Abstract

Background: According to the current situation, Thai adolescents have premature sex and unprotected sex, resulting in pregnancy problems and sexually transmitted diseases in students. This study aims to study the factors affecting to first sexual intercourse among students: a population-based study. Methods: A cross-sectional analytical study was conducted between January 1 and June 30, 2018 among 328 students. That using data from the surveillance participant characteristics for first sexual intercourse among students between the ages of 12-18 years old in the study area, Ubon Ratchathani Province. The instrument used was a self-administered questionnaire. Data analysis was used by EPI Info 7 program and SPSS version 20. Logistic regression analysis was performed to identify the factors associated with first sexual intercourse among students by multivariate analysis (95%CI).

Results: The results findings revealed that respondents were females 53.0% with an average age of 16.5 ± 2.4 years old. Around 64.6% had experienced sexual intercourse, their first sexual intercourse was found at the average age of 14.1 ± 1.6 years old and did not use a condom when having the first sexual intercourse 44.4%. The multivariate analysis found significantly greater for males 2.15 times (ORadj = 2.15, 95%CI= 1.36-3.22), significantly greater for students income >5,000 Bath/month compared to income ≤ 5,001 Bath/month, 3.35 times (ORadj = 3.35, 95%CI= 2.82-7.67), experience alcohol consumption were 6.42 times (OR adj = 6.42, 95%CI= 3.75-9.97) and low-medium of the attitude sexually transmitted diseases were 4.88 times (OR adj = 4.88, 95%CI= 2.89-6.98). Conclusion: The modernized training program in the accurate attitude, first sexual intercourse and sexually transmitted diseases, values, and self-esteem to prevent sexual risk behaviors with appropriate gender norms and the recent era among students need to be considered.

Keywords: First sexual intercourse, Students, Adolescents, Sexually transmitted diseases

Introduction

Adolescents are the ages that go from childhood to adulthood. They are between the ages of 12 and 20, with females entering the adolescence faster. Males are about 1-2 years old. According to the current situation, Thai adolescents have premature sex and unprotected sex, resulting in pregnancy problems in adolescents. Abortion and sexually transmitted diseases are more likely. As adolescents are of physical, mental, and social, changes in all dimensions are at an age when the need for self-reliance increases. Adolescents are sensitive, easy to change due to the complete sexual development of the hypothalamus, pituitary gland, and gonads, and women have the characteristics of femininity and masculinity. The results of sexual changes bring adolescents to a young age. The sex glands are responsible for the

production of estrogen and testosterone, both of which cause the body to become young and influential as sexual drivers. Teenagers are the age of wanting to try it. Early adolescents begin to have sexual desire, interest in the opposite sex, and express sexual behaviors, such as being interested and trying to build close relationships. Talking holding your arm, arranging to be alone, two-on-two. Which makes it possible for there has a sense of satisfaction between each other. Confusion in the role itself between being a child and an adult and a friend has a high influence on the idea. Some teenagers have an emotional imbalance. Cannot adapt to the changes made. Nowadays, Thai society has changed the way of life and culture that embraces western culture values more everyday life, such as dressing. The embrace and handshake has resulted in a decrease in the value of love reserved for Thai culture. Today’s teenagers are teenagers in globalization with modern technologies such as internet, mobile phones, and other technologies. It has a social network like Facebook. Line makes communication easy, convenient to meet up, and talk between teenagers. Other environmental influences are that sexual media, alcohol consumption are easily accessible, and this age has changed psychosocial, with emotional expression, swaying, variability, and lack of mental inhibition. When there is sexual driving. As a result, sexual mismanagement is diminished. The students in school and aged between 12-15 years old are the unique sample group that have the transition between children and adolescents. Their social role and environment including self-esteem and sexual values changes. As a result, it is considered the beginning of sexual intercourse at the same time. Despite everything, Preventive intervention for adolescents because it is evident that sexual risky behaviors such as having sexual relationships with multiple partners and not using condoms act as factors that increase the STD infection rate. Therefore, considering the social lifting style and culture aspect in which sexual behaviors and norms are developed, a sexual risky group with a high rate of sexually transmitted disease, infection, and having sexual can be called a vulnerable group to sexual diseases rather than a socially hazardous group. There is a rarity on the study based on the first sexual intercourse among student group which is specific.

**Objective**

This research aimed to determine the factors associated with the first sexual intercourse among students in school, which provide useful information for the planning of counseling on premature sex in the school and parents.

**Material and Methods**

**Research model and sample**

A cross-sectional study was conducted between January 1 and June 30, 2018, among students in Ubon Ratchathani province of Thailand. Students aged between 12-18 years old were selected by multistage random sampling. After sample size calculation by using the estimated population mean equation, a total 328 students (including 5% missing cases) with males and females were recruited from schools.

**Research instruments**

The tool used for this research was a questionnaire, asking students’ demographic, had sexual intercourse, attitude ever have sexual intercourse, attitude sexually transmitted diseases and knowledge sexually transmitted diseases.

**Human research ethics**

In this research, research ethics were considered by the Human Research Ethics Committee, Ubon Ratchathani Provincial Public Health Office, No. SSJ. UB 2563-098 given on 20 October 2020.

**Data Analysis**

In this study, data were analyzed using frequency, percentage, mean, standard deviation to characterize and risk factors were used to determine the behaviors of the first sexual intercourse among students by univariate analysis and multivariate analysis at the 95% confident interval (95%CI).
Results

Total 328 participants were 154 (47.0%) males and 174 (53.0%) females, average age 16.5 ± 2.4 years old. The results from self-administered questionnaire about risk of characterize behavior and who ever have sexual intercourse among students who ever have sexual intercourse were 212 (64.6%) (Table 1). The mean age of their first sex was 14.1 ± 1.6 years old. The average scores of the attitude ever had sexual intercourse among students were in low and levels. The result shows the participants who ever had sexual intercourse did not use a condom when having the first sexual intercourse 92 (44.4%) participants. The results from univariate analysis found the factor associations between participant characteristics associated with the first sexual intercourse among students were significantly greater for males when as compared with females, 1.97 times (OR =1.97, 95%CI = 1.24-3.14) significantly greater for student age between 16-18 years old as compared to who age between 12-15 years old, 2.30 times (OR = 2.30, 95%CI= 1.45-3.67) significantly greater for students living alone/lover/friend compared to who were living with parent, 4.48 times (OR = 4.48, 95%CI= 2.71-7.40) significantly greater for students experience substance and experience alcohol when compared to those who had no experience. Participants who had Low - medium of the attitude sexually transmitted diseases were 4.14 times (OR = 4.14, 95%CI = 2.56-6.68) (Table 2).

In the multivariate analysis (multiple logistic regressions adjusted for relationships (girlfriend/boyfriend) and experience with alcohol) we found the factor associations between participant characteristics associated with the first sexual intercourse among students were significantly greater for males compared with females, 2.15 times (OR adj = 2.15, 95%CI= 1.36-3.22) significantly greater for students age between 16-18 years old as compared to who age between 12-15 years old, 2.68 times (OR adj = 2.68, 95%CI= 1.65-3.89) significantly greater for students income >5,000 Bath/ mount compared to income ≤ 5,001 Bath/mount, 3.35 times (OR adj = 3.35, 95%CI= 2.82-7.67) significantly greater for students experience alcohol consumption compared to those had no experience were 6.42 times (OR adj = 6.42, 95%CI= 3.75-9.97) and participants who had Low - medium of the attitude sexually transmitted diseases were 4.88 times (OR adj = 4.88, 95%CI= 2.89-6.98). The result show the level of attitude ever had sexual intercourse among students and the level of
knowledge that sexually transmitted diseases not significantly with the first sexual intercourse among students (Table 3).

**Discussion**

According to the study, almost half of the students have ever had a sex with an average age of 14.1 years old for the first time. The rate exceeded national estimates among adolescent samples. This study presented an earlier age than the previous study by the Ministry of Public Health, Thailand, that found adolescences aged 15-16 years for the first sexual intercourse.9 This is likely to continue to decline. Since Thai society is influenced by Western culture, Thai adolescents are imitated and attitudes towards premature sex are common.8 And it has not a bad word to follow. Nowadays, Thai teenagers have changed attitudes and behaviors in their sexuality. Teenagers are getting in love, having girlfriends. The adolescents had first sex from an early age. Some couples have been in a relationship for a while, and there may be more than one sexual partner.9 The result shows the participants who ever had sexual intercourse did not use a condom when having the first sexual intercourse 92 (44.4%) participants. The first sexual intercourse of adolescents in Thailand does not use condoms up to 50 percent, which is at risk of HIV/aids, sexually transmitted diseases, and pregnancy. Because most teens drink alcohol before the first sex causing forgetting or failing to supply condoms. This study finding was supported by Baokhumkong, et al, that reported causes of the first sexual activity in early adolescence were due to having sexual intercourse but did not use a condom.10 And most have experienced sex with a boyfriend or a couple without protection. There have been reports on sexually risky behavior in the general population.9 Because teenagers believe that sex is a show of affection for each other. Most female students are voluntarily. Most of them were living alone/lovers/friends. These behaviors could increase the first sexual intercourse among students in school. The result found that the risk behaviors of HIV and sexually transmitted diseases among students 132 (62.3%) and 40.3% reported among undergraduate students in Canada, respectively.11-12 The earlier young women in Northeast Brazil started sexually, the more pregnancies she had until the time of her reproductive life, as well as the greater number of sexual partners.13 The multivariate analysis in this study showed that sex, age, income, relationships (girlfriend/boyfriend), experience substance, and experience alcohol were related to having sexual intercourse. All socio-demographic characteristics were related to sexual intercourse and HIV knowledge among Indonesian women ($p<0.05$).14 The associations between participants characteristics associated with the first sexual intercourse among students were significantly greater for males compared with females, 2.15 times because in Thai society the male was assumed to be the significant person for the decisions about sexual and reproductive health regarding the role of condom use, this effort and decision have to be empowered in both male and female to promote safe sex.15,16,17,18 The attitudes and behavior of rural Thai adolescent students aged 16 to 20 years from northern Thailand regarding sexual intercourse were significant differences by gender, religion, ethnicity, and household income between those who had previously had sex.8 The level of attitude ever having sexual intercourse among students and the level of knowledge about sexually transmitted diseases had no significant relationship with the first sexual intercourse among students.15 However, during this study and for many young people who start a sexual life in adolescence, this event is perceived as an opportunity to express the exercise of sexual autonomy and freedom, sensations that express a more emotional than rational meaning.19 Thai culture parents do not talk openly about sexual, and the condom used for first sexual intercourse is uncommon to carry. It is believed that people who carry condoms are sex workers and obsessed with sex. Therefore, friends, parents, and teachers should be suggested to be a considerable role for promoting the prevention of sexual risk behavior, the effect of not wearing a condom, in addition to HIV/
sexually transmitted diseases, and premature pregnancy and encouraging to understand and talk openly regarding sexual issues. Although Thai culture and society are conservative about sexual issues, they currently have been changed dramatically among students.20-21 The transition from childhood to adolescence affects the social role to be more freedom and foreign cultures have also influenced the students’ lifestyle and show intimacy with public expression of love with their partners.

**Conclusions**

The adolescents that are those between 12 and 18 years old, experience a stage of life characterized by late childhood to adolescence, with all their biological and psychosocial changes, being a period that usually coincides with entering into high school. Sexual behavior of youth could have reproductive health outcomes with an impact on individual and general population health as a result of the new social and subjective relationships that they should live, making it a vulnerable period of exposure to situations with health risk behaviors, especially those related to lifestyle, such as the use of toxic substances, alcohol and unsafe sexual practices.23-24 Most participants of the study had already begun their sexual life before 15 years old, especially men. There have relationships (girlfriend/boyfriend). Just over half of them were seeking information about sex with friends. Condom use was for the prevention of sexually transmitted infections. Condom was the most commonly known contraceptive and more frequently used while other methods like intra-uterine device, location, amenorrhea, and norplant were rarely mentioned.25 The high school is highlighted as a place of long term for youth, favorable to the construction and reconstruction of knowledge and values. However, due to the plurality of groups that compose it, it favors student’s vulnerability to health risk lifestyles such as alcohol and other drugs, unsafe practices in traffic, and risky sexual practices, among others. High rate of hazardous or harmful use are found and various factors were identified that can be used to guide interventions to reduce problem drinking among university students.26 Thus, it is extremely important to build supportive environments within the high school space for discussion of issues with their health, with emphasis on sexuality as away to manipulate the student, good attitudes ever have sexual intercourse among students are the tools for healthy sexuality issues can reducing their exposure to sexually transmitted infections, unwanted pregnancies and other risk factors.27 The modernized and innovative training program in the accurate attitude, first sexual intercourse and sexually transmitted diseases, values, and self-esteem to prevent sexual risk behaviors with appropriate gender norms and the recent era among students need to be considered. Therefore, early sexual initiation had a negative impact on these variables. Results indicate the need of intervention and continuous education on reproductive health among school students in Ubon Ratchathani province, Thailand.

**Acknowledgment:** We would like to express our special thanks to the Ubon Ratchathani Provincial Health Office. This study was supported by the BSS program of Bureau of Epidemiology, Department of Diseases control, Ministry of Public Health, Thailand. And Faculty of Medicine Vajira Hospital, Navamindradhiraj University and all respondents who cooperated well in this study.

**Ethical Clearance:** In this research, research ethics were considered by the Human Research Ethics Committee, Ubon Ratchathani Provincial Public Health Office, No. SSJ.UB 2563-098 given on 20 October 2020. Participants could refuse and/or leave this research at any time. The data in the evaluation forms was kept confidentially without specifying the participants’ names in the document.

**Conflict of Interests:** The authors have no conflicts of interest with the material presented in this study and research tool was self-assessment questionnaire consisting of questions related to sexual activities among students in school Ubon Ratchathani province. Participants received both written and verbal information before they agreed to participate in the study.

**Source of Funding:** This study was supported by Ubon Ratchathani Provincial Public Health Office,
School in Ubon Ratchathani province, Thailand.

Abstract

Background: Cisplatin is a cytostatic agent used as treatments in head and neck cancer patients. Nephrotoxicity is one of cisplatin major side effects. This study aimed to evaluate the renoprotective effect of mannitol-hydration administration in head and neck cancer patients who receive cisplatin chemotherapy.

Methods: This was a cohort observational study to analyze the renal function of head and neck cancer patients who receives cisplatin before and after mannitol-hydration administration in IRNA Surgery and Soekardja Room of Chemotherapy at RSUD Dr. Soetomo Surabaya during June – September 2018. The data obtained were BUN, SCr, and eClCr Cockroft-Gault of each cycle. Result: A total of 52 patients were evaluated. The average value of creatinine serum, creatinine clearance, and BUN at each cycle were fluctuate. However, the average value of creatinine serum and BUN were within the normal limit. The result of statistical analysis using paired t-test in those parameters at each cycle were not statistically significant (p > 0.05) after mannitol administration except during first cycle to second cycle the SCr increased significantly and eClCr was decreased significantly (p-value 0.024; 0.006, CI 95% respectively ). At fourth cycle the eClCr also decreased significantly (p value 0.008, CI 95%). Conclusion: The renoprotective effect of mannitol in head and neck cancer patients who receive cisplatin chemotherapy is sufficiently adequate which can maintain the value of BUN and creatinine serum of patients at each cycle within the normal limit.

Key words: cisplatin, mannitol, nephrotoxicity, prevention

Introduction

In 2018, the prevalence of head and neck cancer around the world was ranked at seventh of most common cancer with new cases more than 850,000 and deaths around 450,0001. Management therapy of head and neck cancer based on NCCN Guideline can be surgery, radiotherapy, and/or chemotherapy. Cisplatin is the preferred chemotherapy agent which can be used along with radiation as a chemoradiotherapy regimen usually given in high dose (100 mg/m2 every 21 days for three cycles)2,3. Nephrotoxicity is the renowned major side effect (around 28-36%) in the form of both acute or chronic renal insufficiency which also becomes major consideration in giving cisplatin therapy. Cisplatin is mainly eliminated through kidneys (> 90%) approximately 25% is excreted in urine within the first 24 hours after administration4,5. Patients treated with cisplatin about 20% - 30% will experience nephrotoxicity after 10 days administration6,7.

A study by Arunkumar et al8 evaluated the renal injury in several patients at stage IIA to stage IVA with various types of cancer who received a 40-50 mg/m2 cisplatin regimen and reported the incident of renal injury in patients like hypomagnesemia, hypokalemia,
hypocalcemia, hypophosphatemia, increased of BUN and creatinine serum. Kidera et al\(^9\) also assessed the effect of cisplatin on renal who received cisplatin with doses > 60 mg/m\(^2\) for the first time and this study reported that 32% of patients experience nephrotoxicity which characterized by increase value of creatinine serum. Cisplatin nephrotoxicity is dose-dependent toxicity, it’s maybe prevented by hydration and other supplementation strategies like magnesium and mannitol. Mannitol as an osmotic diuretic agent has been widely used for renal protection because it can reduce the contact time between fluid and the tubular epithelium, this way is believed to protect against renal injury by accelerating the removal of renal toxin\(^{10,11}\).

A study by Morgan et al, reported the outcomes in patients who receive mannitol improved and a 2.6 increased probability of developing acute kidney injury among adults who did not receive mannitol\(^{12}\). Another study by McKibbin et al, in head and neck cancer patients who are using cisplatin 100 mg/m\(^2\) showed that the addition of mannitol decreased the incidence of grade 3 acute kidney injury compared to saline only group\(^{13}\). Williams et al\(^{14}\) also assessed the impact of mannitol administration, patients who acquired mannitol administration has lower average increase of creatinine serum (mg/dl) and experienced less frequent grade 2 or higher nephrotoxicity compared with patients who did not acquire it. Meanwhile, study by Beeler et al reported that the addition of mannitol to saline pre-hydration in patients who receive cisplatin therapy did not change the outcome of renal function decline measured by BUN/Cr ratio, GFR, creatinine, and BUN and the decline of renal function is limited to grade 1 and most patients recover\(^{15}\).

Based on the description above, we undertook a study to evaluate the renoprotective effect of mannitol 20% 500 ml administration with saline hydration in head and neck cancer patients who receive cisplatin chemotherapy by observing the renal function (seen from laboratory data BUN and creatinine serum value).

**Material and Methods**

This was a cohort observational study that evaluated the renal function of head and neck cancer patients before and after cisplatin combination chemotherapy administration. The patients were given the combination of mannitol (20% 500 ml) and saline hydration one time after cisplatin combination chemotherapy at each cycle. Laboratory examination according procedure established by RSUD DR. Soetomo including BUN, creatinine serum and estimated creatinine clearance with Cockcroft-Gault formula were carried out before patients received cisplatin combination chemotherapy as the baseline data (pre-data). The change of renal function was observed at the start of the next cycle of chemotherapy.

The study subject were patients diagnosed with head and neck cancer who received cisplatin combination chemotherapy in IRNA Surgery and Soekardja Room of Chemotherapy at RSUD Dr. Soetomo Surabaya during June – September 2018. Patients were included if they aged between 21 years old up to 80 years old and had normal function of liver, heart, kidney and lungs. Another important inclusion criteria was patients voluntarily to be involved in this study by signing the informed consent. Meanwhile, patients were excluded in this study if they were allergic to cisplatin and received another therapy that can also induced nephrotoxicity such as aminoglycoside, cyclophosphamide, and others.

The normality of the data distributions was assessed using the One Sample Kolmogorov-Smirnov test before analysis. Comparison of the patient renal function before and after mannitol-hydration administration was performed using the paired t-test if the data were normally distributed and Wilcoxon signed-rank test if the data were not. The differences of renal function between patients with cisplatin-5FU regimentation and cisplatin-paclitaxel regimentation were also evaluated using independent t-test if the data were normally distributed or Mann-Whitney test if the data were not. P-values ≤ 0.05 were considered statistically significant. The obtained data were recorded in a special form and then processed through SPSS version 24.0 for Windows.
with confidence interval 95%.

**Result and Discussion**

**Patients characteristic**

A total of 52 patients were included in this study between June - September 2018 with sample characteristics shown in Table 1. The percentage of male patients (67%) was higher than female patients (37%). Head and neck cancer is more common and affected significantly in males rather than females with a ratio 2:1 to 4.11,16. In this study, the patient’s mean age range is between 41-64 years (mean 51.92 years), several studies reported that patients with age ≥ 50 years had a higher incidence of cisplatin-related nephrotoxicity17,18. Most of the patients suffering from nasopharyngeal cancer (33%) and then followed by squamous cell carcinoma (23%) and tongue cancer (18%). Nasopharyngeal cancer is the most common site type of head and neck cancer.

All patients in this study receive chemotherapy minimally for three cycles and up to six cycles for several patients with chemotherapy regimentation were combination of cisplatin-5fluorouracil in 42 patients and combination of cisplatin-paclitaxel in 10 patients. Both of them are included as recommended regimens or first-line systemic therapy for advanced head and neck cancer patients2. However, a study by Gibson et al19 showed that there were no statistically significant difference of overall survival or response rate and toxicity between cisplatin-5FU regimen compared with cisplatin-paclitaxel in head and neck cancer patients.

The dose of cisplatin received by the patient varies from 35 mg/m2 up to 100 mg/m2 and the most frequently used was 100 mg/m2. A study by Kidera et al and Prasaja et al showed that cisplatin-induced nephrotoxicity occurred in patients who received doses > 60 mg/m2 in around 32% and 34.1% respectively9,17. Therefore, the dose of cisplatin is one of risk factors that affect cisplatin nephrotoxicity. Hydration frequency in cisplatin-5 fluorouracil regimen was 166 times and in cisplatin-paclitaxel regimen was 47 times, so hydration frequency in this study overall was 213 times.

The change of creatinine serum, creatinine clearance, and BUN value in all patients on each chemotherapy cycle were shown in figure 1 until figure 3 respectively. The average value of those three parameters were fluctuating. Based on analysis using independent t-test, there were no statistically significance difference on patient renal function (SCr p-value 0.223; eGFR p-value 0.418; and BUN p-value 0.677, CI 95 %) between cisplatin-5 fluorouracil group and cisplatin-paclitaxel group.

Several previous studies evaluated the effect of mannitol on cisplatin-related nephrotoxicity. Three studies by Morgan et al, McKibbin et al, and Williams et al revealed that mannitol administration with cisplatin concomitantly has a significant protective effect that allows patients to receive cisplatin therapy with low risk of nephrotoxicity,12–14 . Even though in this study patients had already received saline-mannitol 20% 500 ml hydration combination one time after each cycle, the average value of patient renal function like SCr, eClCr, and BUN were fluctuating. However, the average value of creatinine serum and BUN were within the normal limit.

Effect of mannitol-saline administration in the change of SCr, eClCr and BUN of patients

The differences in patients renal function value (SCr, eClCr, and BUN) in each cycle before and after mannitol-hydration administration were shown in Table 2. Furthermore, the differences in patients renal function during each cycle of chemotherapy before and after mannitol-hydration administration in both cisplatin-5fluorouracil group and cisplatin-paclitaxel group listed in Table 3 and Table 4. In cisplatin-paclitaxel regimen, group, the number of samples that receive chemotherapy up to fifth cycle and sixth cycle only 3 patients so it did not meet the requirements for differential statistical analysis using paired t-test. Based on the statistical analysis result in all 52 patients, it seems renal function impairment had occurred after first cycle cisplatin combination chemotherapy administration which is characterized by increased creatinine serum and decreased creatinine clearance significantly (p-value 0.024; 0.006, CI 95% respectively). It’s only occurred in group of patients with cisplatin-5FU regimentation therapy (p-value <0.05) but not in group of patients with cisplatin-paclitaxel regimenation (p-value >0.05).

Furthermore, the average value of creatinine clearance also decreased significantly after the fourth cycle of chemotherapy (p-value 0.008, CI 95%). It’s only occurred in patients with cisplatin-paclitaxel regimenation which was also accompanied by a significant increase in creatinine serum otherwise it did not occur in the group of patients with cisplatin-5FU regimenation. This result was consistent with the study by Tezcan et al and Prasaja et al. that state renal function reduction occurred after first cycle of cisplatin administration17,20. Based on those two studies, renal impairment function will be worsened along with increasing numbers of chemotherapy which characterized by creatinine clearance decline after each cycle and it might be permanent.
The average BUN value of all 52 patients who received cisplatin combination chemotherapy was increase after each cycle but not statistically significant (p-value > 0.05) and remained within the limit of the reference value. However, after fifth cycle those value was decline but also not statistically significant. It’s happened because in the group patients with cisplatin-5FU regimination had statistically significant decrease of average BUN value after fifth cycle (p-value 0.042, CI 95%). A study by Arunkumar et al and Teczan et al, reported that BUN value parameter will increase after cisplatin chemotherapy treatment, it’s just that in the study by Arunkumar et al the increase was not statistically significant as well as in this study\textsuperscript{8,20}.

This study result was consistent with the study by Leu and Baribeault which performed in patients using 40 mg/m2 of cisplatin (n= 92) showed that there were no statistically significant differences in average eCICr decrease (p = 0.09) in patients received either mannitol-hydration (n=46) or hydration alone (n=46)\textsuperscript{21}. A similar result also showed in a study by Beeler et al, that there were no statistically significant difference (p > 0,05) of BUN/Cr ratio, GFR, creatinine, and BUN between patients received mannitol-saline (n=25) and saline alone (n=23) during 14 days during cisplatin therapy\textsuperscript{15}.

Conclusion

In conclusion, the renoprotective effect of mannitol in head and neck cancer patients who receive cisplatin chemotherapy is sufficiently demonstrated in this study. Mannitol administration can maintain the value of BUN and creatinine serum of patients at each cycle within the normal limit. Although the average value of the patient renal function (SCr,eCICr, and BUN) at each cycle were fluctuating and the result of statistical analysis using paired t-test in those three parameters were not statistically significant (p > 0,05) except on first cycle and on fourth cycle that eCICr decreased significantly. Several risk factors like cisplatin dosage and patient age might affect cisplatin-related nephrotoxicity which can also affect the effectiveness of mannitol therapy as renoprotector.

Abstract

The function of the state in providing health services is divided into the regulatory function, the controlling function, the entrepreneurial function and the supervisory function. In the regulatory function, the state develops policies in the field of health services that ensure that all people can enjoy health services. The state control function is responsible for the availability of equipment and medicines as well as maintaining the stability of the flow of health service distribution. In the entrepreneurial function, the state in addition to providing health services can receive income from health services which can later be used to equalize the costs of health care dependents, especially for the poor and underprivileged. In the oversight function, the state is responsible for carrying out full supervision of health facilities in order to optimally provide health services to the people. Keywords: State functions, health services, the right to health.

Keywords: State Functions, Health Services, The Right to Health

Introduction

The responsibility of the state for its people specifically in the health sector is contained in the constitution, namely in the fourth paragraph Opening of the 1945 Constitution of the Republic of Indonesia, as one of the goals of the state which is protecting all the people of Indonesia and all of Indonesia’s blood spilled. This is in relation to the objectives of the rule of law as constitutional and philosophical foundations as a nation and state. In addition, the mandate of Article 43 paragraph (1) of the 1945 Constitution of the Republic of Indonesia (hereinafter referred to as the 1945 Constitution) expressly stipulates that The poor and neglected children are maintained by the state, further on Article 34 paragraph (2) stipulated that the State develops a social security system for all people and empowers people who are weak and unable to match human dignity. Furthermore, Paragraph (3) regulates that: The State is responsible for the provision of adequate health service facilities and public service facilities.

In addition to Article 34, the constitution provides for the protection of human rights. In protecting human rights in the health sector, it can be seen in Article 28H paragraph (1) which regulates that every person has the right to live in a physical and spiritual prosperity, to live and obtain the environment. good and healthy and have the right to get health services. Furthermore, paragraph (2) regulates that every person has the right to get special facilities and treatment to obtain equal opportunities and benefits in order to achieve equality and justice. Whereas paragraph (3) states that every person has the right to social security which enables the development of himself as a whole with dignified humanity.

Talking about health services, especially about the health service system in hospitals and health clinics, is inseparable with regard to consumer protection efforts.
in Indonesia today, because the health service delivery system concerns the relationship between health service providers and consumers (health service recipients), also very related with regulations and policies in the field of health, this has long been raised especially about the importance of legal protection for the parties, especially the efforts of the state in this case the government in improving the quality of health services that are dignified, humane and fair.

The problem of the health service system since the last few years has attracted a lot of attention, not only in the world of health (medicine), but also outside the health community (medicine), not only domestically, but also abroad. In the health service system there are 3 (three) groups of people who are at least involved, namely, first, the human health service provider (health providers, such as doctors, nurses and other medical personnel), the second is the group receiving health services (health consumers) and third, which is indirectly involved, for example administrators (both among companies and governments in this case the State).

The special nature of health care is that both health providers and consumers rarely consider cost aspects, as long as it involves the problem of healing a disease. Health providers will always be urged to use the latest capabilities, technology and medicines. This fact is also supported by the needs of consumers who want the best possible service, also in order to obtain a sense of security. This situation brings a tendency to ignore economic calculations, cost efficiency, and others. Therefore, it is not uncommon for health services to be considered merely consumptive in nature, regardless of the profit and loss aspects, including the legal aspects.

The above interests will be contrary to the interests of administrators (government, company leaders), who will more or less pay attention to aspects of the cost of health services. It is not uncommon for administrators to complain about the attitudes of consumers and health providers complain about the attitudes of administrators. Conflicts of interest stemming from human behavior will include a balanced solution, if an approach to the development of a balance between obligations and rights is adopted, as well as responsibility and legal protection to the public or health consumers. Besides that, negative behavior must also be eliminated.

The right to health services is obtained since humans are still in the womb. This right is a part of basic human rights known as human rights. Although this basic right has been recognized by various religions and follows the development of the world, the literature records the name of John Locke as its originator. In the fourth paragraph of the Preamble of the 1945 Constitution it is strictly stated that: The state protects all of the Indonesian people and all of Indonesia’s blood spilled (which has been redeemed) protection which is intended is no exception also the issue of guarantee of rights in the health sector. In 1960, the right to health was only recognized in Indonesian law. Article 1 of Law No. 9 of 1960 regulates that: Every citizen has the right to obtain the highest degree of health and needs to be included in government efforts. This provision is updated in Article 4 of Law No. 23 of 1992, that: everyone has the same right in obtaining optimal health status. Likewise in Law No. 36 of 2009 (hereinafter referred to as Health Law), in Article 5 paragraph (1) the Health Law regulates that: everyone has the same right in obtaining access or resources in the health sector. Paragraph (2) regulates that: everyone has the right to obtain safe, quality and affordable health services.

In addition, in Article 4 letter g of Law No. 8 of 1999 (hereinafter referred to as UUPK) regulates that: Consumers have the right to be treated or served properly and honestly and not discriminatory. What is regulated in Article 4 letter g of the UUPK, then becomes the obligation of business / service actors as regulated in Article 7 letter C of the UUPK that: The obligation of business / service actors is to treat or serve consumers properly and honestly, not discriminatory. Likewise in Article 44 of Law No. 29 of 2004 (hereinafter abbreviated as the Medical Practice Law), regulates that: Doctors or dentists in carrying out medical practices must follow medical or dental service standards. Article 52 letter c of the Medical Practice Law stipulates that:
patients, in receiving services in medical practice, have the right to receive services according to medical needs. Thus, all professions involved in the field of health are required to re-explore the foundation of Indonesia’s state philosophy regarding the basic values adhered to, including also in health services, so that they can be consistently described from the central to the regional level. The basic values stated in the legislation need to specify the rights, obligations and responsibilities. For health, as a reference can be used the declaration of the United Nations (UN) on Human Rights and the Health Law are as follows:

1. Right:
   a) Everyone has the right to an adequate standard of living for health, including health care, and is entitled to guarantees in times of suffering (United Nations Declaration on Human Rights in 1948).
   b) Everyone has the same rights in obtaining access or resources in the health sector, including having the right to obtain safe, quality and affordable health services. (Article 5 paragraph (1) and (2) Health Law).

2. Responsible:

   The government is responsible for improving the degree of public health (Article 9 of the Health Law).

   The existence of free health programs as a form of government alignments to the needs of the poor in the health sector, as well as the government’s response to the mandate of the Basic Law, the Health Law and regulations in other health fields. The free health care program is a positive solution for the underprivileged (poor) people who expect a health service system that is safe, quality, and affordable. So that various complicated problems faced by the public so far, especially in the field of health, such as the high price of drugs, as well as the inaccessibility of treatment costs in hospitals, and the inability of the public to go to the doctor because the costs are quite expensive. It is hoped that the free health service program can solve various problems that have been faced by the underprivileged (poor) people.

   Hopefully it turns out that not everything can be in accordance with reality, many problems are still felt and faced by the poor (in poor) in an effort to obtain rights and free health program services.

Research Methods

This research is a normative-legal research using a statute and conceptual approaches. Those legal material collected are analysed descriptively related to the problems and prescriptively.

Analysis and Discussion

The State Functions As Regulator (Sturende)

The implementation of the State’s function of state responsibility in free health services is equitable, which can be seen from various existing laws and regulations. The laws and regulations referred to, among others, are contained in the 1945 Constitution can be seen in Article 34 paragraph (2) that the State develops a social security system for all people and empowers weak and unable to match human dignity. Furthermore, in paragraph (3) it is regulated that: The State is responsible for the provision of adequate health service facilities and public service facilities.

In addition to Article 34 of the 1945 Constitution of the Republic of Indonesia NRI above, the constitution also provides protection of human rights in the field of health which can be seen in Article 28H paragraph (1) of the 1945 Constitution of the Republic of Indonesia which regulates that every person has the right to live in a physical and spiritual prosperity, located living and getting a good and healthy environment and the right to obtain health services. Furthermore, paragraph (2) regulates that every person has the right to get special facilities and treatment to obtain equal opportunities and benefits in order to achieve equality and justice. Whereas paragraph (3) states that every person has the right to social security which enables the development of himself as a whole with dignified humanity.

The right to a healthy life is a basic right that must be guaranteed, because health is part of the primary
needs of every human being. Healthy condition of body and soul will enable every human being to do his activities and works. Health is also part of the needs towards a prosperous life. This kind of right is one of the basic rights in health services. But for low-income people, especially the poor, they need to get free health services for survival in the community and state, so that in the constitution they also provide guarantees for state responsibility.

In this case, it can be seen in Article 34 paragraph (1) of the 1945 Constitution of the Republic of Indonesia that: The poor and neglected children are cared for by the state this provision was formulated to provide guarantees to people who are weak in income to be given health insurance that should be free. The provisions are then formulated further with a social security system for all people and empowering the weak and unable to comply with human dignity and the provision of adequate health care facilities and public service facilities, these are regulated in Article 34 paragraph (2) and paragraph (3) The 1945 Constitution of the Republic of Indonesia. This shows that the state’s responsibility in the health sector is closely related to the state’s guarantee of the poor and displaced children.

Development policy in the health sector which was originally in the form of efforts to cure patients, gradually develops towards the unity of public health development efforts with a comprehensive, integrated and sustainable community participation which includes efforts to promotive, preventive, curative and rehabilitative. Based on the comprehensive, integrated and sustainable health development efforts, every effort to improve the level of public health is carried out based on the principles of non-discriminatory, participatory, protective and sustainable.

Furthermore, according to Article 1 point 1 of the Law No. 36 of 2009, what is meant by health is a healthy state both physically, mentally, spiritually which enables everyone to be socially and economically productive. The right of people to live healthy is a basic right that must be guaranteed. Because health is part of every human’s primary needs. Healthy condition of body and soul will enable every human being to do his activities and works. Health is also part of the need for a prosperous life. Basic rights in general and rights in health services in particular can be distinguished in basic social rights and individual basic rights.

The right to health care is a basic right which includes basic social rights and basic individual rights, so Health Services are all efforts and activities to prevent and treat disease, all efforts and activities to improve and restore health carried out on the basis of individual relations between medical service experts and individuals in need. As according to Wiku Adisasmita that health services are any efforts carried out alone or together in an organization to maintain and improve health, prevent and treat illnesses and restore the health of individuals, groups or communities.

Everyone has the right to health as regulated in Article 4 of the Health Law. The explanation of this Article stipulates that, The right to health referred to in this article is the right to obtain health services from health service facilities in order to realize the highest health status. Furthermore, the provision on the right to health services is regulated in Article 5 of the Health Law that everyone has the same right in obtaining access to resources in the health sector, has the right to obtain safe, quality and affordable health services, and is entitled to independently and independently. responsible for determining the health services needed for themselves.

As for the provisions of Article 6 of the Health Law, it is regulated that, Every person has the right to a healthy environment for the achievement of health status. So the right to healthy living and the right to get health services is a right that everyone has. The provisions of the Health Law further stipulate that the Government is responsible for fulfilling and guaranteeing the realization of these rights. The government is obliged to maintain and improve quality, equitable and affordable health services for all levels of society.

The responsibility that must be shouldered by the government in the health sector is ensuring the
availability of health resources according to the needs and all forms of health service efforts to fulfill the people’s right to health. Health resources in question include: health workers, health facilities, medical devices and pharmaceutical supplies, as well as other resources. The provisions of Article 15 of the Health Law stipulate that, The government is responsible for the availability of the environment, order, health facilities both physical and social for the community to achieve the highest degree of health. As for the provisions of Article 16 of the Health Law, it is regulated that.

In order to realize the right to a healthy life for the community, a source of health funding or health financing is needed. The Health Law regulates Health Financing, under the provisions of Article 170 of the Health Law it is formulated that health financing aims to provide sustainable health funding in sufficient quantities, fairly allocated, and utilized effectively and efficiently to ensure the implementation of health development so that improve the degree of public health as high as possible. The elements of health financing consist of sources of funding, allocation, and utilization. The sources of health financing come from the Government, regional government, community, private sector and other sources.

Based on the provisions on health financing, it can be interpreted that it is not possible for the government to endure or carry out its own health financing which is one of the main elements for the realization of the highest degree of health for the community. Because of that, it is necessary to hold a health financing guarantee which is at the same time the implementation of one of the national social guarantees.

Specifically the Government’s responsibility in the implementation of health insurance is regulated in Article 20 of the Health Law which is formulated that the government is responsible for the implementation of public health insurance through the national social security system for individual health efforts. The government is obliged to fulfill the right of the people to obtain the highest degree of health, namely the fulfillment of the right to live physically and mentally healthy, and fulfill their basic needs. Because the right to health services is a right that comes from human rights. Human rights in question are a set of rights that are inherently inherent and because of human existence as God’s creatures, are His gifts that must be respected, upheld by the state law.⁶

**According to Richard that:**

It is a well recognized principle that it is one of the first duties of a state to take all necessary steps for the promotion and protection of the health and comfort of its inhabitants. The preservation of the public health is universally conceded to be one of the duties devolving upon the state as sovereignty, and whatever reasonably likely to preserve the public health is a subject upon which the legislature, within its police power, may take action.

However, in this case it is necessary to maintain a balance between the implementation of the obligations of the state towards the people and the implementation of the obligations of the people towards the state, because the State / government will not be able to carry out or bear it on their own. The state’s obligation to fulfill people’s rights, including in terms of health financing, must be realized by the state. Instead the community’s obligation is to participate in realizing health in the family environment and itself is one form of social justice in health services, including in health financing. So the responsibility of fulfilling the needs of a healthy life is also the responsibility of the community, the government also regulates community participation in health services as formulated in Article 9 through Article 11 of the Health Law.

In the provision of Article 9 of the Health Law it is formulated that every person is obliged to participate in realizing, maintaining, and increasing the highest degree of public health. The obligations include the implementation of individual health efforts, public health efforts, and health-oriented development. As for Article 10 of the Health Law formulates that Everyone is obliged to respect the rights of others in an effort to obtain
a healthy environment, both physical, biological, and social. Whereas Article 11 of the Health Law stipulates that, Every person is obliged to behave in a healthy life to realize, maintain, and promote the highest health. Furthermore, Article 12 of the Health Law stipulates that, Everyone is obliged to maintain and improve the health status of others who are his responsibility. Whereas community obligations specifically related to the social health insurance program are regulated in Article 13 of the Health Law, which states that everyone has an obligation to participate in a social health insurance program.

