm power, and leg power, and resting pulse rate were measured as a post-test.

Lactic acid measurement

Lactic acid measurements were carried out on capillary blood through a transcutaneous puncture on the medial side of the tip of the middle finger\(^6\). Measurement of lactic acid was carried out before the loading test as a pre-test. And immediately after the loading intervention at 32 and 36 minutes. Measurement of lactic acid using the Accutrend plus, Roche, Germany. Lactic acid analysis results were recorded in units (mmol/L).

Measurement of Shoulder and Leg Muscle Strength

Measuring the strength of the shoulder muscles was measured by pulling the expending dynamometer with both hands and the results will appear in Kg.

The measurement of leg muscle strength was measured by pulling the leg dynamometer with both hands using the leg muscle strength and the results appeared in Kg units.

Arm and Leg Power Measurement

Measuring arm power was done with a 3 kg medicine ball, which was measured by sitting on a chair with the chest part held with a rope to stabilize, then a medicine ball was pushed forward horizontally with both hands. The unit was watts.

The measurement of foot power was done with the DF jump tool which was measured by standing on the mattress then jumping as high as possible. The unit was watts.

Pulse Rate

Pulse rate measurement was in resting condition and using a polar connected to the iPad-4 which is measured before (pre-test) in beat per minute (Bpm).

Data analysis

The Statistical Package for the Social Sciences
(SPSS) software was used for data analysis. Data was presented in tables. The paired T test or Wilcoxon Signed Ranks Test was to examine the difference of before and after physical test. The independent T test or Mann Whitney was to evaluate the difference between physical loading test (continue and interval high intensity) and between swimmers (short and middle-distance).

**Results**

The analyzed data were compared between before and after continuous physical loading test, and compared between the short-distance and middle-distance swimmers (tab. 2). The same was done for the interval loading test (tab. 3).

The response difference of short distance swimmers between continuous and interval physical test can be seen in Table 4. Lactate levels and pulse rates were less increasing and the differences between before and after physical test were also lower for continuous physical test than interval physical test. The decrease in leg power after continuous physical test showed a significant more decreasing, whereas after the interval physical test, the leg power decrease was not significant.

Middle distance swimming athletes responded to continuous and intervals physical test can be seen in table 5. Lactate levels and pulse rate presented less increased and the difference was also lower between before and after continuous test compared to interval physical test. The leg power variable had a significant greater decrease between the pre- and post-interval physical test in middle-distance swimmers (fig. 2).

**Figure 2. The three variables with the significant difference in each groups after physical loading test.**

*: sig. diff compared to the continue physical test in the same group (p<0.05)
Discussion

The results of the study of athletes in moderate and short distance swimming showed significant differences in pre-post oxygen saturation variables. This is because during exercise the sympathetic and parasympathetic nervous systems have an effect on an increase in heart rate which affects oxygen transport and the strength of heart contraction, thereby increasing peripheral vasodilation to the blood flow to active skeletal muscles so that during exercise there will be an integrated control of blood pressure which is controlled by reflex through the autonomic nervous system\(^{(7)}\). Another physiological response that occurs is an increase in oxygen diffusion capacity several times between resting and maximum work. Previously blood flow through the pulmonary capillaries flows very slowly and even stops in a resting state. So when the body performs maximum work activities continuously or at intervals it will increase blood flow through the lungs which causes the capillaries to diffuse maximally, so that athletes need more oxygen which is higher\(^{(8)}\).

Blood lactate was found to be a significant difference in pre-post between the two groups of athletes in middle and short distance swimming because when doing stressful activities the body experiences a lack of oxygen to break down glucose in the blood especially at high intensity it can reach 15-25 mM \(^{(7,9)}\). This is because the production of lactic acid is higher than its destruction (cleaning) when given high intensity loading \(^{(10)}\). So that a person experiences fatigue after exercise and will cause an increase in lactic acid up to 10 times during exercise \(^{(11)}\).

Continuous and interval loading on leg muscle strength did not produce a significant difference between pre-post because athletes who have good physical abilities and are trained must have the capacity and strength ability to manage their energy sources properly\(^{(12)}\). The interval loading test resulted in a significant reduction in leg strength in the middle distance swimmer group. The middle-distance swimmer group who had the dominant aerobic muscle ability was unable to quickly restore ATP energy during interval loading. The dominance of red muscle cells which need oxygen to reproduce ATP cannot work optimally due to the lack of oxygen supply at the interval. Meanwhile, the short distance swimmer group who had the ability of anaerobic muscles was used to it and was able to work optimally at intervals. This is what causes a greater decrease in leg power in the middle distance swimmer group than the short distance swimmer during the interval loading test \(^{(13)}\) proved that middle distance swimmers experienced a decrease in strength after the interval compared to continuous training.

The continuous loading test resulted in a significant reduction in leg strength in the short swimmer group. The group of short distance swimmers who have dominant anaerobic muscle ability, are not able to consistently produce ATP energy during continuous loading. The dominance of white muscle cells which are only able to work for a short time and are unable to produce ATP is due to the low number of red muscle cells so that the muscles cannot work optimally. Meanwhile, the middle-distance swimmer group who has the ability of aerobic muscles (red muscles) is accustomed and able to work optimally when continuous \(^{(14)}\). This is what causes a greater decrease in leg power in the short distance swimmer group than in the middle distance swimmer during the continuous loading test.

The variables of shoulder muscle strength and arm power did not show a significant difference in the pre-post that when doing continuous physical loading tests and intervals using ergocycle, this was because the athlete did not experience significant muscle fatigue during loading\(^{(12)}\), so that he did not give the effect of fatigue, especially on the shoulder muscles.

Leg power shows a significant difference in pre-post short distance swimming athletes because short distance swimmers are more dominant anaerobic and have less aerobic capacity which tends to exercise for a short time \(^{(15)}\). So that when given a long or continuous workload, there is an increase in muscle blood flow during strenuous physical exercise which results in increased muscle...
workload\(^8\)). Intermediate distance swimmers have red muscle that tends to be aerobic, which is more dominant in moderate sports for a relatively long time\(^{15}\). So that when given a load, the activity tends to be high. There is an increase in muscle blood flow during heavy physical exercise and results in increased muscle workload\(^8\). In continuous and short distance athletes, it does not make a significant difference because intermediate distance swimmers tend to have high aerobic metabolism and a cardiorespiratory system that can maintain moderate power for a relatively long time\(^{15}\). So that when given continuous loading the physiological response in the body is not so excessive. Short-distance swimming tends to produce much greater instantaneous strength for a short period of time, sufficient to complete a 50 or 100 meter race\(^{15}\). So that when given the physiological response in the body is not so excessive.

The middle distance swimmer group enjoyed and found it easier to load than the short distance swimmer group. This can be due to rest intervals which aid in energy recovery. The middle distance swimmer group had better energy recovery abilities during rest, because it had red muscle cells that were more dominant than the short distance swimmer group\(^{16}\).

On the pulse rate variable in the two groups of athletes in the middle and short distance swimming athletes showed a significant difference in pre test and post test. Due to an increase in muscle blood flow during physical work, the body responds with an increase in oxygen demand as indicated by a much higher pulse rate frequency than at rest. Oxygen consumption and cardiac output also increase during exercise. Also, it is known that exercise will stimulate the sympathetic nerves and the result is an increase in pulse rate\(^8\).

The continuous physical loading test had a greater increasing lactate levels and pulse rate, and more decreasing leg power in short distance than middle distance swimmers. The short distance swimmers, when compared between types physical loading test (continuous and interval), it was found that lactate levels and pulse rates increased more after doing interval physical loading. This had a similar pattern to middle distance swimmers, where the leg power of middle distance swimmers had a greater decrease than short distance swimmers after doing interval physical loading test (fig. 2).

**Conclusion**

The continuous and interval high intensity physical loading tests with ergocycle in short and middle distance swimmers increase blood lactate and pulse rate. The short distance swimmers have greater increase of blood lactate level and pulse rate in both physical test. The leg power examination for short distance swimmers is more appropriate to continue high intensity physical loading test, whereas for middle distance swimmers is interval high intensity physical loading test. Based on these results, training program for swimmer type can be developed. However, further research is still needed to enhance the swimmers performance.

Abstract

Background & Objectives: Maintenance of nutrition status of a patient is of paramount importance to clinicians treating medical or surgical diseases. Enteral nutrition is preferred over parental nutrition in patients who are unable to swallow. Percutaneous endoscopic gastrostomy (PEG) is the preferred route of nutritional support in patients with a functional gastrointestinal system who require long-term enteral nutrition and are unable to maintain oral intake. PEG offers superior access to the gastrointestinal system over surgical methods.

We aim to see utility of percutaneous endoscopic gastrostomy (PEG) for nutritional support in patients with oropharyngeal dysphagia secondary to neurological deficits and its effect on the quality of life of these patients.

Methodology: we studied retrospectively 25 patients with neurological oropharyngeal dysphagia in last 2 years needing PEG insertion. We reviewed data of the patients for 3 months post insertion of PEG. Study was based on body weight, haemoglobin and serum albumin level prior to and after PEG. All complications including sepsis, perforation, hemorrhage and death were recorded.

Results: Our study showed significant improvement in levels of hemoglobin, albumin and weight gain after Percutaneous endoscopic gastrostomy. There were no major complication.

Conclusion: Percutaneous Endoscopic Gastrostomy is an easy procedure that can be done bedside without complications in patients with neurological deficit. It improves nutritional status of the patient and also prevents aspiration pneumonia in patients with good gastric motility.

Keywords: Percutaneous endoscopic gastrostomy, nutritional support, Oropharyngeal dysphagia.

Introduction

The primary indication for enteral and parenteral feeding is the provision of nutritional support to meet metabolic requirements for patients with inadequate oral intake¹.
Enteral feeding is easy, safe, inexpensive and practical to maintain. It also helps to maintain local gastrointestinal defence and integrity thus decreasing translocation of bacteria. Parenteral nutrition is associated with a higher degree of side effects. It is costly, cumbersome and needs special care for maintenance.

Several methods such as nasogastric tube (NGT), percutaneous endoscopic gastrostomy (PEG), percutaneous fluoroscopic gastrostomy (PFG) and surgical endoscopic gastrostomy are available for enteral feeding.

Oropharyngeal dysphagia has been identified as a serious risk factor for patients developing aspiration pneumonia.

Prolonged nutrition through nasogastric tube is difficult. It has been known to cause severe aspiration pneumonia, esophageal stricture and traumatic bleed from gastric mucosa.

Gastrostomy is a well-established mode of enteral nutrition. It can be either open surgical or percutaneous endoscopic gastrostomy.

PEG needs only local anaesthesia and expertise is needed to perform the procedure. It can be done bedside without needing to shift ventilated patients to the operation room.

**Aims and Objective of the Study**

The Aim of the study was to evaluate the effectiveness of percutaneous endoscopic gastrostomy for nutritional status in the patients with oropharyngeal dysphagia secondary to neurological deficits and its effect on the quality of life of these patients.

**Objective of the study**

1. To assess the nutritional status of the patient
2. To assess the rate of post procedure aspiration pneumonia in patients with oropharyngeal dysphagia
3. To assess any other complications associated with PEG.

**Material and Methods**

This retrospective study was done to include cases with neurological oropharyngeal dysphagia in last 2 years needing PEG insertion. Patients with limited life expectancy, having chest injury, contusion of lung, haemothorax or pneumothorax were excluded. Patients with deranged bleeding and coagulation profile were corrected prior to insertion.

We reviewed data of the patients for 3 months post insertion of PEG.

All cases were with a proven diagnosis and were already on nasogastric tube feeding for at least 2 weeks.

Study was based on body weight, haemoglobin and serum albumin level prior to and after PEG. Body weight was calculated with bed and then subtracting dry weight of bed in patients who could not stand.

Short-term complications (symptoms or signs within 30 days of PEG), and long-term complications (symptoms or signs more 30 days after PEG tube insertion) were obtained as the details available on patient’s record sheets. Major complications were defined as per ESPEN guidelines and included sepsis, perforation, and haemorrhage and death.

All statistics was done using JASP (JASP Team (2020). JASP (Version 0.14.1)) Values of \( p < 0.05 \) were considered statistically significant using student t test.

Our study includes 12 females and 13 male patients, youngest was 8 years of age, while the oldest was 92 years of age. 8 patients were having complex head injuries, 8 had neurological deficits post cerebral vascular events, 5 had deficits post tumour excisions, 3 patients had primary metabolic diseases with altered mentation while 1 had deficit post tubercular meningitis.

All PEG insertions were done by the same team of endoscopists. 5 were done bedside while the rest in the endoscopic suite. The average time taken for the procedure was 18.87 minutes. The minimum time was of 10 minutes and the maximum time taken was 35
All the procedures were done under local anaesthesia with sedation when necessary. The procedure was done with patients supine and head high to prevent aspiration during procedure. Patients were given a test feed after 1 hour of insertion and regular feeding started thereafter. All patients tolerated the procedure and the test feed and went on regular feeding.

There was a rise in pulse rate of the patient by about 10 beats per minute above baseline in all the patients during procedure which returned to normal baseline in about 4-7 hours.

Haemoglobin level, weight of the patient and albumin level were compared based on the information taken from patient’s records just before the PEG insertion and after 3 months follow up.

Figure 1: showing improvement of Hb(gm%) after PEG
There is significant improvement of Haemoglobin(Fig 1), weight(Fig 2) and albumin level(Fig 3) of the patient after PEG insertion.
One patient had accidental decannulation on 27th day, tube was reinserted without any problems. 7 patients could start oral intake and they were decannulated after 2 weeks of regular oral intake.

There was no procedure related death in the study. 1 patient died due to severity of underlying disease. There was minor wound infection in 2 patients which was controlled with dressings for less than 7 days. 2 patients had one episode of tube blockage after 2 months of insertion.

**Discussion**

Percutaneous endoscopic gastrostomy is an easy and safe procedure that can also be safely done bedside.

In 1980 Gauderer et al. described inserting a percutaneous gastrostomy tube under local anaesthetic using endoscopy.

We had a delayed insertion of PEG tube as when patients have had a neurological insult, some tend to develop delayed gastric emptying (gastroparesis) even without a prior history of gastric motility disorder especially following severe head injury. Problem faced post PEG insertion related to gastric motility can be avoided if inserted after 15 days of primary insult. The lower esophageal sphincteric pressure and intracranial pressure have an inverse relationship. This combined with delayed gastric emptying and diminished gag reflex lead to higher incidences of aspiration. In critically ill patients on ventilator with or without a tracheostomy microaspirations are regular. This is increased with under inflation of tracheal cuff, Zero positive end expiratory pressure, low peak inspiratory pressure, tracheal suctioning, nasogastric tube and enteral nutrition. A smaller size of the nasogastric tube does not decrease chances of the aspiration.

Enteral nutrition decreases the translocation of gut bacteria and decreases chances of Multiorgan dysfunction syndrome and endotoxemia. Beneficial in maintaining nutrition due better assimilation of nutrients.

PEG helps in decreasing amount of micro-aspiration as evidenced by improving Chest X-rays and TLC of patients with some aspiration before PEG insertion. This correlates to other studies. This aspiration was further decreased by using semi solid feed instead of liquid feeds and by continuous feeding than bolus feeds.

Our study showed improvement in levels of haemoglobin, albumin and weight gain which correlates with other studies showing increase in albumin levels.

PEG can be done safely with minimal complications even in moribund patients. Patient not fit for anaesthesia can also undergo the procedure. The learning curve is not very steep, and reasonable expertise can be gained with few cases.

**Conclusion**

Percutaneous Endoscopic Gastrostomy is an easy procedure that can be done bedside without complications in patients with neurological deficit. Immediate procedure related complications are negligible. It improves nutritional status of the patient and also prevents aspiration pneumonia in patients with good gastric motility. Overall mortality depends on the primary disease process than on PEG insertion.

**Conflict of Interest:** The authors have no conflicts of interest.

**Source of Funding:** This is a retrospective study. We have used institutional funds for research.

**Ethical Clearance:** This is a retrospective study. There is no direct involvement of the patients. Hence ethical clearance is not needed.