As described above, that community participation is required for the realization of the highest degree of health. This is regulated in the provisions on Community Participation formulated in Article 174 of the Health Law, that People participate, both individually and organized in all forms and stages of health development in order to help accelerate the achievement of the highest degree of public health. Participation is intended to include active and creative participation.

**The State Functions As Provider**

Health services can be seen as an important aspect of social policy. Health is a determining factor for social welfare. A prosperous person is not just someone who has adequate income or a home. But also healthy people, both physically and spiritually.

Of course, health care is not a government monopoly. However, like social security and housing, public health services are also largely intended for underprivileged citizens. Public health service schemes are usually closely related to social security systems, especially social insurance, because some of the services involve or take the form of health insurance. In addition, the role of the government in public health services also includes the ownership of hospitals and health centers, including the establishment of policies on providers and health care providers conducted by the private sector.

Control of health providers is very closely related to doctors and health workers in providing health services to consumers in this case the patients. Therefore, it is very important for the State to provide control over doctors and health workers, so that the first need to be given responsibility to doctors is especially related to the obligations of a doctor because doctors become the main center of health care for patients.

According to J. Guwandi that the patient’s relationship with a doctor, the law establishes obligations as follows:

a) The doctor’s obligation to have the knowledge and skills of his profession. If someone already holds a doctor’s degree and has obtained a license to practice, then he must be expected, at least he has the ability, intelligence and skills of a doctor. If he is a specialist, then the benchmarks are also from a specialist in his field. According to Bambang Wibowo, Director General of Health Services of the Ministry of Health of the Republic of Indonesia that it is an obligation and obligation for every doctor to have knowledge and professional skills of a doctor if someone already holds a degree and works as a doctor, especially if he has obtained a license to practice, then he is already responsible to his profession and is expected to be able to carry out the duties and responsibilities of his profession, at least he has the ability, intelligence and skills of a doctor. He further said that if he is a specialist then the standard measure of a specialist doctor in his field, specialists obtained through special education specialists, knowledge and skills. Sources of knowledge and medical skills obtained from:

1) Faculty of medicine while still in college and clinical practice.

2) The results follow the development of his professional midwife by conducting research and reading literature, attending seminars, queries and international conventions.

3) The results of discussions with friends, conduct observations of the activities of other doctors in hospitals, clinics, etc.
b) The obligation to use their knowledge and skills with care, fairness and conscience as practiced by other doctors in the same circumstances.

The State function in the form of Control which is an important part of the health service system. Serious control from the government, especially for the provision of health services in a national health system to the community, especially for the poor and disadvantaged.

The national health system in question is an order that reflects the efforts of the Indonesian people to improve the ability to achieve optimal health status as a manifestation of public welfare through health development programs as a comprehensive, directed integrated and sustainable as part of national development.8

The aims and basis of health development within the National Health System are described as follows:

a) All citizens are entitled to obtain optimal health degrees, so they can work and live properly according to human dignity.

b) The government and the community are responsible for maintaining and enhancing the people’s health status.

c) The implementation of health efforts is regulated by the government and is carried out in an integrated manner with efforts to heal and recover.

d) Every form of health effort must be based on humanity based on the Godhead by prioritizing national interests, the people at large, and not merely the interests of groups or individuals.

e) The attitude, family atmosphere, mutual cooperation and all existing potential are directed and utilized as far as possible for health development.

f) In accordance with the principle of fair and equitable, the results achieved in health development must be enjoyed equally by the entire population.

g) All citizens are equal in law and must uphold and obey all statutory provisions in the health sector.

h) National health development must be based on a belief in one’s own abilities and strengths and on the basis of the nation’s personality.

Long-term development in the health sector, which is part of the National Health System, is directed towards achieving the main objectives of the health sector. The main objectives of national health include increasing the ability of the community to help themselves in the field of health, improving the quality of the environment that can guarantee health, improving the nutritional status of the community, reducing morbidity and mortality (mortality), developing healthy and prosperous families with increasing accepted the norm of a happy and prosperous small family.

Health services are any efforts carried out independently or jointly in an organization to improve and maintain health, prevent and cure illnesses and restore the health of individuals, families, groups and or communities. Health services according to Benjamin Lumenta all efforts to prevent and treat disease, all efforts and activities to improve and maintain health carried out by social institutions or institutions with a certain population, community or community

Furthermore Hodgels and Casio, differentiate personal health services or medical services and environmental health services or public health services. Leavel and Clark describe the characteristics of the two forms of health care, as follows: individual health services aimed at curative and rehabilitative with the primary goal of individuals and families; while environmental health services are intended to promotive and preventive with the main target of community groups.9

In general, the characteristics of health services raised by Marius Widjajarta, include: consumer ignorance, the influence of large health service providers on consumers so that (consumers do not have bargaining power and select power (supply induced demand), non-health service products homogeneous concept, discussion of competition, uncertainty about illness and health as human rights.
According to Benyamin Lumenta, good health services can be provided, if they meet the following principles:

1) Limited to treatment based on medical science;
2) Stress prevention;
3) Requires fair collaboration between lay people (patients) and medical science implementers (doctors);
4) Treating someone completely;
5) Maintaining personal relationships between doctors and patients closely and continuously;
6) Coordinated with fostering social welfare;
7) Coordinate all types (specialization) of medical services;
8) Utilize all the services needed and that modern medical science can provide to people in need.

Quality health services according to Tabish: Health Services means providing a health service product according to individual and community needs. High-quality health services begin with high managerial ethical standards, including: systems for carrying out professional standards; both from the standpoint of behavior, organization and assessment of daily activities, the observation system so that services are always provided according to standards and detection if there are irregularities; and a system to always support the implementation of professional standards.

The quality of health services is related to the quality and level of patient satisfaction as consumers. Guarantee for quality health services is a process of meeting the quality standards of managing health services consistently and continuously so that consumers get satisfaction. The aim is to maintain and improve the quality of health services on an ongoing basis which is carried out by an internal health service advice to realize the vision and mission and meet the needs of consumers.

According to Somers, that for the implementation of good medical services, many conditions must be fulfilled, covering 8 (eight) main points, namely available, appropriate, continue, acceptable, accessible, and affordable, efficient, and quality.

Health service is one of the efforts that can be done to improve the health status of individuals, groups or the community as a whole. In addition to health services another term of medical services is medical services, which is a service that includes all efforts and activities in the form of prevention, curative, promotive, and rehabilitative of health carried out on the basis of individual relationships between the experts in medicine with individuals who need it.

The State Function As An Entrepreneur Or Interpreneur

The role of the government as an agent of economic activity means that the government carries out consumption, production and distribution activities. The government in carrying out its role as an economic actor, establishing a state company or often known as a State-Owned Enterprise (abbreviated as BUMN). In accordance with Law No. 19 of 2003, BUMN is a business entity whose entire or most of its capital is owned by the state through direct investment from separated state assets. BUMN can be in the form of Perjan (Bureau Company), Perum (Public Company), and Persero (Corporate Company). SOEs make a positive contribution to the Indonesian economy. In a populist economic system, SOEs play a role in producing the goods or services needed in order to realize the greatest prosperity of the people.

BUMN was established by the government to manage production branches and sources of natural resources that are strategic and involve the lives of many people. These companies were established to improve the welfare and prosperity of the people, as well as to control the strategic and less profitable sectors. The government also acts as a consumption agent. Governments also need goods and services to carry out their duties. As is the case when carrying out their duties in the context of serving the community, namely carrying out construction of school buildings, hospitals, or highways. Of course
the government will need building materials such as cement, sand, asphalt, and so on. All these items must be consumed by the government to carry out their duties.

In addition to consumption and production activities, the government also conducts distribution activities. Distribution activities undertaken by the government in order to distribute goods that have been produced by state companies to the public. For example the government distributed nine staples to poor communities through BULOG. Distribution of groceries to the community is intended to help the poor meet their needs. Distribution activities undertaken by the government should be smooth. If the distribution activities are not smooth, it will affect many factors such as the scarcity of goods, high prices of goods, and even distribution of development is less successful. Therefore, the role of distribution activities is very important.

In the framework of carrying out government, community service, and development, the government basically has three main functions, namely the allocation function which includes, among other things, economic resources in the form of goods and services, community services, distribution functions which include, among others, income and wealth society, equitable development, and stabilization functions which include, inter alia, defense-security, economy and monetary. The distribution function and the stabilization function are generally more effectively carried out by the Central Government while the allocation function is generally more effectively carried out by the Regional Government, because the Regions in general are more aware of the needs and standards of community services.

The first task of the state by forming a business entity is to meet all the needs of the community, when these sectors cannot be done by the private sector. Then such tasks are translated as a form of pioneering efforts by the State to make SOEs a development agent / agent of development. The essence was formed of a State-Owned Enterprise (SOE) because it was based on the provisions of Article 33 specifically paragraphs (2) and (3) of the 1945 Constitution of the Republic of Indonesia which meant that: Production branches were important for the State that controlled the livelihoods of the people controlled by the State. Then the earth, water, and natural resources contained therein are controlled by the State and used for the greatest prosperity of the people.

The objectives of establishing a BUMN are (1) Give out contribution on economy national and acceptance cash country; (2) Chasing and looking for profit; (3) Fulfillment intention people’s lives; (4) Pioneer of business activities; (5) Give out helpand protection of small and weak businesses. BUMN is one of the economic actors in the national economy that is based on the principles of economic democracy so that it has a very important role in the administration of the national economy in order to realize the welfare of society as mandated by the 1945 Constitution of the Republic of Indonesia. The function of SOEs as implementing policies in the national economy is (1) Contribute to the development of the national economy and state revenue; (2) Improving the implementation of public benefits, in the form of providing goods and services in sufficient quantity and quality for the fulfillment of the lives of many people.

Health Insurance Administering Agency (BPJS Kesehatan) is a State-owned enterprises specifically assigned by the government to organize health care insurance for all people Indonesia, especially for Government employees, Recipients of civil servants and TNI/POLRI, Veterans, Pioneer of Independence and their families and other business entities or ordinary people. BPJS Health is a government program in unity National health insurance (JKN) which was inaugurated on December 31st 2013. BPJS Kesehatan began operating since January 2014. BPJS Kesehatan was previously called Askes (Health Insurance), which is managed by PT Askes Indonesia (Persero), but according to Law No. 24 of 2011, PT. Askes Indonesia changed to BPJS Health since the date January 2014.

Every Indonesian citizen and foreign citizen who has lived in Indonesia for a minimum of six months must be a member of the BPJS, that is regulated in Article 14 of the BPJS Law. Every company is obliged to register its
workers as BPJS members. Whereas people or families who do not work at companies are required to register themselves and their family members with BPJS. Each BPJS participant will be drawn in the amount determined later. As for the poor, BPJS contributions are borne by the government through the Contributions Assistance program. Being a BPJS participant is not only mandatory for workers in the formal sector, but also informal workers. Informal workers are also required to become members of the Health BPJS. Workers are required to register themselves and pay contributions according to the desired level of benefits.

In addition to the State having a business through BPJS, the State also benefits through hospitals, both government and private hospitals. Based on the legislation, private hospitals are seen as legal entities (rechtspersoon) because in reality hospitals through health workers can enter into therapeutic agreements with hospital service users. For government hospitals all matters relating to management/ management are determined by the government as the party that gives authority to hospital directors.

The difference in status between a government hospital as a public legal entity and a private hospital as a private legal entity/ foundation, makes a difference with regard to the parties responsible and accountable in the efforts of health services in hospitals.

Forms of hospital services can be divided into general hospitals and specialized hospitals. General hospital is a hospital that provides health services for all types of diseases from basic to subspecialistic. Special hospital is a hospital that organizes health services based on certain types of diseases or disciplines.

**The State Functions As A Referee / Umpire Or Oversight Function**

According to Stoner and Wankel that *Supervision means that managers try to ensure that the organization moves in the direction or direction of the goal. If one part of the organization goes in the wrong direction, managers try to find the cause and then redirect it to the right direction.**

Meanwhile according to Mc Farland in Handayaningrat that:

*Control is the process by which an executive gets the performance of his subordinates to correspond as possible to chosen plans, orders, objectives, or policies.*

Next Smith in Soewartojo, states that: Controlling is often translated also with control, including the understanding of plans and norms that are based on managerial goals and objectives, where these norms can be in the form of quotas, targets and guidelines for measuring actual work against those set. Supervision is activities in which a system is carried out within the framework of established norms or in a state of balance that supervision provides an overview of things that can be accepted, trusted or possibly imposed, and the control limit is the upper or lower value level a system can accept as a tolerance limit and still provide satisfactory results. In management, controlling is an activity to match whether operational actuating in the field in accordance with the planning that has been determined in achieving the goals of the organization. Thus, the object of surveillance activities is regarding mistakes, irregularities, defects and negative things such as fraud, violations and corruption.

There are various types of supervision as a form of implementation of the State’s function of the responsibility for health services can be carried out by the government, namely based on Article 23 paragraph (5) of the 1945 Constitution of the Republic of Indonesia. Furthermore, the existence of the Supreme Audit Board is governed by the Law No. 15 of 2006 (hereinafter abbreviated to the BPK Law). Based on Article 1 of the BPK Law, the Supreme Audit Board, hereinafter referred to as BPK, is a state institution whose task is to examine the management and responsibilities of state finances as referred to in the 1945 Constitution of the Republic of Indonesia, so that the BPK has the responsibility for the task and obligation to examine the government’s responsibility regarding state finances and checking all the implementation of the State Budget (APBN).
results of the examination are notified to the House of Representatives. If an examination uses things that give rise to a suspicion of a criminal offense or an act that is detrimental to the country’s finances, the Supreme Audit Board provides input to the government.

Conclusion

The state’s function of the nature of state responsibility in equitable free health services, in the form of a function regulator has issued several regulations related to health service programs, including government regulations that specifically regulate health insurance for the poor and displaced children, but have not been fully implemented well in accordance with the mandate of the 1945 Constitution of the Republic of Indonesia NRI automatically protects and guarantees the right to health insurance for the poor and underprivileged, as well as the controlling function (provider) has not been optimally implemented, as seen distribution and procurement of drugs in hospitals still often have problems, health workers in some the area is not evenly distributed as needed, while the entrepreneurial function has basically benefited the country from the assets and premiums of participants received so far, but these funds have not been utilized optimally to improve the quality of service and satisfaction of some of the participants, especially for the poor who have not been included in the PBI program, and the function of supervision/referee (umpire) will give optimal results if it is truly implemented properly according to its basic principles.

Nonsurgical Management of a Patient with Hypopituitarism Secondary to Nonfunctioning Pituitary Macroadenoma: A Case Report

Martino Handoyo¹, Hermina Novida²

¹Resident in Department of Internal Medicine, Faculty of Medicine, Airlangga University, Dr. Soetomo General Hospital, Surabaya, Indonesia, ²Lecturer and Consultant in Division of Endocrinology, Metabolic, and Diabetes, Department of Internal Medicine, Faculty of Medicine, Airlangga University, Dr. Soetomo General Hospital, Surabaya, Indonesia

Abstract

Pituitary adenoma is a benign neoplasm of pituitary gland. Pituitary adenoma, particularly a macroadenoma, may produce mass effect symptoms by compressing surrounding tissues. Due to pituitary function as a neuroendocrine organ, pituitary adenoma may also cause multiple endocrine disturbances. The authors report the case of a 39-year-old male patient presenting with chronic headache and history of seizure. MRI imaging revealed pituitary macroadenoma with optic chiasm compression. Further diagnostic workup indicated secondary hypogonadism and adrenal insufficiency. The patient was given hormone replacement therapy and was then advised for surgery, but the patient refused any surgical procedure. Subsequent follow-ups were somewhat difficult due to poor patient adherence. Nevertheless, appropriate management of pituitary adenoma is needed to achieve optimal result.

Keywords: pituitary adenoma, macroadenoma, clinically nonfunctioning, hypopituitarism

Introduction

Pituitary adenoma is a group of benign neoplasms arising from pituitary gland, comprising of 10-20% of all intracranial tumors (¹) and more than 90% of intrasellar tumors (²). Prevalence of pituitary adenoma is reportedly to be around 80-100 cases per 100,000 (³), but many studies found the actual number might be far greater, because many are asymptomatic and could only be detected from incidental findings on imaging or autopsy (⁴). Based on its size, pituitary adenoma can be classified into macroadenoma (≥10 mm) and microadenoma (<10 mm). Pituitary adenoma can also be categorized based on its hormonal activity as functioning or nonfunctioning. This differentiation is important because they have different management approach. We reported a case of a male patient, aged 39, with partial hypopituitarism secondary to clinically nonfunctioning macroadenoma.

Case Report

A 39-year-old male was referred from a rural general hospital to our outpatient clinic with a complaint of 1 year of worsening headache. He described the headache as continuous heavy sensation in the head bilaterally. The headache had varying frequency and duration in a nonspecific fashion and only partially responded to analgesics. The patient also had a history of a seizure in previous week which lasted only a few minutes and he fell unconscious during the seizure. It only happened...
once and there was no previous history of seizure before nor thereafter.

Head MRI scan (Figure 1) revealed a solid intrasellar lesion with regular clear boundaries, isointense on T1 and T2 with rim contrast enhancement, with approximately 19x22x29 mm in size, which extended into suprasellar region and abutted the optic chiasm, compressing the latter to anterior and superior, which was suggestive of a pituitary adenoma. No other structural abnormalities were found.

Figure 1. Contrast MRI of the brain on various planes and sequences. (top) T1-weighted coronal. (middle) T1-weighted axial. (bottom) T2-weighted axial.
Hormonal panel evaluation results were as follows: serum morning cortisol 0.8 mcg/dL (N: 4.3-22.4 mcg/dL), ACTH 28 pg/mL (N: 20-52 pg/mL), LH 0.12 mIU/mL (N: 1.5-9.3 mIU/mL), FSH 0.66 mIU/mL (N: 1.4-18.1 mIU/mL), testosterone 5.17 ng/dL (N: 241-827 ng/dL), prolactine 3.01 ng/mL (N: 2.1-17.7 ng/mL), TSH 1.62 mIU/mL (N: 0.55-4.78 mIU/mL), and FT4 0.94 ng/dL (N: 0.89-1.76 ng/dL). Other basic laboratory tests including complete blood count, serum electrolytes and glucose levels were within normal limit.

Further history taking and physical examination revealed diminished secondary male sexual characteristics and decreased libido within the past 6 months, although the patient was at first did not realize that his condition was interrelated. The patient was already married for 15 years and had 2 children from his marriage, aged 10 and 7 years old. Although the patient did not feel any visual disturbance that he might be aware of, the patient was referred to ophthalmology department for evaluation and was subsequently assessed with bitemporal hemianopia.

Based on the examination results, the patient was diagnosed with nonfunctioning pituitary macroadenoma with secondary hypopituitarism, manifesting as secondary hypogonadism and adrenal insufficiency. The patient was referred to neurosurgery department for further management. He was advised for surgery, but unfortunately he refused, asking for more time to discuss it with his family.

The patient was then given hormone replacement therapy to correct hormonal deficiency caused by hypopituitarism. Before initiating testosterone replacement, serum PSA level was 0.02 ng/dL and hematocrit was 45%. The patient was subsequently given 250 mg of testosterone injection (a mixture of 30 mg testosterone propionate, 60 mg testosterone phenylpropionate, 60 mg testosterone isocaproate, and 100 mg testosterone decanoate) intramuscularly every 4 weeks. For glucocorticoid substitution, the patient was given methylprednisolone 4 mg orally in the morning once daily. On subsequent laboratory evaluations, serum PSA levels and hematocrit were always within normal limit, while serum testosterone levels were fluctuating, ranging from 82.45 to 277.75 ng/dL. One major problem concerning the patient’s treatment was poor adherence. The patient was unable to attend our clinic regularly because he lived in rural area very far away from the city, making optimal treatment and follow-ups somewhat difficult.

Discussion

Diagnostic workup for pituitary macroadenoma involves imaging modalities of sellar region, assessment of pituitary hormones function, and optic pathway evaluation. CT and MRI of the sellar region are the preferred imaging modality in detecting pituitary adenoma, with the latter is considered to be more sensitive (4).

Clinical symptoms and signs in patients with pituitary adenoma can generally be classified into mass effect-related symptoms and endocrine abnormalities arising from hormonal overproduction leading to hyperpituitarism. Males were more associated with neurological symptoms such as visual disturbances and seizures, while females were more likely to present with symptoms related to sexual function disturbances such as menstrual disturbances, galactorrhea, infertility, and hirsutism (5). Still, many do not exhibit symptoms and discovered by chance (incidentaloma).

Based on its hormonal activity, a pituitary adenoma can be classified into functioning and nonfunctioning. Among the functioning pituitary adenomas, prolactin-producing tumor (prolactinoma) is the most frequent type (4,6). Other functioning pituitary adenomas producing GH, ACTH, TSH, or LH are also reported in studies but they are less common.

Clinically nonfunctioning pituitary adenoma (NFPA) is defined as pituitary adenoma which is not hormonically active, that is, not associated with clinical syndromes caused by overproduction of any pituitary gland hormones (7). Most pituitary adenomas are clinically nonfunctioning (8); approximately 50%
of microadenomas and 80% of macroadenomas belong to this group (2). NFPA could be categorized further based on transcription factor expression and immunohistochemistry (IHC) staining into silent pituitary adenoma (at least one positive transcription factor expression or IHC staining) and null-cell adenoma (negative transcription factor expression and IHC staining) (1).

Clinically nonfunctioning pituitary microadenomas usually do not cause signs or symptoms, while the main complaints in clinically nonfunctioning macroadenomas are largely related to mass effects including headache, visual field defects, and hypopituitarism. Approximately 40-60% of patients have headache as one of their main symptoms which might be caused by increased intracranial pressure or dura mater stretch. Visual field defect is present in 58% of macroadenoma cases, which has typical bitemporal pattern (9).

Hypopituitarism may occur due to pituitary stalk compression (and thus inhibits signals from hypothalamus) and also compression of the surrounding healthy pituitary tissue by the growing mass (2). In 60-85% patients with nonfunctioning pituitary macroadenoma, at least one pituitary hormone deficiency is present, while panhypopituitarism is less frequent. Among these hormones, gonadotropin deficiency is the most common and accounts for more than 80% of cases, followed by somatotropin deficiency in 70% of cases; while thyrotropin and corticotropin deficiency present in 20-50% of cases (10). Different literatures report somatotropin deficiency as the most common, followed by gonadotropin, corticotropin, and thyrotropin deficiency (9,11).

In our case, a tumor size of ≥10 mm on imaging leads the diagnosis of a macroadenoma, which was accompanied by optic chiasm compression. This explains mass effect symptoms in our patient, including headache, seizure, and visual field defect. A very low serum morning cortisol accompanied by a low-normal level of ACTH is indicative of secondary adrenal insufficiency. Low level of serum testosterone combined with low levels of both FSH and LH suggests secondary hypogonadism.

Management of pituitary adenoma generally consists of several main strategies: surgery, radiotherapy, and medical treatment (using dopamine agonists and somatostatin analogs). Existing hypopituitarism should also be managed accordingly by administering hormone replacement therapy.

The first line and the most effective treatment for clinically NFPA is surgery, particularly in symptomatic macroadenoma. Without surgery, 50% will progress within the next 5 years, while only 10% might regress spontaneously (2). Surgery is indicated if there is optic chiasm compression or visual field defects which ensue from the compression. In these cases, visual function preservation or recovery should be the main goal of treatment. Approximately 78% of patients are reported to have improvement in visual field after surgery. However, only 30% of patients undergoing surgery obtain improvement in pituitary functions (7). These possible outcomes should be carefully discussed with the patient before surgery along with other surgical risks. Other mass effects such as headache could also be a consideration for surgery, although in a more individual approach. In NFPA without optic chiasm compression, the decision regarding surgical treatment should be tailored individually (2).

Regarding surgical method, transsphenoidal approach is preferred because it has lower complications rate and perioperative mortality risk compared to transcranial approach. Some complications that might occur after surgery (less than 5% of cases) include new visual disturbance, cerebrospinal fluid leakage, fistula, meningitis, and diabetes insipidus (7). Newer endoscopic resection method has comparable efficacy and safety (12). While combination of surgery and radiotherapy is reported to have lower risk of tumor recurrences than surgery alone (7), it must be noted that radiotherapy is not recommended in all cases, but may be considered when there is large residual tumor postoperatively or tumor recurrence.
Medical treatment using dopamine agonists and somatostatin analogs are considered to be adjunct therapy in functioning pituitary adenoma \(^{(6)}\). However, the effectiveness of these medications in the treatment for NFPA has not been proven \(^{(3,13)}\). Therefore, currently there is no recommendation for using these drugs in NFPA.

Hypopituitarism due to pituitary adenoma might be permanent despite tumor removal; therefore, the patient may require hormone replacement for a lifetime. Complete assessment of pituitary function is needed to detect hypopituitarism in one or more axis, although panhypopituitarism is less frequent. Management of hypopituitarism should be done on an individual basis. In our case, the patient develops secondary adrenal insufficiency and hypogonadism.

For glucocorticoid substitution, hydrocortisone use is recommended, with daily dose of 15-25 mg in single or divided doses. In our patient, we used methylprednisolone in its equivalent doses because oral hydrocortisone was not available in our center. It should be noted that there is no universal consensus on appropriate treatment for glucocorticoid replacement. There is also no objective monitoring parameter available. Doses should be adjusted based on clinical grounds, which can be increased 2-3 times the usual dose during mild illness or surgery and 10 times in major illness or surgery for a short time \(^{(14)}\). Overcorrection for prolonged period should be avoided to prevent undesirable adverse effects.

Secondary hypogonadism in males can be treated either with testosterone or gonadotropin formulations. Gonadotropin administration is preferred if fertility is desired \(^{(14)}\). Our patient already had 2 children from his marriage and did not have a plan to have another child; therefore, fertility is not an issue. The patient was then given intramuscular testosterone injection as replacement therapy which should have been administered every 3-4 weeks but unfortunately our patient only managed to visit our clinic every 2-3 months. Nevertheless, this formulation was chosen because it was the most readily available in our center and more convenient for the patient considering patient’s poor adherence.

Serum PSA and hematocrit level must be monitored during testosterone replacement treatment. An increase > 1.4 ng/mL of serum PSA from baseline within the first 12 months of treatment or a level >4 ng/mL is an indication for further urologic evaluation. Testosterone treatment should be stopped if hematocrit level is >54% until it decreases to a safe level and then might be reinitiated in a reduced dose. Serum testosterone level should be maintained in mid-normal range (400-700 ng/dL) during treatment and evaluation should be made midway between injections \(^{(15,16)}\). In our patient, baseline serum PSA and hematocrit levels were normal and there was no significant increase throughout therapy. However, achieving treatment goal was challenging since his serum testosterone never reached recommended level due to suboptimal treatment which was influenced by social and economic difficulties.

**Conclusion**

Patient with pituitary adenoma should be evaluated for mass effects related symptoms and complete pituitary axis function in order to give appropriate treatment. Management of pituitary adenoma should be made on individual basis. For symptomatic clinically nonfunctioning macroadenoma, surgery is the first line treatment. Based on data from previous studies, visual disturbance will improve in almost 80%, while pituitary function will improve in only 30% of cases after surgery. Patients with hypopituitarism may need continuous long term hormonal replacement to maintain physiological function. This case is reported to highlight the importance of appropriate workup and management of a clinically nonfunctioning macroadenoma.

Assessment of Pesticide Biohazards in Neurodegenerative Diseases; Data Analysis Statistical Study

Marwan M. Merkhan1,2, Zeina A. Althanoon1, Ahmed A Mohammed3, Ibrahim M. Faisal4

1Researcher, Department of Pharmacology and Toxicology, College of Pharmacy, University of Mosul, Mosul, Iraq, 2Researcher, Department of Pharmaceutics, College of Pharmacy, Ninevah University, Mosul, Iraq, 3Researcher, Alkhansaa Teaching hospital, Ninevah Health Directorate, Mosul, Iraq, 4Researcher, Department of Pharmacology, College of Medicine, University of Mosul, Mosul, Iraq

Abstract

Background: The initiation of late onset neurodegenerative diseases remains unknown. New researches suggested that prolonged exposure to pesticides might lead to the initiation of neurodegenerative diseases, but the results were subject to controversy. Aims: The present study aimed to demonstrate an update data-mining to compare published data for studies comparing role of pesticide in induction of neurodegenerative diseases (Parkinson’s diseases, Alzheimer’s diseases, and Amyotrophic lateral sclerosis) Results: A clear association has been noticed across different studies regarding correlation between pesticide exposure and Parkinson’s disease or Amyotrophic Lateral Sclerosis (Odd Ratio >1), nevertheless, the association was weaker between exposure to pesticide and the development of Alzheimer’s disease (Odd Ratio close to 1) Conclusions: There is good quality evidence that the impact of pesticide in initiation of neurodegenerative disease is statistically approved. However, there is inconclusive evidence from randomised controlled trials to show significant induction of neurodegeneration. More research is needed particularly long-term controlled studies on laboratory animals.

Keywords: agriculture, pesticide, neurodegenerative, Alzheimer, Parkinson, epidemiology.

Introduction

Aging-related diseases are worldwide major health issue, Alzheimer’s disease (AD) distribution constitutes two-third form of dementia and is described as a continuous diminishing of memory and other intellectual capacity1. Alzheimer’s disease (AD), Amyotrophic Lateral Sclerosis (ALS), and Parkinson’s disease (PD) are described as major motor health problems and it has been demonstrated that there is a correlation between these neurodegenerative diseases and the pesticide exposure2. The organophosphate (OP) insecticides are discovered very early last century, however, started to find application worldwide due to their effectiveness as an insecticide with low human toxicity3.

OP can be easily absorbed through GIT, respiratory system, mucous membrane, and skin4. OP toxicity is apparently common in farmers resulting in great morbidity and mortality, particularly in developing countries with rigorous agriculture5. However, the available data provide no clear-cut idea about the prevalence of the disease and the reported acute toxicity cases are relatively high (approximately 3000000 cases worldwide plus 220000 death rates)6. Nevertheless, in absence of accurate statistical study, these records provide only limited information about the real estimate due to unavailability of medical records in all countries and/or undiagnosed cases7.
Inhibition of the enzyme acetylcholinesterase is the principle mode of action of the OP insecticide, reducing the availability of the neurotransmitters acetylcholine (Ach) at synaptic clefts resulting in peripheral and central stimulation of nerve and muscle. Toxicity with OP is associated with autonomic overstimulation, movement impairments, muscular rigidity, reduction of motor activity and respiratory failure. Recovery is usual and it takes 1-2 days until all the symptoms disappear, however, delayed effects are uncertain and continuous exposure results in worsening of the condition overtime leading to neurological impairment, such as, mild paralysis, sensorineural polyneuropathy, cognitive dysfunction and psychiatric disturbances. This systematic review provides statistical clue about possible correlation between pesticide exposure and the potential development of long-term morbidity.

Study design and methods

We searched Iraqi Virtual Science Library (IVSL), PubMed, Cochrane Library MEDLINE, EMBASE, and the Chinese Biomedical Database (CBM), for the 2 target words ‘pesticide, neurodegeneration’ and target English papers. To be included, papers should be original work and full text articles. All published manuscripts were screened by reading the title and abstract for potential relevance to this research topic; whenever the title and abstract did not obviously state the degree of relevance, the manuscript itself was reviewed. To overcome search bias, another researcher conducted the review procedure independently; only studies jointly accepted by the two independent reviewers were taken into considerations. To simplify tracking the results in the present study, the results were categorised into Alzheimer’s disease, Parkinson’s disease, and Amyotrophic Lateral Sclerosis.

The online literature investigation revealed 827 publications, of which 731 duplicate studies were identified and thereby excluded, unrelated or not epidemiological study. The 96 target articles were downloaded and investigated carefully by two independent colleagues. We further removed another 14 unrelated publication from the total (Mixing other disease with other neurodegenerative disease). Ultimately, 82 trials were comparable to our inclusion standards, and the summarised data listed in figure 1, 2, and 3; related to Alzheimer’s, Parkinson’s and Amyotrophic Lateral Sclerosis, respectively. Only 82 epidemiological studies trials included patients diagnosed with neurodegeneration by specific criterion.

Results and Discussion

The collected epidemiological studies confirm that there is a great association between pesticide exposure and the development of neurodegeneration, more than 90% of these collected studies were showed that the odd ratio (OR>1) indication that there is a risk of developing the neurodegeneration due to exposure to these organic substances for long-periods (see figure 1, 2, and 3). The detailed information about the year, author, type of studies, and sample size about the collected epidemiological studies were mentioned below in Figure 1, 2, and 3.

The causative agents involved in initiation and progression of neurodegenerative diseases is yet unknown. A great efforts has been paid by scientists in an attempt to identify the causative agent involved in these diseases. The impact of these disease imposed a great burden on the individual and society due to high rate of morbidity and mortality. The health system funding of the neurodegenerative diseases is relatively high per annum as compared to other diseases including cardiovascular ones. Most of these neurodegenerative diseases start at elderly age group (>60 years). Identifying the causative agents is of great importance in determination of the underlying pathology of the disease to reduce its prevalence; reducing the burden on health care provider and reduce health cost budgets of geriatric-living cost. In the present statistical study we tried to identify the link between pesticide exposure and neurodegeneration in elderly age group through reviewing other case control studies conducted at different timeline and different area in the world. Many variables has been identified in the present study which could be a limitation of our study, including types of pesticides used which are in most cases unidentified by the participant or they reported their exposure to different agents during their life-time. The age of the participant varies (65-90 years) and this needs to be counted as an important variables because the neurodegenerative disease by default is age linked. The duration of our study is extended over 4 decades (1980s-2010s) which is regarded as an additional variables to be considered because during this extended period of time; different new pesticides were potentially introduced in farming. Therefore, the outcome of our
study is questionable and should be explained in the shadow of these variables. The outcome confirm that exposure to pesticide in field area for pesticide-dealers has been clearly associated risk of developing NDD with approximately overall studies showing an odd ratio of greater than 1.

The highlighted studies collected presently confirm that age is important factor in these diseases. There are a clear link between the exposure to pesticide and increased risk of development of neurodegenerative disease and this association is reciprocal to increased age, however, there is no consent on the age or age range at which pesticide could induce or increase the risk of association. Clear association with age were noticed at elderly (after 70) for both PD and AD, however, ALS shown onset at different age ranges excluding the possibility of association between pesticide exposure and age of participant. However, no differences were reported to exist in relation to sex variation. The studies records shown equal involvement of male/female in the study with no reported variation between studied group. The timeline of exposure to the pesticide showed important consideration regarding earlier type of pesticide which were reported to be more neurotoxic than those newer agents. In 1990s the available agents has been shown to be more neurotoxic than those newer agents introduced in 2010s.

The present study aimed at identifying the correlation between the exposure to pesticide and the incident of neurodegenerative ailments. However, so far there is no idealagreement about the link between exposure to pesticide and neurodegeneration initiation, therefore, more investigation and data analysis is needed before a clear–cut conclusion is drawn. Age is a principle factor for neurodegeneration exaggerated by pesticide exposure. Four mechanisms exist for illustration of the pesticide-induced neurodegeneration linked with aging, these include; oxidative mechanism of action, reaction between amyloid and organophosphates, cognitive impairment, and neuronal or haemostatic damage.

The relationship between the rate of exposure to pesticide and the incident of Parkinson’s, Alzheimer’s disease, and Amyotrophic lateral sclerosis is theoretically acceptable due to structural similarities between neurotoxin 1-methyl-4-phenylpyridinium (MPP+), a metabolite of 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP); with some pesticides, insecticides, and herbicides. Researchers has recently found a link between the molecular mechanism of action of the agricultural compounds and the development of different disease. For instance, rotenone an enzymatic process in mitochondrial membrane complexes enzyme (Complex I) which are involved in oxidative phosphorylation reaction resulting in mitochondrial depolarisation leading to cellular necrosis. Simple defect in this Complex I-enzyme could results in pathophysiological features of neurodegenerative disease. Investigators have found that organochlorines generate reactive oxygen species, accumulation of a-synucleinbiomolecules, impairment of the ubiquitin-proteasome system and the disruption of mitochondrial membrane potential, and stimulation of dopamine production leading to intracellular dopamine vesicle exhaustion. Moreover, paraquat long-term dopamine overproduction and consequently reduction in dopamine synthesis due to activation of N-methyl-D-aspartate (NMDA) receptor and suppression of the complex I of the mitochondrial membrane potential transport chain resulting in cellular apoptosis or necrosis. Carbamate inhibits ubiquitin proteasome system (UPS) by preferential damage to TH+ neurons and elevated alpha-synuclein levels. Imidazoles (e.g. benomyl), dithiocarbamates (e.g. maneb, and ziram), organochlorine, and other pesticides can inhibit aldehyde dehydrogenase (ALDH) enzyme. Recent studies indicated the importance of ALDH in involvement in the pathology of neurodegenerative disease.

**Conclusion**

To sum up; oxidative stress and neuronal inflammation, microtubule modification together with compromised axonal transport, beta amyloid formation, calcium homeostasis and mitochondrial dysfunction are
all factors that at least are able to impact on intellectual or motor decline. The major challenge for future investigators is in demonstration of variables which required to be controlled in epidemiological studies and designing more focused and translational experimental studies.

The Leptin Concentration Level in Progression of Hand Osteoarthritis Disease

Maryam Qais Ahmed1, Ghaith Sael Mohammed2

1Researcher, Medical Instrumentation Engineering Department - Al-Esraa University College – Baghdad – Iraq,
2Researcher, Surgery Department - College of Medicine – Al-Nahrain University – Baghdad – Iraq

Abstract

Subject: Hand Osteoarthritis (HOA) is known as degenerative cartilage cell disease in joint association with generation various inflammatory responses. This disease is more common in geriatric and affected by many factors such as obesity. Leptin is hormones secreted of fatty tissue involve as mediators in many pathophysiology process, and support inflammation at cartilage of hand joint.

Objective of the Study: Role of leptin concentration level in progression of hand Osteoarthritis.

Materials and Methods: This study was done on 60 patients with HOA disease and 60 healthy persons (control), the all subjects age within this study were more than 60 years of both genders. After obtained serum, immediately used quantity method (immunoassay) for measured level of leptin concentration.

Results: This study shows elevation of serum leptin concentration level in HOA group compare with healthy control group.

Conclusion: This study confirms that serum leptin concentration level can act as support HOA disease progression.

Keywords: Hand Osteoarthritis, Leptin and Osteoarthritis.

Introduction

Osteoarthritis (OA) is one of joint disorders that consider as chronic, associated with age due to changes in physiologic processes at geriatric, OA know as complex disease characterize degradation of cartilage cells (chondrocytes) that layering end bones in joints, with interaction recognized inflammatory factors. The OA disease has many pathologic factors classified into mechanical (that is effect on weight-bearing joints) and non mechanical (that is effect on non weight-bearing joints), one of the main cause of OA disease is obesity. The hand joints consider as non weight-bearing joints.

Adipokines are hormones secreted of fatty tissue involve as mediators in many pathophysiology process (such as rheumatic diseases), newly recognized family of compounds like leptin. The leptin has role in contribute of OA prevalence in obesity persons.

Many studies suggested the correlation between OA disease and leptin level in weight-bearing joints like knee joints, but few studies included the correlation with non weight-bearing joints like hand joints. Leptin level consider risk factor to degradation of cartilage cells in joints due to it’s has link HOA disease and obesity.

The study aim is evaluate leptin level in HOA group and healthy control group at comparison study.

Materials and Methods

The present study included 60 cases with HOA disease and 60 healthy persons (as control) groups, all individuals age was more 60 years of both sexes. The sampling process of all subjects was random manner.
blood samples separated immediately without any preservative factor to product serum as pure form. The serum used for measured leptin concentration level (as quantity measurement) by immunoassay method.

After measurement, used t-test method for statistic analysis to show different of leptin level by comparison between HOA patients and control groups via used mean ± standard deviation (SD) and p-value (p-value > 0.05 mean significant value).

**Results**

The present study explain a different of leptin concentration level between HOA patients and healthy control groups via used mean ± SD statistic method. The leptin level found in HOA group was 14.1+9.4, while in control group was 11.5+9.9 with P-value was 0.021. The present result confirms elevation of leptin concentration level in HOA group. Show table 1.

**Discussion**

The HOA is degenerative cartilage joint disease consider as more prevalence disease in geriatric, and it consider as complex disease due to interact of many pathological factors to generate this disease such as mechanical factor, non mechanical factor and cytokiens. The cytokines and hormones secreted of fatty tissue like leptin act to support of inflammatory process in joints (3).

There are many studies such as Stannus et al study showed correlation between general OA patients, leptin concentration level and joint pain, this studies showed elevated of leptin level with reduced cartilage thickness that product from cartilage degradation (5). Also there are studies showed correlation between leptin level with HOA at specially form, Veenbrin et al explained that concluded that leptin is partially involved in the relationship between BMI and HOA (6).

The hand joint not effect by mechanical factors such as knee joints, so this study remarkable to focus on involve of metabolic factors on generate of HOA.

This study demonstrated elevated of leptin level in HOA, and agree with previous studies. We recommend to other studies and take more HOA patients to confirm this study results.

**Conclusion**

This study concluded to confirms that serum leptin concentration level are elevate in HOA cases compare with healthy control, this support that leptin involve in pathological process that product cartilage degradation in hand joints.

Formulation Herbal Mouthwash Combination Extract of Ginger and Lemongrass as Antibacterial Causes of Halitosis in Diabetes Mellitus Patients

Masriadi¹, Sukmawati², Hasta Handayani Idrus³

¹Professor, Department of Epidemiology, Faculty of Public Health, ²Lecturer of Faculty of Pharmacy, ³Lecturer of Faculty of Medicine, Universitas Muslim Indonesia, Makassar

Abstract

Background. Ginger and lemongrass are plants known as the king of rhizomes with a healthy stance because empirically many have used them as halitosis treatment in people with diabetes mellitus. The research objective was to formulate herbal mouthwash from extracts of natural ingredients, namely a combination of ginger and lemongrass which has the potential as antibacterial causes of bad breath (halitosis) in people with Diabetes Mellitus (DM). Material and Methods. The extraction of the sample will be carried out by a modified extraction method using ethanol and water solvents, then biological activity testing will be carried out in-vitro with the diffusion method so that the antibacterial activity test against several bacteria that cause halitosis will be tested. Antibacterial sample is an active compound resulting from the extraction process. Bacteria that had been inoculated into the growth medium (NB) were put into sterile soft NA media (0.7%) with a concentration of 10,000, 8,000, 7,500 and 6,000 ppm, respectively. Results. There is an inhibitory effect, on p. gingivalis but the pattern of values is uncertain. A solution of formulation A with a concentration of 75% occurs inhibition with an inhibition diameter of 15.7%. This inhibitory effect is not an activity of formulation A, because acetic acid also has the ability to inhibit bacteria. In the sample solution with a concentration of 100% chitosan (w / v), the highest inhibition occurred with an inhibition diameter of 18.7 mm / mg of the sample extract. Formulation A with a concentration of 25% (w / v), the lowest inhibition occurred. The test solution of formulation A with a concentration of 25% has shown an inhibitory effect on the growth of Streptococcus mutans. This effect is stronger at concentrations of 100%, 75%, and 50%. The antimicrobial effect actually increased with an increase in the concentration of the test solution in succession of 25%, 50%, 75%, 100%. Formulation C with a concentration of 10000ppm, 8000ppm, 7500ppm, 6000ppm showed that the antimicrobial effect actually increased with an increase in the concentration of the test solution in succession. This shows that there is a strong positive relationship between concentration and inhibition zone. Conclusion. All tests for both formulation A and formulation C using several concentrations showed quite good results with the antibacterial activity being directly proportional to the concentration, the greater the concentration the greater the activity.

Keyword: Antibacterial, Diabetes Mellitus, Halitosis, Herbal mouthwash

Background

Assessment of health status can use several indicators that reflect the condition of mortality (death), nutritional status and morbidity (morbidity). The degree of public health in Maros Regency is illustrated through the Mortality Rate, Under-Five Mortality Rate, and Maternal Mortality Rate, Morbidity Rate (Morbidity Rate) such as several diseases including infectious diseases (pulmonary tuberculosis, dengue fever etc.), non-communicable diseases (hypertension, Diabetes Mellitus etc.), as well as oral dental diseases (gingivitis,
periodontitis, halitosis, etc.).

Halitosis is a crippling social problem with a common complaint of up to one-third of the general population.\[^{1}\] Halitosis is a lyrical term derived from the Latin word “halitus” (breath) and the Greek suffix “osis” (condition, action or pathological process). In simple words, it means “Bad Breath”. It is also called as fetor ex ore or fetor oris.\[^{2}\]

In most of the cases (90%), halitosis originates within the oral cavity. This is because the oral cavity harbours a large variety of microorganisms which include a large group of Gram-positive bacteria mainly *Streptococci* and a group of anaerobic microorganisms such as *Porphyromonas gingivalis*, *Fusobacterium nucleatum* and *Prevotella intermedia*. Among the latter, many are Gram-negative oral bacteria whose proteolytic activity is associated with oral malodour and periodontal disease.\[^{3}\] Other bacteria associated with gingivitis and/or periodontitis (viz.- *Actinobacillus actinomycetemcomitans*, *Campylobacter rectus*, *Peptostreptococcus micros*, *Bacteroides forsythus*, *Eubacterium* species and *Spirochetes*) are known to produce large amounts of volatile sulfur compounds (VSC) which are malodorous.\[^{4}\]

Word halitosis is a Latin word which is derived from halitus means breathed air, and the osis means pathologic alteration and it is used to describe any unpleasant or disagreeable bad odor emanating from the mouth breath.\[^{5}\] Halitosis or bad breath is a disease caused by a lack of oral hygiene. Halitosis can cause harm not only to sufferers but also other people and can affect someone’s social life such as shame, avoidance of social interactions and decreased self-confidence.\[^{6}\]

Research by Ravindran et al. in India in 2015 showed that the number of patients with controlled diabetes mellitus had more halitosis (26.7%) than uncontrolled diabetes mellitus patients (20%). This occurs due to bacterial decomposition and the evaporation of Volatile Sulfur Compounds (VSC).\[^{7}\] Research Kumaresan et al. in India in 2017, 149 patients with type 2 diabetes mellitus showed that only 57 subjects knew and were aware of halitosis as a result of type 2 diabetes mellitus, while most subjects did not realize that halitosis was a manifestation of the oral cavity due to diabetes mellitus. This shows the lack of public knowledge about the impact of systemic diseases on oral health.\[^{8}\]

Research by Bisong et al. in Cameroon in 2015 shows that disease of the oral cavity is higher in people with diabetes mellitus compared with non diabetes mellitus, where hyperglycemia is suspected to be factors that play a role in the emergence of disorders in the patient’s oral cavity diabetes mellitus. This study revealed that plaque, calculus, xerostomia and halitosis was significantly higher in people with diabetes mellitus compared to non diabetes mellitus.\[^{9}\]

Everyone certainly wants healthy teeth and avoid bad breath. They think that by brushing their teeth alone, bad breath can be eliminated, even though they need continuous treatment to get maximum results. Apart from regular brushing, other efforts are also needed. Bad breath faced or experienced by a person has many causes, not only from infections in the oral cavity, it can be from other sources that can cause bad breath including throat, lung and stomach disorders, and cadaulin (Diabetes mellitus sufferers), and consumption of certain drugs.

Diabetes mellitus is a chronic disease with hyperglycemia and glucose intolerance that occurs because the pancreas cannot produce insulin adequately or because the body cannot use insulin. This disease affects many Indonesians. Oral complications that commonly occur in people with type 2 diabetes mellitus include xerostomia, periodontal disease, caries and halitosis. Halitosis describes breath that is smelly or unpleasant.\[^{10}\]

Oral and dental health is very important to maintain overall health. Good oral and dental health will improve our ability to speak, speak, smile better, taste food, chew, swallow, and can even improve our facial expressions when communicating.\[^{11}\] Teeth are a very important part of us, because teeth are directly related to health and
appearance. Oral health is often neglected by the public. They consider other health to be more important than oral health. In dental health problems, especially bad breath (halitosis). Many people experience a bad condition in their mouth (halitosis) but they lack awareness of the condition of their mouth. Everyone certainly wants healthy teeth and avoid bad breath. They think that by brushing their teeth alone, bad breath can be eliminated, even though they need continuous treatment to get maximum results. Apart from regular brushing, other efforts are also needed.

Word halitosis is a Latin word which is derived from halitus means breathed air, and the osis means pathologic alteration and it is used to describe any unpleasant or disagreeable bad odor emanating from the mouth breath. The bad breath of diabetes mellitus is very typical like acetone. The substance comes from ketone limbs that can be secreted from the breath. 

Aleman L F J et al conducted a study to determine the effectiveness and sustainability of three commercial mouthwashes against the halitosis and concluded that a decrease in VSC and organoleptic levels after use of mouthwashes for 1st and 3rd hours. Results obtained in that study indicate that mouth rinsing with essential oils, cetylpyridine chloride and triclosan represents a positive option for the treatment of halitosis.

Halitosis treatment aims to improve the quality of life of people with diabetes mellitus due to prolonged disturbances in the oral cavity in the form of halitosis and other oral diseases. Herbal medicine is one of the treatment efforts and/or other methods of treatment outside of medical science and treatment science, traditional medicine needs to be nurtured, developed and supervised so that its benefits and safety can be accounted for.

A preliminary study was conducted at the Tompobulu Public Health Center in October-November 2019 regarding the effect of video method counseling, treatment in improving the quality of life of people with Diabetes Mellitus due to halitosis. The results showed that there was a relationship between counseling, treatment and quality of life for people with diabetes. In that study, provided treatment with a combination of using 0.5% chlorhexidine mouthwash with herbal mouthwash, in this case lemongrass and ginger. Based on the results of the treatment given in the form of 0.5% chlorhexidine mouthwash and it was found that some still experienced bad breath with the criteria that there was moderate mouth rinse (50%) after giving mouthwash to (20%), bad breath was very strong (10%) becomes (0%). Patients using lemongrass and ginger leaves experienced changes in bad breath criteria, namely moderate bad breath (40%) to (15%), strong breath (15%) to (5%). The research objective was to formulate a herbal mouthwash from a combination extract of ginger and lemongrass as an antibacterial cause of halitosis in DM sufferers.

Material and Methods

Materials and tools

The main ingredients used are the formulations made in the Pharmaceutical Microbiology Laboratory of UMI. The bacterial cultures used in this study were Gram negative bacteria, namely P gingivalis and gram positive bacteria, namely Streptococcusmutans. The agar media used were Nutrient Agar (NA), Vogel Johnson Agar (VJA), and Eosin Methylene Blue Agar (EMBA). The chemicals used were 70% alcohol, spirits, pH 4 and pH 7 buffers. The equipment used was a Kotterman-Germany brand Clean Bench (aseptic room equipped with a UV lamp), incubator cupboard, autoclave, hotplate, petri dish, analytical balance, Erlenmeyer, test tube, dropper pipette, volumetric pipette, loop needle, measuring cup, measuring flask, Bunsen lamp, and other supporting tools.

Research Treatment

The treatment applied to this test bacteria is the concentration of formulation A added. The concentration of formulation A (100 gr ginger, 100 gr lemongrass, 100 clove seeds in 100 ml water) used was 100%, 75%, 50%, 25%. For formulation C, it is 10000 ppm, 8000ppm, 7500ppm, 6000ppm with a concentration. Testing the antibacterial activity of the sample using the
agar diffusion method. The experiment was carried out with 3 replications. Observation data are presented in tabular form and then analyzed descriptively.

**Preparation of Test Bacterial Culture**

The test bacterial culture to be used is prepared by taking one bacterial loop from an NA agar slant, then inoculating it into 10 ml of sterile NB. Furthermore, it was vortexed to even out the bacteria in NB, then incubated at 37°C for 24 hours. After 24 hours, an inoculum is obtained which can be directly used for testing antibacterial activity.

**Testing Antibacterial Activity with the Well Method**

The well method (agar diffusion) is based on the ability of the tested antibacterial compound to produce the radius of the inhibition zone around the test well against the bacteria used as the tester. Testing the antibacterial activity of formulation A and formulation C was started by preparing the bacterial growth medium. Making the media begins with weighing the powder media and adding distilled water as directed on the packaging. Then, stirring while heated using a hot magnetic stirrer until the media solution is homogeneous which is marked by a clear color of the solution, then Erlenmeyer is covered with cotton and sterilized at 1210°C for 15 minutes. After sterilization the media is cooled closed at room temperature until the temperature reaches 400°C then 0.1% test bacteria are inoculated into each growth medium (0.1 mL of culture in NB into 100 mL of growth media) then homogenized. The growth medium used for each of the test bacteria. The media that has been inoculated with the tested bacterial culture is poured into a dish and allowed to freeze. Then five holes (wells) were made aseptically with a diameter of 7 mm and put a sample solution of 60 µL containing the added formulation A. The concentration of formulation A used was 100%, 75%, 50%, 25%. For formulation C it is 10000 ppm, 8000ppm, 7500ppm, 6000ppm. The sample solution was prepared by dissolving the sample according to the concentration in a 1% acetic acid solution. Incubation was carried out statically at 37°C for 48 hours.

**Inhibition Zone Calculation**

The zone of inhibition of chitosan antibacterial compounds was measured based on the radius (rp, mm) of inhibition in the form of a clear area around the test well. Measuring radius (rp, mm) is done by measuring the distance from the edge of the test well to the boundary of the zone of the inhibition zone using a caliper (accuracy of 0.05 mm) on several sides of the test well, then averaged. The value of the diameter (d, mm) of the inhibition zone as a result of direct observation is obtained using the formula d = 2 x rp.

**Results**

**Table 1. The results of the antibacterial activity test of formulation A and formulation C with several concentrations**

Discussion

The extract was obtained through an extraction process using 95% ethanol as a solvent. Extraction using ethanol as a solvent was chosen in order to obtain a polar active ingredient. 95% ethanol was chosen as a solvent or extractor because through a series of initial trials it was found that ethanol showed the best effect on the withdrawal of the active ingredient contained in male mayana leaves. The extract obtained is then filtered with filter paper and then evaporated under vacuum pressure, the results obtained have the physical properties of the extract, namely in the form of a very thick precipitate, which indicates that the viscosity level is very high.

Ethanol was used as the solvent because it has two groups with different polarity which are hydroxyl group that is polar and alkyl group that is non-polar, so by the existence of these groups it is expected that the compounds with different polarity levels will be extracted into the ethanol.[15]

The results of the effect test on the growth activity of Gram negative, namely P. gingivalis and Gram positive bacteria, namely Streptococcus mutans. In observations after 24 hours of incubation with 3 repetitions. The test results of male mayana leaf polar extract against the growth activity of Streptococcus mutans and P. gingivalis has a positive value. This is indicated by the presence of a bright area around the culture hole in each of the tested bacteria. There was also inhibition against the comparative antibiotic.

In the table, it can be seen that the sample gives an inhibitory effect, on p. gingivalis but the pattern of values is uncertain. In a solution formulation A with a concentration of 75%, there was an inhibition with an inhibition diameter of 15.7%. This can occur because of the presence of acetic acid in the solution as a solvent. This inhibitory effect is not an activity of formulation A, because acetic acid also has the ability to inhibit bacteria. In the sample solution with a concentration of 100% chitosan (w/v), the highest inhibition occurred with an inhibition diameter of 18.7 mm / mg of the sample extract. This is presumably because the viscosity of formulation A is still low so that it can still diffuse into the medium so that the place where it grows p. gingivalis. In formulation A with a concentration of 25% (w/v), the lowest inhibition occurred.

The modified well method from the Kirby Bauer method was used because this method is more suitable and practical for drug testing than the diffusion method using a disc. Whereas with discs, the volume of the test solution is very limited. The volume of samples that is more than 20 µl per disc has resulted in interference of observation and measurement. The use of distilled water as a negative control is absolutely necessary to rule out the possibility of an antimicrobial effect. In the observations, it turns out that for all wells with distilled water, none of them provide an inhibition zone.

Observations on the Streptococcus mutans test bacteria (table 1), showed that distilled water as a negative control did not have an inhibitory power against the growth of Streptococcus mutans, which was indicated by the absence of an inhibition zone in the area around the well containing the distilled water. The 50 µg/50 µl ciprofloxacin comparison solution had a large zone of inhibition against the growth of Streptococcus mutans. In Table 1, the test solution of formulation A with a concentration of 25% has shown an inhibitory effect on the growth of Streptococcus mutans. This effect was stronger at concentrations of 100%, 75%, and 50% (Table 1). The antimicrobial effect actually increased with an increase in the concentration of the test solution in succession of 25%, 50%, 75%, 100%. This shows that there is a strong positive relationship between concentration and inhibition zone. This relationship can be seen in Figure 2. This means that the extract solution with the ethanol extractor has an antimicrobial effect against Streptococcus mutans.

The results of further observations using formulation C with a concentration of 10000ppm, 8000ppm, 7500ppm, 6000ppm showed that the antimicrobial effect was actually increasing with an increase in the concentration of the test solution in succession. This shows that there is a strong positive relationship between
concentration and inhibition zone. This relationship can be seen in Figure 2. This means that the extract solution of formulation C with the ethanol extractor has an antimicrobial effect on P. gingivarlis and Streptococcus mutans. From the data of all the tables above, it can be shown that the order of the strength of the antimicrobial activity of the laurant test concentrations of 10000ppm, 8000ppm, 7500ppm, 6000ppm.

Even though it has antibacterial ability, it does not mean that male mayana leaf extract is called an antibiotic substance because there is no resistance standard and an assessment of bacterial sensitivity. The ratio of the size of the light zone formed in the extract solution was smaller than that of ciprofloxacin as a positive control. The antibacterial abilities contained in formulations A and C are not only limited to the two tested bacteria used in this study but may still have antimicrobial abilities against other bacteria. The antioxidant activity of astaxanthin is stronger than other carotenoids in reducing free radical activity as a trigger the emergence of such degenerative disease cancer, heart disease, and diabetes mellitus.[16]

One of the herbal medicines that have antioxidants is ginger, lemongrass and cloves.

This research is in line with research conducted by Nivetha R at al. that the Chinese used cloves more than 2000 years ago, to get rid of bad breath. The synergistic effect of clove oil along with other coriander oils, anise, coriander, and cilantro eucalyptus shows a higher level of inhibition in Gram-negative bacteria, thus proving that synergism worsens the antimicrobial activity of clove oil. Clove

The oil can be a short term remedy for halitosis because it is antimicrobial, but cannot be used long term because it is lacking probiotic activity.[17] Halitosis is not a disease but an inconvenience, probiotics are marketed for the treatment of oral and intestinal halitosis. Few clinical studies have proven different strains or probiotic products potent.[18]

Studies have shown an increasing number of type 2 diabetes (T2D) patients with concomitant obesity and hyperlipidemia syndromes, caused by relevant metabolic disorders. However, there are several drugs and therapies that can solve this problem completely. Research conducted by Xiaotong Yu at all stated that herbal formula JTTZ menghasilkanpeningkatan yang aman dan signifikan pada glukosadarah, lipid darah, dan tingkatberatbadan; gejalalægæ; dannemeningkatkan ungssel β untukpasien T2D denganobesitas dan hiperlipidemia. Herbal fomula JTTZ telahmenunjuk kanbahaiberpotensidikembangkansiebagaipengobatanalternatifuntukpasien T2D, terutamamereka yang tidakdapatmentolerir metformin atauobathipoglikemiklianynya.[19]

**Conclusion**

Based on the results of the antibacterial activity test, it can be said that all tests for both formulation A and formulation C using several concentrations showed quite good results with the antibacterial activity being directly proportional to the concentration, the greater the concentration the greater the activity. It should be given the opportunity to continue this research in testing and exploring herbal plants using other bacteria.

Abstract

This was an observational analytic research with cross sectional design carried out at the Clinical Pathology Laboratory and Department of Child health of the Dr. Soetomo Hospital Surabaya in April - November 2020. Urine sediment of glomerular hematuria pediatric patient examined using flowcytometry, low condenser light microscope (LLCM), phase contrast microscope (PCM). The concordance of the results of the examination of dysmorphic erythrocytes and erythrocyte cylinders using flowcytometry with PCM was determined by Cohen’s Kappa Coefficient (κ) and Bland Altman. There were 40 urine samples of children with glomerular hematuria with many diagnose was lupus nephritis of 60%. The analysis of dysmorphic erythrocyte examination from LLCM and PCM had a very strong kappa agreement κ 0.828 (p <0.05); The concordance analysis of LLCM and PCM cast erythrocyte had a strong agreement, κ 0.625 (p <0.05) and the concordance analysis between Flowcitometry and PCM dysmorphic erythrocyte flagging had a weak agreement, κ 0.302 (p> 0.05). LLCM can be considered to replace PCM to determine the origin of hematuria because it is very effective in detecting dysmorphic erythrocytes in patients with glomerular hematuria. The use of automatic tools is useful for pathological urine samples, but it is advisable to review them using a manual macroscope.

Keywords: Dysmorphic erythrocytes, erythrocyte cylinders, phase contrast microscopy, light microscopy, flowcytometry

Introduction

Glomerular hematuria is classified according to the number of erythrocytes found in urine into microhematuria and macrohematuria. The causes of glomerular hematuria in children are IgA nephropathy, post streptococcal acute glomerulonephritis (GNAPS), primary glomerulonephritis, systemic lupus erythematosus (SLE), henoch-schonlein purpura (HSP), membranoproliferative glomerulonephritis (MPGN), rapidly progressive glomerulonephritis (RPGN). The diagnosis of hematuria in children is more difficult than in adults because the symptoms are non specific and often without symptoms. Invasive methods such as kidney biopsy is the gold standard to establish the diagnosis. Birch and Fairy recommend examining the urine sediment using a phase contrast microscope to determine the origin of glomerular or non-glomerular hematuria by assessing the size and formation of erythrocytes in urine. The incidence of asymptomatic isolated hematuria in children ranges from 0.5% and 1%, mostly due to glomerular abnormalities and most often in boys than girls, regardless of age.

Urine sediment examination is a test that can be used to diagnose glomerular hematuria. Dysmorphic erythrocytes and erythrocyte cylinders found in urine are one of the markers of glomerular damage. Examination
of urine sediment with manual microscopy recommended by several international guidelines is a phase contrast microscope (PCM). PCM is considered to be better at identifying cells and formations found in urine compared to low light condenser microscopy. PCM as a reference method has several limitations, namely it is expensive so that it is not available in all laboratories, time consuming and requires reading expertise.

Study by Barthe et. al, 1986 used a non staining light microscope to evaluate dysmorphic erythrocytes, and the results were similar to studies using PCM. Different results were found in the study by Ince et. al. which states that light microscopy is inadequate for the detection of bacteria, erythrocytes and hyaline cylinders. Flowcitometry is a method used in examining urine sediment with an automatic analyzer. Several journals report the use of flowcitometry can overcome the limitations of PCM because the results are more standardized and the operation is fast, thus saving time and effort, however, a scientist stated that flowcitometry was inadequate in identifying particles such as cylinders and crystals in pathological urine samples so that a manual microscope review is still needed.

Examination with a low condenser light microscope and flowcitometry, if it gives the appropriate results as obtained at PCM, can be used as a substitute for examining dysmorphic erythrocytes and erythrocyte cylinders. This prompted researchers to examine the agreement of the results of the examination of dysmorphic erythrocytes and erythrocyte cylinders using flowcytometry, low light condenser microscopy (LLCM), and phase contrast microscopy in children with glomerular hematuria.

Materials and Methods

This study was an observational analytic with a cross sectional design which was carried out in the Laboratory of Clinical Pathology and the Department of Children Health of Dr. Soetomo Hospital Surabaya, Indonesia. Samples were pediatric patients who had been diagnosed with glomerular hematuria by the clinician of the Nephrology Division of Pediatrics, who met the inclusion and exclusion criteria. Samples were collected from April-November 2020.

The first urine sample in the morning from a patient with glomerular hematuria was examined for urine sediment. The volume of urine collected is 10-12 mL. The urine was initially examined with Flowcitometry method by Sysmex UF 5000 automatic tool. Then, the urine was centrifuged at 2000 rpm for 5 minutes, the supernatant was removed by decantation. The remaining sediment was then resuspended with 0.3-0.5 mL of the remaining supernatant. 1 drop of urine was placed between a slide and cover slip then examined under a phase contrast microscope and a low light condenser microscope. The data from the automatic tool was in the form of dysmorphic erythrocyte flagging and the number of cylinders/µL, while PCM and LLCM were the number of dysmorphic erythrocytes and erythrocyte cylinders in 10 fields of view.

The concordance for the examination of dysmorphic erythrocytes and erythrocyte cylinders using flowcytometry with phase contrast microscopy was determined using the Cohen’s Kappa Coefficient (κ) and The concordance of the examination of dysmorphic erythrocytes and erythrocyte cylinders using a low condenser light microscope with a phase contrast microscope was determined by Bland Altman.

Results and Discussion

There were a total of 40 study patients who met the inclusion and exclusion criteria consisting of 23 male patients (57.7%) and 17 female patients (42.5%). The mean age of patients in this study was 11.92 ± 3.323 and most diagnosis was lupus nephritis (Table 1).

The results of dysmorphic erythrocytes examined using LLCM showed dysmorphic erythrocytes in 32 samples (80%) and using PCM 34 samples (85%) of the 40 samples in this study. For erythrocyte cylinders, 4 samples (10%) and 5 samples (12.5%) were obtained from the entire study sample using LLCM and PCM. Dysmorphic erythrocyte flagging was released by the Sysmex UF 5000 as many as 24 samples (60%). Evaluation by LLCM and PCM showed dysmorphic erythrocytes in 32 samples (94.1%). The Kappa result between LLCM and PCM dysmorphic erythrocytes obtained a Kappa coefficient of 0.828 with p <0.001 (Table 2).

</table>
The study subjects consisted of 40 pediatric patients who had been diagnosed with suspected glomerular hematuria. Most of the diagnosis were lupus nephritis. Study by Viteri et al. The most common cause of nephritis is GNAPS\(^1\). Study by Moustafa et al. in Egypt the most common cause of glomerular hematuria in children is Alport Syndrome\(^1\). Current data in Dr. Soetomo Hospital Surabaya, Indonesia in the period from January 1 2020 to December 31 2020, the most common diagnosis for the causes of glomerular hematuria in children were SLE and Nephrotic Syndrome. The difference in diagnosis that is often found as a cause of glomerular hematuria is probably due to differences in patient selection criteria for each study.

The age range of the entire study sample group was 5-17 years with a mean of 11.92 years, with the largest age group being 12-17 years. These results are the similar as studies by Pardede et al. 2005 that Acute glomerulonephritis in children is most often found is 6-11 years old and Huang et al. 2010, where in the population of children with SLE - LN, the mean age at diagnosis was 8.6-13.5 years\(^1\). Most of the subjects of this study were men (57.5%). These results are the similar as studies by Moustafa et al. that male subjects were 60%\(^1\) and Pardede et al. also found male subjects were 58%\(^1\). A literature states that glomerular hematuria is more common in men than in women, regardless of age\(^1\).

Urine sediment examination both microscopic and automatic analyzer can quantitatively describe the number of elements formed in urine\(^1\). Microscopic examination of urine sediment can improve diagnostic efficiency when performed early in the evaluation of a disease\(^1\). Dysmorphic erythrocytes are found in the urine if the glomerular filtration barrier (GFB) is impaired. These erythrocytes are smaller in size and have smaller cytoplasmic protrusions or cell fragments\(^1,15,16,17\). From LLCM examination result by 3 readers, dysmorphic erythrocytes were positive in 32 samples (80%) and negative in 8 samples (20%), while the dysmorphic erythrocytes from PCM was slightly more, positive in 34 samples (85%) and negative in 6 sample (15%). This result was in accordance with previous study by Da Silva et. al. where there was no significant difference in the number of dysmorphic erythrocytes found in low-light condenser microscopes and contrast-phase microscopes in glomerular and non-glomerular hematuria patients\(^9\).

Damage of the GFB can also cause protein and erythrocytes to appear in the urine. Erythrocytes that enter the tubule will be trapped in uromodulin (Tamm-Horsfall protein) to form a cast (erythrocyte cylinder)\(^1\). The results of this study showed that erythrocyte cylinders in LLCM were negative in 36 samples (90%) and positive in 4 samples (10%). The results were not much different from the review with negative erythrocyte cylinder PCM in 35 samples (87.5%), positive in 5 samples (12.5%). Previous study by Ringsrud et al. in patients with interstitial nephritis, cylindrical erythrocytes were only found in 4 patients\(^19\). This result is in accordance with previous study. One literature states that erythrocyte cylinders are rare but highly pathognomic and have a high specificity of 97% for detecting glomerular hematuria\(^20\).

Examination of urine sediment using a conventional microscope, although considered a reference method, has several limitations in its operation. To increase the accuracy and precision of urine sediment examination, several studies have been conducted to compare automatic instruments with manual examination using a microscope\(^21,22,23\). In addition, agreement analysis of dysmorphic erythrocyte count from LLCM and PCM was carried out on 40 child participants in this study. Dysmorphic erythrocytes were positive in 32 samples (94.1%) and 6 samples (100%) negative from both microscopes. Two samples (5.9%) were positive for dysmorphic erythrocytes in PCM but negative in LLCM (Table 1). The kappa test result was 0.828 (p<0.01), it suggest that there is a very strong agreement for the results of dysmorphic erythrocytes in LLCM and PCM. These results are consistent with studies by Barros Silva et. al. PCM has a higher sensitivity than LLCM, both methods have the same accuracy and can be used for examination and a study by Chu shu et al. that LLCM have the same accuracy to recognized isomorifk and
The Kappa coefficient of 0.625 was obtained in the test results between LLCM and PCM erythrocyte cylinders which showed a strong agreement (p <0.05). Furthermore, LLCM and PCM have the same ability to detect dysmorphic and isomorphic erythrocytes. LLCM ability on urine sediment examination was good enough, similar to PCM.

Conclusion

There is a strong agreement for examination of dysmorphic erythrocytes and erythrocyte cylinders using a low light condenser microscope and a contrast phase microscope in children with glomerular hematuria with kappa coefficients of 0.828 and 0.625. With the results, LLCM can be used to replace PCM. The weak agreement between flowcitometry and PCM shows that for pathological urine samples using an automatic flowcitometry method it is recommended to do a review using a conventional microscope.

Knowledge and Practice Regarding Prevention of Renal Calculi among Non Teaching Staffs of a Selected College of Health Sciences at Mangaluru

Maya Shaju1, Amala Elsy Mathai1, Dina Joseph1, Albert Thampi1, Jyothi2

1IVth Year B.Sc Nursing Students, 2Lecturer, Department of Medical Nursing, Yenepoya Nursing College, Yenepoya Deemed to be University, Mangaluru, Karnataka

Abstract

Background and Aim: Mankind has been afflicted by urinary stones and is the most common disease of the urinary tract. It affects all ages, sexes, and races but occurs more frequently in men than in women within the age of 20–49 years. Generally, to prevent the first episodes of kidney stone formation or its secondary episodes, proper management of diet is required. The study aim to assess the correlation between knowledge and practice regarding prevention of renal calculi among Non teaching staffs.

Methods: A descriptive correlation approach was adopted for the study and by purposive sampling technique 95 non-teaching staffs were selected. The data was collected using demographic proforma, structured knowledge questionnaire and Rating scale. Collected data were analyzed by Descriptive and Inferential statistics using SPSS version16.0.

Results: Results showed that majority (75.8%) of the subject had average knowledge and 72.6% of the subjects had good practice towards the prevention of renal calculi. There was a significant correlation (p<0.05) between knowledge and practice among non-teaching staffs regarding the prevention of Renal calculi.

Conclusion: The study concluded Non teaching staffs had average knowledge and good practice towards prevention of renal calculi.

Key words: Knowledge, Practice, Non teaching staffs, Renal calculi

Introduction

Globally, kidney stone disease prevalence and recurrence rates are increasing, with limited options of effective drugs. Urolithiasis affects about 12% of the world population at some stage in their lifetime. It affects all ages, sexes, and races, but occurs more frequently in men than in women within the age of 20–49 years. In Indian population, about 12% of them are expected to have urinary stones and out of which 50% may end up with loss of kidney functions.1

Mankind has been afflicted by urinary stones and is the most common disease of the urinary tract. Kidney stone, also known as urolithiasis, is when a solid piece of material formed within the urinary tract. Kidney stones typically form in the kidney and leave the body through the urine stream.2

The stone formation include anything that either causes stasis or supersaturation of the urine. Immobility and a sedentary lifestyle, which increases stasis. Dehydration, which leads to supersaturation. Metabolic disturbances that results in an increases in calcium or other ions in the urine. Previous history of urinary
calculi. Living in stone-belt areas, high mineral content in drinking water, a diet high in purines, oxalates, calcium supplements, animal proteins, urinary tract infections, prolonged indwelling catheterization, neurogenic bladder, history of female genital mutilation also play a role in kidney stone formation.

Effective kidney stone prevention depends upon addressing the cause of stone formation. Generally, to prevent the first episodes of kidney stone formation or its secondary episodes, proper management of diet and the use of medications is required. Primary prevention of kidney stone disease via dietary intervention is low-cost public health initiative with massive societal implications. Thus nutritional management is the best preventive strategy against urolithiasis.

Good voiding habits, particularly frequent urination, and regular exercise are useful in preventing the stones from forming. Most importantly, a high fluid intake should be maintained at all times, especially during hot, dry weather when the risk of kidney stone formation is greatest. Therefore, of all the preventive recommendations is the most important guideline for people with any type of kidney stones. Hence the awareness regarding the prevention of renal stone is necessary to prevent the occurrence and also helps to modify the life style pattern.

Material and Methods

A Descriptive correlational research is being conducted in Yenepoya Nursing college, Karnataka, India after obtaining the ethical clearance(Protocol no 2019/024) from Institutional Ethics Committee, Yenepoya( Deemed to be University). Nonteaching staffs between the age group of 20-49 years were included in the study and who had a previous history of renal calculi were excluded. 95 Non teaching staffs were selected by Non-probability purposive sampling technique. Informed consent was obtained from the respondents after proper explanation about the purpose, the usefulness of the study and assurance was given about the confidentiality of their responses. Data was collected by using structured knowledge questionnaire and self reported rating scale.

The data were analyzed by descriptive and inferential statistics using SPSS version 16.0. Demographic variable, knowledge questionnaire, rating scale will be analyzed using the descriptive Statistics such as Frequency, Percentage, Mean and Standard Deviation. To correlate the knowledge and practice score of non teaching staffs, Karl Pearson co-relation co-efficient will be used. Chi-square test was used to find the association between the Knowledge and practice score with selected demographic variable

Results

Description of sample characteristics:

Frequency and percentage characteristics distribution was computed to describe the sample characteristics. The baseline sample characteristics of the participants showed that majority (31.57%) of the subject belongs to the age group of 20-30 and majority (82.1%) of the subjects was females. Majority (58.8%) of the subjects belongs to Hindu religion, and most (58.4%) of the subject had completed Degree. Majority of the subjects (56.8%) were resides in rural area and most (90.5%) of the subjects are non-vegetarian. Majority of the subjects (49.5%) had previous information through internet.

</table>

Table 1 shows that Majority (75.8%) of the subjects had average knowledge, 18.9% of the subjects had good knowledge and only 5.3% of the subjects had poor knowledge.

Practice of Non teaching staffs regarding prevention of renal calculi.

Data presented in the Figure 1 shows that majority (72.6%) of the subjects had good practice and 27.4% of the subjects had average practice.

Correlation between knowledge and practice regarding prevention of Renal calculi.

Karl Pearson correlation coefficient was used to correlate the knowledge and practice score of non teaching staffs. There was a positive correlation between knowledge and practice score of non teaching staffs regarding prevention of renal calculi among non teaching staffs (p =0.027).
Association between knowledge score with selected demographic variables

Chi square association with knowledge score indicated that there is significant association between knowledge and demographic variable i.e, education ($\chi^2=0.017$), $P<0.05$. The findings also revealed that age, gender, religion, residence, dietary pattern, previous information from the internet, health professionals in the family was statistically non significant at 0.05 level.

Association between Practice score with selected demographic variables

Chi square association with practice score indicated that there is no significant association between practice and demographic variable.

Discussion

This study was designed to collect information regarding knowledge and practices of renal calculi among nonteaching staffs. Results indicate that the non teaching staffs had average knowledge regarding renal calculi. This findings are supported by a study conducted by Soni GP (2016) on Prevention of Renal Calculi in Terms of Knowledge and Dietary Pattern among Primary School Teachers of Moodabidri, Dakshina Kannada District. Findings of the study showed that less number of primary school teachers had adequate knowledge regarding renal calculi and its prevention.3

Practice of non teaching staffs regarding renal calculi was better than their knowledge. Majority (72.6%) had good practice towards the prevention of renal calculi. This findings are supported by a descriptive cross sectional study (2017) was conducted in the University of Peradeniya, Sri Lanka to determine knowledge, attitude and practices regarding urinary tract stones among final year medical students ,which showed that majority( 55.55%) of them had a good practice towards the prevention of renal calculi.4

In the present study positive correlation was observed between knowledge and practice. Supportive to this findings, Pethiyagoda et al conducted (2015) a study revealed that There was a correlation between knowledge level and Practice.5

This study finding revealed that there was no significant association between knowledge score and practice score with demographic variables. Supportive to this study ,Bakunts V conducted a study (2011) on Knowledge, Attitude and Practice of Kidney Stone Formers in Armenia regarding Prevention of Kidney Stone Disease which revealed that there was no significant association between knowledge and practice score with selected demographic variable.6

Conclusion

Renal calculi is a global health problem that seriously affects human health. Prevention plays a major role in controlling the incidence of renal calculi. In conclusion, findings indicated that Non teaching staffs had average knowledge and good practice towards prevention of renal calculi.

Abstract

The efforts of containing the novel virus (COVID-19) have begun to show signs of psychological impact on teachers and students across the globe. As a result of the COVID-19 pandemic, many school districts have closed for the remainder of the academic year. These closures are unfortunate because, for many students, schools are their only source of trauma-informed care and supports. When schools reopen, they must develop a comprehensive plan to meet their students’ the potential mental health needs as social distancing and awareness campaigns can be a double-edged sword, if handled inadequately. This paper evaluated the challenges of teachers in Dammam in e-learning during the period of the new coronavirus (COVID-19) global pandemic.