Effect of Health Literacy Intervention on Medication Adherence among Older Adults with Chronic Diseases

Magda M. Mohsen1, Bahiga Galal Abd El-Aal1, Sally S. Hassan2, Amal A. El-Abbassy1

1Community Health Nursing, Faculty of Nursing/ Menoufia University, Egypt, 2Geriatric Health Nursing, Faculty of Nursing/ Menoufia University, Egypt

Abstract

Background: Medication adherence is essential for controlling chronic conditions, treating temporary conditions, and overall health and well-being. Aim: Examine the effect of health literacy intervention on medication adherence among older adults with chronic diseases. Design: A quasi-experimental (study and control design). Settings: Family health unit in Dragel village, Menoufia Governorate, Egypt. Sample: a purposive sample of 140 older adults. Tools: 1) Interviewing questionnaire that includes; the socio-demographic data, medical history, medication knowledge, factor affecting medication adherence and physiological measurement 2) The Medication Adherence Scale. 3) Self-Efficacy for appropriate medication use scale. Results: There was remarkable improved medication adherence and self-efficacy in medication use in the study group compared to pre-intervention and the control group. Also, there was improved knowledge and practice regarding medication use. Also, there was significant control in random blood glucose level and blood pressure in the study group compared to pre-intervention and the control group. Conclusion: The health literacy intervention was effective in enhancing medication adherence, successful in improving self-efficacy in medication use, and significantly controlling random blood glucose and blood pressure among older adults. Recommendation: Health care providers especially nurses should provide regular follow up for older adults with chronic diseases regarding medication adherence.

Keywords: Chronic diseases- Health literacy - Medication adherence - Older Adults

Introduction

Chronic diseases are long-lasting in their effects and require ongoing medical attention or limit activities of daily living[1]. Chronic diseases require long-term treatment and an increase in the demand for long-term healthcare services; that lead to decrease elderly people’s quality of life[2]. Aging is often accompanied by a larger burden of comorbid conditions and the seriousness of illness[3].

Pharmacologic therapy is an essential component in chronic disease management. Most elderly people with chronic diseases do not adhere to prescribed medication which usually leads to poor clinical outcomes [4]. Therefore, it is essential to enhance medication adherence in patients with chronic diseases to decrease premature deaths and social burden[5]. Patient adherence to medication is the degree to which patients follow treatment recommendations recommended as prescribed by their clinician[6].

Health literacy is a patients’ ability to obtain, process, communicate and understand basic health information and services needed to make effective health-related decisions. So that, the patients should adequately be informed and understand the health-related instructions[6]. In maintaining medication
adherence for their patients by establishing therapeutic communication with patients before they receive their medication regimen; to be able to determine the common adherence barriers before adherence becomes a problem for the patient[6-7]. The nurses provide information or guide the patient to engage in the teach-back method that helps patients understand their instructions[8-9].

**Aim of the Study**

Examine the effect of health literacy intervention on medication adherence among older adults with chronic diseases (diabetes and hypertension).

**Research Hypothesis**

1. Older adults who will receive health literacy intervention will have improved medication adherence than older adults who will not receive health literacy intervention.

2. Older adults who will receive health literacy intervention will have controlled random blood glucose levels and blood pressure than older adults who will not receive health literacy intervention.

3. Older adults who will receive health literacy intervention will have improved self-efficacy than older adults who will not receive health literacy intervention.

**Methods**

**Design:** A quasi-experimental (study and control design) was utilized

**Settings:** Family health unit in Dragel village, Menoufia Governorate, Egypt that was selected using multi-stage random selection.

**Sample:** A purposive sample of 140 older adults was divided randomly into two equal-matched groups (study and control group) by using simple random selection.

**Inclusion criteria:-**

- Older adults 60 years old and older.
- Older adults with chronic diseases (diabetes mellitus and/or hypertension).

**Sample Size and Power of The study:**

The sample size was calculated based on power analysis performed by Kelsey, Fleiss, and Fleiss, (2010) which indicated that 140 older adults would yield sufficient power of 80% to detect the effect of health literacy intervention on older adults with chronic diseases, based on the following assumptions effect size= 0.5, and alpha=0.05, the power of 80%, and the ratio of exposed to risk factors to those who were not exposed =1:1.

**Instruments:**

I: **Interviewing questionnaire that includes:**

**Part 1:** Socio-demographic data including name, age, sex, marital status, etc.

**Part 2:** Medical history including the type of chronic disease and medication information.

**Part 3:** Medication knowledge.

**Part 4:** A physiological measurement that includes:

- Random blood glucose
- Blood pressure

II: **The Medication Adherence Scale:** The scale was developed by[10]. The total score of the scale was ranged from 0-8 and categorized into: >2 = low adherence, 1 or 2 = medium adherence, 0 = high adherence

III: **Self-Efficacy for Appropriate Medication Use Scale:** This scale was developed by[11]. The total score of the scale was ranged from 16 to 48 and categorized into: 1-16 low self-efficacies, 17- 32 moderate self-efficacy, 33- 48 high self-efficacy.

**Validity of the instruments:**

The study instruments were tested for validity by a jury of five experts in the field of Community Health Nursing and Geriatric Nursing, to ascertain the relevance, completeness, and simplicity of each component in the instruments.
Reliability: The Cronbach alpha coefficient of the Medication Adherence Scale was 0.81 which indicates that the scale is reliable. Whereas the Cronbach alpha coefficient for self-efficacy for medication use scale was 0.85 which indicates that the scale is reliable.

Pilot Study: was carried out to assess the clarity, feasibility, applicability of the study tools, and the time needed to fill each tool. The pilot study was not included in the study sample.

Ethical Consideration:
· An official letter was obtained from the Dean Faculty of Nursing, Menoufia University to the director of the family health unit at Dragel to collect data and gain their help during the study period.
· Verbal informed consent from each participant was taken after explaining the purpose and duration of the study as well as they assured that their data will be used for research purpose only.

Procedure for Data Collection:
· Data were collected during the period from the beginning of January 2020 to the end of October 2020.
· The researcher interviewed the participants in the waiting room at the family health unit at Dragel two or three times every week.
· Pretest data of the study was filled by the researcher after introducing herself to participants and explaining the aim of the study to gain their cooperation.
· The filling of the instruments took about 20-30 minutes for each participant then the measurements of blood glucose and blood pressure were taken.
· The sample of the study was categorized into two groups (study and control group) using simple random selection. The Control group was received routine care and the study group was received health literacy intervention.
· The health literacy intervention was developed by the researcher and carried out in three sessions. Each session was taken 20-30 minutes. The intervention was given in a small group each group contains from 2-5 participants.
   ü The first session included information about diabetes mellitus and hypertension disease.
   ü The second session related to diet and exercise regimen for diabetes mellitus and hypertension.
   ü The third session related to medication adherence and factor affecting it.
· By the end of each session the researcher provides a summary of essential points as well as at the end of the sessions then, the participants of the study group received an educational intervention booklet.
· Posttest was administered for the study and control group at 3 months post-intervention.
· Physiological measures (random blood glucose and blood pressure) were taken once monthly for three months for the study group and control group.
· Participants of the control group have received a copy of the booklet at the end of the study.

Statistical analysis:
The collected data were coded and entered into the computer and statistically analyzed using SPSS version 22 for categorical variable the number and percent were calculated. The relations between the studied variables were tested. The level of significance was adopted at p<0.05.

Results
Population characteristics: The total sample size of 140 older adults were included in the study. 72.9% of the study group was in the age group 60-70 years, 64.3% were females, 58.6% were married, 37.1% do not read or write, 75.7% were not working and 57.1% with not enough income. While 67.1% of the control group was in the age group 60-70 years, 55.9% were females, 62.8% were married, 37.1% do not read or write, 64.3% were not working and 61.4% with not enough income;
there were no significant differences between the study and control group regarding all sociodemographic characteristics.

**Table (1):** Reveals that, post-intervention knowledge of the study group was significantly improved compared to their pre-intervention knowledge and knowledge of the control group.

**Fig. (1):** Shows that, in post-intervention, the high medication adherence degree among the study group increased to 45.8% than the control group 10% also medium medication adherence degree among the study group increased to 47.1% than the control group 24.3% while low medication adherence degree among the control group increased to 65.7% than the study group 7.1%.

**Table (2):** Shows that, mean random blood glucose showed consequently decreased on three occasions post-intervention in the study group compared to the mean random blood glucose pre-intervention and control group. Also, mean systolic BP showed consequently decreased on three occasions post-intervention in the study group compared to mean systolic BP pre-intervention and control group. Also, mean diastolic BP showed consequently decreased on three occasions post-intervention in the study group compared to the mean diastolic BP pre-intervention and control group.

**Table (3):** demonstrates that the third post-intervention mean random blood glucose was significantly controlled in older adults with high and moderate medication adherence among the study group compared to their pre-intervention and the control groups

**Table (4):** Demonstrates that, post-intervention degree and mean total score of self-efficacy in medication use among the study group was significantly improved compared to their pre-intervention and control group.

Discussion

The consequences of medication non-adherence to long-term therapies are poor health outcomes, increased health care costs, and frequent hospitalization of older adults\[12-13\]. The purpose of the present study aimed to examine the effect of health literacy intervention on medication adherence among older adults with chronic diseases (diabetes and hypertension). The first hypothesis suggested that older adults who will receive health literacy intervention will have improved medication adherence than older adults who will not receive health literacy intervention. Support for this hypothesis was found in the present study that revealed a highly significant improvement in the different levels of medication adherence among the study group than the control. This finding was supported by\[14\], who reported that a health literacy intervention may be a
viable mechanism for improving cardiovascular-related medication adherence and outcomes. Besides, the present study result came on the same line with\cite{15} who showed that a greater percentage of intervention patients were adherent to medication compared with usual care patients and there was a statistically significant greater percentage of intervention patients were classified as an adherent for medication.

The second hypothesis suggested that older adults who will receive health literacy intervention will have controlled blood pressure and blood glucose level than older adults who will not receive health literacy intervention. Support for this hypothesis was found in the present study that revealed a significant difference was observed between study and control groups regarding the control of random blood glucose. There was a significant difference was observed between the study and control groups regarding the control of blood pressure. A similar finding was recorded by\cite{16} they showed that a significant improvement in pre and post-intervention was detected in the intervention group’s HbA1c levels and the intervention helped improve HbA1c levels. Also, a similar finding was reported by\cite{14}; they found that at six months post health literacy intervention average systolic blood pressure was decreased 0.5 mmHg and diastolic blood pressure was decreased 1.5 mmHg compared to pre-intervention among American patients’ at primary care clinics.

The third hypothesis suggested that older adults who will receive health literacy intervention will have improved self-efficacy than older adults who will not receive health literacy intervention. Support for this hypothesis was found in the present study that revealed a significant improvement in the different levels of self-efficacy among the study group than the control in post-intervention. The level of high self-efficacy increased among the study group, compared to the control group post-intervention. These findings came in agreement with\cite{17} they reported that older adults in the program intervention group showed significantly higher levels of self-efficacy at follow-up among Korean older adults with chronic disease. Participants with low health literacy had greater benefits from the intervention than those with high health literacy. Also, the present study results were in accordance with the study carried out by\cite{18} who reported that the intervention group had significantly better self-efficacy and diabetes knowledge than the control group.

**Conclusion**

The health literacy intervention was effective in enhancing medication adherence, successful in improving self-efficacy in medication use, and significantly controlling random blood glucose and blood pressure among older adults.

**Recommendation:**

Health care providers especially nurses should provide regular follow up for older adults with chronic diseases regarding medication adherence.

Self-management of Elderly Patients with Osteoarthritic Knee on Recovery Outcomes

Magda M. Mohsen¹, Nabila E. Sabola¹, Nagwa I. El-khayat², Entsar A. Abd El-Salam³
¹Prof. of Family and Community Health Nursing, ²Assist. Lecturer of Geriatric Nursing, ³Assist. Prof. of Geriatric Nursing, ⁴Faculty of Nursing, Menoufia University-Egypt

Abstract

Background: Knee osteoarthritis accounts for almost four fifths of the burden of worldwide. It is the leading cause of mobility impairment, disability and loss of function in older adults. This study aimed to examine the effectiveness of self-management of elderly patients with osteoarthritic knee on recovery outcomes.

Material and Methods: A quasi- experimental design was utilized to conduct this study. The study was carried out at outpatient clinic of Shebin-Elkom University and Educational Hospital, and then they were following up at their homes. 100 elderly patients were selected who met inclusion and exclusion criteria. A constructed interviewing questionnaire, arthritis self-efficacy scale, and Western Ontario and McMaster Universities Osteoarthritis (WOMAC) index were used to collect the data.

Results: there was increase in the mean total pain self-efficacy score, and other symptoms self-efficacy score in study group than control group. There was decrease in the mean total physical function WOMAC score in study group than control group after intervention.

Conclusion: Implementation of self-management for elderly patients was effective in management symptoms of knee osteoarthritis among study group compared to control group.

Keywords: Elderly, Knee osteoarthritis, Self-management, recovery outcomes.

Introduction

Knee osteoarthritis (KOA), known as degenerative joint disease, is typically the result of wear and tear and progressive loss of articular cartilage. It is most common in elderly women and men. Knee osteoarthritis can be classified as, primary and secondary. Primary osteoarthritis is articular degeneration without any apparent underlying reason. Secondary osteoarthritis is the consequence of either an abnormal concentration of force across the joint as with post-traumatic causes or abnormal articular cartilage, such as rheumatoid arthritis (RA). Osteoarthritis is typically a progressive disease that may eventually lead to disability(1).

Globally, 18% of women and 9.6% of men aged over 60 years have symptomatic OA, with a quarter of these individuals unable to perform routine daily activities. By 2050, a projected 130 million people will suffer with OA, constituting a significant societal burden (2). In Egypt, more than five million people have OA, percentage of years of healthy life lost due to OA disability per 100.000 people is 67.6 %. The rate of years of healthy life lost from osteoarthritis has changed over time and relative to the parent region of North Africa & Middle East and the world at large (3).
Self-management intervention has an important role to play in managing osteoarthritis, and suit an integrative model of shared care between conventional and complementary medicine practitioners. Self-management program help to promote health and management of diseases, increasing motivation of elderly and decreasing the negative effects on their daily function (4). It including low-impact activity, balance of rest, range-of-motion exercises, relaxation, heat or cold, taking medication, joint protection, massage, splints and nutrition (5,6).

**Aim of the Study**

The study aimed to examine the effectiveness of Self-management of elderly patients with osteoarthritic knee on recovery outcomes.

**Hypotheses:**

- Elderly patients who will receive self-management will be more likely to have a different score of self-efficacy than elderly patients who will not receive the intervention.

- Elderly patients who will receive self-management will be more likely to have change in their physical function than elderly patients who will not receive the intervention.

**Subject and method:**

**Design:** A quasi-experimental design (study and control) was utilized to conduct this study.

**Setting:** This study was conducted at outpatient clinic of Shebin-Elkom University and Educational Hospital, and then they were following up at their homes.

**Sample:** A convenience sample of 100 elderly patients with osteoarthritic knee, were recruited. They were assigned randomly by tossing a coin for two groups (study group from University Hospital and control group from Educational Hospital).

**Tool I:** A constructed interviewing questionnaire

This questionnaire was developed by the researcher for demographic data: age, gender, marital status, and level of education......etc, history of chronic diseases and medication taken.

**Tool II:** Arthritis self-efficacy scale (ASES) (7) used to assess self-efficacy of patients with osteoarthritis.

**Tool III:** Western Ontario and McMaster Universities Osteoarthritis (WOMAC) (8) used to assess physical function among OA elderly patients.

**Validity of tools:**

The validity of three tools was done by a jury of four experts (two Professors in Community health nursing and two experts in Geriatric nursing) who reviewed the questionnaire for clarity, relevance, comprehension, understanding and applicability, content accuracy and internal validity.

**Reliability of tools:** Reliability was estimated among 10 participants by using test retest method with two weeks apart between them.

Regarding tool 2 (ASES scale): It was 0.76 with the following Cronbach alpha reliability values for its subscales: Pain SE: 0.70, other symptoms SE: 0.78.

Concerning tool 3 (WOMAC): It was 0.74 with the following Cronbach alpha reliability values for its subscales: Stiffness: 0.70, Physical function: 0.78. The Cronbach alpha reliability for the three tools and their subscales indicate that the three tools are reliable to detect the objectives of the study.

**Pilot study:** conducted on 10 of elderly patients to evaluate the effectiveness of the study tools, clarity, techniques and the availability of the study sample.

**Ethical consideration:**

- Approval of the ethical research Committee was obtained at the Faculty of Nursing, Menoufia University.

- The agreements for participation of the elderly patients were taken after the aim of the study was explained to them.
The elderly patients had the full rights to refuse to participate in the study or to withdrawal at any time. Also they were assured that, the information would remain confidential and used for the research purpose only.

The researcher gave copies of general information package (booklet) about self-management to elderly with knee OA for achieving the ethical principles of research as the principle of beneficence that all subjects should benefit from the research’s knowledge.

Data collection procedure

Data collection started on February 2019 and lasted until January 2020.

Filling in the questionnaire for elderly patients (case and control) was conducted at the waiting area of orthopedic Out-patient Clinic affiliated to Shebin-Elkom University and Educational Hospital, after the elderly patients receiving medical examination and treatment.

Each subject was personally interviewed for about 45 minutes-1 hour(according to the level of patient understanding) to fill the questionnaire for case and control group and give simple intervention about knee osteoarthritis only for case group.

The researcher took address and telephone number from each patient to facilitate communication and follow up at their homes. The implementation of the home visit for self-management intervention sessions was achieved within 6 months one session per week for every individual (total duration 3weeks for every individual).

The intervention included telephone follow up to elderly patients for completing intervention sessions for reassurance, support and keep contact.

The final session (fourth): was done after 3 month (post intervention) After the implementation of the self-management intervention each elderly patients was assessed using the study tool to determine the effect of the sessions on their pain, other symptoms and physical function of knee. Time required for the session was 20 minutes.

Statistical Analysis:

- Quantitative data were presented by mean (X) and standard deviation (SD). It was analyzed using student t-test for comparison between two means; Correlation coefficient (r) was used to test the correlation between two quantitative variables. Qualitative data were presented in the form of frequency distribution tables. It was analyzed by chi-square ($\chi^2$) test.

Results

![Fig.1: Percent distribution of age of studied groups](image-url)
Fig. 1. Seventy percent of control group, and 74% of cases of the studied elderly patients with osteoarthritic knee aged between 60 to 70 years with mean of 65 ± 5.1 years and 66.2±6.4 respectively.

Table (1) Highlights that, there was a highly significant improvement in the mean total pain SE score, among case group than control group Post-intervention (28.7 ± 9.4 vr 21.7 ± 9.8, P<0.0001). Similar pattern was observed concerning other symptoms SE subscale. In addition, total SE scale (pain +symptoms) showed similar pattern where mean total SE score, among case group was higher than control group and the difference was highly statistically significant (P<0.0001).

Table 2 reveals that post-intervention mean total score in pain SE and other symptoms SE in both case and control groups were decreased when degree of osteoarthritis and the pain intensity increased.

Fig.3: Mean total WOMAC score pre and post intervention
among control and case elderly groups

Fig 3: shows post-intervention decreases in total WOMAC score in the two groups; however, the case group had more pronounced significant pre–post differences (43.8 and 33.4) compared to the control group (40.2 and 41.4) respectively. This difference was statistically high significant (p <0.001).

Table (3): Relation between post intervention mean total score of stiffness, and physical function with post intervention degree of Osteoarthritis, as well as Pain intensity levels among cases and control groups (N=100).

Table (3) post-intervention mean total scores in stiffness and physical function were increased in both case and control groups when degree of osteoarthritis and the pain intensity categories increased.

Discussion

Knee osteoarthritis causes significant pain and function loss among elderly people. As the disease progresses, it can cause chronic joint pain, muscle weakness, deformity and functional deficiency and leads to dependency for daily life activities and decreased quality of life, thus increasing the need of the elderly for healthcare services (9). The present study aimed to examine the effectiveness of Self-management of elderly patients with osteoarthritic knee on recovery outcomes.

Regarding the effect self-management on pain self-efficacy the current study revealed that there was a highly significant improvement in the mean total pain self-efficacy, among case group than control group post intervention. This result is supported by study conducted by (10) who studied “The Effect of Self-management Training on Self-efficacy of Elderly Patients with Knee Osteoarthritis” in Iran. They reported that implementation of self-management training is effective in improving the self-efficacy of the elderly with knee osteoarthritis.

Also, this finding is consistent with the results of a study by (11) who studied “Feasibility of Imported Self-Management Program for Elderly People with Chronic Pain” in Japan. They concluded that pain self-efficacy was significantly improved immediately after the program compared with baseline and these effects
were maintained at 3-month follow-up, this finding has important implications for the development of pain services in community-dwelling elderly Japanese.

Concerning the effect self-management on other symptoms self-efficacy the current study revealed that there was a highly significant improvement in the mean total other symptoms self-efficacy, among case group than control group post intervention. This result is congruent with study by (12) who studied “Effect of self-management program on outcome of adult knee osteoarthritis” in Iran. They reported that the self-management program, which included pain relief methods, proper diet and exercise, aimed to improve pain, symptoms, function and quality of life. They have demonstrated that participants in the self-management program experienced improvements in the outcome of knee osteoarthritis.

This finding is consistent with the results of study by (13) who studied “The better management of patients with osteoarthritis program; outcomes after education and exercise delivered nationwide” in Sweden. They indicated that patients with knee osteoarthritis showed significant improvements in scores for arthritis self-efficacy other symptoms subscale and arthritis self-efficacy painsubscale.

In addition, this finding is agreement with the results of study by (14) They showed that knee symptoms scores significantly improved and quality-of-life scores significantly increased. Moreover, is consistent with the results of study by (15) They indicated regarding self-efficacy, there was improvement in the confidence that studied elderly abilities to perform a specific task with a significant difference was observed at 8th week post intervention and 6th month follow-up among study group compared to control group. As the exercises, proper diet and pain relief measures included as part of the self-management program (SMP), that can reduce stiffness and help knee pain relief.

In contrast, (16) who studied “Challenges in evaluating an Arthritis Self-Management Program for people with hip and knee osteoarthritis in real-world clinical settings” in Australia. They showed that there wasn’t any difference in improving the quality of life, pain, stiffness of the joints, physical function and psychosomatic symptoms at 3 and 12 months after the intervention. This may be attributed to patients with hip and knee osteoarthritis may have more complication that affect quality of life of elderly patients.

Regarding the effect of self-management on physical function results of the current study revealed a highly significant improvement in function WOMAC score after intervention than control group. This finding is similar to what was reported by (17) They showed that their study supports the importance of a combined self-management and exercise intervention to improve functional lower limb strength and aerobic capacity in a Portuguese sample. Additionally, pain and other symptoms have improved. Also, result is supported by (18) They showed that a self-management program improved the health status of patients with knee osteoarthritis.

In addition, this result came on the same line with study conducted by (15) They suggested that concerning physical function subscales for study group, a statistically significant difference was found between pretest and posttest after implementation of interventions regarding to descending stairs, rising from sitting, standing walking on flat surface, lying in bed, getting in/out of bath and sitting.

Moreover, study by (19) They found that self-efficacy at baseline was associated with change over time in pain intensity and physical activity at follow-up after the intervention. High self-efficacy had a positive effect on pain intensity and physical activity, that increasing the need for exploring and strengthening patients’ self-efficacy. This result may be related to implementation of pain relieve measures and physical exercise that can improve physical function for elderly patients with knee osteoarthritis.

Regarding the relation between elderly knee osteoarthritis, socio demographic characteristic and their mean of post intervention self-efficacy and physical function scores, the current study revealed that, young
age of studied elderly patients from 60-70 years had high self-efficacy and improved physical function compared with other ages from 71-80 years. Also, male, university education, had high self-efficacy and improved physical function compared with others. This results supported by a study by (20) They reported that female gender are significantly related to less self-efficacy and higher disability, and low educational level negatively influences the amount of perceived pain and disability, and older age can affect degree of disability and pain intensity.

Also, study by (21) who reported that indicators of quality of life are equal or even higher in older compared to younger patients. Moreover, Study by (22) they stated that subjective disability was affected by education level. In contrast, study by (20) who studied “Is there a relationship between self-efficacy, disability, pain and sociodemographic characteristics in chronic low back pain?” in Italy. They reported that they did not find any correlation between educational level and pain self-efficacy. This may be related to difference in community cultures.

**Conclusion**

Implementation of self-management for elderly patients was effective in management symptoms of knee osteoarthritis among study group compared to control group which was resulting in increasing their self-efficacy regarding pain and other symptoms. Moreover, it was effective in increasing physical function in study group than control group.

**Recommendations:** Awareness programs, targeted for all elderly patients, their family caregivers and general public about self-management and its importance for increasing self-efficacy and improving physical function.

**Ethical Clearance:** Institutional review committee was informed and study cleared

The Impact of Exclusive Breast Feeding on Infant Morbidity in The First Six Months of Infants Life

Maha A. Muhsen¹, Jabbar T. Ahmed²

¹Researcher, ²Prof., Southern Technical University – College of Medical and Health Technology/Basra - Community Health Department

Abstract

The breast feeding was basic and ideal type of feed for infants especially during first six months of their life, breast feeding has a main role in infant’s life as maintaining on mental and physical health, protecting from many disease and play important role in health of mothers and national and international strategies. The goals of this study is to estimate the prevalence exclusive breast feeding (EBF) in Basra (Southern of Iraq) during period of study, to determine the impact of exclusive breast feeding on morbidity of infant during first six months of life and to assess relationship between some character’s for mothers and babies (Age of mothers at marriage, Age of mothers at baby birth, educational level, occupation, birth interval, methods of delivery, parity, gestational age, age, gender and birth weight of infant). The study found prevalence of exclusive breast feeding in infants for first six months of life is 54.75%, while (23.75%) and (21.5%) for partial and exclusive formula feeding respectively and showed significant relationship between diarrhea disease, respiratory tract infection and gastroenteritis and type of feeding in first six months of life at level p<=0.05. also showed EBF associated with age of mothers at baby birth, education level, occupation of mothers, and mode of delivery, gestational age and parity and found no relation between age of mothers at marriage, birth interval and sex of infant with EBF.

Keyword: type of feeding, exclusive breast feeding, morbidity, infants.

Introduction

The breast feeding was basic and ideal type of feed for infants especially during first six months of their life to achieve good health and growth this was recommended by world health organization ( WHO )¹(1). Breastfeeding had a religious basis in Islam where The Holy Quran it was recommended to the mothers for breastfeed her infant for a period of full two years if possible (2).

Breast feeding has a main role in infant’s life as maintaining on mental and physical health, protecting from many disease and play important role in health of mothers and national and international strategies (3). Breastfeeding contributed to a reduction in incidence of preventable infant diseases, such as respiratory, otitis media, necrotizing entercolitis, gastroenteritis and atopic disease irrespective of family history (4).

The breastfeeding can prevent the development overweight and obesity which reduce risk of several chronic disease as diabetes, cancer and cardiovascular disease, this impact for long term not only in early life⁵. Infants who depend on breastfeeding have a high intelligence rate compared to babies who do not drink breast milk, in addition to this, good development in vision and less retinal disease in premature infants (6).

Breastfeeding also help mothers to return their health after delivery, in terms of help to construction of uterus after birth and reduce bleeding at the time of birth, less cancers of breast and ovarian and reduce chance to fractures in later ages (7). Experts have proven that breastfeeding had a role in preventing conception (lactation amenorrhea method), it have a role in return ovulation, the breast feeding was effective way to prevent pregnancy by 98-99% if follow guides as nursing any six
times a day and not giving any pacifiers or formula, and breastfeeding no more than six months after childbirth (8).

Breastfeeding lengthens post-partum amenorrhea and post-partum weight loss and this amenorrhea also helps to replenish maternal iron stores that were lost during delivery, and thus reducing the risk of anemia. (9).

Also there were ecological benefits of breastfeeding to society include decreased energy demands for the production of infant formula and less solid waste such as formula cans and bottles (10).

Human milk (HM) help to facilitate the infant’s transition from enter to extra uterine life by providing immunomodulatory component provides good nutrition. The HM nutrient affected by the maternal genetics and varying degrees by maternal diet, fat composition and fat-soluble and water-soluble vitamins content were influenced by maternal diet but lactose, minerals, protein and trace elements were not affected by maternal nutrition, also oligosaccharide composition affected by maternal genetics, HM provides all nutrient for infants except vitamins D, K and iron so should be give supplements of vitamins to infants (11).

Patients and Methods:

A cross-sectional study conducted on 400 infants that less than six months of life and their mothers when coming to health care centers for the purpose of vaccination or treatment the infants. The types of variables were included in this study. The first (dependent) variable was the morbidity affecting the infant in the period of the study. The second (independent) variable was the type of feeding from birth to the time of the study. Also we studied other variables as such factors associated with infant as age, weight and gender. Together with the mother’s factors as age, age at marriage, profession, parity, level of education, type of delivery and birth space to explain their affected on selected of mothers to type of feeding. The data was obtained from mothers of infants by interviewing the breast fed currently or discontinued mothers face to face and answering the questions in the questionnaire, and participation rate high in this study.

Statistical Analysis

After collected data entered statistic package social science program (SPSS)22 version for analyzed by descriptive statistic frequencies and percentages to demographic characters for mothers and infants to determine data prevalence, inferential statistic crosstab table, Pearson chi square used to analyzed correlations among variables, statistical significant for (P value ≤ 0.05).

Results

The finding of the 400 mothers according to the feeding type in the first six months of life reported: 219 had EBF at percentage (54.75%) while 95 (23.75%) and 86 (21.5%) had partial and exclusive formula feeding respectively as shown in table (1).

The result in table(2) shows that there was statistically significant relationship between (mother’s age at baby’s birth, mother’s level of education, occupation of mother’s parity, mode of delivery ,gestational age) and type of feeding in the first six months of life in Basra city at P-Value(0.000, 0.000, 0.020, 0.001, 0.027, 0.050) respectively.

**Discussion**

The finding of the 400 mothers according to the feeding type in the first six months of life reported: 219 (54.75%) had EBF while 95 (23.75%) and 86 (21.5%) had partial and exclusive formula feeding respectively as shown in table (1).

This result nearly matches another’s cross sectional study was conducted between October 2006 and November 2007 in four primary health care centers in Thi – Qar, showed EBF (55.1%) (12). This increasing in EBF beyond to that mothers were educated on the advantages, practices, length, and exclusivity of BF, also societal beliefs and traditional attitudes play a significant role in society; this may justify the second and third most prevalent reasons (13).

Poverty is a significant factor in rural women’s decision to breastfeed their children (14). Furthermore, maternal education, social status, cultural background, and religion are associated with the decision to begin and maintain BF (15).

The result of study showed that mother’s age at baby’s birth was for the age interval (16-25) years (66.8%), with secondary education level (71.5%), (58%) house wives mothers, (60%) was for multipara mothers, (59.3%) delivered vaginally mothers, (56%) was for mothers of full term infant all these socio-demographic characters for mothers had statistically significant and highest percentage in using EBF to breastfeed their infant.

This study agreement with study showed the risk of cessation of breastfeeding increased with increasing maternal education (16). Also this result agree with study done by Al-Kohji et al. showed that exclusive breastfeeding is more common among housewives than among employed mothers, owing to the fact that unemployed mothers have more time to practice on-demand breastfeeding, as the WHO recommends (17).

The study agree with several study like this done by Al-Nuaimee et al. showed multipara women more than primipara using EBF may be due to psychological pressure of the pregnancy on these women who didn’t have experience and visit the health center more frequently (18), corresponding with the study by Al-Kohji.
et al showed many factors explains a higher incidence of breastfeeding initiation in mothers who delivered vaginally than those who delivered via cesarean section are: discomfort of surgery, the baby isolation from the mother, and the mothers’ failure to sit in the appropriate position for breastfeeding were all factors in mothers who delivered cesarean section (17).