Key word: E-Learning, COVID-19, Teachers, Ancient learning, Students

Introduction

E-learning: It is defined as providing electronic educational content through computer-based media and networks to the learner in such a way that they can interact actively with this content [1]. With the teacher and their peers, whether simultaneously or concurrently. Also the possibility of completing this education in time and space and at a speed that suits its circumstances and abilities, as well as the possibility of managing this learning through those media [2]. Many sources define e-learning as “an interactive system of distance learning, delivered to learners on-demand and based on an integrated electronic environment designed to build and connect courses online, mentoring, testing, resource management, and processes [3,4]. Stein, S. J., Shepherd, K., & Harris, I. (2011) was a lot of inclusive, summary totally different views on e-learning, the argument that e-learning encompassed a spread of patterns [5]. We’ve little doubt that the management of the academic method depends directly on the human workers of academics and directors WHO area unit able to carry on with the technological developments required by this method, in reviewing the capabilities of employees during this field, we have a tendency to should note, in line with out there data, that a minimum of half the employees within the public education sector area unit academics, academics and supporting bodyworkers WHO area unit nearly old, wherever there are a unit a minimum of 2 totally different generation employees WHO adopt ancient education which Education has principally supported the teacher within the schoolroom, and depends on the book and also the direct paper communicating, that is that the direct tool for the worth of scholars, and within the case of the ministry’s reliance on education (simultaneous), this class won’t be able to influence the talents and technological needs of this method, and also the ministry has not provided the mandatory coaching for this class of teachers, that indicates a scarcity of coming up with for this method to launch this model while not taking into consideration the skills of teachers to keep with the programs and tools needed for the success of this year. [6] The second generation is most capable of handling technological reality and group action data technology.
into the education method - UN agency had effective initiatives within the early stone amount - with their own capabilities and straightforward provision tools from a smartphone and a portable computer, and these initiatives have had an energetic impact in overcoming the primary crisis, and this generation has had innovative initiatives within the entire instructional method from innovative initiatives in tributary to the education method. Benefits: flexibility, convenience, straightforward, and quick access anytime, anyplace [7]. The chance of choosing elements from online courses is consistently increasing in quantities, instant feedback once victimization online assignments, exams and exercises straightforward and quick review, updating, piece of writing and distributing instructional elements. Asynchronous permits the scholar to review consistent with his ability (quickly or slowly), offers numerous instructional facilities and ways that stop ennui, it’s straightforward to follow the scholars notwithstanding there several quick access for thousands of same-time sources aside from paper sources. Time: Save time, organize time in order that he schedules his lessons consistent with his work and his family. Quicker as a result of it permits the scholar to leap faraway from subjects and activities, he is aware of. Money: wherever it cuts the value of travel, quality, and living. Also, the value of production and distribution of instructional materials. Cost of offices and lecturers, the value of wasting workers’ time. Communication and interaction: The possibility of communication and interaction between students and lecturers through online lessons [8]. The chance to review anyplace with a pc and web. The interaction between the lecturer and also the student is best within the case of overcrowded categories. Disadvantages: eLearning suffers from some determinants, that area unit incentives for study and analysis to resolve them: [9]. You need a technological infrastructure that will not be out there in some places. Limited pandowdies might hinder the method of education, particularly in loading and handling multimedia system. [10]. The start value is high. Some students might feel lost or confused regarding instructional activities Some students might feel isolated from their peers and their teacher. This study un concealed academics’ opinion regarding e-learning; Some courses are troublesome to conducted online since it would like a lot of personal communication and require the student to learn laptop skills. The bulk of Arab countries have resorted to e-learning to finish the syllabus. During this paper, the analysis house on the obstacles and challenges of e-learning, wherever there are obstacles for the college, that could be a lack of expertise and mastery of laptop skill [11], and there are issues facing students, the most important of them is the material potential of some and also the temperament to hitch the electronic categories of learning. In Addition that the majority of scholars have an absence of technical expertise [12]. This paper additionally addressed the way to overcome such obstacles by seeking out solutions to every downside so as to finish the course of education, particularly for college students in their final stages of education as they’re near to graduate, by motivating students to be told e-learning, and coaching school members through awareness courses and workshops on e-learning [13].

Method

A. Participants

This survey was conducted from the 10th of September 2020 to 25th of October 2020. In eastern Dammam office /Saudi Arabia. A total of 130 were recruited to the study, the majority of study (91.5%) respondents were in the middle age between 29 to 48 years old. Males were accounted approximately one fourth (26.2%) of sample. The majority of respondents (73.1%) were bachelor degree holders. About one third of the sample had experience between 6 to 11 years. About 60.0% of respondents were from international and private schools.

B. Constructs of the study

We have three constructs Availability of E-learning requirements related to technical, administrative and financial aspects, assessment environment Learning, and E-learning challenges and obstacles. Each category includes several variable: age, gender, educational level and experience.
Statistical Analysis

Data were analyzed by the Statistical Package for Social Sciences (SPSS) software version 25.0 (SPSS®: Inc., Chicago, IL, USA). Means, standard deviations, frequencies and percentages were produced. Independent t-test, one-way ANOVA test with Scheffe post hoc were used to compare between subgroups as appropriate. Furthermore, Pearson correlation coefficient used to test the correlation between overall mean of the outcomes. The level of significance was set at (P \leq 0.05).

Results

A. Sample description

A total of 130 were recruited to the study, the majority of study (91.5%) respondents were in the middle age between 29 to 48 years old. Males were accounted approximately one fourth (26.2%) of sample. The majority of respondents (73.1%) were bachelor degree holders. About one third of the sample had experience between 6 to 11 years. about 60.0% of respondents were from international and private schools.

B. Reliability coefficient

The reliability coefficient (Cronbach’s Alpha) of the study is 0.829, which is a good value reflecting a reliable measure of the study tool.

D. Study of items’ means

The following part shows responses to the levels of the variables. Here, mean and standard deviation are calculated for each item. Higher mean value indicates more agreement on that item.

i. Availability of E-learning requirements related to technical, administrative and financial aspects

Table 1 shows that all items have “agree” attitude. Item 3-The school administration encourages teachers to use the e-learning and computerized curriculum in teaching has the highest mean value of 4.12(SD=0.813) with ‘agree’ attitude. Item 4-E-learning goals branch into more commercial goals than educational and Item 5-The speed of the internet is always suitable to take advantage of the website services at all times “ has the lowest mean with 3.22(SD=1.09, 1.22) respectively with ‘agree’ attitude. In general respondents’ attitude was “agree” regarding the availability of E-learning requirements related to technical, administrative and financial aspects with mean 3.59(SD=0.5).

<table>
<thead>
<tr>

G. T tests and Analysis of variance

Are there significant differences in the levels of the study constructs that can be attributed to age, gender, Educational level, Experience and Type of school? Independent samples t-test will be used to test for gender while, analysis of variance (ANOVA) will be used to test for other personal variables. Age, gender, Educational level, Experience and Type of school.

Table 5: Mean, standard deviation, P-value and F –value according to part A and part B.

<table>
<thead>
<tr>
<th>Part</th>

</tbody>
</table>
From table 5 part A, there is a significant difference in the mean of Availability of E-learning requirements related to technical, administrative and financial aspects for educational level diploma (mean = 4.1) p=0.016 <0.05 compared with another education levels, also there is a significant difference in the mean of Availability of E-learning requirements related to technical, administrative and financial aspects for type of schools where government schools have (mean 3.69) p=0.001<0.05 while private schools have mean 3.24.

From table 5 part B, there is a significant difference in the mean of E-learning disadvantages for type of schools where government schools have (mean 3.30) p=0.02<0.05 while international schools have mean 3.05. there is no significant difference in the mean of E-learning obstacles that can be attributed to Age, gender, Educational level, Experience and Type of school.

**Discussion**

From the teachers’ point view E-learning is not a heavy burden on the head of the family when pursuing his children, E-learning doesn’t lack confidentiality and honesty when answering tests, E-learning doesn’t weaken students’ attitudes and educational values, which are stipulated in the philosophy of education and It doesn’t reduce students’ skills in cooperative learning and learning by playing. The teachers saw that cheat prevention is difficult to control during electronic tests [2].

E-learning objectives correspond to traditional learning objectives, as well as to life-long learning objectives related to cognitive, affective and psychomotor domains. The continuous and rapid change of contemporary society and existing technologies leads to life-long education. E-learning is a part of life-long learning that may become more popular [7]. The lack experience for students and their parents in using computer software is not necessary a problem in E-learning since all middle and high school students have access to mobile devices [3]. We agree with others all over the world that teachers are needed more training courses to develop their experiences of software applications [5].

Online teaching and learning were an unprecedented experience for most teachers and students; although nowadays platforms, training course, and software applications are available [5]. Although teachers at Dammam schools feels that e-learning can’t reduce the control over the course of the educational process. Jordanians teachers found that “the continuing with the online learning model is not acceptable because it is socially and psychologically unhealthy Measures of lockdown, closures, and quarantine, brought by COVID-19 caused stress, frustration, and depression. [11]. Also we can summarize the effect of E-learning on university students and their instructor, the opinions of students that studying using e-learning is not equal as direct education [12].

**Conclusion**

The COVID-19 pandemic has modified schooling forever; The COVID-19 has ended in colleges close all throughout the world. As a result, schooling has modified dramatically, with the one-of-a-kind upward push of e-getting to know, wherein coaching is undertaken remotely and on virtual platforms. Research shows that online getting to know has been proven to boom retention of information, and take much less time, that means the adjustments coronavirus have brought on is probably right here to stay.

**Recommendations**

Educators should be motivated to participate in the training of obtaining

Informed knowledge about new technological changes so as to form a positive attitude towards e-learning for both teachers and students. Whereas, training will not only benefit teachers, but students at the same time.

The smooth implementation of the e-learning system can be ensured by providing the internet for each
as a tool, which will motivate students to improve their knowledge, technologies and skills.

Stature Prediction and Formulation of Regression Equation from Hand and Foot Anthropometry

Megha Rapotra¹, Jaswinder Kaur²
¹Ph.D Scholar, ²Professor, Department of Anatomy, MMU, Mullana, Ambala, Haryana

Abstract

Background: Estimation of stature is a key feature of personal identification. Evaluation of stature from incomplete skeletal and decomposing human remains is particularly important in personal identification for forensic experts and anthropologists.

Methods: The data was collected from 1000 asymptomatic, healthy adults (500 males and 500 females) belonging to border areas of Punjab region of age group ranged between 18-50 years.

Results: The comparison of each parameter of the study shows that all parameters have higher values in males than in females. It is also observed that in males highest correlation is exhibited by Right foot length (r = .418) and in females it is exhibited by Left Foot Length (r = .354). The calculated linear regression formulae show good reliability and applicability for stature estimation.

Conclusion: In all parameters the foot length and hand length are better predictors of stature in both sexes. Using regression formulae the height of subject can be easily determined and this will be used as research tool in anthropological and medicolegal issues.

Keywords: Stature, Anthropometry, Hand length, Foot length, Forensic investigations

Introduction

Stature is considered as one of the important and significant parameters for establishment of personal identification. Anthropometry is being widely used in medical sciences especially in Forensic Sciences for helps in narrowing down the investigation process. These techniques are commonly used by anthropologists especially adopted by forensic anthropologists to estimate body size for the purpose of identification. Estimation of stature from decomposing and incomplete skeletal is important in personal identification.

Anthropometry as adopted by medical scientist is described as a technique of expressing the form of human body quantitatively as it is the systematic collection and correlation of measurement of the human body. Origin of anthropometry dates back to as early as the ancient civilizations of Rome, Egypt and Greece. They use anthropometric measurements for cultural purposes to represents beauty, power and other desirable attributes of the human Form. so it has been the focus of scientists, anatomists and anthropologists for many years.

There is an established relationship between stature and various body parts like head, trunk, upper and lower extremities. It is common to find the peripheral parts of the body such as hand and imprints of the hand, foot or footprints or from shoe left at scene of a crime or in explosions, aircraft and railway accidents. The relationship between specific body dimensions / proportions can be used to help solve crimes in the
absence of complete evidence. Therefore, many different parts of the body have been used to estimate height by different workers globally.9

Many studies have been conducted for assessing stature by anthropometric measurements of different parts of the body. 2,8-15

India is a vast country with varied geographical conditions so these parameters vary from population to population due to the differences in genetic makeup of person, nutrition, environment and levels of physical activity.16

Therefore the purpose of this study is to find the correlation between body height, foot length, foot breadth, hand length and hand breadth measurements in both the sexes and also to derive regression equations for the calculation of stature. The present study is unique in its sample selection as there is no existing anthropological data on the estimation of stature from hands and feet measurements in this group of population of border areas of Punjab, India.

Materials and Methods:

The present study was conducted out in the region of Punjab, mainly border areas like Amritsar, Pathankot, Gurdaspur, Dinanagar Disticts and their surrounding villages. The material comprised of 1000 young healthy adults (500 males and 500 females) of the group 18-50 years. The subjects were from general public. The data was conducted by doing Random sampling.

Steps of collection of data: Inclusion and Exclusion criteria: Study included Apparently healthy, asymptomatic adults, age ranges between 18 to 50 years. Males and females with any physical deformities of stature, hand and foot were excluded from the study.

In order to avoid inter-observer error in methodology, the measurements were taken by one observer. Diurnal variations have been reported in the stature of an individual thus, all measurements were taken during afternoon hours in a well lighted room and were recorded in measurement performa.

The objectives and steps of the study were explained to the study population Prior to the investigation, written informed consent was obtained by taking their signature and thumb impressions. Foot and hand measurements were taken independently on the left and right side of each individual, apart from this stature were also recorded.

Instruments used: Stadiometer was used to measure verticle height for stature estimation. The measurements were recorded in centimeters. Sliding caliper was used for feet measurements.

The data were subjected to statistical analysis using statistical package for social sciences (SPSS21).

Land marks and technique involved in anthropometric measurements:

1. Stature (S): It is the vertical distance between the highest point on vertex and platform of measuring bar. The subject should stand erect, barefoot on level platform, with his back hips and feet touching the bar, arms hanging by the side and head should rest in Frankfurt plane.

2. Hand length (HL): It is the distance between the mid-point of a line connecting the styloid processes of radius and ulna to the most anterior of the middle finger. The subjects will asked to place their hands supine on a flat hard horizontal surface with fingers extended and adducted, following which the hand length were measure by sliding caliper.

3. Hand breadth (HB): It is the distance between the most prominent point of the Lateral aspect of the head of the second metacarpal to most prominent point of the medial aspect of head of the fifth metacarpal.

4. Foot length (FL): It is the distance between the Most prominent posterior point on the heel to the tip of first toe foot lengths were taken independently on left and right side of each individual using a spreading caliper.
5. **Foot breadth (FB):** It is the distance between the most prominent point of the medial aspect of the head of the first metatarsal to most prominent point of the lateral aspect of head of the fifth metatarsal.

**Results:** The following observations were tabulated after statistical evaluation of the observations recorded in the study. The age of study population ranged between 18 and 50 years for both males and females. The mean age of females was 32 years and that of males was 33 years.

[Table-1] shows comparison of descriptive statistics for the stature, foot and hand parameters in both sexes. The average stature of males was 171.13±9.7 cm and for females it was 159.91±7.2 cm. The foot lengths measured 25.05 cm (approx) and hand breadth measured approximately 9.57 cm. Similarly in case of female foot lengths and foot breadths approximately measured 23.08 and 8.83 cm respectively.

</table>

[Table-2] shows comparison of hand dimensions among male and females in study population. The average of the hand lengths measured 18.50 cm (approx) and hand breadth measured approximately 8.24 cm in males. Similarly in female hand length and hand breadth approximately measured 17.17 cm and 7.46 cm respectively.

The comparison of respective readings of various parameters studied shows that all parameters have higher values.
in males than in females. [Table-3] shows correlation between the stature of individual and various parameters studied. All the parameters exhibit statistically highly significant (p <0.001) positive correlation with the stature except female foot breadth.

Correlation co-efficient of the length measurements is higher than that of breadth measurements. It is also observed that in males the highest correlation is exhibited by right foot length (r=0.418) and the lowest by Left Foot Breadth (r=0.152). In females highest correlation co-efficient is exhibited by left foot length (r=0.354).

Linear regression analysis of the observations was performed separately for each sex and also for each parameter studied. (Table 4) The equations also exhibit standard error of estimation (SEE). The SEE predicts the deviations of the estimated stature from the actual stature.

Discussion

The mean stature estimated in the present study in males is 171.13 cm (Range: 149.35-198.13) whereas in females mean stature is cm 159.91 (Range: 149.35-192.03). The stature obtained by different researchers such as Ilayperuma ,Sunil, Manpreet Kaur et al, Rati Tandon, Sunil, was similar to the present study.17-20 In this study, the mean body height of males is higher than that of mean body height of females. This is in agreement with the result of Ebite et al., and Ilayperuma et al.3,17 There are also other studies by Qamara SR et al, Ozaslan A et al and Duyar I et al, Nath S et al, indicating varied mean height due to variations in the morphology of different population group.2,6,20,21

It is also observed that in males the highest correlation is exhibited by right foot length (r=0.418) and the lowest by Left Foot Breadth (r=0.152). In females highest correlation co-efficient is exhibited by left foot length (r=0.354). All the parameters exhibit statistically highly significant (p <0.001) positive correlation with the stature except female foot breadth. There are some studies by Saxena, Bhatnagar et al, Abdel-Malek AK et al, Krishan, in which an attempt has been made to establish correlation between stature and hand dimensions.8,10,11,15 Deopa Deep and Charnalia also observed a significant and positive correlation between foot length and height in individuals of Uttarakhand region.22,23 GN Geetha et al, Manpreet Kaur et al, Rati Tandon, and O.P. Jasuja et al showed the significant correlation between height and hand parameters.16,18,19,24

The presence of positive correlations between stature and other study parameters of hand and foot, facilitates formulation of regression equations which can be successfully utilized for stature estimation in the population. There are various methods to estimate stature but the easiest and reliable method is by regression analysis. In the present study, we had formulated different regression equations separately for both the sexes and on both sides. Research indicated that regression formulae can be derived for stature estimation using foot and hand measurements with a great accuracy and a small SEE, i.e. about 2–6 cm.

Conclusion

The study indicates that stature can be predicted accurately by linear regression analysis even when only some remains of the body are found as in bomb explosions, terror events, mass disaster, accidents, wars etc. If either of the measurement is known the other can be calculated and it will help in establishing identity in certain medicolegal cases and for forensic experts. For calculating height, we used higher number of population and formed different regression equations using hand breadth, with different values, resulting in more correct regression equations. These regression equations are specific for this region only because of geographical variations in the morphology of different population group.

Assessment of Knowledge Regarding First Aid among the Undergraduate Students: A Cross-Sectional Study

Melvin Jacob¹, Hezil Reema Barboza²

¹MSc Nursing, ²Lecturer, Dept of Medical Surgical Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be University), Deralakatte, Mangaluru, Karnataka, India

Abstract

Background: First aid knowledge is very valuable for every individual in the community. It enables the individual to assist the injured person in an emergency situation until medical help arrives at the site.¹ Students are highly exposed to different kinds of physical injuries. Lack of knowledge regarding managing these medical injuries was noted among the students.² Careful management recommended for reducing the complication. This study was conducted to determine the knowledge of first aid and its associated factors among undergraduate students.³⁻⁵

Materials and Methods: A descriptive cross-sectional study was conducted among 100 undergraduate students. Subjects were selected using purposive sampling techniques. The information was collected using a demographic proforma and a self-administered questionnaire. The overall knowledge on first aid was graded as adequate, good and inadequate.

Results: The overall knowledge score was 13.81 ± 4.41. The mean percentage of the overall level of knowledge was 57.54% which indicate the majority had good knowledge on aspects of first aid. In this study there was no significant association between knowledge score and selected demographic variables.

Conclusion: The study showed the majority had good knowledge of first aid. But also identified some key areas in which first aid knowledge was deficient in the management of shock, burns and fracture. Thus there is a need for first aid training to be introduced in the undergraduate curriculum of different disciplines. The study recommends the use of modern techniques such as simulation with computerized mannequins as a teaching-learning method in all the educational institutions.

Key words: First aid, Knowledge, Students, Shock, Undergraduate.

Introduction

First aid is the immediate support given to the person with minor or major injuries. Knowledge regarding basic first aid measures is curtailed to save the life of an injured. It facilitates the rescuer to assist the injured person until the emergency helps arrives. Various types of accidents and injuries are part of our day to day life. Lack of skillful personals in and around the accident sites usually delays the basic management, later it will become a serious life-threatening condition. Prompt action taken during the initial hours will helpful for the person to come back to a normal productive life.¹

Accidents are not completely preventable or unavoidable. Managing the victims in a professional manner from the accident area will be help to reduce the deformity.² The number of persons killed in the road traffic accidents is drastically increased, 2.7 per one lakh population in the year 1970 is upturn to 11.8 per one lakh population in 2015.³ Studies conducted in various parts of the country also focusing the need for basic first aid training. One of the South Indian study results revealed that 12 % of the students are only undergone specific first aid training sessions.⁴ Developing countries like India it is needed to incorporate basic first aid in the graduation level curriculum will help to reduce mortality.
and morbidity related to the mishandling of affected persons.\textsuperscript{5}

**Materials and Method**

The research design adopted for the present study was a descriptive research design. The study was carried out in a professional college, Karnataka. Samples consist of 100 undergraduate students who were selected by purposive sampling technique, based on inclusion criteria. Undergraduate students studying in the first year were selected as study participants. Students who underwent training in first aid were excluded from the study. In the present study first aid refers to immediate care given to the person suffering from sudden illness or injury related to conditions such as cardiac resuscitation, chest pain, ventilation, stroke, shock, fracture, poisoning, burns and snakebite.

**Tools and techniques**

Blueprint of the questionnaire was prepared on the basis of specific areas such as first aid knowledge on cardiac problems 33.32%, ventilation 4.16%, stroke 16.66%, shock 12.5%, fracture 8.35%, poisoning 8.35%, burns 12.5%, snake bite 4.16%. In order to obtain validation of the data collection tool, the draft of the problem statement, objective, demographic proforma, and knowledge questionnaire was submitted to 5 experts. To ensure reliability, the tool was administered to 10 undergraduate students after obtaining permission from the authority. Reliability of the tool was analyzed by split-half method followed by Spearman-Brown prophecy formula. The reliability coefficient of the tool was found to be 0.8. This indicated that the tool was reliable.

The baseline Proforma was used to assess the baseline characteristics of undergraduate students. It had 4 items which include age, gender, type of family, and area of residence. The knowledge questionnaire had 24 items. A score of ‘1’ was given for the correct answer and ‘0’ for the wrong answer. The maximum score was 24. Knowledge score 75% and above was graded as adequate knowledge, 51-74% was good and less than 50% was graded as inadequate knowledge.

Data collection was done after obtaining ethical clearance from the institutional ethics committee (Protocol No: 2017/068). Prior permission from the concerned authority was obtained to conduct the study. Subjects were asked to participate in the study after self-introduction by the investigators. The subjects were informed about the purpose of the study and their consent was attained. The participants were assured about the confidentiality of their information. The data were analyzed in terms of the objectives of the study using both descriptive and inferential statistics. The data obtained were plotted in the master sheet.

**Data Analysis:** The data entry and analysis was performed using Statistical Package for Social Sciences software package version 23. Chi-square test was used to find out the association of socio demographic variables with knowledge score regarding first aid and $P < 0.05$ was taken as statistically significant association

**Results**

The baseline characteristics of the study population showed a majority of them (66%) were 18 years and 24% were 19 years old. The maximum numbers of the subjects (90%) were females. Most of the subjects (88%) belong to the nuclear family and 55% were living in an urban area.

Figure 1 shows almost half of the proportion (49.0%) was with good knowledge and only 36% were with inadequate knowledge regarding first aid. The overall knowledge score was $13.81 \pm 4.41$. The mean percentage of the overall level of knowledge was 57.54% which indicate the majority had good knowledge of the management aspects of first aid which was showed in table 1. Table 2 depicts the analysis of knowledge on first aid management in the specific area found that participants had had poor knowledge regarding first aid management for shock, burns and fracture. Most of the participants had very good knowledge to identify and manage cardiac problems. Data presented in the table 3 revealed that there was no significant association was
found between knowledge of undergraduate students regarding first aid and selected demographic variables such as age, gender, area of resident and type of family.

**Discussion**

Awareness and knowledge regarding first aid play a crucial role in undergraduate students, especially those who are pursuing a medical career, as they are tomorrow’s lifesavers. In the present study it is observed that the majority of the subjects (49%) were having good knowledge regarding first aid, followed by (36%) were having inadequate knowledge and (15%) were having adequate knowledge. A study done by Swetha et al reveals that 96% of the nursing students had basic knowledge of first aid. A study was conducted by Alsayali et al shows that 56% of participants had good knowledge regarding first aid and basic life support.

The majority of study participants were aware of dealing with cardiac emergencies and the study recommends the training of the general population in basic cardiac emergencies. A review article by Toresdahl et al, suggests training for medical providers at sporting events. An efficient response to cardiac emergencies requires a planned emergency action plan, training of potential first responders in cardiopulmonary resuscitation and use of an automated external defibrillator, communication, transportation and coordinated work systems. Prompt recognition and early defibrillation are crucial in the management of athletes suffering sudden cardiac arrest during athletic events. This article reviews cardiac care in athletics, with special considerations to the school and outdoor school events.

Several studies showed poor knowledge in the specific areas of first aid management such as shock,
burns, fracture, seizures and choking. The results of a prospective study of school injuries showed an incidence rate of 5.4 injury events/100 children annually, which appears to be an underestimate of the actual rate. Among all the injury events 28.7% resulted in serious injuries. Most of the children during the study period with either serious or minor injuries were sent to the school office or returned to the classroom, which indicates that the present level of first-aid training among school personnel is inadequate. In this view every teaching and nonteaching staff needs in-service education of management of musculoskeletal injuries.

All students and staff need to be competent in first aid skills and apply in various real-life situations. All felt that these skills need to be taught from the school level onwards and all of them were willing to participate in the first aid training sessions at the college. Courses on First aid and Basic Life Support (BLS) should be made mandatory in universities and this should be done through lectures with hands-on skills to make it more effective. Countries like England have made BLS courses mandatory in the school curriculum and research showed that 86% of school children effectively demonstrated performing CPR correctly. Simulation-based education provides an opportunity for the students to improve education, competency and safety of the patients. Students reported a high level of satisfaction with the hands-on experience as a member of the health care team in a simulated cardiac arrest. With the limited sample size, the researchers acknowledge the limitation of the study regarding the generalization of results of this project to the entire population of students and in the present study samples were selected from a single college.

**Conclusion**

Present study findings showed that the majority undergraduate students had good knowledge about first aid. The incorporation of first aid education and training will be able to improve the knowledge of remaining students with inadequate knowledge. Proper knowledge and efficient skills in different techniques, materials used in first aid and Basic Life Support (BLS) play a crucial role in the effective management of victims of accidents and injury. Institutions should give importance to first aid and BLS skills of their students by conducting refresher courses on a regular basis. Simulation-based education should be incorporated into the medical education curriculum to train the graduates.

Evaluation of Dental Implant Stability Regarding All-on-4 Concept Utilizing Two Different Angles

Mohammad A. Hameed1, Thair A. Hasan2

1Ph.D. Student, Department of Oral and Maxillofacial Surgery, College of Dentistry, University of Baghdad, Baghdad-Iraq, 2Professor, Chairman of Scientific Iraqi Council of Maxillofacial Surgery, Baghdad-Iraq

Abstract

Background: The “All-on-4” technique using 4 implants that has gained popularity in full arch edentulism cases in recent years was presented as a modern technique in implant-denture rehabilitation by Malo in Lisbon, Portugal, for the first time in 2003 and the all-on-four concept that began to be used in atrophic full arch mandibular and in the maxilla in 2005 has emerged.

Aim: evaluation of dental implant stability in relation to All-on-4 concept.

Materials and Methods: This was a clinical prospective comparative study organized from February 2019 to March 2020 in the College of Dentistry Teaching Hospital, Department of Oral & Maxillofacial Surgery/Dental Implant Unit/University of Baghdad. A total of 15 Iraqi patients aged 41-73 years, 9 males & 6 females were enrolled in this study receiving 80 Dental implants (All-on-4 concept). Patients classified into two groups, group A (All-on-4 with 2 anterior axial and 2 posterior with angulation of 17°) and group B (All-on-4 with 2 anterior axial and 2 posterior with angulation of 30°). For both, the surgical site of dental implant was examined for the hard and soft tissues clinically and radiographically utilizing OPG and CBCT.

Results: The mean of ISQ values obtained in this study at each time point in the total dental implant, axially placed and angled implant stability demonstrated significant increase (P = 0.000, 0.031 and 0.004) respectively at different times. There was a significant increase in the mean stability of axial and angled implants concerning males (P = 0.001 and P =0.002) respectively than females. Significant correlation between implant stability and the regions at the three times periods. There was a significant difference in angled implants stability between different intervals (P = 0.001) in patients >50y. Success of dental implants 95.24%.

Conclusion: All-on-4–style full-arch dental implant procedures have one of the highest success rates of dental treatment; the dental implant stability had significant effect in mandible in comparison to maxilla. There was irrelevant clinical analysis result in comparison to the statical analysis in relation to stability with different variables.

Keywords: All-on-4, Implant stability and Dental implant.

Introduction

All on 4 Concept Principle

In 1993, Dr Paulo Malo performed the pilot study to establish All-on-4 concept (1). The design of the “All-on-4” immediate-function concept was developed in 2003 by Malo and colleagues (2), the approach to rehabilitate the fully edentulous mandibular jaw by placing only 4 implants in the following combination: 2 anterior implants placed axially and 2 posterior implants placed distally tilted within the mandibular parasymphysel region. These implants were immediately loaded with a full fixed acrylic prosthesis within 2 hours of surgery.

Corresponding author:
Mohammad A. Hameed
email: mohamed.alrubae84@gmail.com
Building on the mandibular “All-on-4” success, Malo and colleagues replicated the same design for the maxilla in 2005 (4).

**Biomechanical advantages of “All-on-4” design** (3).

1. Implants follow a dense bone structure.
2. Longer implants can be placed by tilting them posteriorly.
3. Tilting improves A-P spread of implants.
4. A-P spread enhances load distribution for prosthesis.
5. Shorten cantilever (maximum of 7 mm for maxilla and 1.5–2.0 _ A-P spread for mandible) reduces prosthetic fracture/instability and marginal bone height stability.
6. Marginal bone height of implants is maintained with rigid prosthesis.
7. Tilted implants have similar success rate as traditional implants when splinted together.

According to Sennerby and Meredith, 2008 and Sachdeva et al., 2016 dental implant stability can be divided into:

- Primary stability refers to the mechanical bracing of the implant in bone and absence of any micromovement.
- Secondary stability refers to successful osseointegration of the implant with the surrounding bone. The majority of implant losses may be explained as biomechanically induced failures, since low primary implant stability, low bone density, short implants and overload have been identified as risk factors.

Resonance frequency analysis (RFA): Meredith, Alleyne (5) suggested a non-invasive method of analyzing peri-implant bone by connecting an L shaped transducer to an implant in an animal study. The transducer provides a high frequency mechanical vibration and record the frequency and amplitude of the signal received. The resonance frequency was thus defined as the peak of frequency-amplitude plot and converted to a value representing stiffness of bone implant interface (6).

A new generation of RFA technology has been developed by members of the original team behind the commercialisation of RFA (Integration Diagnostics Sweden AB, Gothenburg, Sweden). A small pen-like battery-driven instrument (PenguinRFA) is used together with reusable transducers (MulTiPeg™) as (Fig. 1.5B). These are made from biocompatible titanium and can consequently be autoclaved and used numerous times. The instrument can be packed in a sterile pouch and kept on the surgical tray and used without the assistance from a second person (7). The instrument measures the frequency of the vibration and translates it to an ISQ scale value between 1 and 99. The higher the ISQ value, the better the stability. RFA measures implant stability as a function of interface stiffness, which correlates with implant displacement, i.e. micro-mobility. More than 700 references, ISQ> 70 represents “high stability”, ISQ between 60 and 69, “medium stability”, and ISQ <60 is considered “low stability” (8). Values above ISQ 70 indicate a very stable implant with low micro-mobility. This value is typically recommended for one-stage and immediate loading. A second measurement is recommended before the final restoration to verify osseointegration (9).

**Materials and Methods**

A total of 15 Iraqi patients aged 41-73 years, 9 males & 6 females were enrolled in this study receiving 80 DI (All-on-4 concept).

Patients classified into two groups, group A (All-on-4 with 2 anterior axial and 2 posterior with angulation of 17°) and group B (All-on-4 with 2 anterior axial and 2 posterior with angulation of 30°). For both, the surgical site of DI was examined for the hard and soft tissues clinically and radiographically utilizing OPG and CBCT.
The total performed implants was 80 DI was for both groups, 40 DI for each group.

**Inclusion Criteria:**

1. Patient’s ≤18 years with complete jaw edentulism.

2. Patient was with good general condition or with other diseases that not influences BHP (like hypertension … etc.).

3. Completely edentulous maxilla and mandible or presence of teeth with an unfavorable long-term prognosis to be extracted.

4. Adequate available alveolar bone height and width in between premolars regions.

5. Patients who refused any kind of sinus augmentation procedure on undergoing any kind of Inferior Alveolar Nerve (IAN) transposition procedure (lateralization) when indicated.

**Exclusion Criteria:**

1. Presence of local acute infection at the implant site or any evidence of local pathological conditions in implant zone.

2. Poor oral hygiene and poor motivation to initiate/maintain good oral hygiene.

3. Any systemic diseases or condition that influence bone healing.

4. Anatomical limitation that interfere with the performance of this procedure.

5. Clinical evidence of parafunctional habits.

**Clinical examination:**

A detailed medical, family and dental history were taken from the patients regarding any systemic diseases, smoking and other conditions that could influence bone healing. A clinical examination of the patient to evaluate regional lymph nodes, facial profile and symmetry, and temporomandibular joint function. The intraoral examination assessed mouth opening, oral hygiene, any clinical evidence of parafunctional habits.

**Radiological examination**

A preliminary preoperative OPG was taken as a standard radiograph for documentation and assessment of the available alveolar bone height taking in consideration the amount of magnification and important anatomical structures such as (the anterior wall of maxillary sinus, floor of nasal cavity, mandibular canal and mental foramen and its loop). Also, it was important to identify the presence of any pathology in the implant zone and the relation of the proposed DI to the anatomical limitations. CBCT for indicated cases (candidates) was taken to evaluate the available bone of the maxilla and mandible in a 3-dimensions view.

**Surgical Procedure**

Prophylactic oral rinse with 0.2% chlorhexidine was performed about 1 minute before surgery. Topical spray anesthesia of Lidocaine 10% was applied to the buccal/palatal and lingual mucosa to decrease pain of local anesthesia. Surgical procedures were performed under local anesthesia infiltration with Lidocaine 2% (Septodent). A crestal incision was made from first molar to first molar region with distally bilateral buccal vertical oblique incision, full-thickness mucoperiosteal flap reflection using Molt # 9 and/or Haworth periosteal elevator was performed to locate a bluish hue and bulge of maxillary sinus to determine anterior boundary of maxillary sinus and attention to locate and avoid damaging the mental nerve and locating neurovascular bundle clinically with direct vision, alveolar osteotomy was made with surgical bur. The ridge crest was trimmed to remove any sharp edges and irregularities using surgical bur and surgical hand piece with copious irrigation of normal saline solution, as seen in Figure (1A).

After drilling with a ø 2.4 mm drill to 10-mm depth using a dental engine handpiece set at 800 rpm and torque equal to 35 N/cm, an All-on-4 Guide (Trigonometer, Nucleoss Turkey) was placed in the midline. The
contour of the guide should be adjusted so as it follows the opposing arch; this allows implants to be directed against the opposing arch for proper inclination, as presented in Figure (1B).

Starting with the anterior implant sites, drilling with a pilot drill (starter drill) at least 10 mm from the previously midline guide (lateral incisor position) according to jaw size and anatomical variation, sequential drilling until reaching the final size with 0°. The two axially anterior implants were installed in the anterior region parallel to the midline following the jaw axially to avoid buccal bone plate penetration, Implant placed with 35 rpm speed using motorized way and then finally seated with manual ratchet Figure (1C&D).

Posterior implant position at second premolar position with the same technique and insertion torque. The exact location of the anterior wall of maxillary sinus was important to be located and with attention to locate and avoid damaging the mental nerve and neurovascular bundle clinically with direct vision because it allows the posterior implants to be placed angulated distally with either 17° or 30° with respect to the guide and with anterior wall of maxillary sinus according to group selection as illustrated in Figures (E & F).

After the instillation of dental implants in their position using same speed and torque, a multipeg on each fixture was applied and measure the primary implant stability at time of surgery mesio-distally and buccolingually using penguin® device, as demonstrated in Figure (1G).

This step was followed by seating the multiunit abutment on implant fixture. Wound closure was performed with interrupted (3/0) black silk suture.

Within 72 hours, the provisional denture was inserted with the use of temporary multiunit collar as demonstrated in Figure (2A&B).

The stability was measured after 12 weeks and 24 weeks. The metal framework and final restoration was performed after 12 weeks. A passive fit was essential to ensure accuracy and not to translate undue strain onto the implants. The occlusal contacts were adjusted. Regarding the screw-retained restoration, the abutments and restorations were gently tightened to the implant bodies using a manual screwdriver to facilitate it is opening as seen in Figure (2C&D).

**Results**

Distribution of patients data concerning the age and gender

Fifteen patients contributed to this study aged from 41-73 years with an average of 59.8 years. The highest percentage (73.3%) was reported >50y this study included 9 males and 6 females (60% vs 40%) respectively with a male to female ratio of 1.5:1.

**Distribution of dental implants (DI) per patients according the gender in each jaw**

Eighty-four DI were installed in twenty-one jaws according to All-on-4 concept, one case dropped out after four weeks. Nine male patients (twelve jaws) were contributed in this study with six females (eight jaws).

The effect of time on the dental implants stability.

Table (1) explain the statistical correlation between dental implants stability in ISQ that were installed in axial (anterior), angled (posterior) direction in relation to time interval T1 (baseline), T2 (12 weeks) and T3 (24 weeks). In the total DI, axially placed and angled implant stability demonstrated significant increase (P = 0.000, 0.031 and 0.004) respectively at different times.

Relation of gender and times differences regarding the stability of dental implants

There was a significant increase in the mean stability of axial and angled implants concerning males (P = 0.001 and P =0.002) respectively, on the other hand, the axial inserted implants stability presented a significant correlation between gender at T2 & T3 (P =0.010 & 0.023) as explained in a table (2).
Age and time differences regarding the stability of dental implants

There was significant difference in angled implants ISQ between different intervals (P = 0.001) in patient >50y.

**Jaws and time difference regarding the stability of dental implants**

Regarding to mandible there was a significant difference in the mean of ISQ values at different periods (p = 0.024) as explained in a table (3).

Angle and time differences in the posterior region regarding the stability of dental implants

The posterior implants were inserted at two different angles (17° and 30°), there was no significant difference in ISQ value concerning DI angle at each time data. Furthermore, there was a significant difference in the mean of implant stability for DI inserted at (30°) (P=0.040) as demonstrated in the table (4).

**Survival rate**

The total number of DI installed in the study was 84. Four dropped out of the total number due to failure during healing period. All implant undergoes early loading and success rate was 95.24%.

Discussion

Dental implant stability in all-on-4 design in the current study, the mean of the 2nd measurement of total DI stability (12 weeks following DI placement) was significantly increased when compared with the primary stability (baseline) with values of 74.42 vs 73.34 respectively. Furthermore, the 3rd reading (24 weeks following DI placement) was significantly increased also compared to the primary stability and the 2nd measurement after the healing period (74.76 vs 73.34 and 74.42) respectively. However, there was significant increase in both axial and angled insertion dental implants separately (P= 0.031 and 0.004) respectively.

One important point to mention is that the increase in stability may be attributed to that all of DI were placed in the anterior region of maxilla and mandible. the bone density than the posterior mandible, followed by anterior maxilla, this opinion is supported by Farré (10) who stated that there was a significant statistical relationship obtained between the implant location and Hu and was in turn between the location and primary stability in terms of ISQ measurements.

All the initial measurements of DI stability registered higher than 60 ISQ so there was a contrast with Suzuki (11) who found that The ISQ values increased when the initial ISQ is lower than 60 ISQ, whereas ISQ values mostly stay unchanged or decreased when the initial ISQ is higher than 60 ISQ.

The present study is supported by Olsson (12) who examined a total of 61 oxidized implants (6 or 8 implants per maxilla). The mean ISQ, which was 60.1 at placement and increased to 62.8 after 4 months.

Hassan and Emarah (13) is contradict in their
study with the present research, they reported two groups, Group 1 included 5 patients received all on four maxillary prosthesis, and group 2 included 5 patients received all on six maxillary prosthesis. The Implant stability significantly increase from base line (60) to (62) after 6 months then insignificantly increased at 12 months (63). The reduced number of the implants in group 1 may subject the implants in this group to higher biomechanical load, which may decreased percentage of bone to implant contact and decrease implant stability. In contrast, wide implant distribution in the group 2 may cause physiologic loading of the bone, thus increasing the implant stability.

In the present study, there was a significant change in stability for males 9 (60%) than females (40%) (P=0.000 and 0.215) respectively this may be related to the small sample size.

On the other hand there was a significant change in implant stability in both axial and angled dental implants separately (P= 0.031 &0.004). This is in close relation to the study performed by Wentaschek \(^{(14)}\) who stated that the mean ISQ value for osseointegrated of 57 all on six implants after 3 months was significantly higher (p < 0.001) than their means at baseline. The DI were separated into axial (No. = 39) and tilted (No. = 18) implants, the differences were also significant (p < 0.005).

The patients that were treated according to all-on-4 concepts presented with significant change in total DI stability in relation to mandible than maxilla (P=0.024) this may be contributed to the bone type in the mandible which is highly compact than cancellous bone in the maxilla and this is supported by Sthita \(^{(15)}\).