The result showed significant relationship between diarrhea disease, RTI and gastroenteritis and type of feeding in first six months of life at level p<=0.05. Also another’s study showed same effect 14 (22%) of breast-fed infants developed diarrhea, compared to 29 (42%) of bottle-fed infants and 25 (36%) of combined breast-and-bottle-feeding infants (19). this due to human milk have antiviral, antibacterial, and antiprotozoal properties have been found in fatty acids and monoglycerides, this operation could strengthen the stomach’s ability to serve as a protector against ingested pathogens (20).

This result same result of another’s study showed infant of 6 months of exclusive breastfeeding is often associated with lower rates of gastro-intestinal tract infections (21). Antibodies pass on maternal immunity to the fetus. Both transplacentally transferred maternal IgG and breast milk IgA can protect the infant from infections by neutralizing microbe infectivity, Breast milk also contains other antimicrobials. Substances that could also play a role Breast milk reduces the morbidity of gastroenteritis (22).

Our result agree with study conducted in Erbil city showed that 69% of bottle-fed infants developed lower respiratory tract infections compared with 31% infants of breast-fed (23). Breast milk appears to influence the infant’s systemic immune response through a variety of mechanisms, including maturational, antiinflammatory, immunomodulatory, and antimicrobial, many changes in immune phenotype of newborns following exposure to maternal milk, such as rises in post vaccination interferon-Y levels and natural killer cell numbers, which are associated with age-related changes and indicate increased immune maturation, these immune effects that may result in extended defenses against respiratory infections. (24).

Conclusion

Prevalence of EBF among mothers who ever breastfed was 54.75%. Most mothers in Basra exclusively breastfeed their babies in the first 6 months means positive trend for the rate of EBF in Basra / Iraq. Breastfeeding exclusively until the age of six months, was associated with a significantly decrease in respiratory and diarrhea and gastrointestinal infectious diseases.

Ethical issue: Gaining formal approval from ministry of higher education then public health department in Basra province to conduct this study, also permission was obtained from each Primary health care centers. All data was obtained from mothers who agreed to take part in this study .this participation was voluntary and anonymous.

Conflict of Interest: Nil

Food Hygiene Knowledge and Practice among South Indian Women

Mahadeva1, Manasa P1, Melby Elizabeth1, Nancy Ruby1, Priya Joy1, Hezil Reema Barboza2

1Student, 2Lecturer, Department of Medical Surgical Nursing, Yenepoya Nursing College, Yenepoya Deemed to be University, Mangalure

Abstract

Background: Food is essential for the existence of all living organisms. The main purpose of food hygiene is to prepare and provide safe hygienic food and consequently contribute to a healthy family. Lack of adequate food hygiene can lead to a number of food-borne diseases and death.

Methods: A descriptive study design was adopted in order to assess the level of knowledge and practice among women regarding food hygiene. The tool used for this study was structured knowledge questionnaire and self-reported practice checklist. The content validity of the tool was established in consultation with 7 experts. The reliability of the knowledge questionnaire was tested by split-half method and self-reported practice checklist by Cronbach’s Alpha. The reliability of the knowledge questionnaire was 0.8 and the practice checklist was 0.9. Both the tool was found statistically significant. Data collected from the 132 women were analyzed by descriptive and inferential statistics using SPSS.

Conclusion: The results revealed that majority of the women (80.4%) belong to age group of 20-30 years. There was a positive correlation found between food hygiene knowledge and practice. Majority of the women had good knowledge (77.3%) and had good practice (70.3%) towards food hygiene.

Key words: Foodborne diseases, Food hygiene, Knowledge, Practice.

Introduction

Food poisoning is a common health problem worldwide. All over the world people are seriously affected every day by diseases that are caused by consuming unhygienic and unsafe food.1 Initially food-borne diseases were estimated to be responsible for 6-8 million illnesses and 9000 deaths each year. The US Centers for Disease Control and Prevention (CDC) estimates 1 in 6 Americans (48 million people) are affected by food-borne illness annually. The 31 known pathogens account for an estimated 9.4 million annual cases, 55,961 hospitalizations, and 1,351 deaths.2-4 In 2011 about 100 million cases of food borne diseases reported in India. Researchers found that number of cases expected to rise 150-177 million in 2030.5,6 The data from the World Health Organization food borne disease epidemiology reference group in 2015 reported urban and rural population will be affected disproportionally, where every third person fall sick from food borne diseases.7 Ensuring food safety at the household level is important and an understanding of the status of the food handling knowledge and practices is very much needed to prevent the food borne diseases.8-10

Objectives

The objectives of the study were to:-
to assess the knowledge on food hygiene among women

• to determine the food hygiene practice among women

• to find correlation between knowledge and practice score on food hygiene among women

• to find association between knowledge score with the selected demographic variables

• to find association between practice score with the selected demographic variables

Materials and Methods

The aim of this study is to understand the status of knowledge and practice among South Indian women regarding food hygiene. In this study food hygiene is referred to as all the conditions and measures that are necessary during the purchase, storage, preparation and serving of food to ensure that it is safe, wholesome and fit for human consumption.

This study assumes that safe food hygienic practices can reduce the incidence of food borne diseases. When individuals adopt better practices that promote health, food contamination can be minimized.

The descriptive design was selected for the study. The data was collected from women (n=132) who visited the tertiary care hospital OPD at Mangalure. Subjects were selected by non-probability convenient sampling technique. Women between 20-50 years of age and who were involved in the food preparation, preservation, storage and serving were selected as study participants.

Description of the tool:

As per the review of literature the following tools were constructed by the researchers.

(a) Demographic Proforma

(b) Structured Knowledge Questionnaire

(C) Self-Reported Practice Checklist

Demographic Proforma: It consisted of items for obtaining information regarding age, marital status, occupation, educational status, type of family and religion.

The Structured Knowledge Questionnaire on Food Hygiene: It consisted of 20 Multiple Choice Questions (MCQ’s) with one correct answer and four distracters. Each right answer carries one score and the total score of the questionnaire was 20.

Self Reported Practice Checklist: It was prepared to assess the practice of food hygiene with 15 questions. The total score of the Self reported practice checklist was 15.

To determine the content validity, the prepared tools were given to 7 experts. For establishing the reliability the tools were administered to 6 subjects who met the inclusion criteria. The reliability was calculated by split-half method for structured questionnaire and test-re-test method for self reported practice checklist. The reliability of the Structured Knowledge Questionnaire on Food Hygiene was 0.8 and Self-Reported Practice Checklist was 0.9. Both the tools were found to be reliable.

Data collection method:

A formal permission was obtained from Scientific Review Board and Institutional Ethics Committee before the data collection process. A pilot study was conducted for a smaller sample size to assess the feasibility of the study.

The Structured Knowledge Questionnaire and Self-Reported Practice checklist was administered to women (n=132) through Google Forms. The data obtained was analyzed in terms of objectives of the study using descriptive and inferential statistics. The collected data was coded and transformed to master sheet. Demographic data was computed using frequency and percentage. Mean, median, mean percentage, and standard deviation for knowledge and practice score was computed. Karl Pearson’s Correlation Co-efficient
was used to find the correlation between knowledge and practice score. Chi-square test was used for finding association between knowledge and practice score with selected demographic variables.

**Results and Discussion**

Statistical Package for the Social Sciences (SPSS) version 24 was used to analyze the data. Majority of study participants were between 20-30 years of age and also many of them were graduates. The results of other studies highlight the importance of education and educational programs to improve food safety knowledge and practices among mothers.\textsuperscript{11,12} World Health Organization (WHO) also suggests that advance education is comprehensively required to reduce the food-borne illnesses globally.\textsuperscript{13}

| Table 1: Level of knowledge and practice regarding food hygiene among women |
|---|---|---|---|---|
| Variable | Grade | Score | Frequency (f) | Percentage (%) |
| Knowledge | Poor | < 6 | 18 | 13.6 |
| | Good | 7-13 | 102 | 77.3 |
| | Very Good | 14-20 | 12 | 9.1 |
| Practice | Poor | 1-6 | 10 | 7.0 |
| | Average | 7-10 | 29 | 21.5 |
| | Good | 11-15 | 93 | 71.5 |

Table 1 depicts 77.3\% were had good knowledge on food hygiene. The mean knowledge score of women was 9.74±2.81. In other studies conducted in Nigeria and Sri Lanka showed good level of knowledge among study participants.\textsuperscript{14,15} In a community based study conducted in Ethiopia, almost 72\% of food handlers in food establishments had a good level of food hygiene knowledge.\textsuperscript{16}

In the present study practice of food hygiene among women was good which was assessed by self reported practice scale as depicted in the table 1. The mean practice score of women regarding food hygiene was 2.70±.475. In another study conducted in Saudi Arabia showed that food handlers had excellent practices towards food and personal hygiene. In a cross sectional study conducted among the street vendors in Kuching City revealed food safety knowledge, attitude, training and age of the food vendors influence the food safety practice.\textsuperscript{17,18}

**Correlation between food hygiene knowledge and practice score**

The hypothesis will be tested at 0.05 level of significance

\[ H_1: \text{There will be a significant correlation between knowledge and practice score on food hygiene} \]

Table 2 shows that there was a positive correlation between food hygiene knowledge and practice among women. Hence H₁ is accepted. In another study conducted on food safety among women of Khaza bazar, Karnataka depicted a positive correlation between knowledge and practice. In a survey conducted in Poland and Thailand also showed correlation between food hygiene knowledge and practice.

Association between the knowledge score and selected socio demographic variables:

The findings of the study revealed that there was no significant association between practice score and demographic variables. Hence $H_3$ is rejected.

**Limitations of the study:**

The study participants were finding it difficult to recall the information regarding the practice of food hygiene. Direct observation of food hygiene practice by the researcher is one of the limitations which influenced the study results. No other record was available to verify the practice responses given by the participants. It was a cross-sectional study, limited to smaller a small sample size; hence results cannot be generalized to the entire population.

**Conclusion**

The practice of food hygiene needs to be based on scientific knowledge. Every woman involved in the preparation, storage and serving of food to the family has to gather information regarding new trends, changes and myths about food hygiene. Research helps in carrying out this in a better way. This can possible through mass media. Communication through media can play a very important role in giving information to the women with simple messages in newspapers, pamphlets, magazines and television in local language which help in dispelling the myths and propagating the concepts and importance of food hygiene.

How Can the Maternal Age and the Basal Level of Serum FSH Predict the ICSI Outcome?

Maher Abbood Mukheef1, Rihab Abbas Ali2, Hind Hadi Majeed3

1Lecturer at University of Karbala/ College of Medicine/ Department of Biochemistry, Iraq, 2Assistant Lecturer at University of Karbala/ College of Medicine/ Department of Anatomy, Histology And Embryology, Iraq, 3Assistant Lecturer at Jabir IBN Hayyan Medical University/College Of Medicine/ Department of Human Anatomy

Abstract

Background: Age is an important factor affect female fertility, it is important to consider it while planning for intracytoplasmic sperm injection (ICSI). Basal follicular stimulating hormone(FSH) level can be an indicator of the ovarian reserve as the high level is associate with poor ovarian reserve and subsequently poor intracytoplasmic sperm injection outcome.

Objective: we aimed in this study to emphasize the role of age and basal serum follicular stimulating hormone level in predicting the intracytoplasmic sperm injection outcome.

Patients and Method: a sixty sub-fertile couple were involved in this study. They were divided into two groups according to the age of female partner. Group 1 ≤35 years old and group 2 >35 years old. We compared the difference in the basal follicular stimulating hormone level and the intracytoplasmic sperm injection outcome. Then we studied the association between the basal follicular stimulating hormone level and the intracytoplasmic sperm injection outcome.

Results: the study revealed that female ≤35 resulted in significantly better the intracytoplasmic sperm injection outcome. The no. of follicles, the no. of collected oocytes, no. of injected metaphase II oocytes (MII), no. of two pronuclei (2PN), total no. of embryos and no. of transferred embryos all were significantly higher in younger patients (P-value <0.05. The pregnancy rate was significantly higher in younger age group (47.5 % vs 25%, P-value = 0.04). There was a negative association between the basal follicular stimulating hormone level and the no. of follicles and no. of oocytes.

Conclusion: Maternal age is a good indicator for the success of the intracytoplasmic sperm injection procedure. The younger the female partner the better the intracytoplasmic sperm injection outcome. Basal level of follicular stimulating hormone is closely related to the ovarian reserve and subsequently the intracytoplasmic sperm injection outcome.

Key words: maternal age, basal FSH, ICSI.

Introduction

The assisted reproductive techniques involve both intracytoplasmic sperm injection (ICSI) and in vitro fertilization (IVF). In 1992 the Intracytoplasmic sperm injection (ICSI) was introduced to treat subfertility in couples due to severe male factor to allow fertilization and subsequent pregnancy whatever the semen characters were (1,2). However, (IVF) or (ICSI) was also helpful to patients with tubal factor subfertility, unexplained subfertility as well as some cases of polycystic ovarian syndrome (3).
The age of female partner in assisted reproductive techniques (ART) cycles is an important influencing factor, the association between the advanced maternal age and the poor ART result is well known (4). The diminishing ovarian reserve together with the decreased endometrial receptivity caused by aging are the possible explanation for this fertility reduction (5), this is beside increasing the follicular disappearance starting after the 37 years old (6). It is important to mention that advanced age is significant cause of increasing aneuploidy and spontaneous abortion rates (1). Different responses to the controlled ovarian stimulation were obtained from women in the same age. Moreover, diminished ovarian reserve and poor IVF outcome have been noticed in women under the age of 35 years old (7).

Basal level (cycle day 2 or 3) of serum follicular stimulating hormone (FSH) has been studied as additional factor predicting the ICSI outcome (8). Elevated basal level of serum FSH in sub-fertile women was associated with poor responses to the ovarian stimulation and subsequently lowering the pregnancy rate regardless the age (9). Conversely other authors, mentioned that basal serum FSH level could be unreliable predictor for reproductive potential in older group of women as measuring FSH concentration represent an indirect ovarian reserve assessment (10, 11).

Basal FSH level and maternal age are associated with the ART outcome independently. They are related to the ovarian reserve phenomenon, which reflect the quality and quantity of remaining follicles in the ovary (12).

In this study we aimed to estimate the role of maternal age and basal FSH level in predicting the ICSI outcome.

Patients and Method

This is a retrospective cohort study was done in the sub-fertility center of AL-Sader Medical city in Iraq- Al Najaf governorate. It involved retrieving data of sub-fertile couples who were referred to the center by their gynecologist for ICSI procedure during the period from October 2017 to May 2019. The study involved randomly collected 60 couples with different causes of sub-fertility (male factor n= 36, tubal factor n= 4, unexplained factor n=10 and anovulatory cause n= 10). For the female patients age, type of infertility (primary infertility: the patient had never get pregnant previously or secondary infertility: the patient had get pregnant at least once regardless the fate of the pregnancy) and duration of infertility were recorded. The female age ranged from 21 years old till 44 years. The female gynecological, medical and surgical history were taken into account. On the menstrual cycle day 2 (CD2) baseline transvaginal ultrasound (TVUS) was done to assess uterus, endometrium and ovarian condition. Blood sample was collected in the second day of the menstrual cycle for the measurement of basal level of serum FSH, serum estradiol (E2) and serum leulnizing hormone (LH) level.

Male partners were evaluated by seminal fluid analysis; biopsy was done for azoospermic patients. Sever endometriosis, anatomical uterine abnormalities, female age > 44, cancelled cycles and male partner with testicular atrophy were excluded. The whole study was clarified to the patients and an informed verbal consents were taken. The patients were grouped according to the maternal age into two groups: Group1≤35 and Group2 > 35. The ICSI outcome was compared between the two groups. CD2 serum FSH level was measured and the correlation between it and the ICSI outcome and patients age were analyzed.

Ovarian Stimulation, Oocytes Pick up and ICSI: The patients were involved in controlled ovarian hyperstimulation (COH) programs using recombinant follicular stimulating hormone +/- human menopausal gonadotropin (HMG) with pituitary desensitization by agonist /antagonist protocols which were chosen according to the patient’s age, body mass index (BMI) and cause of subfertility. Follicular maturation was followed by U/S and serial measurement of serum E2. Ova pick up was performed under general anesthesia guided by transvaginal ultrasound 36 hour after ovulation trigger with 0.1 mg decapetyl (gonadotropin releasing hormone
GnRH agonist) or 10000 IU of pregnyl (the human chorionic gonadotropin Hcg). In the ICSI procedure the good quality metaphase II (MII) oocytes were injected and incubated in special media. The fertilization was assessed 16_18 hr. after injection by identifying the two pronuclei(2PN). On the day 2 or 3 post injection the top quality embryos were transferred, not more than 3 embryos. The number and quality of picked up oocytes and the ICSI outcome in form of number of 2PN, number and quality of embryos, number of transferred embryos, fertilization rate, cleavage rate and pregnancy rate all recorded and statistically explained.

Statistical Analysis
The data analysis was done using Microsoft Office Excel 2016 and the SPSS 21 program (Statistical Package for social sciences). The categorical data were represented as number and percentage while numeric data were represented as mean ±SE. The difference between two numeric variables was studied by independent sample t-test and the association of categorical data analyzed by Chi-Square test. Pearson’s correlation test shows the correlation between variables. The significant P value is < 0.05.

Table 3 show the correlation between the CD2 serum FSH and the ICSI outcome. The CD2 serum FSH correlate negatively with no. of follicle and no. of collected oocytes.

**Discussion**

Female age and basal FSH level are independently associated with IVF outcome (7). The increased maternal age and its effect on the reproduction is a subject of interest because it affects negatively oocytes and embryos quality and pregnancy rate (13,14). In addition to that the rates of obstetrical and maternal complication such as maternal death, prematurity, fetal and early neonatal death, and caesarian section deliveries (15).

The elevated basal FSH in many women discourage the option of ICSI/IVF as treatment option for them. This is due to that the high basal FSH is associated with lower assisted reproduction treatment results (16). The age and elevated serum level of basal FSH in women are used as predictive criteria associated with diminished fertility (17). In this study we re-evaluated the association between the ICSI outcome and the maternal age and basal FSH level.

The study showed significantly better ICSI outcome in women younger than 35 years old. This is probably due to the better oocytes quality and better ovarian reserve in young women. The no. of follicles, no. of oocytes, the no. of injected oocytes, no. of 2PN (fertilized oocytes), no. of embryos and pregnancy rates were all significantly higher in younger group of patients. Many studies were in agree with this results (12,15, 18, 19,20, 21,22). On the other hand, the level of basal serum FSH was higher in older women group but still the difference was not significant may be due to the minimum differences in the age of the individuals between both groups. The higher level of FSH in older women is indicative of decreased ovarian reserve. A study reported that there were no significant differences in level of FSH with age (23). When we studied the association of the basal serum FSH level and the ICSI outcome, there was significant negative correlation between the FSH level and the no. of follicles and the no. of collected oocytes. This is because the FSH secretion from the pituitary gland increases with diminished ovarian reserve and women with high basal FSH frequently have lower no. of collected oocytes. There were studies which were in agreement with our finding in that the elevated FSH level is associated with poor ICSI outcome (7,12,24).

The limitation for this study

Conclusion: the maternal age is a cornerstone factor affecting the outcome of ICSI. The basal FSH is a good indicator of the ovarian reserve. Both of age and basal FSH are a good predictor for the success of the ICSI procedure.

Conflict of Interest: Non.

Source of Funding: Self-Funding.

Ethical Clearance: We obtained the ethical approval for our study from the institutional ethical committee. The patients were voluntarily participated in the study after they understood the aim of the research and verbal consents were taken from them. The participants were awarded that their information would remain strictly
confidential and would be used for research purpose only.

Abstract

Worldwide, Snakebite is an important and preventable health hazard in many of the tropical and subtropical countries. Death following snake bite is a cumulative effect of all the toxic reactions that are produced by the snake venom in the body of the victim. Globally it is estimated that the true incidence of snake envenomation could exceed 3 million per year and about 1,00,000 of these develop severe sequelae. With this background, a study has been conducted to determine the pattern of snakebite death cases, autopsied at KIMS, Hubballi, Karnataka. The study revealed that maximum number of snakebite cases were recorded in the rainy season (34.9%) followed by the winter season (31.7%). In a greater number of cases the incidence of snake bite occurred predominantly in lower limb (54%) as compared to upper limb (46%). Peak incidence of snake bite was recorded in the time between 08:00 am to 04:00 pm (41.3%) followed by 04:00 pm to midnight (30.2%). Majority of the cases were declared dead (47.61%) within 24 hours of initiation of anti-snake venom. The cause of death in majority of the study population was respiratory failure (92.06%) followed by shock (7.93%).

Key words: Snakebite, Death, Autopsy, Survival period and Cause of death.

Introduction

The word ‘Snake’ is derived from the Anglo-Saxon word ‘Snaca’ meaning the creeping. Nearly 240 million years ago the creeping animals were seen and were called as ‘reptiles’. They became enormous in size and predominated till the time mammals were about to be born. Evolution of reptile’s dates back to 240 million years during the cretaceous period, crocodiles, turtles, lizards and snakes all of them belong to reptiles, once inhabited the earth surface in enormous numbers. Origin and evolution of peculiar structure of snakes is not clearly known, so many hypotheses have been formed to explain it. There are more than 3500 species of snakes in the world and about 216 species are found in India, out of which only about 52 are poisonous. Snake bite remains a major public health problem in most of the countries even though it is difficult to be precise about the actual numbers involved. Various estimates have shown almost the same statistics that 15,000 to 25,000 people die annually in India due to snake bite envenomation. Maharashtra state with highest incidence of snakebite reported, 70 bites per 1,00,000 population and mortality of 2.4 per 1,00,000 per year. With this background present study has been carried out at KIMS, Hubballi, Karnataka to find out the most common site of snakebite in humans, most common season of the year, where maximum number of snakebites are occurred, most common time of snakebite in a day, most common cause of death and survival period of a snakebite victim after initiation of anti-snake venom.

Materials and Methods

This study has been carried out at the department of Forensic Medicine and Toxicology, KIMS, Hubballi, Karnataka, by taking all the cases brought for medico
legal autopsy with the history of snakebite and cases that were diagnosed as snakebite injury case after post mortem examination during the period of two and half years, from July 2016 to December 2018. Total 63 cases were selected for this prospective study. In all the cases of snakebite, the detailed history and information were collected from the police and the relatives of the deceased with the help of questionnaire, and post mortem findings were analyzed. In case of hospital admitted and treated cases the information’s were collected by the perusal of hospital records. The cases with the history of scorpion bites, bee sting and any other insect bite envenomation were excluded from the study group. Meticulous autopsy was done in all cases.

The present study has been carried out after obtaining the ethical clearance and consent from the relatives to take the relevant information.

## Results

Total 63 cases were selected for the present study and the following observations were made. The study revealed that Maximum incidence of snakebite i.e. 22(34.9%) were in third quarter (rainy season) July to September month, followed by in fourth quarter (winter season) October to December 20(31.7%) and 13(20.6%) in second quarter. Least incidence was seen in between January and March.

From the above study it is observed that maximum incidents of snakebite poisoning occurred between 8:00am to 4:00pm i.e. 26 cases (41.3%) as in this period, people commonly will be working in outdoor field, followed by evening time 4:00pm to midnight i.e. 19 cases (30.2%) and least incidence was seen from midnight to morning 8:00am.

From the above study it is observed that among total 63 cases of study population, 42 cases were admitted in hospital after a snakebite, and were managed with anti-snake venom initiative and 21 cases were brought dead. Among those snake bite admitted cases maximum number i.e. 20(47.61%) were declared dead within 24 hours of initiation of anti-snake venom.

Discussion

The objectives of the present study are to find out the common site of snakebite in humans, most common season of the year; where maximum number of snakebites are occurred, most common time of snakebite in a day, most common cause of death in snakebite poisoning and survival period of a snakebite victim after initiation of
anti-snake venom.

Our present study has showed the highest similarities with all the parameters mentioned above, when compared with other similar studies done in the past.

In our present study majority of snakebite cases 22(34.9%) occurred during month of July to September. Similar findings were observed with the study conducted by Sharma et al7, where in maximum cases of snake bite were seen in July to October i.e. 54%. This study proves the fact that there is a definite seasonal pattern in cases of snakebites. This is due to the fact that this is the monsoon season and rainfall forces snakes to venture out of their water-filled pits and also there will be increased human activity in fields at this period as it is the sowing season. A similar trend was observed in studies conducted by Viramani SK et al8 and Sani UM et al9.

In our present study many of study population was got bitten by snake on the lower limbs i.e. 34(54%). Similar findings were observed with the study conducted by Rao et al10, where in out of 60 cases of snake bite poisoning, 27(45%) of bite sustained in lower limbs. Another study done by Ashok Kumar Shetty et al11, observed maximum number of snake bite was found in lower limb (75%).

In the present study, the maximum incidence of snakebite occurred between 08:00 to 15:59 hours i.e. 26(41.3%), followed by 16:00 to 24:00 hours i.e. 19(30.2%). Similar study done by Rao et al10 found that maximum bites were seen in between 12:00 PM to 04:00 PM. Another study conducted by Halesha BR et al12, it is found that maximum incidence of snake bite occurred during the day time (70.5%). These findings are in agreement with the present study.

In our present study 42 patients received anti-snake venom treatment. Out of it 20(47.61%) victims died within 24 hours after giving treatment with anti-snake venom. Similar findings were observed with study conducted by Ramakrishna Set al13 and UM Natarajan et al14. When treatment was started before 12 hours of bite, the mortality rate was 2.6% and if treatment was delayed for more than 12 hours of bite, the mortality rate was 13.5%.

In this present study, it also observed that in maximum number of snakebite poisoning cases the cause of death is respiratory failure 58(92.06%) followed by shock 5(7.93%).

Conclusion

In the present study it is concluded that, maximum number of snakebite cases were recorded in the rainy season (34.9%) followed by winter season (31.7%). In a greater number of cases the incidence of snake bite occurred predominantly in lower limb (54%) as compared to upper limb (46%). Peak incidence of snake bite was recorded in the time between 08:00 am to 04:00 pm (41.3%). Majority of the cases were declared dead (47.61%) within 24 hours of initiation of anti-snake venom. The cause of death in majority of the study population was respiratory failure (92.06%).

To reduce the incidence of snakebite poisoning, we advise people not to work in an endemic area without footwear, especially at night. People working in the field are motivated to use low cost footwear’s. Especially in rainy season, people should be very cautious while working to avoid stepping on the snake. Area surroundings of any human habitation or working fields should be kept clean from all kind of debris, garbage and rubbish.

Mortality and morbidity due to snakebite poisoning can be reduced by providing first aid as early as possible. All primary health centres should be fully equipped with facilities to give first aid measures and administer specific anti-snake venom if required. Admit the patient to the nearest hospital for further management. Since snake bite is primarily a rural occupational hazard, dissemination of information regarding readily available effective treatment may drastically bring down the morbidity and mortality associated with treatment by quacks.

Comparative Study Thymol Oil and Some Gel Face Washing on Resistance Propionibacterium Acnes

Mais E. Ahmed\(^1\), Jenan A. Ghafil\(^1\), Walaa Najim\(^2\)

\(^1\)Assistant Professor, Lecturer, College of Science, Department of Biology, University of Baghdad, Baghdad, Iraq, \(^2\)Instructor, Institute of Laser Graduate Studies, Baghdad, Iraq, Department of Biology /College of Science /University of Baghdad

Abstract

Acne is elevated of skin secretion with hyperkeratosis causing Propionibacterium acnes. The goal of study was to assess the anti-inflammatory, and antibacterial potential of Thymol oil compare Gel face, and is the main bacterium involved in the acne. The unpredictable use of antibiotics for the treatment of acne may end up within the advancement of bacterial resistance.

Key words: Thymol oil, P. acnes, oil, Gel face, Hyperkeratosis

Introduction

A Gram-positive P. acnes is, anaerobic bacteria which colonizing the lipid-rich sebaceous surface of the human skin\(^1\). It has a place to the clinical gather of skin commensals, but can very soof ten cause genuine contaminations deciding the nearness of P. acnes contamination can be troublesome. Due to its less harmfulness, contaminations are less dolente \(^2\).

Skin break out could be an incessant incendiary illness of the pilosebaceous joins together, fundamentally of the confront, nose, shoulders and upper arms. It is one of the most common dermatoses affecting high school populace \(^3\). Acne vulgaris one of the most common skin disarranges, and dermatologists are still have long struggled to treat acne completely. It primarily influences young people, in spite of the fact that it may display at any age. It is nearly all inclusive malady happening in all races. The rate of seriousness of skin break out, top at (40%) in 14-17 year ancient young ladies and (35%) in boys matured 16-19 year \(^4\). It influences the skin of the confront, neck and upper trunk. These specific sebaceous follicles have capacious follicular channels and voluminous, multiacininar sebaceous organs. Skin break out creates when these specialized follicles experience pathologic change that comes about within the arrangement of non-inflammatory injuries (comedons) and fiery injuries (papules, pustules and knobs \(^5\). The intemperate utilize of anti-microbial for long periods has led to expanded resistance in skin break out causing microbes i.e. P. acnes and S. epidermidis against a number of anti-microbial utilized to treat skin break out \(^6\).

The antibacterial properties of EO has long been recognized and broadly tried in vitro against a broad run of pathogenic microscopic organisms, counting both (G\(^+\)ve) and (G\(^-\)ve) bacteria\(^7\). One of the foremost copious bunches of normal compounds is spoken to by the fundamental oils, Fundamental oils (EOs) are fragrant sleek fluids gotten from plant fabric.

They can amplify the rack life of natural or prepared nourishments by decreasing microbial development rate or reasonability. A few of these substances are moreover known in its contributions to self-defense of plants against irresistible life forms \(^8\).

Thymol a phenolic compound show in fundamental oils, may be a common monoterpene and carvacrol isomer that extricated from thyme and the other sorts of plants. Thymol is less water dissolvable at unbiased pH,
but it is as well dissolvable in some natural solvents and liquor \[9\].

The carvacrol and thymol antioxidant impacts of have been affirmed in a few considers, recommending their organization as nutritious components within the enhancement of novel useful nourishments. Thymol defensive nature against chars the field of drugs in dental caries\[^{10,11,13}\].

**Material and Methods**

Isolates strain were identified by microscopy and microscopy tests for identification of \textit{P. acnes}\[^{16, 18}\]. Directly transport from the pus and sterile disposable cotton swabs, transport media and carry to the laboratory.

Final identification by ViteckSystem 2: All the presumptive isolates (on blood agar (BA) medium and Brain heart infusion (BHI) agar were tested by Viteck2 system (Biomerix, France). This system used for diagnosis of \textit{Propionibacterium acnes}.

### Antibiotic sensitivity test \textit{P. acnes}:

The antibiotic sensitivity test was done accordance to \[^{14}\] by disc well diffusion using 5 type antibiotics.

### DNA extraction and Electrophoresis:

According to the extraction kit the samples’ examine the accuracy of the DNA extraction, photo absorption between (260 and 280) nm using a bio photometer.

The gel was then transferred to a transilluminator and the duplicated 1202 base pairs were examined under UV light.

### Emulsion preparation:

Three samples of anti-acne O/W washing with different compositions were obtain commercial market (Table I).

**Discussion**

The current results were coincides with previous results studied in Iraq of *P. acne* in different age (15). that acne prevalence was more in female than male, agree with most cases were in ages group between (15-20). Also agree with study in Iraq isolated *P. acne*.[17]

These results for identification *P. acne* were in agreement with[18,19] Viteck 2 System was a rapid, sensitive, to distinguish clinical isolates (20). The result agree with [21] The most using treatment (erythromycin) were anti *P. acne*.[22]
The antibiotics is topical application like clindamycin, tetracycline most common treatment of acne but the major problems growing in resistance of P. acnes to antibiotics caused[23].