In the present study, on the other hand, a significant increase in stability of angled DI was noted in the maxilla this may related to the high bone implant contact because the adequate available bone quantity in the maxilla than mandible which may be returned to the fact that of the resorption in mandible more than maxilla, in addition to that there was insufficient articles written about stability of both jaws.

In this research, there was a significant increase in the 2nd & 3rd values of total dental implants ISQ in patients aged > 50 y; this may be related to that, the majority of patients was enrolled in this age group.

In addition to the stability was increased in patient > 50 in angled dental implants.

**Clinical Analysis**

Considering the clinical analysis one important point to be mentioned is that according to the ISQ device manufacturer that is based on more than 700 references, the ISQ values are divided into three levels Andreotti et al., 2017.

1. ISQ < 60 = low stability.
2. ISQ 60-69 = medium stability.
3. ISQ ≥ 70 = high stability.

Accordingly, in the present research, a clinical analysis of the data is contemplated and performed by the researcher based on calculating the number of DI in which their ISQ values remained or changed to a different level when compared to the baseline data. The results were considered clinically significant or not, dependent on the number of DI that resided in the same level of ISQ or changed to another level regarding the 2nd and 3rd measurements compared with primary stability. This clinical analysis of data illustrated and confirmed that not all the statistically significant results essentially being clinically relevant as follows:

The statistical analysis reported a significant increase in the 2nd measurement in the age group >50 y and an increase in the 3rd one in the same age group of males. While, the clinical analysis demonstrated no significant change in age group > 50 y (15 out of 16 DI resided in the same level).

In spite of that, the statistical analysis reported a significant increase in stability of dental implants in relation to males in regards to the total, axial and angled DI implants (P= 0.000, 0.001&0.002) respectively, and the mandible showed non-significant change in relation
to any site and angle.

The clinical analysis using McNemar test demonstrated non-significant change in both genders in relation to different site and angles (P=1).

The patients >50y showed statically a significant change in total DI stability (P= 0.000) while clinically there was non-significant change (P= 1).

Regarding the angles, the statistical analysis was reported a significant change in axial and angled DI stability, however it was clinically irrelevant.

The stability of total DI of the mandible, tilted implant in maxilla and angled 30° inserted dental implants presented with statistically significant changes (P= 0.024,040, 0.026 & 0.040) respectively, in spite of that there was no clinical relevant in relation to that (P=1,0.25&1).

**Conclusion**

All-on-4–style full-arch dental implant procedures have one of the highest success rates of any treatment in dental treatments; the technique is also among the most difficult and can be fraught with obstacles. With careful planning and knowledge of potential pitfalls associated with performing, the procedure clinicians can incorporate All-on-4–style dental implant treatment into their practices with a high degree of confidence and less stress.

Survival rate if DI was 95.24% and patients benefited from the use of the All-on-4 treatment concept. The present study showed good clinical outcomes when using two tilted and two axial implants and a fixed prosthesis for rehabilitation of the edentulous ridges. The DI stability had significant effect in mandible in comparison to maxilla.

The Effect of Oxidative Stress on Vitiligo Patients

Mohammed Hasnawi Ali¹, Muthanna M. Awad²

¹Master of Biology Student. ²Prof., University of Anbar, College of Education for Pure Sciences, Department Biology

Abstract

The purpose of the study to shed light on one of the hypotheses keys in causing disease vitiligo is the stress hypothesis of oxidative, stable of vitiligo have been identified active stages or on the basis of the development or the emergence of new spots in the past three months and the absence of new or patches development in the past six months, the in a row, this study included three groups, all of them were male. The first group included the active group, patients with vitiligo of the active type 30, the second person, the dormant group, includes static type vitiligo patients 25, one person, the third, the control group (apparently healthy) included 20 People. We have examined the serum levels of Superoxide Dismutase enzyme, catalase enzyme, and Malondi- aldehyde, our results revealed that the level of higher than Malondi- aldehyde at the level of probability (P <0.05) In the serum of the disease group compared to the control group, a significant increase in the activity of superoxide dismutase was observed in the serum of the disease group at the level of probability (P <0.05) Compared to the control group, the catalase activity decreased at the probability level (P <0.05) In the pathological group compared with the control group, our study shows that stress Oxidative has a role in the physiology pathogenesis of vitiligo active and static. An imbalance of antioxidants was observed in the blood of active Vitiligo patients.

Key Words: Vitiligo, Oxidative Stress, SOD, MDA, CAT

Introduction

Vitiligo Of skin diseases resulting from the absence of melanin pigment in some areas of the body (1). The skin is the outer covering of the body and works to protect it from external influences and the melanocytes are counted Melanocyte One of the components of the skin and these cells are responsible for the formation of the pigment melanin Pigment Which give your skin color, people who suffer from vitiligo disappear to have this dye due to the absence of cells melanocytes of the skin complexion (2,3), Vitiligo appears in both sexes and in all age groups, as it spreads among 2 - 1(%) Of the world’s population and the true causes behind the occurrence of Vitiligo are not clearly known and may be the result of the contribution of several pathological factors (4), Vitiligo disease appears in the form of milky spots is crusted with distinct margins (5). There are theories that explain the breakdown of melanocytes and the pigmentation process in the skin that ends with the emergence of Vitiligo. One of these theories is the theory of oxidative stress. This theory refers to the case of disturbance balance between the oxidizing substances of the types of oxygen and effective types of nitrogen effective and between the systems defense antioxidant during metabolism (6). Oxidative factors contribute to the pathophysiology of vitiligo patients through a significant increase in antioxidants in the serum of vitiligo patients. The antioxidant is Superoxide Dismutase enzyme, catalase enzyme, and Malondi- aldehyde.

Literature Review

Superoxide dismutase enzyme(SOD): a commonly discovered enzyme 1969 by Worlds Mikord
and Friedovich\(^{(7)}\). Works of this enzyme to convert the root of the super Oxide to hydrogen peroxide H2O2 And oxygen O 2 As in the equation:

\[
O_2^- + O_2^- + 2H^+ \xrightarrow{SOD} H_2O_2 + O_2
\]

Catalase enzyme\((\text{CAT})\): It is an enzyme found in all living things, which is considered one of the main antioxidants \(^{(8)}\), the dismantling of hydrogen peroxide The H \(_2\) - O \(_2\) to oxygen and water \(^{(9)}\), as in the equation:

\[
2H_2O_2 \xrightarrow{\text{Catalase}} H_2O_2 + O_2
\]

Malondialdehyde\((\text{MDA})\): It is a compound that results from the process of fat oxidation and represents the final product of the oxidation of membrane lipids in melanocytes \(^{(10)}\), a compound aldehyde tri - high interaction produces peroxide polyunsaturated fatty acids \(^{(11)}\).

Materials and Methods of Work

Study type was determined and is a pathological study of vitiligo patients compared to control. Samples were collected from a consultant dermatologist from Ramadi General Hospital and with the help of Dr. Abdullah Saleh Al-Hassan, a dermatologist in Anbar Governorate, during the period of time. 2020/7/1 Up to 2021/1/1. As it included the patient group 55 Sick and this group is divided into 25 Patient with static state, 30 Patients with active status in addition to the control group and their number 20, a person who was shown to be free of any pathological symptoms in this group. With the exclusion of smokers, patients taking Vitiligo treatment, and those suffering from other diseases, it was withdrawn 5MI of venous blood by medical syringe for the subjects under study. Blood samples were collected in tubes EDTA Anticoagulant and the serum was separated using a centrifuge. 3000 A diuretic course 5 For minutes, the serum was collected in clean and sterile Abendorf plastic tubes and kept in the freezer at some degree-20M until use. And the use of a serum to check for levels of antioxidants SOD, CAT, MDA In the study groups. The method for determining the efficacy of the enzyme superoxide dismutase in the blood serum depends on the susceptibility of the enzyme SOD On activating the oxidation of epinephrine into adenine and chromium, as the latter is a chemical substance that is produced naturally when the oxidation of epinephrine and the reaction takes place at a temperature 37°C \(^{(12)}\), Take 1 ML of serum and diluted in 1.8 ML of solution Carbohydrate buffer Concentrated 50m It is an acidic function 10.2 Then add 0.1ML of epinephrine and 1ML of solution EDTA (Ethylene diamine Tetracetic acid ) Function acid10.2 I read the absorbance with a spectrophotometer at a wavelength 480 Nanomer, as the first reading took the case of adding epinephrine A Control The second reading was taken after 5Minutes from the first reading A Sample The effectiveness of the catalase enzyme in the blood serum was estimated, and this method depends on the ability of the catalase enzyme to break down the hydrogen peroxide compound into water and oxygen gas, thus reducing the absorption during the reaction period \(^{(13)}\), 50 MI of serum has been added to 5MI of Phosphate buffer solution At PH = 7. The reaction begins immediately after adding hydrogen peroxide to the solutions, and after mixing them the first absorbance is read. \((t1)\) After passing \((15)\) Sec and then I read the second absorption \((t2)\) at a wavelength 240 Nm using a Spectrovoltmeter. Then estimating the concentration of peroxidation of lipids in the blood serum by measuring the amount of Malondi- aldehyde and the method depends on the interaction between the lipid peroxides. MDA And between thiobarbituric acid and this reaction takes place in an acidic medium and is a colored product, the intensity of absorption for it is measured when 532 Nanometer using a spectrophotometer \(^{(14)}\), Use 200 ml of serum 4 ml of solution TCA Trichloroaetic acid plus 1 ml of thiobarbiturl acid (TBA The solutions were mixed well and then placed in a water bath 100C For a period 15th A minute was then left to cool, the solution was placed in a filtrate separator device, and the spectrometer was read at a wavelength of 532 nm.

Results

The results are indicated in the figure (1) High level of superoxide dismutase at the level of probability \((P <0.05)\) in serum in the disease group compared to the
control group. The results indicated in the figure (2) Low levels of catalase at the level of probability (P <0.05) in the disease group compared to the control group in serum. The results are shown in Figure (3) High Malondi- aldehyde at the level of probability (P <0.05) in the disease group compared to the control group in serum.

Figure number (1): To estimate the efficacy of an enzyme SOD In the study groups

Figure number (2): To estimate the efficacy of an enzyme CAT In the study groups
Discussion

Vitiligo is one of the diseases resulting from the disappearance of melanin pigment from the skin due to the absence of melanocytes, and among the theories that lead to the destruction of these cells is the theory of oxidative stress that leads to the production of toxic compounds, these compounds have a great effect on melanocytes and their destruction. A significant increase in the enzyme superoxide dismutase was observed at the level of probability (P <0.05) In the disease group compared to the control group, as a result of the continued production of these toxic compounds in the blood serum, due to the oxidative stress on melanocytes (15). The This enzyme disposal of toxic super oxide, which is considered toxic compounds in the Melanotene cell formed as a result of oxidative stress, which leads to damage to DNA as well as destroying the enzymes that make proteins and other molecules in the cell as a result of oxidative stress (16), and Superoxide Dismutase enzyme works on converting the super Oxide root of hydrogen peroxide H2O2 and oxygen. Low levels of catalase were observed at the probability level (P <0.05) In the disease group compared to the control group. Schalreuter and his group (1999) Confirmed the reason for this enzyme decrease is because it helps the cell get rid of the toxicity of the toxic compound (H2O2) In the cell, which consists of this compound as a result of oxidative stress in the cell melanocytes and thus the catalase enzyme to neutralize the toxic action of this compound was observed high levels of Malondi- aldehyde (MDA) at the level of likelihood (P <0.05) In the disease group compared to the control group. Malondi- aldehyde (MDA) it is a final product of lipid oxidation in the melanocyte as a result of the oxidative stress process in the cell (18). The significant increase in Malondi- aldehyde in vitiligo patients illustrates a state of oxidative stress in the cell (18, 19, 20). The lipid peroxidation leads to the destruction of the cell membrane of the melanocytes, which leads to the removal of the melanin pigment in the skin of vitiligo patients (21).

Conclusion

Oxidative stress is one of the hypotheses that have a role in the destruction of melanocytes in vitiligo patients and the disappearance of melanin pigment from the skin due to the resulting disturbances between antioxidants and oxidants in the cells.

Effect of Exotoxin a isolated from *Pseudomonas Aeruginosa* against Human Cancer Cell Lines

Muthanna Hamid Hassan

Assist. Prof., Department of Biology, College of Science, University of Anbar, Iraq

Abstract

In this study, the presence of *Pseudomonas aeruginosa* was investigated from many clinical samples, and then about 54 isolates were obtained, diagnosed with all different diagnostic methods, and then the bacterial isolates produced for Exotoxin A were detected by the ELISA method and then the most productive isolate was chosen for purification by means of precipitation with ammonium sulphate and ion-exchange column and detection of molecular weight was (M.W 65.03 KD). The competent isolation tested its toxicity against two cancer cell lines HeLa and PC3 which were an inhibition ratio 69.1% and 61.6% respectively in high concentration.

*Key words*: p.aeruginosa, exotoxin A, chromatography, cancer cell line

Introduction

*Pseudomonas aeruginosa* is considered an important opportunistic pathogen\(^{(1,2)}\), causing dangerous infections, especially in immunocompromised patients \(^{(3)}\). This infection is difficult to treat due to the great resistance it possesses \(^{(4)}\). In addition; it has a great ability to resist a wide range of antimicrobial agents. Exotoxin A (ETA) is regarded as the important virulence factor secreted by *P. aeruginosa*. Liu was 1st who disgonized and purified it \(^{(5,6)}\). That ETA is considering an ADP-ribosylating toxin which works in the inhibition of protein synthesis and finally cell death \(^{(7)}\). ETA is a single chain polypeptide of a MW 66-kDa. It is binding to receptors as specific via endocytosis receptor-mediated \(^{(8)}\).

Material and Methods

Collection of Samples

This study have collection about 73 samples from pathogenic cases as Burns, Wounds, UTI infection, Otitis media, in AL-Ramadi Teaching Hospital and AL-Fallujah Teaching Hospital, throughout the period from 1/7/2020 to 20/9/2020. Samples were obtained by utilizing sterile cotton swaps whereas sterile UTI infection was taken by sterile container. Samples were streaked directly on agar of MacConkey and incubation was done for 24 at 37 °C.

*P. aeruginosa* Isolation and Identification

For the purpose of isolating and diagnosing bacteria, several tests were performed:

**Morphological examination**: Morphological examination was performed with Gram stain and spore-forming stain by light microscopy

**Culture examination**: Culture examination was performed by cultured bacterial colonies on the selective media MacConkey agar, cetrimide agar and incubation was done for 24 at 37 °C.

**Biochemical exams**: many biochemical exams were conducted for diagnosis bacteria including: IMVC, urease, triple sugar iron, oxidase and catalase tests for
diagnosing confirmed of the isolates were performed vitek-2 system.

**Production of pyocyanine:** The bacteria were cultured on agar of cetrimide and incubation was done for 24 at 37 °C, as a result, the green color presence indicates +ve results.

**Growth ability at 42 °C:** The bacteria were cultured on agar plates and incubation was done for 24 at 42 °C, bacterial growth at such temperature mentions +ve results.

**Protease test:** For the detection the ability of bacteria to produce protease enzyme that were streaked on skim milk agar.

**Detection of ETA:** For the detection the ability of bacteria to produce Exotoxin A were tested using ELISA kit.

**Partial Purification of ETA**

**Precipitation with (NH₄)₂SO₄:** the procedure adopted in this study was performed according to (9). Toxin was precipitated by addition of (NH₄)₂SO₄ at (20, 30, 40, 50, 60, 70, 80) % saturation. The product of 80% saturation that precipitated was utilized for obtaining complete toxin precipitation, and centrifugation for 30 min at 10,000 rpm was done for separating the precipitant.

**Ion exchange chromatography Purification:** Such was performed based on (10) through using column of DEAE-cellulose 2.5 x 15 cm that several times was washed with buffer of equilibration 0.01 M Tris-OH of pH 8.

**Toxin MW determination:** gel filtration chromatography was used for toxin MW purified partial determination, toxin A was kept to flow via a glass column (1.5 x 60) cm which packed with Sepharose 6B, and then in a flow rate eluted ( 3 ml /fraction). Trypsin 23KDa, ovalbumin 43KDa and bovine serum albumin (BSA) 67 KDa were protein standards.

**Protein concentration determination:** concentration of protein was performed based on (11) as following: A standard curve of BSA was carried out by utilizing various concentrations from stock solution of BSA based on volumes.

**Cell lines and growth conditions:** Cell lines of cervical cancer (HeLa), prostate cancer (PC-3), and normal ones were utilized for determining the ETA effect. Such cells were on media of MEM and RPMI were cultured that were enriched with mixtures of FBS (10%) and penicillin streptomycin (1%). Incubation was done at 5% CO2 and 37 °C (12).

**MTT cytotoxicity assay:** Based on (13) Exotoxin A cytotoxicity was performed.

**Statistical Analysis**

The data that obtained were displayed as mean ± SD and statistical significances were measured utilizing test of ANOVA(14).

**Results and Discussion**

The Results of this study refer to clinical samples as total of 73 were taken from various cases as showed in (Table1). About only 54 isolates (71.05 %) gave morphological features and biochemical tests in relation to *P. aeruginosa*, while the remaining isolates of 19 might related to other bacteria being pathogenic from various genera as illustrated in (Figures 1,2). Diagnosis of the bacterium was done by means of Gram stain, and looks as non-sporulating, slightly or a straight curved, motile G- rod that aerobically growing, this is agreement with (15). Generally, once clinical samples are cultured on agar of MaConkey, it showed all the essential traits of growing on that medium. The isolates cultured on agar of blood and appear as β hemolytic. Morphological suspected isolates features were perforemed based on the shape of colonies which if formed as colorless if cultured on agar of MaConkey because of no fermentation of lactose. Also, sub-culturing on agar of Cetrimide was added for bacterial inhibition other than *P. aeruginosa*(16). According to the results of biochemical tests that revealed that only 54 isolates were belong to
*P. aeruginosa*. These isolates gave +ve results for tests of catalase, oxidase, citrate utilization, while -ve results were obtained in production of indol and test of methyl red- vogesproskour.

Colonies cultured on nutrient agar for 24 h at 42°C can grow normally; where growth appearance mentions +ve results. also All the bacterial isolates are represented *P. aeruginosa*, and were positive for protease this is in agreement with (17) who revealed that isolates of *P. aeruginosa* as over than 95% were +ve for Exotoxin A and protease. For the purpose of pigment production from such bacteria, it cultured on agar of cetrimide for production of pyocyanin (H$_2$O soluble, a blue green, non-fluorescent, phenazine pigment) that is stimulated by the inclusion of MgCl$_2$, and K$_2$SO$_4$ in the broth. Cetrimide was added to inhibit other bacteria. Its function as cationic detergent being quaternary ammonium leads to release of N and P from cells of bacteria other than *P. aeruginosa*(16).

**Exotoxin A Detection**

For exotoxin A detection produced by *P. aeruginosa* isolates, kit of ELISA was utilized. About of 54 isolates, only 21 were detected of exotoxin A production. For concentrations measurement, the same kit was utilized also as the displayed in (Table 2). Isolates screening mentions that isolates mostly show +ve results. Nevertheless, only one isolate was elected based on their productivity being the highest besides their distribution in various sites when infections, highest isolates called *P. aeruginosa* 15, which produce (27.56) ng/ml and distributed in burn cases.

**Purification of Exotoxin A: such steps are includes:**

**Proteins precipitation by (NH$_4$)$_2$SO$_4$:** for toxin crude extract concentration and H$_2$O removing as abundant as possible, (NH$_4$)$_2$SO$_4$ was utilized at (20, 30, 40, 50, 60, 70, and 80) % saturation. For exotoxin A precipitation, the ratio of saturation as 80% was elected. Such step permits the molecules salting out of from H$_2$O. Since (NH$_4$)$_2$SO$_4$able to neutralize charges at the protein surface and disrupting layer of H$_2$O contiguous the protein, it will cause eventually a decline in the protein solubility that in turn cause protein precipitation via the salt effect (18,19).

**Exotoxin A partial purification via ion-exchange chromatography:** Exotoxin A partial purification via ion-exchange chromatography was done by DEAE-cellulose utilizing. Figure 3 illustrated the DEAE-cellulose column wash and elution to select isolate. In the wash steps, exotoxin A was detected, whereas the fractions as eluted were revealed. The obtained results revealed the existence of two peaks. Nevertheless, just one peak for each select isolates elution exposes activity as found via kit of ELISA. The purified partial proteins amounts mention as much as protein of 0.053 mg/ml produced via isolates PA15, the number fraction was between 35-37. Results revealed that there are one protein peak will seemed following elution by gradient NaCl concentration, and then the absorbance was measured at 280 nm.

**Toxin M.W detection**

The M.W was assigned to ETA produced by *P. aeruginosa* was measured via gel filtration utilizing Sepharose 6B in the existence of three proteins as standards (BSA, ovalbumin, trypsin). Every standard of protein and Exotoxin A were column-applied and individually eluted and then Ve of every standard protein were measured then recorded Ve/Vo for every one. The Results indicate that ETA has M.W (65.03) as illustrated in Figure 4.

**Assay of Cell viability**

Effect of cytotoxicity was done by using technique of MTT. Figure 4 showed that declining in cells viability of PC3 and HeLa by concentrations and incubation period increasing of the extracts was noticed. Significant inhibition against HeLa (P<0.05) in most concentrations and incubation periods was observed. ETA extract of (400 µg/mL) as the highest concentration caused effect in maximum time as highest inhibition against PC3. High effect as cytotoxic against Hela and PC3.
was noticed if with ETA extract were treated which were 61.6% and 69.1%, respectively. However, they were of week activity versus cell line being normal. Normal cells were growing well in around 91%. These results might be explained due to cancer cells death that occurred by apoptosis that is recognized as a controlled event. The cytokines production are known to be as anti-inflammatory molecules besides phagocytosis can cause this type of cell damage\(^{(20)}\). Consequently, it was believed that the ETA was of biological activity that might inhibit proliferation of cancer cells\(^{(21)}\).

A Comparison between Retro-Clavicular and Proximal Infraclavicular Approaches for Brachial Plexus Block for Anesthesia of the Upper Limb

Mohammed Sami Hassan 1, 2, Mohammad Asi Jabbar 2, Mortada Abd Al-Hussian Jubara 2, 3

1 Lecturer, Consultant, F.I.C.M.S., Hamorabi Medical College, University of Babylon, Babylon, Iraq, 2 Specialist of Anesthesia, C.A.B.A., Department of Anesthesia, Al-Shaheed Ghazi Al-Harriri Hospital, Baghdad Medical City, Ministry of Health and Environment, Baghdad, Iraq, 3 Specialist of Anesthesia, F.I.C.M.S., Department of Anesthesia, House Nursing Private Hospital, Baghdad Medical City, Ministry of Health and Environment, Baghdad, Iraq

Abstract

Background: This comparative study hypothesize there are differences between ultrasound guided retro-clavicular and proximal infraclavicular approaches for brachial plexus block for surgeries involving lower part of arm, elbow, forearm and hand with the use of tourniquet.

Method: About 36 patients randomly allocated into 2 groups, first group block done through retro-clavicular approach (RCB) and the other group done by using proximal infraclavicular block (PIB). In RCB group needle inserted posterior to the clavicle and directed posterior to the first part of axillary artery. In PIB needle inserted from lateral to medial after abduction of the arm more than 90° where the cords are clustered together.

Results: Block performance time was (6.11±2.58) and (6.05±2.61) for RCB and PIB, respectively without significant difference (p= 0.94). The onset of sensory was (12.8±1.4) and (11±2.3) for RCB and PIB, respectively. For motor onset (17.4 ±2.3) and (15.3±3.3) and there is significant difference between both groups (p=0.009 and 0.04), respectively. There was no significant difference in block-related pain between the two groups (p=0.809) VRS for RCB was (1.41±0.712) and for PIB was (1.32±0.67). Tourniquet pain reported by the patient for RCB was 1.24±0.56 and for PIB was 1.11±0.315, there is no significant difference between both groups (p=0.392)

Conclusion: Ultrasound guided BPB by retro-clavicular and proximal approaches are with a comparable quality of surgical anesthesia for operations of the lower arm, elbow, forearm and hand with the use of tourniquet, the onset of surgical anesthesia is earlier for PIB, the RCB is preferred for patients who cannot abduct the arm.

Keywords: Retro-clavicular; Proximal infraclavicular; Brachial plexus block; Upper limb anesthesia

Introduction

Infraclavicular block is easy to learn effective and useful to provide analgesia and anesthesia below the shoulder. Although Ultrasound guidance regional anesthesia have increased the interest in ICB it is still underused regional anesthesia technique of the upper limb (1, 2).

The common approaches are: Medial approach around the middle of clavicle; Lateral approach around the coracoid process; Retro-clavicular; Parasagittal (3). Coracoid approach is most popular (3, it has gained

Corresponding author:
M AsiJabbar
Baghdad, Iraq
7733962400
Medicalresearch68@yahoo.com
popularity because of the presence of a consistent bony landmark, less chances of vascular puncture or pneumothorax and adequate neural blockade\(^{(4)}\).

The ultrasound-guided parasagittalmidclavicular method has several disadvantages: Needle visualization can be difficult because of its steep insertion angle; The lateral cord is vulnerable to injury; The acromial branch of the thoraco-acromial artery is prone to puncture\(^{(5,6)}\).

Retro-clavicular approach (RCB) was first described in 2007 by Hebbard and Royse\(^{(7)}\), the needle is inserted posterior to the clavicle and passes underneath it in a cephalad-to-caudal direction. This allows excellent needle visualization as the ultrasound beam is perpendicular to the shaft of the needle. The needle trajectory is posterior to the lateral cord and acromial artery and therefore might reduce the chance of direct needle trauma to these structures during the procedure\(^{(7)}\).

The technique is quick and reliable, Reduced performance time, and fewer paresthesias than with the conventional approach. However, there is one significant disadvantage to the retro-clavicular approach: the bony clavicle causes acoustic impedance, creating a “blind spot” that the needle must traverse before appearing on the ultrasound image. Structures behind the clavicle cannot be visualized and therefore are at risk of damage. Preexisting anatomical descriptions of the area indicate that the subclavius muscle, supraspinatus muscle, and subscapularis muscle may be encountered during needle insertion, and the supra-scapular nerve and its attendant artery and vein may be vulnerable to injury\(^{(6-8)}\).

Proximalinfraclavicular approach (PIB) done by use Ultrasound-guided infraclavicular approach at a more proximal position in the costo-clavicular space, where the cords are grouped together cephalad to the artery this allows access to all three cords along one needle path. Using this technique, the onset time is faster, the axillary nerve is more reliably anesthetized, and the intercostal brachial nerve is often blocked as well when compared to a more lateral approach\(^{(8)}\). The drawback is that the cords lie close to the first and second ribs so that pleural puncture is more likely if the user does not have a thorough understanding of the anatomy and good technical skills. The proximal approach is performed with the blocked arm abducted same as axillary block moving the brachial plexus away from the thorax and closer to the dermal surface because the pectoralis major muscle, which is located superficial to the brachial plexus and the axillary artery, is stretched by the arm abduction this position elevates the clavicle slightly in the cephalad direction\(^{(9)}\).

The aim of our study was to compare two approaches of ICB (ultrasound-guided retro-clavicular and proximal infraclavicular) for surgery of lower arm, elbow, forearm, wrist or hand with tourniquet use. The outcomes to be studied include time for performing the block, pain during performance of the block, complications and pain related to tourniquet.

**Methods**

This study was conducted in AlKafeel Super-specialty Hospital from June 2018 to January 2019. Patients belonging to ASA status I to III admitted for elective or urgent lower arm, elbow, forearm, wrist, or hand surgery were divided into two groups. Patients were randomly allocated into two groups using randomization.com where random sequence generated by the website. Informed written consent was taken, the procedure explained to the patient and the 5-point verbal rating scale (VRS) score explained to the patient. Age, sex, BMI, type of surgery was recorded. Patient excluded from the study: refusal of regional anesthesia, coagulopathy, infection at the site of needle entry and inability to abduct the arm for PIB group.

Block done in the surgery operating room, standard monitoring was applied and a 18-gauge intravenous cannula was inserted in the contralateral arm. Intravenous midazolam 1 to 2 mg was given based on patient preference.

Patient positioned supine in a comfortable position to the patient make placement of the ultrasound transducer and needle insertion easier, small folded towel inserted behind shoulder of the side to be blocked to make the...
needle advancement easier with the head elevated 30 degree and turned away from the side to be blocked. The arm is by patient side and not abducted for RCB. The high-frequency linear transducer 12M Hz GE Healthcare used to scan from medial side of the clavicle in parasagittal planeto the Deltopectoral groove, Sonographically visualize the first partaxillary artery lies lateral to the first rib and proximal to the pectoralis minor crossing over the 2nd rib, thencourses away fromthe thoracic cage. The injection target which lies just posterior to the axillary artery.

We used Vishal Uppal technique where the needle length to the target place was marked and held by the index and thumb fingers for more safety and to avoid needle probe mal-alignment or acoustic shadow of the clavicle. After sterile preparation, Needle insertion point was 1-2 cm posterior to the clavicle after palpating supraclavicular fossa medial to the trapezius muscle insertion on the clavicle, the needle directed more towards the anterior axillary line. Under sterile condition a skin wheal raised using a 30-gauge needle, 100-mm 18-gauge needle inserted into the skin wheal and advanced strictly in-plane with the US beam, the needle should be appeared at the predetermined length behind the posterior wall of the clavicle and must not be angled posteriorly, to avoid any risk of pneumothorax.

The PIB group arm is abducted and externally rotated, the linear transducer is placed adjacent to the inferior border of the clavicle, parallel to the clavicle, and lateral to the midclavicular line, the axillary artery was seen in short axis. Needle was inserted from lateral to medial in plane to the transducer, the needle directed to the clustered cords and local anesthesia injected in single shot. All blocks were performed with 25-32 mL of bupivacaine 0.5% with adrenaline 1:200,000.

The collected data were:
1. Performance time: expressed in minutes. The duration of each block procedure was measured from first needle insertion for skin infiltration to the termination of the injection of local anesthetic and removal of the block needle. The time recorded by the anesthesia assistant.
2. Block onset assessed for sensory and motor: Onset time was defined as the time from block completion to the onset of analgesia and motor block checked every 1 minute after 5 minutes from the end of the block to decrease discomfort to the patient from repeating assessment by pinprick the area supplied by five nerves and movement as follow:
   - Radial (lateral aspect of the dorsum of the hand and wrist extension)
   - Median (volar aspect of the index and thumb-fifth finger opposition)
   - Ulnar (volar aspect of the fifth finger and fifth finger abduction)
   - Musculocutaneous (lateral aspect of the forearm elbow flexion)
   - Medial cutaneous nerve of the arm (medial aspect of the arm)
3. Pain during the procedure: after finishing the needling 5-point verbal rating scale (VRS) score after the removal of the needle. The VRS was scored from 0 (no pain) to 4 (the worst pain imaginable).
4. Tourniquet pain assessed 30, 45 and 60 minutes after inflation by using the 5-point verbal rating scale.
5. Complications: Any complication related to the procedure was searched and recorded intraoperatively and post operatively including: pneumothorax, vascular injury, paresthesiadiuring the procedure, nerve injury, phrenic nerve block, Horner’s syndrome and hematoma formation.

Exclusion criteria: Patient with infection at site of injection, bleeding tendency, inability to abduct the arm, patient refusal.

Statistical Analysis
Statistical analysis was performed using the SPSS
version 23 statistical software (SPSS Inc., Chicago, IL, USA). All numerical data were tested for a normal distribution. The continuous variables are presented as the mean±standard deviation (SD). Categorical variables are presented as the number (n) and the percentage (%) of patients. Differences between mean values for normally distributed variables were compared using Student’s t test. Fisher’s Exact test was used for categorical data where appropriate. A value of (p<0.05) was considered to indicate statistical significance.

**Results**

About 36 patients enrolled in this study seventeen patients given RCB, nineteen patients given PIB. In group RCB the mean age was (42.2±20.4) years while for the PIB was (34.8±15.2) years. In RCB group nine male patients and eight female patients, while in group PIB thirteen male and six female (Table 1). BMI was (28.3±4.8) m²/Kg for RCB and (27.6±5.2) m²/Kg for PIB.

Block performance time was (6.11±2.58) and (6.05±2.61) for RCB and PIB respectively without significant difference (p=0.94). The onset of sensory block was (12.8±1.4) and (11±2.3) for RCB and PIB, respectively (p=0.009). For motor block onset (17.4±2.3) and (15.3±3.3)(p=0.04), there was a significant difference between both groups, (Table 2).

There was no significant difference in block-related pain between the two groups (p=0.809) VRS for RCB was (1.41±0.712) and for PIB was (1.32±0.67), (Table 3). Tourniquet pain reported by the patient for RCB was (1.24±0.56) and for PIB was (1.11±0.315), there is no significant difference between both groups (p=0.392), (Table 4).

Dose of local anesthesia used for both groups was 28.5±1.5 and 28.6±1.4 and there is no significant difference (p >0.933). Procedures done under both approaches are shown in (Table 5).

Discussion

Although the two approaches differ in direction of needle when injection of local anesthetiabut both approaches are considered proximal approaches to the ICBPB where the needle directed toward first part of axillary artery, the main concern with needletip visualization was the clavicle shadow before visualize needle at its trajectory to the target site in RCB while in PIB approach the needle is well visualized throughout its whole length and this will avoid the penetration of the superficial pleura at this site, in our study no vascular or pleural injury noticed\(^7, ^15\).

One case was planned to be given RCB but we faced technical difficulties in insertion of the needle and directing it to the target of posterior cord due to morbid obesity, short neck and acutely angulated clavicle and we decide to use the other approach and it was successful this is also what was seen by Zhi Yuen Beh\(^16\).

One case planned to be given PIB according to the randomization and the patient can’t abduct the arm and he preferred regional anesthesia so given RCB which...
was more comfortable to the patient this is what was seen by ChandniSihawho prefer the RCB approach for acute trauma patient who can’t abduct his arm \(^{(17)}\).

Performance time: the two approaches studied not differ in duration of block performance and Block performance time was 6.11±2.58 and 6.05±2.61 for RCB and PIB respectively without significant difference \((p 0.94)\) other studies show performance time shorter (median 3.77 (2.90–6.53)) in RCB \(^{(18)}\).

While Bigeleisen findings for PIBwas median time nine(7–12) min and the difference from our study related to including the scanning time and identification of the nerves before needling\(^{(19)}\).Sensory onset: there is insignificant difference between both groups in sensory andmotor onset they are earlier in PIB and this also found by P. Bigeleisen where motor block was complete in all nerves at 20 minutes after the block also this finding noticed by Manoj Kumar \(^{(15, 18)}\).

Pain during procedure performance no significant difference in pain experienced by the patients during the block and \((p=0.567)\) and most of the patients report (70% of RCB and 78% of PIB group) it is mild pain, Charbonneau et al \(^{(20)}\) reported that in the retro-clavicular approach, the needle path avoids the puncture of the pectoralis major and minor, which results in less pain during the procedure. And the results of this study are also found by Nilgun\(^{(21)}\).

Both groups show well tourniquet pain toleration and no pain reported by most of the patients and for both groups (82.4 and 89.5% for RCB and PIB respectively). These findings goes with many studies comparing ICB with other brachial plexus blocks they found tourniquet tolerated better and it is explained by local anesthetic spread to the intercostobrachial nerve\(^{(22)}\).

Maximum Bupivacaine dose given in our study was 160 mg while in the published literature of 175-225 mg with epinephrine still regarded safe dose although site of injection not included in these literatures and we didn’t notice any complication related to this dose further study to be done for plasma concentration in these blocks approaches \(^{(23, 24)}\).

This high dose not gone with findings of Jia Wei Li et al, where relatively small volume and dose used for proximal or costo-clavicular approach with 100% success rate and explained by the grouping of the cords at the costo-clavicular space together lateral to the axillary artery\(^{(24)}\).

Complications no complications from both groups noticed for the cases included in the study and this may be related to small number included\(^{(18)}\).

Conclusion
Ultrasound guided BPBby retro-clavicular and proximal approaches are with a comparable quality of surgical anesthesia for operations of the lower arm, elbow, forearm and hand with the use of tourniquet, the onset of surgical anesthesia is earlier for PIB, the RCB is preferred for patients who cannot abduct the arm.

Declaration of Competing Interest- Nil

Source of Funding- Self.

Ethical Clearance- Taken from AlKafeel Super-specialty Hospital committee.

Abstract

Background-The current study aims to highlight the importance of autopsies in not just finding the cause of death; but also, incidental discovery of various rare lesions, that may or may not be the cause of death. The study also aims to highlight the common cause of death, spectrum of common incidental findings and reporting of various rare, interesting cases. Method- This is a retrospective study conducted between year 2013 to 2020 on 800 autopsies and their histopathological examination in Pathology Department, GMC, Patiala. Conclusion- Finding of this study concludes the importance of histopathological autopsy in not just highlighting the cause of death but also finding many rare diseases, thus enriching the field of medicine and pathology by observing the histological findings and also sometimes the course of rare diseases.

Keywords- Autopsy, Histopathology, medico-legal autopsy.

Introduction

An autopsy and histo-pathological examination are an important tool to establish the cause of death, manner of death, time of death and solving the medico-legal cases.[1] It can be carried for clinical purpose or medico-legal purpose. Clinical autopsy or pathological autopsy is done not just to establish the cause of death but also to study the course of a disease and highlight rare disorders with help of histopathology and adding to the knowledge pool.[2]

A medico-legal autopsy is on the other hand carried with a sole purpose to establish the cause of death and confirm the physical findings of autopsy with histological findings. [2,3]

Many times, findings which are unrelated to the cause of death are noticed in routine histo-pathological examination of medico-legal autopsies. These findings provide an opportunity to study various infrequent lesions which go unnoticed when a person is alive. It has been documented that autopsies have led to discovery and clarify the pathology of many medical disorders (87 over a span of 46 years).[4] They help in studying not only medically diagnosed and treated neoplasm’s, but also natural evolution of many untreated diseases.[5] Many incidental findings have been highlighted on histo-pathological examinations which have proven to be a great learning tool for the pathologists as well as the forensic experts. It is also important for assessing statistics of mortality which are essential for public health and health service planning.[6]

The current study was carried out with the purpose to establish the importance of autopsy, histological examination of viscera to find the cause of death, common cause of death and its use as a tool to study various rare lesions. Also, to report interesting cases which otherwise would have gone unnoticed.
Material and Methods

The present study is a prospective study conducted in Pathology Department, GMC, Patiala between year 2013 to 2020 on 800 autopsy viscera received from the forensic department of our institution and adjacent civil hospitals of many districts. The viscera was received in 10% formalin solution along with post-mortem papers containing the personal details of the deceased, post-mortem examination report and suspected cause of death. The tissue was processed after fixation, stained with haematoxylin-eosin stain and viewed under light microscope to outline cause of death. Special stains like PAS, Zeil Neilson were done as and where required for confirmation of the histopathological findings.

Results- Of the 800 studied cases, 30 were autolysed. Males were more common than females with a ratio of 5:1. Age distribution showed 21-40 years as the most common age group (45%). The youngest of the received viscera was from infants (3 cases) and the oldest was 100 years old. (Table 1)

System wise division showed, of the 800 cases studied, cardiovascular system (27%) was the most common system followed by renal (24%), hepatic system (11.5%), respiratory system (9.5%), spleen (8%), pancreas (6%), CNS (5%), uterus (4%) and products of conception (3%). (Table 2)

The most common (m.c) diagnosis was acute tubular necrosis (ATN) (44%) followed by fatty liver (17.6%), congestive liver (8%) and atherosclerosis (7.7%).

System wise comparison of different cases was done and common as well as incidental findings were noted.

Cardiovascular system: This is the most common system which was affected. Various spectrum of lesions observed were- atherosclerosis (7.7%), MI (1.8%) and cardiomegaly (1.4%). MI acts as a direct cause of death. Out of 25 cases of MI, 2 were acute infarcts leading to death and rest were old healed infarcts.

Renal system: This is the second most common system to be affected. The spectrum of lesions affecting kidneys were- ATN (44%), chronic pyelonephritis (0.5%) (Figure 1) and acute pyelonephritis (0.1%). Diagnosis of ATN is a histological diagnosis as grossly no abnormality is noted and it was also the m.c histological diagnosis and m.c incidental finding.

Liver: The various lesions noted in liver were- fatty liver (17.6%), congested liver (8%) and liver cirrhosis (3.3%). Fatty liver was the second m.c histological diagnosis made on visceral examination. Equal incidence was noted in both men and women.

Respiratory system: Spectrum of lesions noted in lung were- congestive lung (5.9%), pneumonia (1.8%), alveolar edema (1.4%), pulmonary TB (1.4%) and lung abscess (0.4%). Various other interesting as well as incidental findings noted were- miliary TB (0.2%), one case of metastatic deposits of sarcoma in lung, one case of extra-medullary deposits of blast phase of CML, one case of fungal infection of lung and one case of small cell carcinoma lung.

Central Nervous system: Brain was not a common specimen to be autopsied. The specimens that were received showed largely normal histology with occasional age related changes like gliosis seen in 0.2% cases. However, there were three cases of meningitis and one case of diffuse astrocytoma.

Spleen and Pancreas: One case of spread of miliary TB to spleen was noted. Pancreatitis was seen in two cases.

Miscellaneous: Products of conception were reported in 0.4% cases. These were received from females in the age group of 21-40 years. Autolysed viscera were received in 0.2% cases.

Cases with multiple diagnosis- Out of these, any one or their combined outcome could have been the cause of death (Table 3)

Rare and interesting Case diagnosis-

1) In one case, incidental finding of acute pyelonephritis was made. Gross showed areas of
suppuration involving the cortex along with areas of patchy necrosis. Microscopy showed collections of neutrophils in tubules with relative sparing of glomerulus. (Figure 2)

2) In a case of miliary TB, bilateral lung involvement and tubercular deposits were also noted in spleen and liver. This was an incidental finding as cause of death was unnatural. (Figure 3)

3) In another rare case, metastatic deposits of sarcoma was noted in lung. On gross lung presented with firm, grey-white coloured, irregular mass. On microscopy, highly pleomorphic spindle cells with bizarre tumor cells were seen. Diagnosis of sarcoma was made, which was an incidental finding. (Figure 4)

4) Fungal hyphae were detected in a case of lung, an incidental finding. (Figure 5)

4) In one case, small cell carcinoma of lung was diagnosed which presented as tan white coloured, firm small nodules in the hilar region. This was an additional finding to the unnatural cause of death in autopsy findings.

5) A case of extramedullary infiltration of CML, blast phase in lung was noted in another autopsy. On microscopic examination, there were seen collections of myeloid blasts and predominance of myeloid series of cells.

| Table 1: Age wise distribution of various cases |
|-----------------|--------|--------|
| Age group       | No of cases | % age  |
| <20 years       | 40     | 5%     |
| 21-40 years     | 360    | 45%    |
| 41-60 years     | 240    | 30%    |
| 61-80 years     | 112    | 14%    |
| >80 years       | 48     | 6%     |

| Table 2: Various histo-pathological diagnosis in order of frequency |
|-----------------|--------|--------|
| Diagnosis       | No of cases | % age  |
| Acute tubular necrosis | 603     | 44%    |
| Fatty liver     | 240    | 17.6%  |
| Liver venous congestion | 110    | 8%     |
| Atherosclerosis | 105    | 7.7%   |
| Venous congestion of lung | 81     | 5.9%   |
| Liver cirrhosis | 45     | 3.3%   |
| Pneumonia       | 25     | 1.8%   |
| Myocardial infarction (MI) | 25     | 1.8%   |
| Alveolar edema  | 20     | 1.4%   |

Discussion

Current study was conducted between the year 2013-2020 and 800 cases were studied in the Department of Pathology, GMC, Patiala for histo-pathological examination. The male: female ratio was 5:1. Similar observations were made in different studies. [2,6,7,8] Most common age group according to present study was 21-40 years. The results were similar to the studies published. [2,7,8]

The present study highlights the importance of microscopic examination in addition to autopsy not just for exact cause of death but also to study rare diseases. Similar findings were suggested by Selvam et al, Costache et al and Vougiouklakis et al. [7,9,10]

The most common overall incidental finding was ATN seen in 44% cases. The results were similar to studies. [6,11] And the second mc incidental finding was fatty liver. These results were similar to the studies published. [8,12]

Maximum cases were seen involving the cardiovascular system (27%) followed by renal system (24%). This was similar to studies published by Pathak et al, Jhajj et al, Vij et al and Reddy et al.[2,6,13,14] Atherosclerosis was m.c finding in cardiac autopsies. Other lesions detected were MI (1.8%) displaying fibrosis in old infarcts. The findings were in accordance with published studies. [15, 16]

Renal system was the second m.c system involved and ATN as the leading diagnosis, as already discussed above. Also it is the m.c cause of acute renal failure. [11,17] ATN can be either due to direct effect of toxin/chemical substance or due to ischemia. In current study, these were mostly seen in cases of poisoning and trauma leading to myoglobinuria and hemoglobinuria, which is directly nephrotoxic.

In the hepatic system, the m.c diagnosis was fatty liver followed by venous congestion and cirrhosis. These findings were similar to studies published by Algarsamy et al, Singal et al and Simon et al. [18,19, 20]
The m.c finding in lung was CVS lung, followed by pneumonia, pulmonary edema, pulmonary TB and lung abscess. This is in agreement to study published by Kaur et al. but in contrast to studies published by Arunlatha et al and Patel et al, showing pulmonary edema as the m.c finding followed by CVS lung. A case of fungal hyphae in lung was reported using PAS stain. In our study pulmonary TB was noted in 1.4% cases and miliary TB was noted in 0.2% cases. The results were similar to study published by Patel et al with low incidence seen in 3.4% cases, but in contrast to study published by Garg et al where incidence of pulmonary TB was high. Many cases of tuberculosis remain undiagnosed and are diagnosed only at autopsy, thus highlighting the importance of autopsy. In a study of 73 cases of sudden deaths, by Rastogi P, 61.64% were due to tuberculosis.

One case of extramedullary CML (blast phase) was seen in the lung. CML has been reported in extramedullary organs in only 10% of cases. In most reported cases extramedullary involvement was indicative of impending progression of CML into blast crisis. In patients with blast phase, extramedullary blast crisis has been reported in about 7-17% cases.

One rare case of lung sarcoma was seen (0.07%). Primary lung sarcomas are rare, less than 0.5% of lung malignancies. Cameron and Miller and Allen reported lung sarcomas in 0.15% and 0.3% of lung neoplasms in lung malignancies, respectively.

In CNS, 03 cases of meningitis, 01 case of diffuse astrocytoma and 03 cases of gliosis were reported. This is significant because normally we don’t receive biopsy for cases like meningitis, hence autopsy plays a role here.

**Conclusion**

The study stresses on the need of histopathological autopsy in not just highlighting the cause of death but also studying many rare disorders. It thus enriches the field of medicine and pathology by not just studying the histological findings but also sometimes the course of rare diseases.

Incidental Neoplastic Tumours on Histo Pathology of Medico Legal Post Mortem Cases: A Ten Year Study

Mohanvir Kaur¹, Kanwardeep Kaur Tiwana², Lachhima Bhandara³, Shaina Goyal³, Shiv Kumar³, Monika Kalyan³

¹Associate Professor, ²Assistant Professor, ³Junior Resident Department of Pathology, GMC Patiala

Abstract

Background: Autopsy has been an important tool for detection of many rare lesions as well as studying the course of such lesions, highlighting the cause of death and also helps in indirect collection of data for mortality and forming health policies. Aim of present study was to detect the rate and type various neoplasms which were either clinically undiagnosed or not the direct cause of death and their system wise analysis.

Material and Methods: This is a retrospective study conducted on viscera Received between year 2011-20 on 810 medico legal autopsy cases coming to Department of Pathology for histopathological examination.

Result: Out of 810 cases, 09 tumours were diagnosed (1.1%). In 6 cases, it was completely incidental finding while in 03 cases history of malignancy was present. Tumours were mostly seen in older age group (>50 years).

Conclusion: The study concludes the importance of histopathologic study in autopsies in detection of clinically undiagnosed neoplasms and evaluating the cause of death. Thus, autopsies also indirectly aid to the true cancer incidence statistics.

Keyword: Autopsy, Neoplasms, Histopathology, Statistics.

Introduction

An autopsy is a highly specialised procedure that consists of a thorough examination of a dead-body to determine the cause, time and manner of death. It also helps to evaluate any disease or injury that may be present as an additional finding.[¹] It aids to the knowledge of pathologists, clinicians and forensic experts by incidental discovery of various lesions that otherwise would have gone un-noticed. The medico legal autopsy gives an opportunity to study medically diagnosed and treated neoplasms as well as natural evolution of untreated diseases.[²] It also aids in diagnosing various undiagnosed or misdiagnosed malignant tumours irrespective of the underlying cause of death, which may or may not be related to malignancy.[³] Thus, autopsy also helps in maintaining the mortality registers as well as collect data for cancer registry programmes.

The current study was conducted with an aim to diagnose various neoplasms, their type, rate and system wise distribution in the autopsies sent for other purposes. These neoplasms were either an incidental finding or already diagnosed and treated for the same with recurrence. This study also aims to establish the importance of histo-pathological autopsy.

Material and Method

This was a retrospective study conducted on 810
autopsy cases received in Department of Pathology between year 2011-20. The viscera were received in 10% formalin along with post-mortem report, personal details of deceased and suspected cause of death. multiple viscera were received in majority of cases. Grossing and processing of organs was done as per standard protocols and H&E staining was done with special stains wherever required.

**Results**

Out of 810 autopsy cases, 09 cases (1.1%) of tumour were diagnosed histologically. 08 cases were malignant and 01 case of benign neoplasm was diagnosed. Mostly the tumours were seen in older age group i.e > 50 years and the youngest age with tumour was 30 years. Males were more commonly affected than females with M:F ratio of 2:3. (Table 1)

Most commonly metastatic deposits were diagnosed rather than primary tumour of affected organs (4 cases-metastatic deposits of adenocarcinoma in lung, deposits of sarcoma in lung, infiltration by blast phase of CML in lung and deposits of adenocarcinoma prostate in liver). In one case, recurrence of tumour was seen in already diagnosed and treated case of Anaplastic Astrocytoma brain. (Table 2)

Most commonly affected organ was lungs; where total of 4 cases were diagnosed (0.49%). Second most common (m.c) affected organ was brain; 3 cases were detected (0.37%) followed by liver and kidney with one case each (0.12%).

Lung: It was the m.c system involved by malignancy. Total 4 cases of malignancy were noted in lung. Primary malignancy was small cell carcinoma seen in 64 yr male who was chronic smoker. Gross showed small tan white coloured firm, nodules in hilar region of lung. Two cases of metastatic deposits were noted-one squamous cell carcinoma (Figure 1) in 66 yr male and in second case deposits of Malignant Mesenchymal Tumour (Figure 2) were seen in 58 year female. In both cases, primary malignancy was unknown and deposits in lung were incidental finding on autopsy, with unknown primary. In another case, in 70 yr male, who was already a known case of CML. Extra-medullary infiltration of lung with blast phase of CML was an incidental finding. Microscopic examination revealed sheets of myeloid blasts.

Figure 1 Sections from lung shows Squamous cell carcinoma lung (H&E x400)

Figure 2 Sections from lung shows Malignant Mesenchymal Tumour (H&E X100)
**Brain:** It was next m.c system involved after lung. 3 cases of primary malignancy were detected in brain. Out of which 2 were malignant and 1 was benign. These were mostly seen in middle aged population. In one case, patient was already a known and treated case of Anaplastic Astrocytoma (Figure 3); had presented with recurrence which was an incidental finding as the cause of death was asphyxia. Diffuse Astrocytoma was detected incidentally in 30 yr male who died in road traffic accident. Gross examination showed a small, ill defined mass in frontal lobe of brain. One case of benign meningioma i.e angiomatous meningioma (Figure 4) was seen in 36 yr female who died by suicide. Gross showed a well defined, round mass attached to duramater. This mass was readily separable from durameter and not invading it.

![Figure 3 Sections from brain shows Anaplastic Astrocytoma (H& E X 100)](image)

![Figure 4 Sections show Angiomatous Meningioma (H& E x400)](image)
Liver: Only one case of metastatic deposits of adenocarcinoma in liver with known primary malignancy in prostate was seen in a 70 yr male. The metastatic deposits were an incidental finding during histo-pathological autopsy. Gross showed multiple grey-white coloured nodules of variable sizes on liver parenchyma.

Kidney: Single case of RCC was seen in 59 yr female. It was an incidental finding on grossing as a small, circumscribed growth less than 1 cm was seen on upper pole of kidney and microscopy showed clear cell features. Hence, a diagnosis of clear cell renal cell carcinoma was made (Figure 5)

![Figure 5 Sections examined from kidney exhibiting Clear cell carcinoma](image)

Discussion

Current study was conducted on 810 autopsy cases over a period of 10 years to know the cause of death in a person and establish relation between autopsy findings and actual cause of death.

The total incidence of neoplasia was 1.1% (9/810 cases). The findings are close to studies by Patel et al and Sinhasan et al showing 2.47% and 4% incidence, respectively.[4,5] But the incidence was quiet high in studies published by Burton et al and Karwinski et al with 9% and 11%, respectively. [6,7]

Lung was the m.c system with malignancy in present study (0.49%). This is close to study by Sinhasan et al with a detection rate of 0.5%, but in contrast to Manser et al where detection rate is as high as 28%. [5,8] This discrepancy could be due to large number of cases included in the study.

One case of extra-medullary CML (blast phase) was seen in lung, which is again a rare presentation. The patient was already a known case of CML and had progressed into blast phase. CML has been reported in extra-medullary organs in only 10% of cases by Inverardi et al and between 4 to 16% by Gao et al. [9,10]

A case of metastatic deposits of sarcoma in lung was seen (0.12%). This was again an incidental finding on autopsy. Primary lung sarcomas are rare, less than 0.5% of lung malignancies. [11] While isolate pulmonary metastases occurs in 20% and 40% cases diagnosed with soft tissue sarcoma and primary bone sarcoma, respectively.[12]

In CNS, three tumours were detected which is 0.37% of the total cases. Out of these anaplastic astrocytoma is grade 3 tumour and fatal if not treated earlier. According to study published by Bogdanovic et al, undiagnosed brain tumours caused sudden death in 3.9% cases. The autopsy showed both benign and malignant tumours including meningioma, anaplastic astrocytoma which are included in present study. [13]

RCC was detected in 1 case (0.12%) incidentally as it was a small mass. However, it could have been detected with radiological tools in life of patient, later on. The findings are similar to Shah et al and Patel et al with detection rate of less than 1% and 1.98%, respectively. [14,15] However, there are studies where detection rate is as high as 26%. [16]

In liver, metastatic deposits from prostatic cancer were detected. According to study published by Wang et al, showed metastasis rate to liver from prostate was 4.29% and the mean survival was 38 months. [17] This shows, it is an uncommon finding with poor survival. Hence, autopsy has a role in detection of rare lesions.

Conclusion

The study stresses on the importance of autopsy in detection of many rare and important findings that would have a direct impact on life of the patient if alive. It also highlights the importance of histopathological study in autopsies in detection of clinically undiagnosed neoplasms and evaluating the cause of death. Thus, autopsies also indirectly aid to the true cancer incidence statistics

Abstract

Background: Human beings are unique in number of physical characteristics like shape and form of an individual. These characteristics are influenced by a wide range of racial, ecological, psychological, geographical, gender and biological variations. Human external ear is often overlooked during anthropometric measurements. The structure of human ear is so much variable that even two ears are different in same individual and it also varies according to age, sex, race and ethnic group. Authentic anthropometric data of ear for a particular population is necessary for designing of ear products for occupational environments, to find out the age, sex and stature of an individual in that population. This data on ear measurements can also be helpful in forensic and medico-legal cases for personal identification of an individual. The main objective of the study is to find any relationship between ear parameters and stature and also to formulate regression equation for estimation of stature in Haryanvi adult Jaats.

Methods: The present study was conducted on 300 healthy Haryanvi Jaats (150 females and 150 males) aged 20 to 60 years. Measurements of ear length, ear breadth and stature were taken on each subject.

Conclusion: Ear length and ear breadth are not significantly correlated with stature (p>0.05) in both the sexes except ear breadth which is significantly correlated with stature in males (p<0.05).

The present study concluded that stature cannot be estimated from ear length and ear breadth in Haryanvi population.

Key words: Anthropometry, Measurements, Parameters, Stature.

Introduction

Human beings are unique in number of physical characteristics like shape and form of an individual. These characteristics are influenced by a wide range of racial, ecological, psychological, geographical, gender and biological variations. Human external ear is often overlooked during anthropometric measurements.

Anthropometric landmarks are described to measure the dimensions of external ear¹. People often feel embarrassed and depressed who have abnormal structure of ears that may be due to accidental or natural. To rectify the auricular defects like missing parts or inappropriate size, surgery is needed. For that, the data regarding bilateral position on face and normal auricular dimension in different ethnic groups is required. The structure of human ear is so much variable that even two ears are different in same individual and it also varies according to age, sex, race and ethnic group². Authentic anthropometric data of ear for a particular population is necessary for designing of ear products for occupational environments, to find out the age, sex...
and stature of an individual in that population. This data on ear measurements can also be helpful in forensic and medico-legal cases for personal identification of an individual. Stature prediction is required in people whose height cannot be measured due to neuromuscular disorders, lower limb or spinal deformity. For them it can be measured through anthropometry. For estimation of stature various body dimensions like arm span, hand and foot length and different cranio-facial parameters are used because they exist a definite biological relationship with stature. Agnihotri et al did not find any significant relationship between stature and ear parameters but Laxman K and Abdelaleem & Abdelbaky etc reported a significant relationship. Very few studies are there to estimate the stature from ear parameters. so, the present study attempted to find any relationship between ear parameters and to formulate regression equation for estimation of stature.

Material and Method

The present study was a community based anthropometric study conducted on 300 healthy Haryanvi Jaats (150 females and 150 males) of age group 20 to 60 years. Purposive sampling method was used to collect the samples. The purpose of the study was explained and consent from all the subjects were taken.

Along with stature, ear length and ear breadth were measured from healthy Haryanvi jaats without any craniofacial deformity by anthropometric rod and sliding caliper. The measurements were taken according to the landmarks and procedure recommended by Nath S and Krishan & Kumar. The taken anthropometric measurements are described as:

1. **Stature (S):** It is the vertical distance between the plane (where the subject stands barefooted) and the highest point on the vertex on the head. For measurement of stature, the subject was asked to stand straight upright on horizontal surface with arms hanging at sides and shoulders relaxed. The subject’s head was kept in Frankfurt Horizontal Plane and shoulder blades, buttocks and heels touching the measurement surface.

2. **Ear length (EL):** The straight distance between the superaurale (sa) and subaurale (sba).

3. **Ear breadth (EB):** The straight distance between the two most lateral points of the ear. One lies at the base of the ear and other lies at the helix.

Statistical analysis like mean, standard deviation using Z-test, Karl Pearson’s correlation coefficient and derivation of regression equation using Statistical Package for Social Sciences (SPSS) was done.

**Results and Discussion**

Table 1 shows the descriptive statistics i.e mean, standard deviations, minimum and maximum values for ear length, ear breadth and stature measurements in adult Haryanvi males and females respectively. All the parameters are higher in males than females.

In the present study, ear length and ear breadth are not significantly correlated with stature (p>0.05) in both the sexes except ear breadth which is significantly correlated with stature in males (p<0.05). Agnihotri et al\(^6\) also finds that ear breadth is not significantly correlated with stature in Indo-Mauritius population but ear length is found to be significant. The other studies done by Laxman K\(^7\), Abdelaleem & Abdelbaky\(^8\), Ekemini & Ekanem\(^11\) and Taura MG et al\(^12\) shows that there is significant correlation between the stature and ear parameters of different population (p<0.05).

**Conclusion**

The present study concluded that stature cannot be estimated from ear length and ear breadth in Haryanvi population as these parameters are not significantly correlated with stature (p>0.05). Further it is believed that large sample size should be examined to validate the findings of this study and to make a definite conclusion.

Facial Anthropometry: A Reliable Tool for Stature Estimation in Haryanvi Population

Monika Rathee¹, Jaswinder Kaur², Suresh Kanta Rathee³

¹Demonstrator, Department of Anatomy, Pt. B. D. Sharma PGIMS, Rohtak, ²Professor, Department of Anatomy, MMIMSR, Mullana, Ambala, ³Sr. Prof. & Head, Department of Anatomy, Pt. B. D. Sharma PGIMS, Rohtak

Abstract

Background: Facial anthropometry is a part of cephalometry that involves the measurements of face. It is very helpful in reconstructive surgery, forensic medicine, orthodontics and to find ethnic differences by defining various shapes of face. Facial features of every individual are different even in siblings. These features vary according to gender, racial and biological group, ecological and geographical region. Anthropometry can also be used for estimation of stature, where it cannot be measured directly such as spinal or lower limb deformity or any other neuromuscular disorder. So, the present study attempted to find that is the facial parameters are reliable in estimation of stature in Haryanvi jaat population and also aims formulate regression equation for estimation of stature in the same.

Methods: A sample of total 300 adult Haryanvi jaatsof age group 20 to 60 years was taken for the present study. Out of them 150 were females and 150 weremales. Anthropometric measurements of face and stature were taken on each subject.

Conclusion: All the studied facial parameters showed positive significant correlation with stature (p<0.01) both in males and females So, it can be concluded that facial anthropometry is a reliable tool for stature estimation in Haryanvi population.

Key words: Anthropometry, Facial, Haryanvi, Identification, Stature.

Introduction

Identification of every human being is unique. This identification can be done by various methods like physical examination, fingerprinting, DNA printing and anthropometry etc. Facial anthropometry is a part of cephalometry that involves the measurements of face. It is very helpful in reconstructive surgery, forensic medicine, orthodontics and to find ethnic differences by defining various shapes of face¹. Males comprises large stature, more prominent cranial and facial features, greater muscularity and strength as compared with females. These differences are not visible in infants, children and sub adults but are noticeable in adult stage due to the effect of hormonal changes occurring at puberty. These features vary according to gender, racial and biological group, ecological and geographical region². Anthropometry can also be used for estimation of stature, where it cannot be measured directly such as spinal or lower limb deformity or any other neuromuscular disorder³. Its the most applied, non-invasive and inexpensive method of measurement to assess the size, proportions of the human body.⁴ Stature can also provide circumstantial and presumptive identification of individual. It is a good indicator of growth and development and may be used in clinical settings for health and nutrition research.In the past,

estimation of stature from various body parts like bones, fingerprints, skulls, upper and lower limbs, hand and foot has been achieved by many researchers with varying degree of accuracy. Many studies showed that there presents a definite biological relationship between stature and facial parameters\(^5\). So, the present study attempted to find the reliability of facial parameters in estimation of stature in Haryanvi jaat population and also aims to formulate regression equation for estimation of stature in the same.

**Material and Method**

A sample of total 300 adult Haryanvi jaats of age group 20 to 60 years was taken for the present study. Out of them 150 were females and 150 were males. Written consent was taken from every subject. Measurements of stature, Bigonial diameter, morphological facial length and physiognomic facial length were taken on each subject according to the landmarks and procedure recommended by Nath S\(^6\) and Krishan & Kumar\(^7\).

Type of Study: Community based Anthropometric study

Sampling Method: Purposive sampling method

Instruments Used: Anthropometric rod, Spreading caliper and Sliding caliper.

The taken anthropometric measurements are described as: -

1. **Stature (S):** It is the vertical distance between the horizontal surface (where the subject stands straight upright and barefooted) and the highest point on the vertex on the head. The subject’s head was kept in Frankfurt Horizontal Plane.
2. **Bigonial diameter (BD):** It is the maximum breadth of the lower jaw between two gonion points on the angle of mandible.
3. **Morphological facial length (MFL):** It is the straight distance between nasion and gnathion.
4. **Physiognomic facial length (PFL):** It measures the straight distance between trichion and gnathion.

Statistics Done: Mean, standard deviation, Karl Pearson’s correlation coefficient and derivation of regression equation using Statistical Package for Social Sciences (SPSS).

**Results and Discussion**

*Insignificant

Table 5 showing p- values of facial parameters of present study and previous studies. It is evident that the facial parameters i.e. bigonial diameter, morphological facial length and physiognomic facial length showed positive significant correlation with stature in present study and in previous studies. Except the morphological facial length of Gujarati population studied by Shah et al9 which is insignificant. So, these parameters can be used for estimation of stature in Haryanvi jaat population effectively.

Conclusion

All the studied facial parameters showed positive significant correlation with stature (p<0.01) both in males and females So, it can be concluded that facial anthropometry is a reliable tool for stature estimation in Haryanvi population.

Abstract

Background: Human beings are unique in number of physical characteristics like shape and form of an individual. These characteristics are influenced by a wide range of racial, ecological, psychological, geographical, gender and biological variations. Human external ear is often overlooked during anthropometric measurements. The structure of human ear is so much variable that even two ears are different in same individual and it also varies according to age, sex, race and ethnic group. Authentic anthropometric data of ear for a particular population is necessary for designing of ear products for occupational environments, to find out the age, sex and stature of an individual in that population. This data on ear measurements can also be helpful in forensic and medico-legal cases for personal identification of an individual. The main objective of the study is to find any relationship between ear parameters and stature and also to formulate regression equation for estimation of stature in Haryanvi adult Jaats.

Methods: The present study was conducted on 300 healthy Haryanvi Jaats (150 females and 150 males) aged 20 to 60 years. Measurements of ear length, ear breadth and stature were taken on each subject.

Conclusion: Ear length and ear breadth are not significantly correlated with stature (p>0.05) in both the sexes except ear breadth which is significantly correlated with stature in males (p<0.05).

The present study concluded that stature cannot be estimated from ear length and ear breadth in Haryanvi population.

Key words: Anthropometry, Measurements, Parameters, Stature.

Introduction

Human beings are unique in number of physical characteristics like shape and form of an individual. These characteristics are influenced by a wide range of racial, ecological, psychological, geographical, gender and biological variations. Human external ear is often overlooked during anthropometric measurements. Anthropometric landmarks are described to measure the dimensions of external ear¹. People often feel embarrassed and depressed who have abnormal structure of ears that may be due to accidental or natural. To rectify the auricular defects like missing parts or inappropriate size, surgery is needed. For that, the data regarding bilateral position on face and normal auricular dimension in different ethnic groups is required. The structure of human ear is so much variable that even two ears are different in same individual and it also varies according to age, sex, race and ethnic group². Authentic anthropometric data of ear for a particular...
population is necessary for designing of ear products for occupational environments, to find out the age, sex and stature of an individual in that population. This data on ear measurements can also be helpful in forensic and medico-legal cases for personal identification of an individual. Stature prediction is required in people whose height cannot be measured due to neuromuscular disorders, lower limb or spinal deformity. For them it can be measured through anthropometry. For estimation of stature various body dimensions like arm span, hand and foot length and different cranio-facial parameters are used because they exist a definite biological relationship with stature. Agnihotri et al. did not find any significant relationship between stature and ear parameters but Laxman and Abdelaleem & Abdelbaky etc reported a significant relationship. Very few studies are there to estimate the stature from ear parameters. so, the present study attempted to find any relationship between ear parameters and to formulate regression equation for estimation of stature.

**Material and Method**

The present study was a community based anthropometric study conducted on 300 healthy Haryanvi Jaats (150 females and 150 males) of age group 20 to 60 years. Purposive sampling method was used to collect the samples. The purpose of the study was explained and consent from all the subjects were taken.

Along with stature, ear length and ear breadth were measured from healthy Haryanvi jaats without any craniofacial deformity by anthropometric rod and sliding caliper. The measurements were taken according to the landmarks and procedure recommended by Nath S and Krishan & Kumar. The taken anthropometric measurements are described as:

5. **Stature (S):** It is the vertical distance between the plane (where the subject stands barefooted) and the highest point on the vertex on the head. For measurement of stature, the subject was asked to stand straight upright on horizontal surface with arms hanging at sides and shoulders relaxed. The subject’s head was kept in Frankfurt Horizontal Plane and shoulder blades, buttocks and heels touching the measurement surface.

6. **Ear length (EL):** The straight distance between the superaurale (sa) and subaurale (sba).

7. **Ear breadth (EB):** The straight distance between the two most lateral points of the ear. One lies at the base of the ear and other lies at the helix.

Statistical analysis like mean, standard deviation using Z-test, Karl Pearson’s correlation coefficient and derivation of regression equation using Statistical Package for Social Sciences (SPSS) was done.

**Results and Discussion**

Table 1 shows the descriptive statistics i.e mean, standard deviations, minimum and maximum values for ear length, ear breadth and stature measurements in adult Haryanvi males and females respectively. All the parameters are higher in males than females.

<td>5.69</td>
</tr>
</tbody>
</table>

In the present study, ear length and ear breadth are not significantly correlated with stature (p>0.05) in both the sexes except ear breadth which is significantly correlated with stature in males (p<0.05). Agnihotri et al6 also finds that ear breadth is not significantly correlated with stature in Indo-Mauritius population but ear length is found to be significant. The other studies done by Laxman K7, Abdelaleem & Abdelbaky8, Ekemini & Ekanem11 and Taura MG et al12 shows that there is significant correlation between the stature and ear parameters of different population (p<0.05).

Conclusion
The present study concluded that stature cannot be estimated from ear length and ear breadth in Haryanvi population as these parameters are not significantly correlated with stature (p>0.05). Further it is believed that large sample size should be examined to validate the findings of this study and to make a definite conclusion.

Abstract

This study aimed to prove that giving hCG injection at the time of artificial insemination and five days after artificial insemination in dairy cows with repeat breeder can cause pregnancy. This study employed 30 dairy cows with repeat breeder. All samples of dairy cows were divided into two treatments, P1 using hCG at a dose of 100 IU given intramuscularly at the time of artificial insemination and P2 using hCG at a dose of 100 IU intramuscularly given five days after artificial insemination. The results were analyzed using the Chi-Square test. Analysis using Chi-Square showed that all treatments caused pregnancy (100%). In summary, hCG injection at the time of artificial insemination and five days after artificial insemination in dairy cows experiencing repeat breeding can cause pregnancy.

Keywords: Artificial Insemination, Dairy Cows, hCG, Pregnancy, Repeat Breeder

Introduction

Most of the dairy cows kept in Indonesia are FH cows, the production of FH cow milk can be increased, among others, by increasing reproductive efficiency¹,²,³. Reproductive efficiency is very important for raising dairy cows. Reproductive efficiency is also a parameter that shows the ability of livestock to become pregnant and produce offspring⁴.

Low reproductive efficiency in dairy cows indicates reproductive problems, one of which is repeat breeder with cases of ovulation failure on day 21 and cases of implantation failure on day 28. Cows that experience repeat breeders are generally characterized by long calving intervals (18-24 months), low conception rates (<40%), and high service per conception (>3)⁵,⁶,⁷.

Repeat breeder is the occurrence of female cows that are mated more than 2 times and do not experience pregnancy with an average age of 3-7 years who have given birth with the cow healthy, sexually mature, normal lust cycle and not experiencing pregnancy⁸. The factors that cause repeat breeders are fertilization failure and early embryo death⁹. KUD Tani Wilis is one of the largest KUDs in Indonesia with good management in managing the business/main unit of dairy cows. In 2018, there was the latest data from the Reproductive Engineering Assistant (ATR) in the KUD Tani Wilis, the number of repeat breeder cases was 20%, a decrease of 10% from the previous year, which means that there were 1,385 cows that experienced repeat breeders or around 115 cows per month. The high number of repeat breeders that occurs in the KUD Tani Wilis area can cause losses to breeders. Therefore, in this study continued the handling of these reproductive disorders, namely repeat breeders with cases of ovulation failure on day 21 and cases of implantation failure on day 28, by administrating the hormone human chorionic gonadotropin (hCG) at IB and five days after AI, to treat ovulation failure. on day 21 and failure of implantation on day 28 in order...
to cause pregnancy events in the KUD Tani Wilis area, Tulungagung, East Java, Indonesia.

Method

Materials

This study used a sample of 30 female Friesian Holstein (FH) dairy cows with an average age of 3-7 years who have had children. The cows are healthy, sexually mature, normal short and long lust cycles, do not experience pregnancy, 15 cows as treatment during artificial insemination with cases of ovulation failure on day 21 and 15 as treatment five days after artificial insemination with cases of implantation failure on day 28. Treatment using the hCG hormone which is injected intramuscularly at a dose of 100 IU 1 mL/head/im.

Selection of FH Cows

Selection of cows in lust, reproducing actively and not experiencing pregnancy. Cows in the 2nd AI (repeat breeder) who still show symptoms in the normal heat cycle with cases of ovulation failure on day 21 and cases of implantation failure on day 28.

Artificial Insemination (AI)

Artificial insemination is carried out on cows that have repeated heat breeder using a straw owned by the inseminator, namely the Friesian Holstein cow. Insemination is carried out once after a dairy cow is in heat.

Treatment

Cows that experience repeat breeder will be given hCG hormone at a dose of 100 IU 1 mL/head/im to cows that have repeat breeders. The cows will be divided into two groups P1 and P2, each group consisting of 15 FH cows. Group P1 was injected with 100 IU hCG 1 mL/head/im at the time of artificial insemination with cases of ovulation failure on day 21 and group P2 was injected with 100 IU hCG 1 mL/head/im at five days after artificial insemination with cases of failure of implantation on day 28.

Pregnancy Examination

Pregnancy examinations are carried out by inseminator officers who have PKB certificates and veterinarians on duty at KUD Tani Wilis, Tulungagung, East Java, Indonesia. PKB will be carried out 90 days after IB, the goal is that the enlarged uterine cornua containing placental fluid is palpable and prevents miscarriage.

Data Analysis

The data obtained were tabulated, to analyze the incidence of pregnancy the Chi-Square test was presented.

Results and Discussion

This study was conducted to determine the success of giving the hCG hormone during artificial insemination and five days after artificial insemination given to FH dairy cows with repeat breeder with cases of ovulation failure on day 21 and cases of implantation failure on day 28 at KUD Tani Wilis, Kabupaten Tulungagung. The samples were divided into 2 types of treatment, namely 15 FH dairy cows that were treated with the hCG hormone injection during artificial insemination and 15 FH dairy cows which were given the hCG hormone injection treatment five days after artificial insemination.

The incidence of pregnancy in FH dairy cows that experienced repeat breeder cases and were injected with the hCG hormone at the time after artificial insemination and five days after artificial insemination by rectal palpation method examination can be shown in Table 1 below.

<p>| Table 1. Percentage of Pregnancy in Friesian Holstein (FH) Dairy Cows with Repeat Breeder that has been Injected with the hCG Hormone. |

</tbody>
</table>

Note:
P1: Administration of the hCG hormone when IB 100 IU 1mL/head/im.

P2: Administration of the hCG hormone for five days after IB 100 IU 1 mL/head/im.

The results of the test using the Chi-Square 2x2 show that the Chi-Square test cannot be done because pregnancy is constant. This is because the first treatment and the second treatment showed a rate of 100% at the time of pregnancy examination. From these results, it shows that the hCG hormone can increase the incidence of pregnancy in dairy cows that experience repeat breeders.

![Figure 1. Pregnancy diagram of FH Dairy Cows experiencing repeat breeders who have been injected with the hCG hormone.](image)

In the 21st day case, Fertilization failure is the main factor causing repeat breeder. Fertilization failure factors include anatomical abnormalities of the reproductive tract, ovulation abnormalities, abnormal sperm, abnormal egg cells and reproductive mismanagement including factors that can cause fertilization failure\(^{10,11}\). Ovulation abnormalities can be caused by ovulation failure due to hormonal disorders where there is a lack or failure of the release of the LH hormone\(^{12}\). In the case of repeat breeders, failure to ovulate on day 21 often occurs in the dry season with a delay in ovulation time due to the influence of heat and weather. The administration of the hCG hormone during IB aims to meet the needs of the LH hormone in ovulation disorders and ensure the ovulation process so that there is no repeat breeder in cases of ovulation failure and also the hCG hormone given in cases of delayed ovulation in order to induce ovulation at the right time so that pregnancy occurs.

In the case of day 28, embryo mortality indicates the death of a fertile embryo until the end of implantation, which is 40 days, factors from premature embryo death include lactation which can be related to ineffective defense mechanisms of the uterus, stress during lactation and imperfect endometrial regeneration Environmental factors can also result in the mother when her body temperature increases, the factor imbalance of the hormones estrogen and progesterone can also cause premature embryo death\(^{13}\). The occurrence of early embryonic death is marked by an extension of the cycle
of lust after the last IB. The adverse effects of lactation on embryo development are thought to be related to hormonal imbalances during lactation, particularly the hormone progesterone on embryo life in the uterus. High milk production can cause the embryo in the uterus to not get enough food for its development, besides that the involution process of the uterus that is not yet complete after giving birth is also one of the causes of embryo death during lactation, the uterine wall during the implantation process so that it is easy to die of the embryo. In repeat breeder cases with failed implantation on day 28, the most cases occurred because of mild infections or subclinical endometritis which made the uterine temperature uncomfortable, therefore hCG hormone was given to keep the growth of the corpus luteum growing and accelerate the growth of the corpus luteum to produce progesterone, the hormone progesterone functions to maintain pregnancy and prevents contractions in the uterus and the fetus does not abort. The administration of the hCG hormone at five days after IB aims to increase the level of hCG in the blood. On days 5 to 9 after insemination, the concentration of interferon-τ was increased. Interferon-τ causes the endometrium to suppress PGF2α so that the corpus luteum is not regressed.

Both P1 and P2 treatments are 100% pregnant, this can be caused by several factors such as the right time of insemination, good farmer knowledge of the incidence of lust, good feed management and good cage hygiene management. Understanding livestock management and optimal breeding techniques, including fulfilling the nutritional needs of sterile labor, can maintain fertility. Pregnancy rate can be influenced by the quality and handling of semen, female fertility, time of mating, detection of estrus, and insemination techniques. The increase in the incidence of pregnancy obtained is influenced by the increase in the concentration of progesterone. The reduced concentration of progesterone in the blood can affect embryo development.

**Conclusion**

Based on the results obtained, the administration of the hCG hormone during artificial insemination and five days after AI in FH dairy cows that experienced repeat breeder short normal heat cycles (21 days) and long normal heat cycles (28 days) caused pregnancy.

The Impact of the COVID-19 Pandemic on Stopping and Completing the Period of Appeal Against Judicial Rulings in Accordance with Jordanian law

Muhaned Farhan Al Taani

Assistant Professor/ Faculty of Law- Applied Science Private University – Jordan

Abstract

This study attempts to shed light on the applicability of the Jordanian Civil Trials Law No. 24 of 1988 and its amendments in light of the COVID-19 pandemic and the prevention of litigants’ access to the courts because it is an official holiday on the grounds constituting it to be a force majeure or an emergency circumstance which is considered an unexpected event. The law did not explicitly stipulate a cessation of appeal against judgments. When this impediment is present, the appellant can complete the appeal period when this impediment ceases to exist. The completion of the prescribed periods becomes in effect, while Defense Order No. 5 bridged the gap in the provisions of the Civil Trials Law in light of the country’s passage through the COVID-19 pandemic, which came suddenly being an unexpected event. The legislator was unable to address the issue of stopping and completing the appeal period against the ruling issued for its appeal within the legal period stipulated in the law. Besides, this study includes the opinions of jurists in the Civil Trials Law.

This study indicated that the event of force majeure or an emergency situation (COVID-19 pandemic) with the activation of Defense Law No. 13 of 1992 as it is pointing that completing the period of appeal with judicial rulings and the necessity of its application during the existence of the COVID-19 pandemic with the need to amend the Jordanian legislature for the legal loophole in this regard.

Keywords: COVID-19 pandemic, the period of appeal, judicial rulings, Jordanian law, Defense Law No. 13 of 1992.