The acne-gel with retinol had lower effect in agar dilution test. But shown that is highly effective at high concentrations against aerobic and anaerobic bacteria including P. acnes[24] the antiacnemore acts of oregano EO that of other evaluated including commercialized overthecounter acne treatment tea tree [25].

Conclusion

The antibiotics play an important treatment in acne administers. Resistance P. acnes treatment by antibiotic compares using natural oil most affections alternative commercial washing gel in pharmacy.

Conflict of Interest: The authors declare that there is no conflict of interest regarding this study.

Drug Abuse Prevalence and Effects in Coffee Shop Workers: A Cross Sectional Study

Makloph MG¹, Mohamed Masoud²

¹Lecturer of Forensic Medicine and Clinical Toxicology, Faculty of Medicine Fayoum University, Fayoum,  
²Assistant Prof. of Public Health, Faculty of Medicine, Fayoum University, Fayoum, Egypt

Abstract

Background: Drug abuse among population have become more common than before, coffee shops workers are of increasing chance to drug abuse, the facing of such big problem necessitates collection of information regarding the prevalence of drug abuse types and effects on health, and this will result in prevention of its hazardous on population at all.

Patients and Methods: cross-sectional study during the first day of April 2019 till the last day of September 2019, one hundred and twenty coffee shop workers were included. The workers were chosen from 12 randomly selected coffee shops located in rural and urban areas. The data were gathered through a questionnaire and urine samples from participants. The collected samples were taken to the lab and screened for drug abuse using dip stick, thin layer chromatography (TLC) and gas chromatography (GC-MS). The collected data were organized, tabulated, and statistically analyzed using statistical package for social science (SPSS Inc, version 22).

Results: the study showed that The prevalence of tramadol and cannabis and other synthetic drugs among coffee shop workers in urban and rural area nowadays more than before and their detection easily done by using GC-MS. hazardous on health among abusers more than non abusers.

Conclusion: The prevalence of drug abuse among coffee shop workers of increasing popular especially tramadol, cannabis and other synthetic drugs, between all age groups in urban and rural area, these drugs of abuse can be detected using dip stick, TLC and the most specific method of detection using GC-MS to confirm the results. Countries should plan for facing this cancer due to its bad hazardous and consequences on health, family and society.

Keywords: abuse, coffee shops, drugs, gas chromatography.

Introduction

Drug abuse is one of the important problems facing governments and people as it affects the population in their productive period of life resulting in decreased work productivity and national income of countries. Drug abuse results in destruction to patients and societies. For example, 25% of condemned prisoners have committed crimes under the influence of drugs.

Cannabis is one of the most common illicit drug in most of the world and its abuse increasing progressively. A large number of people have become users of cocaine, amphetamine and other new synthetic medications.

Tramadol has become increasingly popular among people for consumption and for sexual gratification especially in young adults, despite its prevention nowadays.
in Egypt, due to its low price and easy availability[6].

The real prevalence of drug abuse in developing countries not accurately detected due to lack in data regarding that problem[7].

In 2005, the Egyptian government has declared the report of the National Addiction Research Program which found that more than 12% of the Egyptian citizens are drug abusers. Cannabis was the most commonly abused substance (77%) followed by opiates in upper Egypt and the 3rd most common was alcohol, then pharmaceutical substances, stimulants and organic solvents, respectively[8]. Since 2008 tramadol abuse in Egypt has increased dramatically in all age groups and among a lot of people[9].

**Subjects and Methods**

**Study design**

This study was a cross-sectional study.

**Study sample**

One hundred and twenty coffee shop workers were included. The participants were chosen randomly from 12 selected coffee shop located within Fayoum governorate, 6 in rural and 6 in urban area.

The current study was conducted for 6 months from the first day of April 2019 till the last day of September 2019

Inclusion criteria includes coffee shop workers work for more than 2 year at this field, their age should be between 25 and 44 years old. We exclude those refuse to participate, those beyond the age and work limit .

**Data collection**

The following data were gathered through a questionnaire constructs of two parts:

The first part: demographic data such as Age from their birth certificate, education level, residence, marital state, social problem and smoking habit .

Second part: type of drug abuse, method of drug abuse and health state of the participant.

Pretested Pilot test of 30 coffee shop student was done to detect reliability of the questionnaire and cronbach alpha test was calculated where it was 0.877. According to its result certain questions were omitted and others were changed.

Followed by open ended questions containing the above mentioned data urine samples were collected from each individual accept to participate in the study, 50 ml of urine sample were collected in plastic container and freezed at minus 20 degree celesius at ice box. Samples were collected in front of examiner to prevent adulteration.

The collected samples were taken to the lab of forensic department Fayoum university to screen for drug abuse using dip stick (tramadol and cannabis) and thin layer chromatography(TLC).

Confirmation was done using Gas chromatography at the faculty of science Fayoum university. Chemicals for TLC had brought from Alnasr pharmaceutical co, Sleeve Hanover co Switzerland and Adwic chemicals co Egypt, while in G.C the column used was C18 and the reagent used was G.C grade using flame ionizing detector(FID).

**Statistical Analysis**

The collected data were organized, tabulated, and statistically analyzed using statistical package for social science (SPSS Inc, version 22). Data were presented as frequencies and percentages; chi-square ($\chi^2$) was used as a test of significance. For interpretation of the results of tests of significance, significance was adopted at $P \leq 0.05$ in the results. Sensitivity and specificity of the detection methods of the drug abuse in the collected samples were done using ROC curve (receiving operating characteristic).

**Results**

Descriptive statistics.
120 middle aged workers are working for 2 years or more in coffee shop were included in this study. 40 of them (1/3) were abuser, Basic characteristics were presented in table (1) with statistically significant $P \leq 0.05$ regarding smoking habit and marital status.

**Analytical Statistics:**

**Regarding** Prevalence of drug abuse according to types of drugs in descending manner

About one third of the participant 16/120 (13.1%) reported abusers of tramadol followed by cannabis (11.6%), tramadol and cannabis (8.3%), benzodiazepine (2.5%), morphine and MDMA (1.6 % for each), amphetamine and parkinol (.8% for each).

**Regarding** drug abusers (16/40) about 40% of the drug abusers are tramadol abusers followed by 35% for cannabis abusers, 25% for both drugs, 7.5% for benzodiazepine abusers, 5% for morphine and MDMA.
Regarding relation between smoking and drug abuse, the percentage of smokers among abusers were found more than 80%.

Regarding Age group and drug abuse the prevalence of abuser among age groups it was found that cannabis abuser among the first two age groups (25-29,30-34) higher than the other two age groups(35-39,40-44), while in tramadol the prevalence in the first age group less than other 3 age groups with the most higher level at the 3rd age group (cannabis abuse at younger age groups than tramadol), with non statistically significant p-value.

Regarding distribution of abuse in relation to residence, it was found that drug abusers more in urban than rural while in relation to type of drug abuse tramadol and other drug of abuse more in urban than rural and the reverse for cannabis.

Regarding Health status of the study participants, 46.6% of the study population were free from disease other than sex related problem , while the remaining participants suffering chronic hepatitis C were 16/120 (13.3%), musculoskeletal disorder, varicose vein and visual troubles skin problem, diabetics and hypertension in descending order . While health status of abusers 30% of them were free with significant p-value(0.005), the remaining participant suffering musculoskeletal disorder 9/40(22.5%) mostly those with tramadol abuse with
significant p-value<0.05, chronic hepatitis 8/40(20%) mainly those with tramadol and morphine with significant p-value(0.019), respiratory problem mainly those abusers of cannabis with significant p-value(0.001), flat foot, visual trouble, varicose vein, poliomyelitis, DM and hypertension in descending manner of order with non significant p-value>0.05. About one third of workers had sexual problems 44/120 (36.7%), while drug abusers suffer more complications regarding sexology 18/40 (45%) than non abusers with significant p value regarding ejaculation mainly abuse tramadol p-value (0.05)

Regarding dip stick sensitivity in diagnosis of drug abuse versus TLC and GC.MS, As compared to GC.MS, both TLC and dip stick had a sensitivity and NPV of 100% in diagnosing Tramadol, Cannabis & combined Tramadol and Cannabis abuse. However, specificities were 98.1%, 99.1%, and 98.2% for TLC and 96.2%, 98.1%, and 95.5% for dip stick in identification of Tramadol, Cannabis and combined Tramadol and Cannabis abuse, respectively. As regards PPVs, they were 88.9%, 93.3%, and 83.3% for TLC and 80.0%, 87.5%, and 66.7% for dip stick in diagnosis of Tramadol, Cannabis and combined Tramadol and Cannabis abuse, respectively.

*Not mutually exclusive
about one third of those reported drug abuse had taken drugs to relief pain 14/40 (35%) mainly tramadol, while the other use drugs for sexual desire and increasing work effort mainly tramadol, respectively. A little use drugs for fun and curiosity ,mainly cannabinoid. Majority 28/40 (70%) had taken drugs in the form of oral tablets followed by smoking , syrup , and injection . about 3/4 of the participant 30/40 (75%) reported that they take drugs frequently. Most workers 30/40 (75%) had used drugs at night, table (3).

**Regarding** Social effect Majority of workers with drug abuse reported that they had quarreled at work 28/40 (70%) while less than one quarter of abusers were imprisoned before 8/40 (20.%), also delivery and family problem is more in abusers (35%) than in non abusers.

**Discussion**

Drug abuse refers to the self-administration of any drug in a way that deviates from the approved medical or social pattern within a given culture and it may not necessarily involve any physical, psychological or physiological dependency like an occasional experimental use of LSD for fun is drug abuse but not drug dependence[10].

Regarding smoking habits the present study in agreement with those found by Degenhardt L, et al 2009[11] which stated that there is a strong relation between smoking and drug abuse so smoking is the door for abuse.

In reference to the drug of abuse , In the present study we found cannabis and tramadol were the predominant drug of abuse contrary to that was found in china by Hong et al,2014, where it was found that amphetamine like synthetic drugs is the predominant drug of abuse with reduction of opiate abusers due to strong control[12]. Also in Japan in a study done by Wada K.2010[13] and Yasukazu Ogai,2015[14] they found methamphetamine , cannabis and MDMA the predominant drug of abuse with shift to new designer drugs to avoid arrest and imprisonment.

Regarding the epidemiology of abuse , the present study show that a little bit more than one third of the study population were abusers the same was found by Maryse Lapeyre et al,2004[15]. abuse started at younger age with tendency to abuse polydrugs either naturally or synthetically, the same was found by Hong et al,2014[12]. multi drug abuse were found in the present study in accordance with that was found by Jones et al ,2012[16].

Tramadol widespread abuse found in this study in agreement with those found by Aboelmaged et al,2013[9] and Fawzi ,2011[17] in Egypt, spiller et al ,2010 in the USA[18] and Nazarzadeh et al ,2014 in Iran[19]. The widespread use of tramadol in Egypt was probably due to its easy availability, its low cost and its use in sexual desire.

Contrary to the present study results regarding prevalence of drugs of abuse, Hamdi et al,2016[8] found cannabis is the main drug of abuse , this is my be due to difference in the study population or the place or size of the study participants.

Opioid abuse in the present study found to be less than other drugs of abuse In consistency with those found in the report of united nation office (UNODC,2014) [20] which stated that the use of opioids in north Africa lesser than other abused drugs the same was found also by Senna et al ,2010[21].

In other countries benzodiazepine abuse as common as THC as that occur in Australian study done by Drummer et al,2012[22] also in Brazilian study done by De boni et al, 2014[23] this contradiction with the present study may be due to study population difference, legislation done by countries , availability of drugs or cost.

From the present study tramadol and other synthetic drugs were abused in urban more than rural areas while cannabis abuse in the village more in the town , Rigg and monnat ,2015 found that urban residents show increased prevalence of opioid in urban than rural population[24] contrary to that Domingo et al 2015 found that the prevalence of cannabis was found more in urban area.
than rural area\textsuperscript{25}. While Wang et al, 2013 found that there is no big difference in prevalence of opioids among urban and rural areas\textsuperscript{26}.

The present study show that cannabis abuse mostly occur at younger ages than tramadol, Domingo et al, 2015 found that the prevalence of cannabis was found more in younger age groups\textsuperscript{25}, contrary to that Tjaderborn et al, 2016 found increasing prevalence of tramadol among younger age groups in Sweden\textsuperscript{27}.

The present study agreed with that done by Elsawy et al, 2010 regarding the motive for drug abuse which was due to peer pressures, get pleasure and mode improvement\textsuperscript{28}. While el akabwi, 2001 found that curiosity and desire to have fun were the main motive for abuse\textsuperscript{1}. Maryse Lapyere et al, 2004 found that regarding the motive for drug abuse in work, 20% used drugs to be in good form at work, 12% used drugs at the workplace for an awkward symptom, and 18% used drugs to relax after a difficult day’s work\textsuperscript{15}.

Drug abuse definitions are used in public health, medical and criminal justice contexts. In some cases criminal or anti-social behaviour occurs when the person is under the effects of a drug, use of some drugs may also lead to criminal penalties\textsuperscript{29}, the same was found in the present study where a lot of workers with drug abuse reported that they had quarreled at work others were imprisoned before for committing a crime under the influence of drug abuse.

Regarding sensitivity for analysis of drug of abuse we found GC and TLC was better than dip stick in detection of poisoning, the same was found by kim et al, 2016\textsuperscript{30}. Where the presence of codeine may give false positive results with dip stick confounding opiates as that found by Botvin et al, 2010\textsuperscript{31}. Also ibubruphen can cause false positive results confounding for THC as that found by James, 2011\textsuperscript{32}.

**Conclusion**

The prevalence of drug abuse among coffee shop workers of increasing popular especially tramadol, cannabis and other synthetic drugs, between all age groups in urban and rural area, these drugs of abuse can be detected using dip stick, TLC and the most specific method of detection using GC-MS to confirm the results. Countries should plan for facing this cancer due to its bad hazardous and consequences on health, family and society.

Psychosomatic Effects of Sexual Harassment and Violence on Undergraduate University Female Students; A Cross Sectional Prevalence Study

Makloph MG

Lecturer of Forensic Medicine and Clinical Toxicology, Faculty of Medicine Fayoum University, Fayoum

Abstract

Background: Sexual harassment is the plague of that century due to its tremendous prevalence in various societies, it is unwanted and unaccepted sexual conduct with a female either verbal, non-verbal or physical, and it affects the physical and psychological wellbeing of the victim.

Patients and Methods: Cross-sectional study was done during the period of October 2019 till January 2020. Five hundred and four participants aged between 19 and 25 years old randomly selected, distributed on nine faculties, a questionnaire constructed of three parts given to each participant to collect data about type of abuse and psychosomatic effect through the use of standardized questionnaire. The collected data were organized, tabulated, and statistically analyzed using statistical package for social science (SPSS Inc, version 18).

Results: The study showed significant relationship between physical harassment and psychosomatic effects also method of harassment and frequency of harassment is a risk factor for occurrence of psychosomatic effects, and family response regarding perpetrator affect profoundly psychosomatic effects. The main harasser were university students.

Conclusion: The prevalence of sexual harassment now days resemble a cancer due to its wide spread and diffusion within the societies and its profound effect on the well being of the victim causing profound psychosomatic effects. These effects are affected by the method of harassment and the frequency of exposure. Families should have strong reflex against the perpetrator as this help the victim recovery and affects its profound effects on her well being.

Keywords: harassment, students, perpetrator, psychosomatic, verbal.

Introduction

Sexual harassment is defined as verbal, non-verbal or physical contact of sexual nature with a female without her permission. It is unwanted sexual contact with a female without her consent and affects her physical and psychological wellbeing. So it is any annoying or unpleasant behavior towards someone that occurs through any sexual form either corporeal, verbal or non-verbal act.

Sexual harassment is the commonest form of abuse and violence against women world wide generally and locally and increased tremendously at the last 25 years changing physical and psychological wellbeing of the harassed victims.

Sexual harassment takes many forms namely: Verbal as sexual comments, words, jokes, threats, sounds
or whistlers. Non-verbal as pictures, photos, graphics, twinking, gestures or massages. And Physical as sexual violence, inappropriate contact, touch, fingering, attempted sexual intercourse or assault[5].