Introduction

COVID-19 was first discovered on December 31, 2019, after a group of people were reported to have contracted viral pneumonia in Wuhan, the People’s Republic of China. The virus can be transmitted from one person to another, usually by close contact with the infected person, as it occurs in the context of family, work, etc1,2. Due to the spread of COVID-19 all over the world, the Jordanian Cabinet decided to announce the implementation of Defense Law No. 13 of 1992 throughout the Hashemite Kingdom of Jordan as of 3/17/2020 and under the text of Article (3) of the Defense Law, the Jordanian Prime Minister is entitled to take necessary procedures and measures to secure public safety, where the prime minister exercises his powers under written orders, including placing restrictions on the freedom of people to meet and move.

Defense Order No. (5) was issued to impose a comprehensive general ban from the period 3/18/2020 until 05/31/2020, preventing the exit of citizens, closing all court work and considering it an official holiday, stopping the periods for submitting appeals against judicial rulings issued by civil courts and moving them until after the official holiday ends and to complete it so that it becomes effective again after the end of the official holiday. As the Prime Minister issued a communiqué No. (6) issued in accordance with the provisions of Defense Order No. (5) of 2020 and stipulates that the courts, institutions, and official departments shall start their work as of May 31, 2020.
The appellant is the one who submits a list of appeals against the judgment issued by the court of the first instance to the Court of Appeal, as the Jordanian Civil Trials Law stipulated in Article (180) in Chapter 10 (Methods for Appealing Judgments) from the following: issuing the appealed judgment to be filed with the case documents after making notifications to the appealed court.

The date for submitting an appeal list to appeal the judgment issued by the court of the first instance with the judgments in front of the court starts from the day following the date of its issuance, and in the judgments issued as notable from the day following the date of its notification, unless the law stipulates otherwise Article (171) so that the appeal list is not accepted if it is not registered during the period legal time. This rule of public order enables the appellant or the court to raise what is related to the date of submitting the appeal after the prescribed legal period has passed. This legal text applies to all appeal dates for civil judicial decisions, meaning, in other words, the loss of the right to appeal a penalty that results from the failure of the opponent to appeal the judgment on the date specified in the law.

The dates for appealing judicial decisions are considered one of the procedural dates. Part of the Egyptian jurisprudence opinions refers to the term of the procedural data in the Civil Trials Law, which relates only to the period between two times, the moment of beginning and the moment of completion (Nabil, 2004). The problem exists here: is it possible to stop and complete the appeals period against the judgment issued by the court of the first instance during the legal period in light of the existence of the COVID-19 pandemic on the grounds that it is (force majeure or an emergency circumstance) based on Defense Order No. (5) or is the legal texts contained in the law sufficient, the origins of civil trials.

Electronic Trial in Jordan

The extent of modern technology in the criminal justice system in Jordan has escalated during the time of COVID-19. The use of modern technology in criminal justice in Jordan has been issued in accordance with Article 158 paragraph two of the Jordanian Code of Criminal Procedures. During the coronavirus (Covid-19) pandemic where quarantine, lockdown and self-isolation have become the new norm. To continuously guard and provide an unprejudiced administration of justice during this pandemic, it is legitimate to utilize the means of modern technology to facilitate remote court appearances in line with the criminal justice system.

Public Hearing During COVID-19

The Jordanian Constitution clearly states that courts’ sessions are public unless the court decides to conduct them in secret in order to preserve public order or morals. However, in all cases, the pronouncement of judgment is made in a public session. In the same vein, the Jordanian Code of Criminal Procedures addresses the principle of public hearing when it asserts that the trial is conducted publicly unless the court decides to conduct it in secret, in order to preserve public order or morals. However, in all cases, juveniles or a certain group of people can be prevented from attending the trial. In light of those as mentioned above, it can be noticed that the principle of public hearing has been dealt with in both the Jordanian Constitution and the Jordanian Code of Criminal Procedures. Therefore, such principle should be followed in all trials unless otherwise provided. Additionally, both legislations affirm that courts sessions and trials should be conducted publicly unless they contradict with public order or morals.

In light of the above, it can be argued that the technology of videoconferencing – as one of the means of modern technology - satisfies the requirements of the principle of public hearing as the hearing will be screened. Hence, the public can still follow the proceedings if they are allowed into the courtroom.

Results and Discussions

The law specifies dates for procedures with the aim of ensuring that litigation guarantees are not wasted and giving litigants an adequate opportunity to prepare a list of appeals against a judgment issued by a civil court.
The litigants cannot agree to violate the provisions of the law related to the dates for the appeal by appealing during the legal periods, such as agreeing to file the appeal after the legal period has passed or agreeing to find new legal periods that contradict what the law stipulated. Therefore, the general provisions for challenging judicial rulings in the Civil Trials Law must be taken into consideration.

Where Article (178) of the Civil Trials Law states the following point:

1. The period for appealing the appeal shall be thirty days for judgments ending the litigation unless a special law provides otherwise.

Whereas the Jordanian Court of Cassation decided that it is necessary to respect the deadlines for appeal by appealing during the legal period, that this is a waste of the time of the courts and judges and that it delays the execution of judgments, and that is a departure from the conduct of the profession of the lawyer who is considered a helper to the judiciary and strengthens it (Judgment No. 923/2000 on 4/24/2000).

It is observed that the rule is that the judge may not amend the appeal deadlines set by the law, either more or less, as they achieve stability for the parties to the case, but it seems that in certain circumstances, the law can recognize the judge with the exception of modifying the procedural dates, including the extension of the deadline due to an official holiday; where Article 23 of the Civil Trials Law states that: "(Notwithstanding what is stated in any other law: The dates specified by the month or year shall be calculated according to the Gregorian calendar unless the law stipulates other than If the last date coincides with an official holiday, it is extended to the first working day after that.)"

For example, with the existence of emergency conditions in the country, the Jordanian Court of Cassation decided that the last day of the appeal period coincided with (snowfall, road closures, and irregular working hours in official departments). The deadline for appeal extends to the next day, and the submitted appeal is within the legal period (The law “Judgment” No. 3119 of 2003 Court of Rights Cassation).

The Civil Trials Law stipulates that:

1) Article (122) (The court shall order the suspension of the lawsuit if it deems that the judgment in its merits is suspended on the adjudication of another matter upon which the judgment depends. As soon as the reason for the suspension is removed, any of the litigants may request to proceed with the case).

2) Article (123) (A lawsuit may be suspended based on the litigants’ agreement not to proceed with it for a period not exceeding six months from the date of the court’s approval of their agreement).

3) Article (174) (If one of the parties to the lawsuit dies, or if it is decided to declare him bankrupt, or if he has lost the capacity for litigation during the appeal dates, the judgment shall be communicated to whoever legally takes his place).

There is no judicial application in Jordan according to the Civil Trials Law that decides to complete the period of appeal with the appeal in the period between the issuance of the judgment and its appeal if force majeure or a sudden accident (such as the COVID-19 pandemic) is achieved so that the period that ended from the date of submitting the appeal and starting from the date that this bar is removed.

On the other hand, the Jordanian jurisprudence believes that the legislator has canceled the status of suspending the case by virtue of the law from the provisions of the current Civil Trials Law No. 24 of 1988 and its amendments; and that what came from a ruling related to stopping the case in the Civil Trials Law is by court order or by agreement of the litigants.
Accordingly, the Jordanian judiciary and legislator did not resolve the issue of stopping and completing the period of appeal against a judgment issued by the Court of First Instance in the event of force majeure or an emergency situation, including the COVID-19 pandemic during another period, so that the period is completed by starting the first working day after the end of the impediment and completing the remaining period during the suspension to the original appeal period.

According to Defense Law No. (13) of 1992 - and based on Defense Order No. (5) and as of 3/18/2020:

The validity of all periods and deadlines stipulated in the legislation in force shall be suspended, whether they are statute of limitations, lapse, failure to hear a lawsuit, or periods for taking any of the litigation procedures in all types of courts in the Kingdom, public prosecution departments, arbitration bodies, enforcement departments, wages authority and any conciliation and mediation council. Disciplinary and others who exercise competencies similar to those of these councils, even if these periods are among the periods to which the suspension does not apply.

The validity of the suspended periods, based on the Prime Minister’s decision, shall continue to be carried out by institutions, official departments, and courts.

The Jordanian Prime Minister’s Communication No. (6) was issued in accordance with the provisions of the Defense Order for the year 2020, as follows:

(As of 5/31/2020, institutions, official departments, and courts begin their work, and all periods and dates suspended under Defense Order No. (5) of 2020 will be completed.)

In the implementation of this, the Jordanian Court of Cassation decided (to accept the appeal submitted on 6/18/2020 within the legal period, as it was decided to suspend the calculation of appeal periods as of 3/18/2020 under Defense Order No. (5) of 2020, while it was decided to complete the calculation of the periods on 31/5/2020, based on Communication No. (6) issued based on the aforementioned Defense Order).

Case No. (Case: 2773/2020).

Consequently, Defense Order No. (5) issued under the Defense Law was decisive in its stipulation of completing the calculation of an appeal period against a judgment issued by the Court of First Instance during the period it decided in the case of force majeure or the exceptional circumstances that the world witnessed in the COVID-19 pandemic and this is what the Jordanian courts decided in adhering to the defense order, applying it to deadlines and completing the period of appeal against judicial decisions.

Conclusion

The current research shows the difference in how to clarify the time limits for submitting an appeal to challenge judicial rulings and to complete them after the impediment is removed in the Jordanian courts in the event of force majeure or exceptional circumstances. The Civil Trials Law and related judicial applications in Jordan has not resolved the issue of stopping and completing the periods for submitting the appeal in an appeal against a judicial ruling suspended due to the COVID-19 pandemic, which is expressed as (force majeure or an exceptional circumstance) and thus completing the validity of the remaining period for the end of the appeal period after the impediment is removed. This constitutes a legislative deficiency in the provisions of the Civil Trials Law that dealt with cases of stopping the deadline for appeal periods for reasons related to the death of the convicted person, to lose the capacity to litigate, or to the disappearance of the capacity of the person who was engaged in the judicial litigation, and in light of this there were many jurisprudential opinions in determining the concept of stopping and completing the deadline for appeal in Judicial judgments when there is force majeure or an emergency situation, and the Jordanian legislator must expand in addressing this legislative deficiency in accordance with certain legal standards. Defense Order No. (5) came in light of the COVID-19 pandemic, decisive in the issue of stopping the validity and completion of the deadlines for appealing judicial rulings. It has imposed on judicial applications in the COVID-19 period. In terms of commitment to what was stipulated, and the obligation to set and complete the scheduled appeal dates as imposed by them and obligate the courts to adhere to them.
The Jordanian legislator has to expand the provisions of the Civil Trials Law to address such exceptional circumstances in the future, accordingly:

1) The Civil Trials Law did not provide for the suspension and completion of the remaining period for appealing judicial decisions in emergency circumstances or force majeure, such as the COVID-19 pandemic.

2) The defense law has been decided according to Defense Order No. (5) the issue of stopping and completing the period of appeal against judicial rulings due to the legislative deficiency in the Jordanian Civil Procedure Law in Articles (23,122,123,174).

3) The application of the Jordanian courts and their commitment to the defense law in accordance with Defense Order No. (5) on calculating and completing the remaining appeal period according to the judicial rulings.

Unanticipated Ligature Strangulation: A Case Report

Mukul Sharma¹, Kimi Soumya Padhi², Manas Ranjan Sahu³, Utkal Keshari Suna², Govinda Balmuchu²

¹Senior Resident, ²Junior Resident, ³Associate Professor, Department of Forensic Medicine & Toxicology, All India Institute of Medical Sciences, Bhubaneswar

Abstract

Strangulation is a form of mechanical asphyxia by compression of the neck with an outside force either by a ligature or hands, in which a constricting force other than the weight of the body is directly applied. Such deaths are generally considered homicidal. Here we present a case of 60-year-old female, who got trapped in the rice huller machine with the saree she was wearing and accidentally got strangled.

Key words: Mechanical asphyxia, Occupational hazard, Farm equipment, Autopsy, Strangulation

Introduction

India is an agricultural country, where agricultural workers play an essential role. They operate animal-drawn equipment, tractors, power tillers, self-propelled and power-operated machines. The population of agricultural workers in the country is about 242 million, of which 50% are female workers¹. Thus, there is a significant role of farmworkers in the country’s agriculture. Attention needs to be given to their safety and occupational health issues to have higher productivity and fewer accidents. Strangulation is a form of mechanical asphyxia by compression of the neck with an outside force either by a ligature or hands, in which a constricting force other than the weight of the body is directly applied². Such deaths are generally considered homicidal unless proved otherwise³. Here we present a case with compression of the neck and crush injuries, where the victim got accidentally strangled in a rice huller machine.

Case Report

A 60-year-old female, collecting husk from the rice huller machine, got trapped in it with the saree she was wearing which resulted in accidental strangulation along with near total amputation of the left upper limb. She succumbed to the injuries on her way to AIIMS, Bhubaneswar, where she was declared as brought dead. Medico-legal autopsy was conducted on the same day of her death. On external examination, a friction abrasion with contused margins was present over the anterior aspect of the neck, starting at a point that was 11 cm below the left mastoid and running downward in an oblique fashion crossing the thyroid cartilage and reaching on the other side of the neck at a point which was 10 cm below the right angle of the mandible (Figure 1). The maximum width of the abrasion was 4 cm which was at a point adjacent to the left side of the thyroid cartilage, and the total circumference of the abrasion was 21 cm. A layered dissection of the neck revealed contusions in the subcutaneous plane and strap muscles of the neck corresponding to the external mark of compression. The thyroid cartilage, hyoid bone, carotid, and jugular vessels were intact. The deceased had sustained a crush injury of the left upper arm with visible humerus bone (Figure 2). A laceration (17 cm x 8 cm skull deep) was present over the scalp in the right temporal region, starting at a point, 12 cm above the right mastoid, moving anteriorly and reaching at a point which was 7 cm medial to right parietal eminence. Margins of the laceration were contused.

Dr. Kimi Soumya Padhi:  
Junior Resident  
Email: kimi.soumya@gmail.com  
Department of Forensic Medicine and Toxicology, 3rd Floor, Academic Block, AIIMS, Bhubaneswar
(Figure 3). There was a grazed abrasion (38cmx 18cm) over the left back involving the inferior axillary area of the left side. On opening the thoracic cavity, chest wall on the left side was contused. The body of the sternum was fractured in the middle with a substernal hematoma of 60mg. On the left side, 2nd to 6th ribs were fractured in the midaxillary line and lung was collapsed with multiple perforations, the left pleural cavity contained one liter of fluid blood. The cause of death was opined to be hemorrhage and shock arising out of multiple injuries sustained, which could be fatal even if present alone in the ordinary course of nature.
Discussion

The accidental strangulation associated with agriculture happens due to entrapment of wearing apparel like stoll, gumcha (towels), and saree which are common in Indian wear in the crop thrashers, rice huller machines, etc. Zine et al\(^4\) reported ligature strangulation by Indian garment saree caught by crop thrasher with injuries to neck and avulsion laceration of scalp, which is quite similar to our findings in the reported case. Parchake et al\(^5\) presented a case of accidental ligature strangulation around the neck, which described the possible mechanism could be because of the rotating motion and pulling action of machineries. Arun et al\(^3\) emphasized on adoption of fitting a guard to prevent entanglement of clothing in moving belts as well as avoiding loose apparel while working in close proximity. Souza et al\(^6\) described the mechanism of death depends on two factors: the amount of resistance made by the victim and the amount of force of the moving machine. Verma et al\(^7\) mentioned strangulation can occur accidentally if someone moves into the vicinity of a moving object without caution. In the present study the findings are consistent with the studies mentioned above.

Conclusion

Education and training to the population involved in agricultural practices dealing with various types of types of machinery is an essential requirement to prevent occupational hazards. Encouragement for the use of safety gear like helmets, body fit clothing, rubber boots, etc. The concern for us here is that the vicinity of these operating equipment should be taken care of in order to avoid preventable accidents.

Self-Administration of Vecuronium by a Medical Student: An Autopsy Case Report

Mukul Sharma¹, Biplab Rath², Naveen A¹, Manas Ranjan Sahu³
¹Senior Resident, ²Junior Resident, ³Associate Professor Department of Forensic Medicine and Toxicology, AIIMS Bhubaneswar

Abstract
During COVID-19 pandemic the frontline healthcare workers have been at risk the most. Long working hours, emotional stress from not seeing families for days together takes a toll on the psychological well-being of a person. This leads to increase incidence of self-harm amongst the individuals. Vecuronium bromide is a muscle relaxant, easy availability of such drugs amongst the medical professionals is a matter of great concern. Monitoring and cautious dispensing of them should be done. Here we report a case of self-administration of vecuronium by a medical student. The purpose of documenting this case is to create awareness among healthcare workers to keep a watch on mental health of fellow colleagues. Psychological support groups in medical college hospitals are the need of hour.

Key words: Vecuronium, Self-Administration, Medical Student, COVID-19

Introduction
Vecuronium is a mono-quaternary ammonium compound. It works by competitively inhibiting acetylcholine at post junctional nicotinic cholinergic receptor sites. It is used worldwide as muscle relaxants prior to intubation and surgical procedures. Though not available as over-the-counter medication, but it is easily available in the operation theatres worldwide. The easy availability and simple administration technique make it a potential drug of abuse amongst the medical and paramedical staff. COVID-19 times have been emotionally stressful for all people¹. Healthcare professionals are not an exception. This has led to widespread use of easily available drugs. Vecuronium is a steroidal, mono-quaternary ammonium compound acting as a non-depolarising muscle relaxant. It competitively inhibits acetylcholine at post junctional nicotinic cholinergic receptor sites. It has intermediate duration of action, so used widely during intubation. Patient recovers about 95% within 45 minutes to 65 minutes. It is available as a lyophilised powder. Adverse drug reactions are rare and seen in 1% of the cases². It is mainly excreted via bile and urine. Due to causation of the respiratory insufficiency caused by vecuronium, it should be administered cautiously and only by experienced doctors and nurses. The respiratory depression is the main cause of death in cases of toxicity. Here we present autopsy findings of a case of self-administration of vecuronium by a medical student.

Case Report
We received a case of a 26-years-old medical student with an alleged history of vecuronium injection. On investigation of crime scene, it was found that the room was locked from inside and a syringe along with an empty vial of vecuronium (Brand NEOVEC-10) was retrieved. Upon taking history, we came to know that the deceased had completed his duty at COVID-19 ward
following which he contracted COVID-19. This had caused a great emotional trauma and was depressed for which he was taking psychiatry consultation.

External examination of the deceased showed that the face was congested. The conjunctiva of both the eyes was deeply congested. Nail beds were bluish. Seminal fluid discharge was seen from the penile tip. Multiple injection puncture marks were seen over the left cubital fossa.

On dissection, the lungs were deeply congested and oedematous. (Fig. 1). Right lung weighed 1200 grams and the left lung weighed 880 grams. The stomach contained 500 grams of partially digested food materials with no appreciable odour. Mucosa was deeply congested and Submucosal haemorrhage was present diffusely. All the internal organs were congested. Skin along with subcutaneous tissue taken from punctured wound site, blood and routine viscera comprising of stomach, small intestine, liver and half of each kidney were collected and sent for chemical analysis at State Forensic Science Laboratory.

Chemical analysis of the skin along with subcutaneous tissue revealed presence of vecuronium which was also found in blood. The technique used for determination was High Performance Liquid Chromatography. The routine preserved viscera report was negative for presence of any toxic compounds.

The final opinion regarding cause of death was stated as respiratory failure as a result of self-administration of Vecuronium.
Discussion

COVID-19 pandemic times have been stressful to all, but the frontline healthcare workers have been the most at risk. Long working hours, emotional stress from not seeing families for days together takes a toll on the psychological well-being of a person\(^1\). This has led to increase incidence of self-harm amongst the individuals. Vecuronium is an easily available drug to the healthcare workers which leads to its misuse \(^3\)-\(^4\). Very few cases have been reported in literature regarding suicides by vecuronium and most of them are of healthcare workers\(^4\)-\(^5\). Post-mortem quantitative analysis of vecuronium and its active metabolite concentration is important for arriving at the conclusion\(^6\). Though suicides using vecuronium is uncommon, but suicides by using similar compounds have been stated in literature\(^7\)-\(^8\).

This case during the COVID-19 times gives an insight about the stress both emotional and physical which a health care worker endures while performing his duties. There is now a dire need of psychological support system to be in place for the healthcare workers to prevent such instances. The easy approachability of the drugs should be controlled. The need for prompt treatment and research into safer alternatives is the need of the hour.

Copper Beaten Skull: An Incidental Finding in Autopsy

Mukul Sharma1, Sasank Shekhar Maharik2, Sarthak Aeron3, Biplab Rath4, Manoj Kumar Mohanty5

1Senior Resident, Department of Forensic Medicine and Toxicology, AIIMS Bhubaneswar, 2Assistant Professor Department of Forensic Medicine and Toxicology IMS and SUM Medical College, Bhubaneswar, 3Senior Resident, Department of Forensic Medicine and Toxicology, AIIMS Jodhpur, 4Junior Resident, 5Professor and HOD, Department of Forensic Medicine and Toxicology, AIIMS Bhubaneswar

Abstract

The Sutures in the human skull are zones of separation between skull bones, which also allows the skull bones to grow in a fashion along with increase in size of brain, early closure of sutures (craniosynostosis) may lead to increase in intracranial tension and it pushes the soft skull outward which leads to undulating patterns formation in inner plate of skull called as silver beaten or copper beaten skull. Here we document an incidental finding of copper beaten skull pattern in a case of road traffic accident brought to Mortuary of AIIMS Bhubaneswar.

Keywords: Copper beaten skull, silver beaten skull, skull sutures, autopsy.

Introduction

Variations and anatomical anomalies of skull are usually related to primary maldevelopment of the brain.1 ‘Copper-beaten’ skull refers to the projecting convolutional marks found in inner table of multiple bones of the skull. Underlying cause is thought to be related to increased intracranial pressure resulting from such processes as craniosynostosis, obstructive hydrocephalus and/or intracranial masses.2 The growing brain yields a constant pulsatile pressure on the soft cranium, creating a gyral pattern on the inner table. This appears as ‘copper-beaten skull’ on plain skull X-rays. We report an incidental finding of Copper Beaten Skull which we came across during autopsy of an road traffic accident case brought to mortuary of AIIMS Bhubaneswar.

Case Report

We received a case of Road Traffic Accident victim who had died during treatment six hours before the autopsy. On taking history from the relatives, we came to know that he was mentally retarded since childhood. On day of incidence he was travelling as a pillion rider when the motorcycle met with the accident. He suffered head injuries and died 7 days after.

Upon external examination, corpse of a 18 year old male with evident dwarfism .The total body length was 136cm and 52kg in weight. There was subconjunctival haemorrhage on left side. Evidence of bleeding from right ear in form of dried blood was present. All the teeth had braces to fix them in shape. Stapled surgical incision mark was present on left parieto-temporal region underneath of which sub-scalpal hematoma was present. Multiple fractures of facial bones were present. There was Multiple abrasions and contusions were present over the body. There was a palpable left femur fracture.

Upon removal of the skull cap, we noticed multiple gyral impressions over the inner table of the skull bones. The impressions were also present over the skull base. There was comminuted fracture of the frontal bone

Corresponding author:
Dr. Mukul Sharma:
Senior Resident, Department of Forensic Medicine and Toxicology, 3rd floor, Academic Block, AIIMS, Bhubaneswar, Email- mukul.med@gmail.com
and roof of left orbit. Skull base was fractured in right middle and posterior cranial fossas. Left frontal lobe was lacerated. There was transection of brainstem. The cause of death was attributed to head injury and its complications.

Figure: On opening the skull, the inner table of skull showing - COPPER BEATEN pattern.

Discussion

Copper beaten appearance of the skull is the least common appearance found in craniosynostosis of evolving skull.\textsuperscript{1,3} The pattern was firstly presumed to have been caused from chronically raised intracranial pressure but currently widely thought to be a reproduction of normal brain growth on the inner table, without pathological significance.\textsuperscript{3} The markings are most prominent during periods of rapid brain growth that is between age 2 - 3 years and 5 - 7 years. They become less apparent after about 8 years of age.\textsuperscript{4}

Diffuse, severe beaten-copper pattern is an indicator of chronic elevated intracranial pressure, which is more common in patients with craniosynostosis.\textsuperscript{5,6} Van Der
Meulen et al. concluded that the occurrence of the copper-beaten skull pattern did not significantly affect long-term intelligence levels⁴. Though, there could be a negative effect on more subtle areas of development, like reading, spelling and behaviour.⁴ These convolutional patterns should be distinguished from Lückenschädel (lacunar skull), which is due to mesenchymal dysplasia of calvarial ossification. It is characterised by many oval lucencies of the inner table and diploic space. These are generally present at birth and are related with meningocoele/myelomeningocele/encephalocoele, spina bifida, cleft palate and Arnold Chiari II malformation.⁶ It is most prominent in the parietal and occipital bones. Seldom these findings are normal and disappear by 6 months of age.¹ Incidental finding of copper beaten skull in adult without pathological ICP rise is rare.⁷

Though an incidental finding we cannot wholly disagree on the fact that the copper beaten appearance of the inner table of skull presents lot of surfaces to the brain to have friction during a trauma to head like in case of head injury. This could be maximising the trauma caused to the brain. The hypothesis put forth need more studies for correlation.

Effects of Ascorbic Acid on Insulin Resistance in Hyper Insulinemic and Euglycemic Persons

Muntadher H. Dawood¹, Taha H. Al-Yasiri²

¹ Lect., Department of Pharmacology and Toxicology, College of pharmacy, misan University, Iraq,
² Lect., Department of Sciences Basic College of Education, University of Misan Misan, Iraq

Abstract

This experiment was conducted in the city of Amara in southern Iraq at Al-Sadr Hospital. The study aimed to evaluate the effect of administering Ascorbic Acid on 50 diabetic patients who had insulin resistance after they were diagnosed clinically. 25 patients were treated with Ascorbic acid at dose 500 mg twice a day for 12 days and the others 25 were considered as control.

The study group demonstrated a significant decrease in the fasting patient’s blood sugar (F.B.S), insulin and fasting blood, and Insulin resistance at the end of 12 weeks (P<0.05) as compared to baseline measurements. The reduction in F.B.S, Fasting Insulin, and Insulin resistance was significantly reduced in the ascorbic acid group at week 12 of the study relative to the control group (P <0.05).

Keywords: Ascorbic acid, Insulin, diabetic, Blood sugar, Fasting

Introduction

Insulin resistance is characterized by weakness of the biological responses for target tissue, mainly adipose tissue, liver and muscle, to insulin stimulation. Insulin resistance has inhibited elimination of glucose, resulting in a compensatory rise in the insulin production from beta-cell and results hyperinsulinemia. [1][2] Hyperglycemia, hypertension, dyslipidemia, visceral adiposity and hyperuricemia, elevated inflammatory signs and impairment of the endothelial function, and prothrombic state can result in the metabolic sequel of insulin resistance which lead to metabolic syndrome, diabetes mellitus type 2 and non-alcoholic liver fat (NAFLD). [3,4]

Type 2 diabetes is the primary result of insulin resistance (T2DM). Resistance to insulin is thought to before T2DM production by 10 to 15 years. high level in the production of endogenous insulin results from growth compensatively of Insulin resistance which is associated with weight gain that occurs with an increase in the level of anabolic hormones (endogenous insulin) is associated with insulin resistance in turn, aggravate insulin resistance [5] This harmful cycle continues until the beta-cell function of the pancreas is unable to produce the insulin that meets the demand caused by insulin resistance, leading to hyperglycemia. With a The constant discrepancy observed between the demand for insulin from the body’s cells and the production of insulin, blood sugar levels elevate to levels compatible with type 2 diabetes mellitus T2DM. [6]

Vitamin C is an antioxidant vitamin with water-soluble properties and an essential cofactor in the synthesis of carnitine, collagen and catecholamine metabolism and serves to absorb dietary iron. A person cannot synthesize or produce vitamin C; Therefore, they can only get it through food such as eating fruits and vegetables. [7]

Corresponding Author.
Muntadher H. Dawood
mntzrhwn2@gmail.com
Citrus fruits, bananas, and green leafy vegetables such as onions and potatoes are a rich source of vitamin C, which is fully absorbed from food in the small intestine, and its absorption decreases with increasing concentration in the lumen of the intestine.[8] The residues of Proline amino acid that are found on procollagen allow vitamin C to be hydroxylated, making it possible to form a triple-helix for mature collagen. [9]

Skin integrity, blood vessels, bone, and mucous membranes, are impaired by the absence of a healthy triple-helical structure. Scurvy is the sequel that results from vitamin C deficiency which presents with hematological abnormalities, hemorrhage and hyperkeratosis [10]

**Aim of Study**

The aim of the trial was to evaluate the effects of vitamin C administration on insulin resistance parameters in subjects with indications of increased insulin resistance.

**Materials and Methods**

**Study design:**

The current research was performed at Al-Sader Teaching Hospital on 50 individuals with hyperinsulinemia and hyperglycemia (31 males, 19 females) aged 30-65 years. The patients were clinically diagnosed as having insulin resistance by the doctor. Criteria for the HOMA model-based diagnosis of insulin resistance.

In order to determine the effectiveness and ability of the medication used (vitamin C) in the study to change the habit of changing due to insulin resistance to the correct normal and to understand the true values of the research criteria, another 20 patients should be considered, in addition to (50) patients.

**Patients:**

In this pilot study, 25 patients were treated with ascorbic acid and changed lifestyle and diet control for 12 weeks. (500 mg), twice daily plus 12 weeks with dietary control and lifestyle changes.

**Sample Collection and Preparation:**

Blood samples were obtained from all patients and healthy people after about 12 hours of fasting by taking a sample of venous blood (10 ml), before starting drug therapy (vitamin C) and (at zero) and after 12 weeks of treatment and then changes in standards examined, blood patient samples were collected in spatial tubes, and after being centrifuged with the device at (3000) rpm for 10 minutes at 4 °C.

In Eppendorf tubes, the plasma fraction obtained was divided into two sections and stored frozen before analysis was conducted.

**Measurements:**

**Fasting blood sugar Level (FBS):**

Using a ready-made kit for this reason, serum glucose level was assessed according to the technique [11]. Based on glucose enzymatic oxidation to form hydrogen peroxide and glucuronic acid, accompanied spectrophotometrically at 505 nm by the subsequent reaction with phenol and formation of quinonimine. The results obtained were expressed as mg / dL, which corresponded to a normal glucose solution, which was treated with the same treatment.

**Serum Insulin levels:**

The Demeditec insulin ELISA, based on the sandwich concept, is an ELISA solid phase.

The microtiter holes are coated on the insulin molecule with antibody monoclonal directed toward a partially on site of antigenic with enzyme conjugate in the coated holes. A portion of the patient’s sample containing internal insulin was incubated with anti-insulin antibodies linked with amino acid (biotin). The unbound conjugated antibodies were then washed from the hopper after they were incubated. Through the second incubation period cycle the Streptavidin-Peroxidase-Enzyme linked to the antibody of the biotin.

The mounting of the horseradish peroxidase (H.R.P) complex is relative to the sample insulin concentration.
The strength of the color obtained after adding the substrate solution is in proportion to the amount of insulin concentration in the patient blood sample. The binding potential was expressed as uU/ml. The HOMA Model is a very simple and practical method for assessing insulin resistance and for testing insulin sensitivity and represents a type of glucose reaction. This assay was then used to determine stable fasting glucose and insulin levels for a variety of insulin-resistant cell function groups. Both primary HOMA and modified HOMA2 are thought to be a feedback loop from the liver to the cell.

[12,13]

Insulin-dependent HGP controls glucose concentrations, while the levels of Insulin to glucose depend on the reaction of the pancreatic B cells. Deficient function of β-cell thus indicates a decreased reaction of β-cells to glucose-induced insulin secretion. Likewise, the diminished suppressive effect of insulin on HGP is expressed in insulin resistance. This glucose insulin homeostasis is defined by HOMA via a series of nonlinear equations derived empirically. For any interference in pancreatic cell activity and insulin sensitivity, the model used predicts steady levels of glucose and insulin in the blood. (14) For a fasting plasma analysis study that includes a constant and tests glucose (fasting plasma glucose; FPG) and insulin (fasting plasma insulin; FPI) the IR approximation equation has been simplified the product of FPG×FPI/HOMA-IR = (glucose × insulin)/405 is the index of the IR.

It tests the concentration of insulin in uU/ml and glucose in mg/dl. A normalizing factor is the 405 constant, i.e. a normal FPI of 5 uU/mL 81 mg/dl normal FPG usual for a ‘normal’ healthy person = 405. Therefore, HOMA-IR =1 for a person with ‘normal’ insulin sensitivity.

Statistical Analysis

The dual t-test was used to compare the values of the result that taken from each group before and after treatment of ascorbic acid administration, and separate control t-tests were used to compare the values obtained for all patients and healthy subjects. In several comparisons to compare between groups in a variables differences before and after 12 weeks of treatment, post-hoc LSD variance analysis (ANOVA) was used. The data is provided in the form of means and standard deviations (SD).

Using a two-tailed test, P<0.05 was considered statistically relevant for all statistical analyses. Statistical data analysis was conducted using software version 16.0 of the Statistical Program for Social Sciences.

Results

Comparison of insulin resistance subjects and healthy subjects with respect to various parameters:

Mean± SD was determined for F.B.S, Fasting Serum. Insulin and Insulin reluctant, respectively, in apparently stable and patient groups, as shown in the following table. The baseline characteristics of the population of healthy and prediabetic patients were compared using the unpaired t-test. showing substantial differences in tolerance to F.B.S, Fasting S. Insulin and Insulin (p<0.001). As defined in the table.

As compared to baseline tests, the research group reported a substantial lowering in F.B.S, Fasting Insulin, and Insulin Resistance in the 12 weeks of the end of experiment (P0.05). At week 12 of the trial, the ascorbic acid group had a significantly lower F.B.S, Fasting Insulin, and Insulin resistance than the control group (P0.05).

Figure (1): Fasting Insulin before and after 12 weeks of the study treatment
Figure (2): Fasting Insulin before and after 12 weeks of the study treatment

Figure (3): Changes in Fasting Insulin from the baseline to 12 weeks of the study
Discussion

As compared to baseline measures at the end of 12 weeks, the experiment showed a substantial lowering in F.B.S, Fasting Insulin, and Insulin Resistance (P0.05). Vitamin C is an important water-soluble micronutrient. It is usually used traditionally for the prevention and treatment of scurvy. Vitamin C called sorbate or ascorbic acid has a universal role in both plants and animals. New fruits and vegetables are the main dietary sources of vitamin C. Based on many factors, vitamin C has been proposed to be helpful in reversing MetS-related abnormalities. Body mass index (BMI), body fat percentage and waist circumference were inversely correlated with plasma vitamin C concentration.\textsuperscript{15}

Important reductions in debits (blood glucose ) 16.5, BP 18.25, TG and LDL-C 18.5 resulted from supplementation with vitamin C. Moreover, vitamin C is a potent antioxidant since it serves as a reducing agent that prevents oxidation of other compounds.\textsuperscript{16}

Vitamin C scavenges harmful free radicals by contributing electrons, resulting in the stable and non-reactive ascorbyl radical.\textsuperscript{17}

Vitamin C’s ability to reduce oxidative stress has been documented in previous studies. Vitamin C affects neutrophil chemotaxis in response to inflammatory mediators, improves neutrophil microbe phagocytosis, and promotes macrophage neutrophil clearance, both of which help to reduce inflammation.\textsuperscript{18,19}

Conclusions

It is easy to infer that vitamin C administration will enhance glycemic control with beneficial effects on insulin as a result. resistance in hyper-insulin and hyperglycemic individuals, according to the findings presented in this report.

Relation between Level of Some Immunological Markers and Liver Functions with Respiratory Bacterial Infection in Sheep

Mustafa Ghazi Saeed¹, Bashar Sadeq Noomi², Entedhar Rifaat Sarhat³

¹MSc. Student, ²Asisst.prof., Dept. of Microbiology, Collage of Veterinary Medicine, University of Tikrit, Tikrit, Iraq, ³Prof., Department of Basic Medical Science, Dentistry College, University of Tikrit, Tikrit, Iraq

Abstract

Sheep pneumonia remains an important cause of morbidity and mortality worldwide. The aim of the study report to determine Interleukine-6, IL-10, and liver function test, and kidney function test of sheep suffering from respiratory disease. Blood samples were collected from the diseased and healthy sheep during field study, for biochemical analysis. The results of 50 diseased animals were compared with results of 50 healthy animals. Data of selected biochemical parameters implicated a significant increase in Interleukin-6, alanine aminotransferase and aspartate aminotransferase, and Gamma glutamyltransferase in the diseased group compared to the healthy sheep’s. On the other hand, a significant decrease was seen in the levels of IL-10, lactate dehydrogenase and total protein in the diseased group compared to the control. The results of this study could conclude that respiratory infections in sheep were associated with significant biochemical and immunological alterations which upon understanding can provide us with rapid diagnostic tools for pneumonia process in sheep and thus lead to better management and proper treatment. Future research is warranted to determine the response of individual animals to this disease and to describe the metabolic changes which occur during the course of respiratory diseases.

Keywords: Sheep, Pneumonia, blood, clinical biochemistry

Introduction

Sheep represent an important aspect of livestock in Iraq and the Arab world, the number of sheep in the Arab world is more than 105 million, while the number of sheep in Iraq is estimated at about (9) million (¹). It is a great wealth that deserves attention, care and development. Sheep constitute a major source of meat in the Arab world about 33.3% of the total meat, as is the case in developed countries. In addition to being an important source of 16.74% milk, leather and wool (¹). The diseases caused by many microorganism has a negative role in limiting the prosperity and growth of livestock in most countries of the world, including Iraq. This is due to the economic losses resulting from the death of large numbers of animals and obstruction of their normal growth and the decrease in their production, as well as the costs of control and treatment (²). Bacterial infections are widespread among sheep flocks widely, and at the forefront of this comes the infection of respiratory infections due to open breeding of sheep flocks provides direct and indirect contact among them and other animals for the transmission of these infections between different animals, and epidemiological and environmental factors play an important role in this field (³). Many epidemiological surveys indicated that sheep are exposed to many infections especially those that infected the respiratory system (⁴). These injuries also affect animal health, represented by weight loss, lack of milk production, poor wool, poor birth control and decreased reproductive efficiency, as well as economic damage from veterinary health services and the effort exerted for that (⁵). Consequently, infection with these germs can cause severe anemia in affected animals, loss of appetite, weight loss and a decrease in wool growth that in some causes leads to the animal’s death. Young animals are more susceptible to infection while larger
animals are susceptible to resistance to some types of disease\(^6\).

Because of absence of a comprehensive study on the epidemiology and infection of respiratory infections in sheep in the Tikrit province, the purpose of this study was to determine Interleukine-6, IL-10, and liver function test, and kidney function test of sheep suffering from respiratory disease.

**Materials and Methods**

In the current study we used sheep that suffers from respiratory signs represented by coughing, sneezing, and respiratory secretions in the same time the temperature, pulse and respiratory speed has been measured and other pathological signs associated with respiratory injuries such as enlarged lymph nodes or joints, diarrhea or others were recorded. 60 ewes were used which were divided into two groups. The first group consisted of 30 healthy ewes that were considered as a control group, while the second group consisted of 30 ewes with respiratory diseases that represented the studied group.

**Blood samples**

Blood samples were obtained from the jugular vein of healthy and infected sheep using test tubes that do not contain anticoagulants to study some biochemical parameters in the serum. It was left at room temperature for 20 minutes, then a centrifuge was used at 3000rpm for 10 minutes for the purpose of separating the serum and then kept in the Apendorf tubes for the purpose of conducting biochemical analyzes.

The IL-6, and IL-10 were measured by using the commercial enzyme-linked immunosorbent assay (ELISA) kits. Serum AST, ALT TP, albumin, GGT levels were measured by spectrophotometric kit.

**Statistical Analysis**

Statistical analysis of data was performed using SAS (Statistical Analysis System - version 9.1). Independent t test was used to assess significant differences between means. P < 0.05 is considered statistically significant.

**Results**

In Tables 1, 2 & 3 values of serum biomarkers are expressed as mean and mean of standard error (mean ± SEM) of the measured biochemical and immunological parameters in healthy and diseased sheep.