Sexual harassment has rapidly increased recently in the Middle East’s countries especially, Egyptian society. in 2006 holiday of Eid El Fetr, Egypt got up on mass sexual harassment events in Cairo governorate. Two Years after, a worse mass sexual harassment incidents occurred in Giza governorate. 62% of Egyptian men said that they had sexually harassed women; and above 80% Egyptian women reported that they were sexually harassed once before [6].

High rates of sexual harassment against female was found at the academic universities and work places and it happens to be around 50% in university[1].

Effects of harassment on individuals include

- Decline academic performance.
- Failure in exam and career loss.
- Loss of motivation, anxiety, stress.
- Loss of interest and trust in people.
- Discrimination and introversion.
- Reference loss and relocation[7].

**Subject and Methods:**

**Study design:**

A cross-sectional study was done during the period of october 2019 till January 2020.

**Study sample:**

Five hundred and four participant aged between 19 and 25 years old randomly selected, distributed on nine faculties in relation to their students percentage of the university, (social science(22%), agriculture(18%), education(15%), science(12%) rights and law(10%), nursery(8%), engineering(6%), medicine (5%), arts(4%) education they were involved in the current study after explaining the purpose of the study and taking their consent.

Inclusion criteria: undergraduate Female Egyptian population study at Fayoum university, aged more than 18 year and below 26 years old.

Exclusion criteria: those refuse to participate in the current study, the above 25 and those below 19 years old, those with chronic illness, mentally deficient or handicapped and those with bad conduct and reputation.

**Data collection**

Pretested Pilot test of 30 female student was done to detect reliability of the questionnaire and cronbach alpha test was calculated where it was 0.785, according to its results certain questions were omitted and others were changed.

**The Questionnaire constructed of three parts:**

The first part: open ended questions regarding demographic data such as Age of the victim from their identity card, faculty, residence, marital status, family response regarding harassment, whether the harassed was alone or not, who was the perpetrator, whether the harasser was a lone or in group, his smoking habit and his relative age.

Second part: We use modification of sexual experience questionnaire including 19 items resembling the three types of sexual harassment, In addition to site of harassment, time of harassment and way of dressing of the harassed[8].

The third part: about psychosomatic effects on harassment and it was taken from WHO in the form of standardized self reported questionnaire of 20 item(SRQ20) to diagnose for psychological insult if more than 6 items of the questionnaire were positive[9].

Well trained faculty employees at student affairs unit at each faculty included within the study were used to collect data after explaining the purpose of the research, information collected were ascertain privacy and only for research purpose and collected data was
under direct observation of the researcher of the study.

Statistical analysis

The collected data were organized, tabulated, and statistically analyzed using statistical package for social science (SPSS Inc, version 18). Data were presented as frequencies and percentages; chi-square ($\chi^2$) was used as a test of significance, and multinomial logistic regression analysis was used to predict for future psychosomatic effects as the dependant factor was categorical dichotomas variant. Also univariate analysis used to document relationship between certain variables. For interpretation of the results, the 2 tailed-significance was adopted as a test of significance at $P \leq 0.05$.

Results

From seven hundred and fifty interviewed female undergraduate students Only 5 hundred and four female undergraduate students accepted to participate and completed the questionnaire given, of whom only one hundred and twenty four showed exposure to harassment within a year.95% were single, sexual harassment at social science faculty and education faculty was more than other faculties (22%,18% respectively) with the least prevalence of harassment within the faculty of medicine and rights and law(6%,5% respectively), mean age (22 years+SD2.2) with non specific p-value regarding harassment.

The results showed that statistically significant p-value($<0.05$) regarding phi and chi ($\chi^2$) square between Reaction of harassed toward harassment and Type of harassment and Site of harassment. family reaction toward harasser strongly and significantly dependant on the type and method of harassment as pulling harassed clothes and rape attempt was faced by strong family response against harasser but verbal or non verbal harassment not faced as such by the family of the harassed victim.

The results showed also that statistically significant p-value( < 0.05) regarding phi and chi($\chi^2$) square between Perpetrator reaction later and Family reaction where the family response toward the harasser affect later recurrence of the effect. and between perpetrator and being alone or in group as harassment occurs once the perpetrators are in groups than being a lone and also with the Site of harassment.

Using multinomial logistic regression several factors can predict psychosomatic effect of harassment on the harassed in the future with statistically significant p-value (<0.05) such as frequency of exposure, family reaction toward the perpetrator, individuality of the harassed victim and method of physical harassment.
Discussion

Sexual harassment has been known as the most frequent form of sexual abuse and violence and against women. It is a form of social control done by male to keep female in place under control\[^{[1]}\].

Regarding the prevalence of sexual harassment, the present study should that 24.6% of females within the Fayoum university were sexually harassed, contrary to that Sang et al, 2016 in their study at Eldoret found that about 50% of the interviewed students have experienced various forms of sexual harassment against their well\[^{[10]}\]. Fitzgerald et al reported prevalences of more than 70% for women from a US military sample in 1999\[^{[10]}\].

In Europians the percent of sexual harassment within the universities were 30-50%\[^{[12]}\]. One third of college victims in the USA were a victims of harassment\[^{[13]}\]. More than two third of college victims in Ethiopia were victims of harassment\[^{[14]}\]. Also Hussain JH, 2015 found that 28% of Lebanon were sexually harassed\[^{[15]}\]. Danish union survey found that, 26.5% of women had experienced some form of unwanted sexual harassment in the workplace during the last year\[^{[16]}\].

The Present study found statistically significant p-value between only physical type of harassment and psychosomatic effect except if the harasser was one of the relatives of the harassed victim, this is because some form of harassment doesn’t consider as a form of harassment in some societies and once the relative is the harasser it is shameful and destructive to the wellbeing of the harassed as the relatives are supposed to defend the victim not to harassed him. This was in contrast with that found by Almaz et al, 2015 where he found statistically significant p-value regarding all types of harassment\[^{[17]}\].

Borge et al, 2019 found that 17.1% of women, had been verbally harassed since. At a similar level, 15.2% of women reported unwanted touching, hugging or kissing since they started on the college/university studies\[^{[18]}\].

Victims of sexual harassment are more likely to suffer from short-term and long-term health problems\[^{[21]}\], those exposed to sexual harassment have more mental and psychological\[^{[22]}\] and somatic health problems\[^{[20]}\]. Harassment is related to mentality disorder such as anger and depression also related to abuse\[^{[23]}\].

The present study showed that the harassed female students were affected by psychosomatic disorder in 40% of cases contrary to those found by Ogbonya 2011 where he found More than 85% of Nigerian female students at Ebony State university suffer from psychological distress after harassment\[^{[24]}\], also 63% of Ethiopian female students at Jimma university suffer from psychological distress after harassment\[^{[17]}\].

Regarding the psychosomatic effects of harassment on the harassed victim the present study showed that the victims suffering headache (10%), phobia (6%), loss of appetite (5%) and menstruation problem (4%) contrary to that Sang et al, 2016 found that Effects of Sexual Harassment on students, most of them indicate Feeling angry" (40%), phobia (38%) and lost contact with people (36%). However, fewer students express that their daily life will be affected, such as Sleep disturbances (7%) and Eating disorders (10%)\[^{[10]}\].

The present study showed that the in campus harassers were mainly male students and to a less degree
staff persons the same was found by sang et al ,2016 they found that Most Sexual Harassment incidents is perpetrated by male students. Also teachers and teaching staff to a minor degree[10],Timmerman ,2005 in his study in Netherlands and found that most harassers were male students rather than teaching staff[25], also male Students were the most harassers in US study[26], the present study also showed drivers are the most harassers out campus, The majority of recent harassment acts were committed by someone outside of the university setting, while a student and university staff member committed the harassment in 25% and 3%, respectively, of the instances as found by Borge,2019[18].

The present study showed significant p-value regarding the way of dressing of the victim and occurrence of harassment the same was found by Hussain JH 2015 where he found that 63% of Lebanon think that their way of dressing is the cause[15].

**Conclusion**

The prevalence of sexual harassment now days resemble a cancer due to its wide spread and diffusion within the societies and its profound effect on the well being of the victim causing profound psychosomatic effects , these effects are affected by the method of harassment and the frequency of exposure. Families should have strong reflex against the perpetrator as this help the victim recovery and affects its profound effects on her well being.

Abstract

Cleft lip/palate (CL/P) is one of the most common birth defects in humans. Haploinsufficiency in genes Bone Morphogenetic Protein (BMP) 2 is thought to play an important role in the incidence of CL/P. This study aimed to identify changes in the nucleotide (Single Nucleotide Polymorphism/SNP) BMP 2 rs235768 A>T gene in CL/P patient in Indonesia. Seventy samples of DNA that were successfully amplified and restricted consisted of patient and control samples with the three of which were used for sequencing. Based on the analysis using restriction enzymes and Finch TV and Bioedit software programs, this study identified a change from nucleotide A to nucleotide T which is a mutation missense (Serine-Arginine/TCA-TCT). Based on the results of the Fisher’s exact test, there was difference in genotype frequency between the CL/P group and the control. Meanwhile, there was no difference in allele frequencies between the two groups. The allele frequency T has a higher value than the frequency of the allele A.

Keywords: Gene BMP2, SNP, Cleft lip/palate, Indonesia.

Introduction

Cleft lip and/or palate (CL/P) is the most common congenital abnormality caused by a complex multifactorial interaction between gene variation and environmental exposure. Individuals with CL/P face many challenges, such as anatomical deformities, dental problems, eating and speaking difficulty, hearing loss, and impaired maxillofacial growth. Psychologically, individuals with CL/P also experience a low quality of life index. The incidence of CL/P varies between countries, socioeconomic status, race, or ethnic group. This variation causes the Asian population to have the highest prevalence (1/500 births) and the African have the lowest (1/2500 births) while Caucasians have the prevalence 1/1000 births.

In recent years, advances in genetics and molecular biology have begun to reveal the basis for craniofacial development. A number of genes associated with the incidence of CL/P have been identified and developed...
to study the etiology of CL/P, namely genetic and environmental. Bone Morphogenetic (BMP) is an important gene candidate in the craniofacial pattern located on chromosome 14q22-23 in humans. More than 20 BMP genes have been identified. Currently, BMP 2 and 4 are classified as subfamily of dpp (decapentaplegic) due to similarities with the dpp gene in Drosophila. BMPs 5, 6, 7, and 8 are classified as the 60A subfamily, BMP3, and 3b (GDF10) in which are classified as separate subfamilies. BMP has receptors, namely BMP (BMPR) type I and type II (BMPRI and BMPRII).

A small proportion of SNPs become biological markers for the determination of a disease on the human genome map because these SNPs are located on genes that are found to be associated with the disease. The SNPs associated with a disease can be used to find and isolate the gene that causes the disease. The SNP pattern in target genes from the results of comparative studies between case and control groups in association studies can be used to design therapeutic targets and response of drugs in a population.

In the study of Sahoo et al., haploinsufficiency in the BMP 2 gene plays an important role in cleft palate formation. Two individuals with similar cleft defects are reported to have microdeletions that only included BMP2. Microdeletions associated with CL/P have also been reported in several studies including 20p12.3 in which BMP2 was deleted. In 2018, Saket et al. published the results of a study on the variation of the BMP2 gene sequence at risk for the incidence of NSCL/P in the Iranian population. It is noted that there is a significant association between the polymorphism of BMP2 rs235768 A>T and the incidence of CB/L. This study aimed to identify changes in nucleotide bases (Single Nucleotide Polymorphism/SNP) of the BMP 2 rs235768 A>T gene in CL/P patients in Indonesia.

**Materials and Methods**

This study examined patient (CL/P) and control groups. The CL/P patient group consisted of 34 samples and 36 samples from the control group. DNA was extracted from peripheral blood using Promega A1120Wizard® Genomic DNA Purification Kit DNA at the Human Genetic Laboratory, Institute of Tropical Diseases, Universitas Airlangga. This research has been approved by the ethics committee of the Faculty of Dentistry, Universitas Airlangga with a certificate number 606/HRECC.FODM/IX/2019.

Polymorphism of the BMP2 gene rs235768 A>T was analyzed with PCR-RFLP method. The primers used were produced by Integrated DNA Technologies, namely 5’ GAAACGAGTGGAAGAACAC-3’ and 5’GAGACACCTGGTCTTCTCTCAA-3. The reaction among PCR 25 µl 2.5 µl Promega Go Taq™ Master Mixes, primary forward 2.5 µl (10 µmol), reverse primer 2.5 µl (10 µmol), template 7.5 µl was amplified with the BioRadCycler PCR machine. The PCR machine procedure is at 58°C for 00:30 seconds and 34 cycles followed by elongation at 72°C for 00:40 seconds. Electrophoresis was conducted using 2% of agarose gel (Promega) at 100 V for 30 minutes and a PCR product was observed at 353 bp length. Furthermore, the RFLP method was carried out using BsrI restriction enzyme from Thermo Scientific. Afterwards, the enzyme mixture and PCR products were incubated at 65°C for 1 hour and inactivated at 80°C for 20 minutes. Visualization of the RFLP band was electrophoretic 100 V for 35 minutes and the cut tape could be seen in a UV light to read the results.

There are three variations of the genotype results, namely 353 bp for wildtype homozygote (AA); 353 bp, 200 bp, and 153 bp for mutant heterozygote (TT); 200 bp and 153 bp for mutant homozygote (AT). All statistical analysis was performed using SPSS Inc., IBM Corporation, NY, and USA Statistics Version 16. The Fisher’s exact test was used to analyze the distribution of genotypes between two groups. Genotype and allele frequencies were calculated and assessed by the Hardy Weinberg Equilibrium where a p-value <0.05 was considered to be statistically significant in all groups.

**Results and Discussion**

This study consists of 70 samples from the
Indonesian population with the 34 of whom were the CL/P group and 36 were the control group. Genotype distribution between CL/P groups and control for BMP2 gene polymorphisms 235768 A>T is significantly different (Table 1).

PCR products and RFLP results with the restriction enzyme BsrI on BMP2 gene rs235768 A>T are presented in Figures 1 and 2.
Figure 1. Visualization of the PCR BMP2 gene rs235768 A>T product.

Lanes 1, 2, 3, show bands at 353 bp, and lane 4 shows a 50-bp DNA ladder marker.

Figure 2. Results of PCR products carried out by RFLP with the enzyme BsrI.

Lane 1, 4, and 5 indicate TT; lane 2 indicates AA; and lane 3 indicates AT genotype.
Lane M is 50 bp ladder marker.

The conformation of PCR results using sequencing read with Finch TV and Bioedit programs from three samples that were examined and obtained three SNP genotypes on the BMP2 gene rs235768 A>T, namely AA (homozygous wild type), AT (heterozygous), and TT (homozygous mutant).

![Figure 3. (A) AA genotype (wild type), (B) AT genotype (heterozygous), (C) TT genotype (homozygous mutant), (D) Finch TV application, (E) Bioedit application](image)

The BMP2 gene encodes a ligand that is secreted from the TGF-β superfamily. The ligands of this superfamily bind to various TGF-β receptors that play a role in the activation of transcription factors, especially the SMAD protein in regulating gene expression. The BMP2 protein plays a role in bone and cartilage development. In addition, BMP2 stimulates myoblast differentiation into osteoblasts via the EIF2AK3-EIF2A-ATF4 pathway. Activation of BMP2 EIF2AK3 stimulates phosphorylation of EIF2A which leads to increased expression of ATF4 which plays a central role in osteoblast differentiation. BMP2 also stimulates TMEM119 which can increase the regulation of ATF-4 expression.14

The BMP2 gene is located on chromosome 20p12.3 (short arm of chromosome 20 area 1, band 2, and sub band 3). The length of the BMP2 sequence in the NCBI annotation (GRCh38.p12) starts from 6,768,098 to 6,780,280 along 10.6 kb (Homo Sapiens Annotation Release). Consisting of three exons, the focus of this study was Exon 3 with reference to SNP (rs235768), a change in the amino acid Serine to arginine at position 190 in the BMP2 gene. Other names for the BMP2 gene are BDA2, BMP2A, and SSFSC.14

Single Nucleotide Polymorphism are is a small change to genetics or variations that can occur in a person’s DNA sequence. The genetic code is determined by the four nucleotides A (adenine), C (cytosine), T
SNP variation occurs when one nucleotide, such as A replaces one of the three other nucleotides, such as C, G, or T \cite{11}. Based on molecular analysis using restriction enzymes and bioinformatics analysis of Finch TV and Bioedit programs, it was identified that there was a change from nucleotide A to nucleotide T which was a mutation missense (Serine - Arginine/TCA-TCT). Missense mutase is a change in the composition of nitrogen bases which causes changes in amino acids in a polypeptide chain. Changes in amino acids can produce a mutant phenotype if the changed amino acid is an essential amino acid for the protein. This type of mutation can be caused by transitional and transformation events. \cite{15}

The genotype frequency showed that the highest percentage of 82.4% in the CL/P group was the TT genotype (homozygous mutant). The results of the Fisher’s exact genotype test in the two groups were significantly different. The allele frequency in the CL/P group was the highest in the T allele which was a polymorphic allele, namely 88% and the Fisher’s exact test results were not significant between the alleles and the two groups. There are differences in the research results obtained by researchers from previous research, in Iran which indicate there was an association between BMP2 and the incidence of CL/P, but this difference can be due to the different number of samples even though the procedural laboratories were the same from the primary arrangement, the annealing temperature of the PCR, and the type of restriction enzymes used. The difference in results was also seen in the PCR product and the resulting RFLP cut results between the Iranian and Indonesian samples. However, the differences between PCR and RFLP products have been confirmed by sequencing the PCR results and studying the nucleotide bases one by one with the Finch TV and Bioedit programs. The difference in each place is influenced by the number of samples in the study as well as differences in ethnicity and sex. \cite{16}

From this study, the SNP genotype results can be ascertained that the changes are the same, namely AA (wild type), AT (heterozygous), TT (homozygous mutant) which differ only in their position. Thus, the BMP 2 gene still needs to be examined more deeply in this study, one of which is the addition of research samples and analysis studies at certain points in the BMP 2 gene. The high percentage yield for the mutant genotype (TT) and T allotype could potentially suggest a possible etiological link between CL/P and mutations in the BMP 2 gene.

**Conclusion**

There is a change from nucleotide A to nucleotide T on BMP2 gene rs23576 which is a missense mutation (Serine - Arginine/TCA-TCT). There was significant relationship between the rs235768 A>T polymorphisms of the BMP2 gene in CL/P patients. The allele frequency T (Polymorphic) has a higher value than the frequency of the A allele (non-polymorphic).

Inhibitors in Hemophilia A with Posterior Dextra Femoral Region Hematoma

Malfira Iswary\textsuperscript{1}, Hartono Kahar\textsuperscript{2}

\textsuperscript{1}Resident, Clinical Pathology Specialization Program, Department of Clinical Pathology Medicine, \textsuperscript{2}Lecturer, Department of Clinical Pathology, Faculty of Medicine, Airlangga University - Dr. Soetomo Hospital, Surabaya, Indonesia

Abstract

Hemophilia A is a hereditary coagulation disorder caused by deficiency or dysfunction of clotting factor (F) VIII. FVIII inhibitors are antibodies that functionally have the ability to inhibit FVIII activity. Patients are suspected of having FVIII inhibitors if the response to FVIII replacement therapy is inadequate. In this research, we observed a case of a 60-year-old woman with complaints of pain and swelling of her right thigh for the past 3 days. Physical examination revealed anemic conjunctiva and hematoma in the right posterior femur region. Laboratory results showed Hb 9.1 g / dL, WBC 10.96 / \(\mu\)L, PLT 351.000 / \(\mu\)L, APTT 74 seconds, CT 40 minutes, FVIII 1% and inhibitor assay 928 BU. Patient received Koate therapy, tranexamic acid and RICE (Rest, Ice, Compression, Elevation). Hemophilia A cases are generally seen in males with history of bleeding in the family and most often characterized by repeated bleeding in the joints. In this case, we found a female patient with a hematoma in the right posterior femur region. The result of FVIII examination was 1% and inhibitor assay was 928 BU. It can be concluded that the patient in this case suffered from hemophilia A with inhibitor.

Keywords: Hemophilia A, inhibitor, hematoma.

Introduction

Hemophilia A is a hereditary coagulation disorder caused by F VIII deficiency. The severity of bleeding in hemophilia A correlates with FVIII activity. In severe hemophilia A cases with FVIII activity <1%, there can be spontaneous bleeding in joints, muscles and internal organs. Meanwhile, in moderate hemophilia A cases with FVIII activity 1-5%, bleeding can occur due to minor trauma, and in mild hemophilia A cases with FVIII activity> 5- 40%, bleeding may occur due to severe trauma or surgery. Patients are suspected of having FVIII inhibitors if the response to FVIII replacement therapy is inadequate\textsuperscript{1}.

Inhibitors against F VIII can occur in 20-30% of cases of hemophilia A. The incidence of inhibitors in severe hemophilia is 25-50%, whereas in mild and moderate hemophilia 3-13%. Factors associated with inhibitor formation include patient factors and therapeutic factors. Patient factors include type and severity of hemophilia, race, genotype of hemophilia and age at first F VIII replacement therapy. Therapeutic factors include the type of FVIII product, exposure day, and intensity of therapy\textsuperscript{1,2}.

FVIII inhibitors can be identified by examining the inhibitors according to Bethesda. ISTH (International Society of Thrombosis and Haemostasis) classifies hemophilia A patients as high responders if the inhibitor titer is >5 BU/mL and low responders if the inhibitor titer is ≤5 BU/mL\textsuperscript{3}.

Based on the case report by Malfira Iswary, the results of the hematology examination were F VIII of 1% and Inhibitor Assay of 928 BU.

Case

Patient identity: Woman, 60 years old
Main complaint: Pain and swelling of the right thigh

Current medical history: The patient presented with complaints of pain and swelling of the right thigh for 3 days of SMRS, fever (-), bleeding gums (-), nosebleed (-). Defecation and bowel movement within normal limits.

Past medical history: The patient was aware that she suffered from hemophilia since the previous year and was treated 3 weeks earlier with the same complaint. The patient has routinely received 1000 units of factor VIII transfusion every 2 weeks since the last 8 months.

Physical Examination

General condition: Moderate, composmentis, GCS 456

Vital signs: Pulse: 115x/minute, Temperature: 36.5°C, Respiration rate: 20x/minute, Blood pressure: 120/70mmHg

Head / neck: Anemic conjunctiva

Thorax: Cor and Pulmo within normal limits

Abdomen: Supple, bowel sounds (+), liver and spleen impalpable

Extremities: Warm acral, posterior dextra femoral hematoma (+)

Clinical Diagnosis and Procedure

The patient was diagnosed with hemophilia A with posterior dextra femoral hematoma by the clinician. The patient received tranexamic acid, ketorolac and koate injection therapy.

Discussion

Cases of hemophilia A with posterior dextra femoral hematoma in women is a very rare case. Hemophilia A generally occurs in men. Siddiqi et al. (2010) reported 19.92% cases of hemophilia A from the total male population in America. Karim & Jamal, 2013 reported that 1 in 10,000 male births suffer from hemophilia A. The most recent data on cases of hemophilia A in Indonesia were 314 cases in 2001. The United States Universal Data Collection project (UDC) describes the ratio of women to men with hemophilia A of 1:32. The incidence of hemophilia A cases in women is associated with lyonization phenomena, the lack of X chromosomes and genetics of both parents of the patient4–7.

In this patient, a hematoma was found in the right posterior femur region. Repeated episodes of bleeding can result in joint deformities in the patient’s knee, known as Haemophilic Arthropathy. Hemarthrosis is the most common clinical characteristic, especially in cases of severe hemophilia A. The AUC value of joint involvement in hemophilia A is 63% (p = 0.099), when combined with the AUC value of the clinical degree of hemophilia 73% (p = 0.004) it becomes an important diagnostic value in describing the quality of life of hemophilia A patients, where AUC increases to 76.6. % (p = 0.001)8,9.

The result of hematological examination in this patient showed FVIII of 1%, therefore the patient was classified as ‘severe hemophilia A’ and the patient routinely received FVIII infusion therapy for the last 8 months. Patients are suspected of having an FVIII inhibitor if they do not respond after receiving adequate FVIII infusion at the time of bleeding or if FVIII levels are lower than prediction after receiving infusion or if there is no increase in FVIII after infusion. The stagnant levels of FVIII indicates the presence of FVIII inhibitors. Rikarni et al. (2013) found that patients who first received FVIII replacement therapy at <12 months of age had 2.66 times the risk of forming FVIII inhibitors compared to patients who first received FVIII replacement therapy at ≥12 months of age with p value <0.032,3.
ISTH (International Society of Thrombosis and Haemostasis) classifies hemophilia A patients as high responders if the inhibitor titer is >5 BU/mL and as low responders if the inhibitor titer is ≤ 5 BU/mL. In this case, the FVIII Inhibitor Assay examination result was 928 BU. Miller et al. (2015), reported 23 (2.8%) hemophilia A patients with inhibitors of which 9 were high responders. High responders tended to be younger than low responders (median value 2 years vs 11 years, p value <0.016). There were significant differences in the severity of hemophilia in the high responder group, namely severe, moderate, and mild with percentage of 78%, 22%, and 0% respectively, and with p value <0.05\(^{10,11}\).

There were limitations in this case, namely other antibody tests and genetic testing was not performed. Aside from hemophilia patients treated with FVIII (alloantigen), antibodies against FVIII can also occur in healthy individuals and patients with autoimmune diseases (autoantigen)\(^1\).

**Conclusion**

The diagnosis was made based on the results of hematological examination of factor VIII and its inhibitors, so it could be concluded that the patient was diagnosed with hemophilia A with inhibitors.

Topical Application of Povidone Iodine to Minimize Post Appendectomy Wound Infection

Mamoon Othman Khalid Alabdulla¹, Asaad Mohammed Kadhim², Hussein Abduljabbar Shihab Al-Katrani³

¹Surgent, Researcher, Department of Surgery, AL-Mawani Teaching Hospital, Basrah Health Directorate, Ministry of Health and Environment, Basrah, Iraq, ²Assistant Professor, College of Medicine, University of Basrah, Department of Surgery, AL-Mawani Teaching Hospital, Basrah Health Directorate, Ministry of Health and Environment, Basrah, Iraq, ³Surgent, Researcher, Department of Surgery, AL-Mawani Teaching Hospital, Basrah Health Directorate, Ministry of Health and Environment, Basrah, Iraq

Abstract

Background: Despite the use of prophylactic antibiotic and sterilization techniques and nemours methods of wound care, post appendectomy wound infection is still high.

Methods: A randomised control study (RCS) has been implied to prove, whether uses of povidone iodine just prior to wound suturing could decrease surgical wound infection rates after surgery for appendectomy. A total number of 120 patients operated for acute appendicitis with open appendectomy at AL-Mawani Teaching Hospital during the period from March 2016 to October 2020.

Results: After appendectomy patients were randomised into three groups, group A which include 40 patients the subcutaneous tissue was irrigated with 1% diluted povidone-iodine solution before skin closure. Group B which contained other 40 patients the wound has been washed with normal saline, and in group C (control group) no irrigation was done. All patients were followed for surgical site infection according to Southampton wound grade system for ten days after surgery. In this study we notice that a reduction happened in the number of wound infection in group A compare with group B and C.

Conclusion: The uses of povidone iodine 1% before skin closure is an effective method in reducing the rate of infection of the wound after surgery for acute appendicitis.

Keyword: Povidone iodine, wound infection, Acute appendectomy

Introduction

Acute appendectomy is a common surgical emergency in a wide range of ages and sexes. Post appendectomy wound infection is a frequent complication after appendectomy even by the use of antibiotic before surgery as prophylaxes and proper sterilization techniques, percentage of post appendectomy wound infection are quite high reaching to 18% - 20% (1,2). Povidone iodine is composed of iodine, iodide and polyvinyl pyrrolidone dissolved in sterilized water. Data had been shown that its action against bacteria will be increased by dilution in a range between 0.1 – 1% and its effect as bactericidal will be more than 10% strength (3), at this concentration it is neither toxic to the tissue cells or interfere with healing of the wound and has been FDA approved for short course therapy to prevent superficial wounds infection (3-6). The present study was designed to compare the efficacy of povidone – iodine 1% irrigation versus normal saline irrigation and no irrigation applied.

DOI Number: 10.37506/ijfmt.v15i4.16956
to the wound before closure. Importance of this study as if 1% povidone-iodine decreases. The surgical site infection, then it will be a simple and inexpensive remedy for prevention of surgical site infection.

Methods

A prospective randomized controlled study was conducted in the surgical units of AL–Mawani Teaching Hospital, Basrah, Iraq, from March 2016 to October 2020. It included patients from the two sexes who were brought to the hospital with a diagnosis of acute appendicitis with the aid of clinical, laboratory and radiological investigations and confirm during operation, later by histopathological studies of the removed appendices. A total number of 120 patients above 13 years of age (55 female and 65 male) who underwent open appendectomy via a grid iron incision. We exclude patients who were sensitive to prophylactic antibiotic use in the study (third generation cephalosporin), patient with immune deficiency (diabetic mellitus, chronic renal failure, chemotherapy, radiotherapy or corticosteroids therapy).

All patients were given 1 gram of third generation cephalosporin intravenously as prophylaxis against infection at induction of anesthesia.

In this study group A, before skin closure, subcutaneous tissue was irrigated by 1% povidone-iodine using 10cc syringe, kept there for 2 to 3 minute and then aspirated. Group B the subcutaneous tissue was washed by normal saline using 10cc syringe. Group C no irrigation was done.

Skin closure was done by interrupted sutures and then aseptically dressed. Other two doses of ceftriaxone 1gm given postoperatively intravenously. Patient examined for surgical site infection after 10 days in the outpatient clinic.

Results

In this study we included a total number of 120 patients [65 male (54.16%) and 55 female (45.84%)]. All patients ages were from 13-45 years. The wound of the patients was examined post operatively after tendays, and had been graded by using Southampton grading system into 5 grades (0 – 4) as in figure 1, 2, 3. Surgical site infection in Southampton grading system was from grade II and above. It was presented in overall 24 (20%) of patients. In group A it presented in six patients (15%) and in group B eight patients (20%) and in group C ten patients (25%).

Discussion

In this study we try to compare the three methods and substances. That may assist in decreasing the rate of the infection in the surgical wound. After appendectomy we notice that the rate of wound infection was decrease.

In group A When we use syringe irrigation with 1% povidone – iodine (15%) In comparison with group B in which we use syringe irrigation with normal saline (20%). And in group C in which no irrigation was used to (25%).

The wound infection is due to operative contamination and many ways are used to reduce such contamination\(^7\), many factors play a role in postoperative wound infection, including perioperative and intraoperative care and management with evaluation of any surgery to reduce infection rate\(^8\); wound wash and debridement are important for wound healing as shown by many experimental trauma cases\(^9\).

In surgical wound infection pus discharge from the wound indicate infective process. This pus discharge is believed to be due to production of inflammatory mediators.

Antiseptics are substances that kills or inhibit the microorganisms growth, so it will reduce the formation of pus in the wound cavity\(^3^,\(^4\). Sindelar and Mason study show that wash of abdominal and urological wound with 10% povidone-iodine solution will lead to reduce pus formation from the wound\(^10\). The study done by Hiramatsu and colleagues show that there is a benefit from use of povidone-iodine applying to the wound in reducing wound infection postoperatively\(^11\).

Conclusion

The present study we conclude that wound syringe irrigation with diluted 1% povidone-iodine is a safe way, low cost and currently available in any theater room which does not interfere with healing process and it will significantly reduced the surgical site infection and pus formation.

Conflict of Interest: The authors declare no conflicts of interest.

Funding: This study was unfunded.

Ethical Clearance: Taken from AL– Mawani Teaching Hospital committee