The obtained results revealed that a significant increase in IL-6 162.49±16.04 vs 71.42±6.16 pg/ml: <0.01 values while decreased in IL-10 (3.24±0.42 vs 5.39±0.65 pg/ml: <0.01) were observed in the diseased group compared to the healthy group as shown in Table (1).

Discussion

Cytokines are a heterogeneous group of soluble small polypeptides with a wide range of inflammatory, metabolic and immunomodulatory properties and tissue homeostasis, that play a critical role in mediating inflammatory processes and tissue homeostasis underlying pneumonia\(^{(7,8)}\).

Serum biochemical alterations in respiratory diseases were common and might display reasonably predictable changes in response to inflammation. In this regard, the results of the our study revealed higher serum levels of IL-6 in the diseased group versus control group, suggesting the implication of systemic inflammation in diseased groups.

Interleukin-6 (IL-6) is a multifunctional inflammatory cytokine produced in response to tissue damage and infections. Multiple cell types including fibroblasts, keratinocytes, mesangial cells, vascular endothelial cells, mast cells, macrophages, dendritic cells, and T and B cells are associated with the production of this cytokine. After targeting its specific receptor\(^{(9,10)}\),

In an animal trial, IL-6 was shown to affect megakaryocytopoiesis, leading to bigger platelets released into the circulation\(^{(11)}\). The mechanism of action of IL-6 on platelet size in pneumonia is unclear.

Interleukin 10 (IL-10) is considered an immunoregulatory cytokine produced by monocytes, macrophages, B and T lymphocytes, brain cells such as neurons and microglia that capable of inhibiting proinflammatory responses. Despite the previous fact,
IL-10 is a pleiotropic cytokine that can exert either immune-stimulatory or immunosuppressive properties on many cells\textsuperscript{(12-14)}. In the present study, the IL-10 in affected sheep in farm (A) showed significant decrease which was similar to Fernández et al.\textsuperscript{(15)} who reported a significant interaction between the microorganisms and cytokine markers that leads to significant decrease in IL-10 in diseased group.

Liver is one of the largest organs in the body. It has many important metabolic functions. Liver tissue has a relatively large amount of enzymes activity and produces inflammatory cytokines\textsuperscript{(16,17)}. Data obtained from the present study implicated a significantly high serum enzymatic activity of AST, ALT, ALP in the diseased group. These changes could be changes in the antioxidant abilities that occurred in liver, may be attributed to cellular damage in the liver alters their transport function and membrane permeability, leading to leakage of enzymes from the cells. For it, the marked release of AST and ALT from liver cytosol into circulation refers to the extensive damage of hepatic tissue membranes\textsuperscript{(18,19)}, which attributed to dysfunction of various organs including liver due to hepatic degenerative and necrotic changes caused by bacterial infection and toxins. Similar to findings observed by Hassan HY\textsuperscript{(20)}, El-Deeb et al.\textsuperscript{(21)}, and Donia et al.\textsuperscript{(22)}. Furthermore, a significant increase in the ALP may be resulting from the elevated biliary pressure and acute cell necrosis caused the release of ALP from its membranes bound site and its entry into blood\textsuperscript{(23)}. LDH is one of the potential variables presented in the literature as a possible indicator of lung damage. Increased LDH activity in sheep in the diseased group probably resulted from increased respiratory rate and muscle work during prolonged duration or severe cases of respiratory disease\textsuperscript{(24)}. Similar finding were recorded by Nagy et al.\textsuperscript{(25)}.

As markers of renal function, serum concentrations of creatinine and blood urea were measured. Creatinine is a breakdown metabolite of creatine phosphate in muscle. It is eliminated by kidneys, mostly via glomerular filtration and partly via secretion at proximal tubule. Therefore, creatinine clearance could be used to estimate the glomerular filtration rate (eGFR) by measuring serum creatinine (SCr), urine creatinine, and volume. Additionally, SCr can be a reflection of muscle mass and diet\textsuperscript{(26)}. Blood urea nitrogen (BUN) is a common marker of kidney function, and hence its blood concentrations vary according to change in glomerular filtration rate (GFR). BUN levels are increased by the catabolism of lean body mass and lower levels of BUN may be a marker of the cessation of catabolism, which is certain for respiratory muscle recovery and a well-known predictor of weaning\textsuperscript{(27)}.

The results revealed that the mean values of serum creatinine and urea blood urea concentrations were significantly higher in the diseased ewes compared to control. The obvious implication of this observation is that, the high level of serum urea has been attributed to excessive tissues protein catabolism associated with protein deficiency and could be explained also by the accelerated catabolism of body protein and could result as a response to infection. The present study demonstrate that the increasing level of serum creatinine in diseased group than control group 1.35&1.09 mg/dl respectively. High creatinine is indicative of poor protein and amino acid metabolism that can lead to impaired renal function or might be attributed to kidney dysfunction after infection, which would be promoted by a reduction in the glomerular filtration rate\textsuperscript{(28,29)}. Creatinine is formed by the degradation of phosphocreatine for energy release in the skeletal muscle\textsuperscript{(30)}.

A Protocol of Low Dose Chest CT to Verify Suspected COVID-19 infection

Muthana Hussien Mohan¹, Mahmood Radhi Jobayr², Salam Mohmad Joori¹

¹Research Scholar, Medical City Complex, X-Ray Institute, Baghdad, Iraq, ²Professor, Middle Technical University (MTU), College of Health and Medical Technology, Dept. Radiology Technology, Baghdad, Iraq

Abstract

Chest CT scanning is significant in verifying COVID-19 infection in patients with clinical symptoms, although CT scanning uses ionizing radiation. So we aim to investigate the demonstration of relevance and accuracy of chest tomography using a low-dose protocol compared to the standard auto-modulation protocol of 50 – 210 mAs. Moreover, to assess whether any distinguishing signs in patients might help determine the severity of the respiratory infection from COVID-19. A standard auto-modulation protocol of 50 – 210 mAs was performed for all patients (120 patients), Rotation time 0.5 second. Of the 120 patients whose CT scan showed signs of COVID-19 infection, 47 patients aged over 50 years were selected. Low dose CT scanning (30 mAs) was performed on these patients immediately. Of the 120 patients over the age of 50 with COVID-19 according to a PCR underwent a CT chest, only 47 showed signs of COVID-19. When compared to standard-dose, low-dose demonstrated excellent sensitivity in detecting typical findings of COVID-19 (coefficient of significance (C.S) = 0.98–0.99, P-values < 0.05 one reader and P-values < 0.01 two readers). The mean effective dose values were 6.32±2.82 and 1.45±0.29mSv in the stander and low-dose, respectively. A low dose protocol can be used with high reliability and accuracy to reduce the ionizing radiation risks in the state of reproducible assessment. On the other hand, we emphasize there are indicators with high reliability of a relationship between infection with COVID-19 and its severity and the work nature, environment, age, body mass index (BMI) and Patient Health Status.

Keywords: COVID-19, Chest CT, Computed tomography, Low dose.

Introduction

This research was performed in an Iraqi hospital following the outbreak of COVID-19, which has surpassed the highest number of cases since disease registration began in Iraq (500000). As it is known, the first cases of COVID-19 patients were recorded in Wuhan, China, in December 2019. Since then, the disease has spread like a pandemic in various countries of the world. The number of confirmed cases has reached more than eighty million cases all over the world, according to the statistics of the World Health Organization, and the number is constantly increasing¹. It is possible to limit the rapid spread of the COVID-19 and reduce deaths to a minimum through a set of measures represented by early detection of infection, appropriate intervention and commitment to appropriate preventive measures ². Unenhanced chest CT may be considered for early diagnosis of viral disease, though “real-time polymerase chain reaction (RT- PCR)” detection of viral nucleic acid remains the standard of reference. Real-time verse transcription-polymerase chain reaction (RT-PCR) is
the primary basis for diagnosing COVID-19\(^{(3)}\). Some incorrect practices may lead to incorrect readings, including the sample, the adequacy of the sample, the type of the sample, and the stage of infection in which the sample is obtained \(^{(4)}\). The COVID-19 in image computed tomography (CT) appearance are similar to those of viral pneumonia \(^{(5)}\), with ground-glass opacity and uniformity in peripheral distribution being the most common findings \(^{(6)}\). Precise diagnosis of Chest CT-based viral pneumonia may indicate Isolation and has a major role to play in the treatment of suspected SARS-CoV-2 in patients Infection, particularly when there is no scientifically validated recovery therapies About COVID-19. Early conversations indicated that recommended diagnostic modality for CT should be about COVID-19. The use of CT, however, for diagnosing COVID-19 is controversial. As a result of the large radiation dose received on CT scans is of great concern to communities. Also, there are relatively few cases in the literature that demonstrate detailed CT characteristics of COVID-19 \(^{(7-8)}\). The purpose of this study was to statement the importance of low dose computed tomography of the chest and evaluate the diagnostic accuracy to detect lung lesions related to COVID-19, using a low-dose chest CT protocol compared with standard protocol. Moreover, to assess whether any discriminatory signs in patients might help determine the severity of the respiratory infection from COVID-19.

**Patients and Methods**

This study included 120 patients who have clinical features (such as fever and/or disorder of the respiratory system) suspected of having COVID-19 for the period from October 1 to December 30, 2020, at the X-ray Institute / Medical City Complex / Iraq-Baghdad. All the suspected patients were tested by RT-PCR tests conducted at Medical City Complex / Baghdad that throat and nose swab specimens were obtained and considered as COVID-19-positive cases. Patients with positive RT-PCR tests were selected and were over 50 years old. Patients under the age of 50 were excluded, to reduce the risks associated with exposure to ionizing radiation, which is higher in younger subjects \(^{(9,10)}\). Only 47 patients, over the age of 50, with an average age of 57.63, participated in the analysis, of whom 31 were males and 16 were females who were exposed to an additional, reduced dose of Multi-Detector CT (MDCT). A 64-row detector multislice helical CT system was used to acquire the CT chest (Aquilion CXL- TSX-101A/Q, Toshiba, Japan) capable of generating 128 slices per rotation. Assessment of image quality was undertaken by three experts (Consultant Radiologists within X-ray Institute / Medical City Complex); images from the two modalities, i.e. protocol A, and protocol B, were qualitatively evaluated to ensure that the quality criteria for diagnostic radiographic images.

**CT scanning protocols**

A simulation experiment was performed using a standard protocol (Protocol A: 120 kVp, automatic modulation ranging from 50 – 210 mAs), in addition, four proposed protocols to choose the appropriate protocol (Protocol B: 120 kVp – 30 mAs, Protocol C: 120 kVp – 25 mAs, Protocol D: 120 kVp – 40 mAs, and Protocol E: 100 kVp – 30 mAs). As shown in Figure 1, where the experts agreed that (Protocol B: 120 kVp – 30 mAs) as shown in figure 2 could give clear results and high diagnostic accuracy compared to the other proposed protocols.
Figure 1: A simulation experiment for five protocols: (a) Protocol A: standard protocol, (b) Protocol B: 120 kVp – 30 mAs (c) Protocol C: 120 kVp – 25 mAs (d) Protocol D: 120 kVp – 40 mAs (e) Protocol E: 100 kVp – 30 mAs

Result

First of all, our study included one hundred twenty patients with common symptoms that showed PCR that they had the COVID-19, of which 47(39.2%) patients, with an average age of 57.63 years were diagnosed with COVID-19 by CT imaging.

Table (1) shows the age groups of the patient according to gender, Body Mass Index, blood groups, severity disease, and chronic disease. The age group (50-55) included the highest percentage of males 15(31.9%) and females 9(19.2%), with the highest percentage of 14(29.8%) of overweight for body mass index. This group also included the highest percentage of 11(23.4%) of blood group O+, the severity of mild symptoms 13(27.6), and non-chronic disease 14(29.8%).
Table 1: Distribution of Age groups of the patient (Low dose n=47) according to gender, Body Mass Index, blood groups, the severity of disease and chronic disease.

**Radiation dose analysis**

When we compare the volume CT dose index (CTDI), which is a standardized calculation of CT scanner radiation dose production and a common tool to estimate patient radiation exposure from a CT procedure, the instrument automatically measured (8.95mGy) in the standard dose CT scan and (2.21mGy) in the low dose CT scan. This implies that patient radiation exposure will be reduced by 40% - 85% when we decrease the mAs automatic modulation from (50-210) to 30 mAs.
Figure 3: Chest CT scan of a 54-year-old man with COVID-19; (a) Standard-dose image, (b) the low-dose image

Figure 3a, standard-dose CT scan, showing multifocal ground-glass opacity of the chest predominantly in the peripheral and anterior regions associated with an interlobular septal thickening. Whereas Figure 3b shows a low-dose CT scan for the same patient. All experts agreed to diagnose the COVID-19.

Figure 4: Chest CT scan of a 56-year-old man with COVID-19; (a) Standard-dose image, (b) the low-dose image.

Figure 4a, standard-dose CT scan, showing demonstrated bilateral ill-defined ground glass opacities scattered in both lungs predominantly posterior and peripheral regions associated with interlobular septal thickening “crazy” paving image suggesting COVID-19. Figure 4b, CT scan image using the low-dose, the image with same standard dose markers indicative of COVID-19 infection.

Tables 2 and 3 show the Wilcoxon signed-rank test, the comparison between the reading of the three radiologists according to diagnostic image quality and anatomical structures. We observe statistically significant
differences between the reading of the three radiologists (Rad.1, Rad.2 and Rad.3) according to the diagnostic image quality of the standard doses and the lower doses of the number of patients as positive and negative ranks.

This means that the rank descriptions between the three radiologists’ readings were statistically significant differences [P=.046 (S), P=.001(HS) and P=.001(HS)].

Table 4 shows the mean value and standard deviation of body mass index according, mAs standard-dose, mAs low dose, DLP1, DLP2, CTDIvol1 and CTDIvol2 of the normal body mass index level group. The mean and standard deviation were (30.28±6.00) for body mass index, (1034.77±376.69) was the mean and standard deviation of mAs standard dose, while (428.62±39.75) of mAs low dose. Also, the mean and standard deviation of DLP1 was (316.34±141.33) for standard dose but (72.56±14.93) for low dose (DLP2). The mean and standard deviation of CTDIvol1 was (8.95±4.06) for standard dose but (2.21±0.94) for low dose (CTDIvol2). Using the tissue weighting factor of the chest (WT = 0.02), the effective dose value in both protocols, the standard dose and the low dose, were 6.32±2.82 mSv and 1.45±0.29 mSv respectively. The effect of body mass index on mAs standard-dose, mAs low dose, DLP1, DLP2, CTDIvol1 and CTDIvol2 was a highly significant difference (P< 0.01 HS).

**Discussion**

In the assessment of patients complaining of chest disorders, CT scanning of the chest is a vital imaging modality, since it can verify COVID-9, detects a wide range of chest diseases with high precision, and is important for the care of those patients. Therefore several experiments have been performed to reduce the radiation dose as low as possible. In this study, the low-dose protocol used a tube current setting (30mAs) and automatic modulation ranging from (50-210) mAs was used in the standard dose protocol. The image quality evaluation was divided into two categories: the diagnostic and related radiological results and the clarity of COVID-19 significant detection\(^{(9)}\).

The results of our study showed that COVID-19 diagnostic and related radiological characteristics can be clearly and adequately visualized on low-dose protocol scans without any noticeable difference from the standard-dose protocol, although there was some increase in noise that did not have a significant effect on
image quality. There were no large variations between the two protocols given by the 1st and 2nd reviewers in the total and individual scores and only minor differences in the scores given by the 3rd reviewer. The results show that the number of differences between findings in low-dose and findings in standard-dose MDCT scans either did not vary or were even less than the number of differences between all reviewers, depending on the features considered, when defining diagnostic image quality and the clinically important and significant anatomical structures of the chest. When we compare the volume CT dose index (CTDI), which is a standardized radiation dose performance calculation of the CT scanner and a typical method of estimating patient radiation exposure from a CT procedure, the instrument automatically measured (8.95mGy) in the standard dose CT scan and (2.21mGy) in the low dose CT scan. This means that patient exposure to radiation will be decreased by (40-85)% when we decrease the mAs from (50-210) to (30).But this does not reliably quantify the patient’s absorbed dose, which depends on the body mass index$^{[10]}$.

The protocol for a low-dose chest CT scan can be of particular importance in determining the severity of infection with COVID-19 and using it in the follow-up of patients to determine the appropriate treatment. Of 120 patients with COVID-19 infection according to PCR, a CT scan using the standard dose protocol showed only 47(39%) infection when compared to PCR. The possible explanation for this could be that patients are examined early for infection, that is, at the onset of symptoms, since the CT test depends on the signs that appear on the lung. This differentiation with PCR could give an important indication that CT imaging has not played a role in the effective triage of potential COVID-19 patients, particularly during the early stages of COVID-19 infection. Using a low effective radiation dose CT (1.45±0.29 mSv) protocol the 47 patients were subjected to comparison with the standard dose (6.32±2.82 mSv) protocol.

**Conclusion**

In conclusion, we emphasize that COVID-19 diagnostic and related radiological characteristics can be clearly and adequately visualized on low-dose protocol scans (120 kVp – 30 mAs) without any noticeable difference from the standard-dose protocol (120 kVp – Automatic modulation ranging from 50 – 210 mAs), despite there was some increase in noise that did not have a significant effect on image quality. On the other hand, it was emphasized that the absence of radiological signs by tomography does not mean that there is no injury. So, we emphasize can be utilized low-dose protocol and a reproducible assessment particularly in patients with symptoms moderate and severe. We also indicate a possible relationship between infection with COVID-19 and its level of severity, the patient’s environment, work, and health status.

Enhancement of Coping Patterns among Parents of Children with Attention Deficit Hyperactivity Disorder

Nabila Atallah Attia Moawad¹, Ghada Mohamed Mourad², Fatma Ata³

¹PhD, ²Professor, ³Assistant Professor of Psychiatric Mental Health Nursing Department, Faculty of Nursing, Ain Shams University

Abstract

Background: Families of children with ADHD encounter greater difficulties such as family conflict, negative parent-child relationship, higher rates of parent stress and ineffective coping. The aim of study: was to enhancement of coping patterns among parents of children with ADHD. Study design: a quasi-experimental design was utilized to conduct this study. Setting: This study was conducted at Pediatric Out-Patient Clinic at El-Abbassia hospital for psychiatric and mental health. Method: convenient sample of 50 parents were chosen for conducting this study. Data collection tools: (1) Socio demographic and clinical characteristics data for children and their parents. (2) Parental stress scale. (3) Ways of coping Questionnaire. Results: the present study revealed that there were highly statistically significant differences between pre- and post-program of parental stress regarding level of stress, there were highly statistically significant improvement between post-program compared to pre-program regarding coping patterns of the parents have children with ADHD. Conclusion: parents of children with ADHD had high level of stress, which decreased after implementation of the educational program with a highly statistical significant difference. In addition to the current study revealed that after the intervention there were improvements in coping patterns of parents. Recommendations: Continuous education programs and counseling are important to improve parents’ adjustment toward care of their ADHD children.

Keywords: Parents of children with ADHD, Stress, Coping patterns, Educational program

Introduction

Attention Deficit Hyperactivity Disorder (ADHD) is a common neurodevelopmental disorder with an estimated worldwide prevalence of approximately 5% (¹). It is the most common childhood behavioral disorder, affecting 5–7% of school-aged (²) children characterized by a persistent pattern of inattention and/or hyperactivity/ impulsivity that interferes with functioning and/or development (²).

Parents having children with ADHD had higher levels of conflict and low levels of family organization.

Parents of children with ADHD are also more experience problems in their relationship with their partner or spouse and greater mental health problems themselves. Additionally, parents of children with ADHD are more likely to experience disagreements about child- rearing and have higher rates of marital conflict, separation, and divorce than parents of children without ADHD (³).

The response of parents to the stresses of raising their child with ADHD depends on a wide variety of factors influencing their ability to cope, such as their interpretation of the crisis event, the family’s sources of support, resources, and family structure. Depending upon which type of strategy is used; one form of coping patterns can be more effective than another. Characteristics of personality of the family members,
their financial status, educational level, problem-solving skills, and spirituality influence a family’s ability to cope. Additionally, strong marital relationship and social support also help determine parental adjustment(4).

Coping patterns identified two main types: adaptive coping methods (e.g., information seeking and problem solving) and palliative coping strategies (e.g., efforts to deny, minimize, or escape the stressful situation). Adaptive coping patterns are directly aimed at coping with the source of stress, whereas palliative patterns indirectly help reduce a person’s awareness of the stress(5).

Maladaptive coping can adversely affect physical and emotional health. Using of maladaptive coping strategies for challenging behavior constitutes a risk for parental stress (6). So, parenting interventions are recommended for ADHD (7).

Nurse have important role in raising the level of awareness about ADHD through help parents understand the reason of the diagnostic process, the process of treatment, and the importance of follow-up to re-evaluate their child’s case and make sure that the diagnosis and treatment are appropriate over time. (8).

Significance of the Study
The behavior of children with ADHD is often perceived by parents as challenging to manage, and research has shown that parents of children with ADHD experience more stress than do those of children without disabilities(9). Parents of children with ADHD need support often they are frustrated that there are much stress, which make them feel emotionally, physically, financially, and perhaps spiritually stressed and upsetting, therefore they can learn more about the disorder to help them to reduce their blame and guilt about the children problem and to cope accepting their children with ADHD. So, this study designed to achieve long-term benefits through appropriate practice for parent caring ADHD child, to enhance their coping patterns.

The aim of the study
The study aimed to enhancement of coping patterns among parents of children with ADHD.

This aim achieved through:
1- Assessing level of stress among parents of children with ADHD.
2- Assess coping patterns among parents of children with ADHD.
3- Accordingly designing and implementing an educational program for enhancing coping patterns among parents of children with ADHD.
4- Evaluate the effect of the educational program on the coping patterns among parents of children with ADHD.

Research Hypothesis
The educational program will have positive effect on enhancement of coping patterns among parents of children with ADHD.

Materials and Method
The study design
A quasi-experimental design (one group pre/posttest) was used in the current study.

Setting
This study was conducted at Pediatric Out-Patient Clinic at El- Abbassia hospital for psychiatric and mental health.

Subject of the study:
Sample type: A convenience sample. Sample size: The sample was chosen as the number of available parents of children with ADHD and the parents of the present study included (50) parents who meet the following criteria: -A- For parents: Both sexes (mothers and fathers). All ages. Parent wholiving in the same dwelling and responsible for caring ADHD child. B- For children: Males and females.Ages from 6 to 12
years (school age). Free from any physical disease and without mental retardation or neurological disorders.

Tools of data collection:

1- Socio-demographic and clinical characteristics data sheet for children and their parents: This tool was designed by the researcher, it included (13) items for socio-demographic data divided into two parts which included: part one was used to identify personal characteristics of parents as: age, sex, marital status, job of parents, level of education, and monthly income. Part two was developed to personal and clinical characteristics of ADHD children: age, sex, and diagnosis, number of sibling, family birth order, and family history of ADHD.

2- Parental stress scale (Berry and Jones, 1995): This scale was developed by(7). After adaptation of this scale by researcher, it consists of 24 items answered by parents before and after the program. The scale was divided into three subscales as: psychological stress, physical stress, and social and financial stress. Scoring system: Scoring system was done using three points Likert scale ranging from Zero to 2 respectively: “agree=2, uncertain=1, and disagree = Zero”. Items 1,5,6,10,11 and 18 were reverse scored as “agree= zero, uncertain= 1, disagree= 2”. Parents with a total score reach or more than 60% were considered to have high level of stress and those with less than 60% were considered to have low level of stress.

3- Ways of coping (8): This scale was developed by(9) after adaptation of this scale by researcher; it consists of 50 items answered by parents before and after the program, the questionnaire was divided into three parts: Patterns of avoidance adaptation, patterns of seek support, and patterns of effective adaptation. Parents are presented with three graded responses: used, used somewhat, and not used.

Scoring system: Scoring system was done using three points Likert scale ranging from Zero to 2 respectively: “used =2, used somewhat=1, and not used = Zero”. Items 1,2,3,4,5,6,7 ,9,10,11,12,13,14,15,17,18 and 30 were reverse scored as used = Zero, used somewhat=1, and not used = 2”. Subjects with a total score reach or more than 60% were considered to have Positive coping and those with less than 60% were considered to have Negative coping.

Operational design

The operational design consists of (the preparatory phase, implementing phase, evaluating phase, limitations of the study, and ethical considerations). This study was conducted from October 2019 to Mars 2020, in Cairo, Egypt.

1- Preparatory phase:

Validity of the tool: A panel of five experts in three different specialties: Psychiatric nursing, Pediatric nursing and Public health nursing validated the tool. They assessed the tool for relevance, comprehensiveness, and clarity. The tool was finalized based on their comments and suggestions.

Reliability of the tool: The reliability of the tools was assessed through measuring their internal consisted by Cronbach’s Alpha coefficient test, and re-testing. Tool reliability test carried out on ten parents having children with ADHD, and after two weeks carried out re-testing on another ten of parents. To achieve the criteria of trust worthiness of the tool reliability, it was proved to be good. The validity and reliability process was done during the period first of October 2019 until end it.

Pilot study: A pilot study was carried out on 10% of the studied parents to test the clarity and applicability of the tools, and the feasibility of the research process. The pilot study was also used to estimate the time required to respond to the questionnaire. The pilot study was excluded from the study results.

2-Implementing Phase:

Fieldwork

The actual fieldwork for the process of the data collection has consumed three months and half started on beginning of half of December 2019 and was completed
by the end Mars 2020, through the following steps:

**First step:** Before starting the data collection, the researcher met with parents having children with ADHD after introducing herself, explained the nature and purpose of the study to seek participants’ co-operation, emphasizing that all collected information is strictly confidential, then oral approval consent was obtained from them before the intervention method was applied. Additionally, set time table for sessions.

**Second step:** Interviewing sessions were implemented twice / week Saturday and Tuesday during afternoon period (9:30 Am to 11:30 Am) from 40 - 45 minutes according to the parents understanding and span of attention. The parents were divided into 4 groups and each group didn’t exceed 13 parents. Collection of data as begun with the socio-demographic questionnaire, and parents need about 20-25 minutes to complete the questionnaire. After distributing the tools, the researcher explained the aim and objectives to them, while the researcher was present to assure that all questions were completed.

**Third Step:** The teaching sessions were conducted in a classroom located at the ground floor of the psychiatric hospital. The classroom was quiet, well ventilated, well furnished, and had adequate lighting and adequate spacing for implementing educational program activities. The program content and its objectives were developed by the researcher in the form of (14) sessions to be covered in (10) hours, (4 Theoretical hours and 6 Practical hours).

Every session of the program has general and specific objectives, the researcher was used different teaching methods and media such as; lecture, and open-group discussions. In addition, the researcher also used the role play, demonstration, re-demonstration, real life situations, colored posters and handouts.

**The program content was as follows:**

**Introductory Session (1):** During this initial session the researcher explained the aim of the program, determined the place of meeting, the time table, and administered the pre-assessment. During this session the parents fill in data collection tools (pretest).

**Session (2):** The focus of this session was to provide an overview about Meaning, symptoms, causes and problems caused by such disorder and treatment of Attention deficit hyperactivity disorder.

**Session (3):** The focus of this session was to provide an overview about Meaning, sources and effects of stress.

**Session (4):** The focus of this session was to provide an overview about Meaning and Types of Patterns of Coping.

**Session (5):** The focus of this session was to provide tips for stress management and how to deal with it.

**Session (6):** The focus of this session was to provide Critical problem solving techniques to management the range of difficult behavior.

**Session (7):** The focus of this session was applying steps of deep breathing technique.

**Session (8):** The focus of this session was applying Progressive muscles relaxation techniques.

**Session (9):** The focus of this session was to apply Guided imagery technique.

**Session (10):** The focus of this session was to provide Skills of how to stop negative thoughts and promoting the art of self-dialogue.

**Session (11):** The focus of this session was promoting positive feeling towards children and replacing negative feeling with positive ones.

**Session (12):** The focus of this session was to improve daily communication with the child and apply the skills of good communication, and nonjudgmental acceptance of self and child.

**Session (13):** The focus of this session was to apply the methods coping with the task of give orders, increasing
child attention and punishment of the child.

**Evaluation Session (14):** This session was the termination of the educational program and final evaluation and fill in data collection tools (posttest).

**3-Evaluation phase:** Evaluation of outcome of the program was carried out by the researcher immediately after implementation of the program (post-test) by using the same study tools that have been used in pretest to estimate the enhancement of coping patterns among parents of children with ADHD.

**Ethical considerations:**

The ethical research considerations in this study include the following:

1. A written initial approval was obtained from the research ethical committee at the faculty of nursing, Ain Shams University.

1. Individual oral consent was obtained from each participating parents after explaining the nature and benefits of the study.

2. The researcher cleared the objectives and aim of the study to participating parents.

3. The researcher maintained anonymity and confidentiality of participating parents.

4. Participating parents were allowed to choose to participate or not in the study, and given the right to withdraw at any time from the study without giving reasons.

**Statistical Analysis**

Data collected were checked for accuracy and completeness and were coded and entered into statistical package for social science (SPSS) software version 20. Describe of quantitative variables as mean and SD. Description of qualitative variables as number and percentage. Description of qualitative variable of between pre & post program through chi-square and P value were used. Measure, including frequency; percentages, arithmetic mean and standard deviation were presented and r-Pearson tests for Correlation.

**Results**

**Table 1:** reveals that, three quarters of children (76%) were in the age group 6–9 years with a mean age of 8.43 ± 1.90, and more than three quarters of children sex (80%) were male and 20% were female. Regarding to child diagnosis 88% was Combined Type (ADHD). According to number of siblings were (44%) of children had two of sibling, and less than half (42%) of the child arrangement between siblings were second, 38% were first. According to the presence of ADHD in family slightly three quarters (74%) of the sample have not.

**Table 2:** clarifies that, there are highly statistically significant differences between pre-and post-program of parental stress regarding level of stress, “P-value <0.001”.

**Table 3:** clears that, there are highly statistically significant improvement between post-program compared to pre-program regarding coping patterns of the parents have children with ADHD, “P-value <0.001”. 
Table 4: Reports that, there was positive correlation between Pre-post of total score of stress and total score of ways of coping among parents and statistically high significant.

Discussion

The current study aimed to enhance the coping patterns among parents of children with ADHD through the Implementation of the educational program. In the present study, the findings showed that, more than half of parents were in the age group 31-40 years with a mean age of 37.81 ± 6.25. This result is similar to that of (9) in study entitled “Relation between Attention Deficit Hyperactivity Disorder among School Age Children and Parent’s Stress and Sense of Competence” who found that, about half of parents were between the ages 31-40 years old. While this finding was in contrast with (10) who stated that age of mothers of ADHD children was ranged between 20-30 years.

The findings of the present study reveals that, majority of the studied parents have children with ADHD were mothers, and the majority of parents were married. These findings may be due to the care given is often expected performed by mothers because the mothers traditionally take more responsibility of children care, observe any behavioral changes in their children and spend a part of their effort and time to meet the demands of medical treatment and they are caring their child such as, periodical visits to psychiatric clinic, giving medication on time and follow up the child condition. Moreover, it reflects the strong emotional ties between mothers and their children.

The finding of the present study reveals that, more than half of parents in the studied sample had Intermediate education level while illiterate parents in the studied sample were lowest percentage. Based on the present study finding, this might be due to the fact that ADHD as a disease is difficult to be noticed by uneducated parents. Meanwhile, this generally the education might have a positive impact on the care and management of the ADHD child.

The finding of the present study indicates that, more than half of the parents were not working and more than three quarters of them had enough monthly income, these results might be due to different reasons; unemployment, unavailable job, low level of education, inability to work. Or due to that majority of the parents were mothers, this means that they preferred to stay at home to taking care of their children.

Concerning Socio-demographic and clinical characteristics of children with ADHD the present study findings show that, about three quarters of children were in the age group 6>9 years with a mean age of 8.43 ± 1.90, It might be due to that this age characterized by pervasive developmental changes and ADHD begin in early childhood and the main complain in this age is impulsivity, hyperactivity and lack of attention in duties of schools.

The finding of the present study reveals that, about more than three quarters of children sex were male. This might be due to the prevalence of ADHD more common in the boys than girls. In addition, the girls may also develop the symptoms of ADHD at a later age than boys and girls sometimes show symptoms of ADHD in less obvious ways, such as being inattentive. This result was supported by Harold, (2018) in study entitled “Prevalence of attention deficit hyperactivity disorder” who found that, the majority of the studied samples were boys while the minority was girls.

Concerning the types of ADHD, the current study showed that, the majority of the children included in the study had combined type (ADHD), while the minority was predominantly inattentive type and Hyperactive – Impulsive type. This result was supported by (11) who conducted a study about the prevalence of attention-deficit/hyperactivity disorder in Fayoum city (Egypt) among school age children found that the combined ADHD subtype was the most prevalent.

In this respect, (12) found that, in a sample of Egyptian children, the distribution of the subtypes of ADHD was combined type the first, then hyperactivity predominant type and lastly attention deficit predominant type.

The findings of the present study revealed that, slightly more than three quarters of parents had a negative family history of ADHD, while less than one quarter had positive family history of ADHD. Based on the finding of
the current study, high negative family history in Egypt may be due to that most of parents do not say to anyone about the status of their children for their thinking it is a stigma for going to psychiatry hospital.

The findings of the present study clear that, less than half of the child arrangement between siblings are second. Based on the finding of the current study, high positive family history in Egypt may be due to no tendency for families to stop reproduction after the diagnosis of an affected child.

The findings of the current study revealed that, there was reduction in the total level of stress post program implementation as regards low stress (pre 24% vs. post 66%), high stress (pre 76% vs. post 34%).

This result may be due to that the educational program sessions helped parents to know sources and effects of stress, replace negative emotion with positive ones, and improve their emotional status that can lead to reduce the emotion of over involvement and reduce level of stress, by relaxation technique such as deep breathing exercise, progressive muscle relaxation and effective coping with negative thought and emotion.

This result also came in harmony with a study was conducted by (13) in study entitled” Development of an Executive Function Training Program for Preschool and School-aged Children with ADHD” who noted that, lower scores of parenting distress were found for parents of children that participated in the executive function training program than parents of the controls.

The finding of the present study represents that, after the intervention there were improvements in coping patterns of parents as regards Negative patterns (pre 60% vs. post 32%), positive patterns (pre 40% vs. post 66%). These results might be due to the educational program helped the parents to know more about ADHD, ways of effective communication and coping skills to dealing with their children and their problems. This led to that the parents had positive patterns to deal with their children and stress.

This finding also was consistent with the study by (14) about” Treatment effects of combining social skill training and parent training in Taiwanese children with attention deficit hyperactivity”. He found that after the program enhancement of positive parenting and release parenting stress in order to decrease negative and ineffective discipline.

The present study represented that there was highly statistical significant correlation between total score of Parental Stress and their total score of ways of coping during pre- post of program implementation (P≤ 0.001).

The result of the current study could be due to Parental Stress and ways of coping among parents of children with ADHD are correlated to each other. Parents who have high level of stress cannot cope effectively. This result nearly in agreement with (15) (22) who showed that there was a significant relation between parental stress level and coping strategies.

Limitation of study

Difficulties faced in gathering groups of parents to attend the program and the necessary preparation regarding time and place. In addition, some parents’ withdrawal from the study before program implementation completely (5 parents) and they were replaced by other parents.

Conclusion

In the light of the current study, it can be concluded that, parents of children with ADHD had high level of stress, which decreased after implementation of the educational program with a highly statistical significant difference (P≤ 0.001). In addition to the current study revealed that after the intervention there were improvements in coping patterns of parents with a highly statistical significant difference (P≤ 0.001).

The study recommendations

- Continuous education programs are important to improve parents’ adjustment toward care of their ADHD children.
- A hotline must be available to solve immediate problems of parents having children with ADHD.

- Counseling clinics for parents of children with ADHD are needed to minimize their burdens and inform them about the coping strategies for dealing with their children and to ensure an effective response to the needs of the ADHD children and their families.

- Further researches about the social stigmatization among parents of children with ADHD are important in support of the parents.

- Strengthening the role of sources of support (family, teachers, media and social networking), and maintaining its positive role

**Ethical Clearance:** The study was approved from ethical and research committee faculty of nursing Ain Shams University, Egypt.

Abstract

Background: One of the preventive efforts that can be performed to avoid dental and oral health problems is by maintaining oral hygiene. Currently, there are various tools for maintaining dental and oral hygiene that are sold in the market. Purpose: To reveal the knowledge, attitude, action, Ability to Pay (ATP), and Willingness to Pay (WTP) of young adults in fulfilling the need for maintenance of oral hygiene. Methods: This research was a descriptive research type. The sample size was determined as 100 people, targeting the group of young adults aged 20-29 years who have worked or earn. A cross tabulation test was conducted between the ATP and WTP variables with demographic characteristics, namely age and work experience. Results: Based on the age frequency of ATP sufferers, those aged 20-29 years are able to meet the needs of oral hygiene at most at a cost of Rp. 51,000- Rp. 100,000, and the age frequency with the most WTP at a cost of Rp. 141,000 - Rp. 160,000. Based on the length of time working with the ATP, most of the oral hygiene needs are Rp. 51,000-Rp. 100,000. Meanwhile, the frequency of working with WTP is the maximum cost of Rp. 141,000 - Rp. 160,000. Conclusion: According to the research results, it can be concluded that the level of knowledge, attitude, and action of young adults in fulfilling the needs for maintenance of oral hygiene is good.

Keywords: knowledge, attitude, action, ability to pay, and willingness to pay, young adults, oral hygiene.

Introduction

Teeth are part of the body that play an important role in performing several functions such as chewing, speaking, and maintaining the shape of the face. Hence, WHO defines oral health as a state free from oral and facial diseases, throat cancer, infections, and sores in the mouth, gum and periodontal tissue disease, and disorders that limit an individual’s capacity to chew, bite, smile, speak, and psychosocial well-being[1]. Dental and oral health are not only about dental health, but also related to the tissues that support them, such as the gingiva, alveolar bone, all oral mucosal tissues, the tongue, and lips[2,3].

The dental and oral health situation in Indonesia according to the results of the 2018 Basic Health Research stated that 45.3% of the population experienced cavities / damaged / sick teeth, 19% experienced tooth loss either due to extraction or self-loss, 10.4% experienced loose
teeth, and 4.1% of the teeth were filled. Meanwhile, as many as 14% of oral health problems as a whole had swollen gums / abscesses due to cavities. Tooth and mouth disease is a disease that can affect all age groups from children to adults. Based on data compiled by the Central Statistics Agency in 2019, the proportion of adolescents and young adults in Indonesia aged 15-24 years is 83.58% of the total population. Pain or other discomfort that is felt due to disruption of oral health will certainly have a negative impact on one’s productivity.

Oral and dental health are absolutely closely related to oral hygiene. Oral and dental problems such as caries, bleeding gums, bad breath, plaque, and tartar build-up can occur due to lack of maintenance of oral hygiene. Currently, there are many various tools for maintaining oral hygiene that are sold in the market including toothbrushes, toothpaste, mouthwash, dental floss, toothpicks, and miswak. The various choices of tools for maintaining oral hygiene have differences in use, age, and socioeconomic targets.

Based on previous research, it was found that there was a significant relationship between the work of the head of the family and the DMFT index. Work is related to the level of income or level of expenditure. The lower the level of income and expenditure, it is assumed that the lower the ability to perform oral hygiene maintenance efforts such as the purchasing power of toothpaste and toothbrush. In other words, a person’s purchasing power for oral hygiene maintenance facilities is highly dependent on Ability to Pay (ATP) and Willingness to Pay (WTP). Thus, the purpose of this study is describing the knowledge, attitude, action, ability to pay (ATP), and willingness to pay (WTP) of young adults in fulfilling the need for maintenance of oral hygiene.

**Material and Method**

This type of research was a descriptive study with a quantitative approach. The population in this study was a group of young adults who have worked and were earning. The young adult group was people aged 20-29 years. The research instrument was an online questionnaire with the Google Form tool which was distributed through social media platforms to the target sample group community. Data collection procedures: distribution of questionnaires via social media (Line, WhatsApp, Instagram, and Twitter), Subjects filling out, and answering questionnaires, questionnaire data will enter the database, data processing. The data obtained from the results of filling out a questionnaire in a group of young adults in Surabaya city used descriptive analysis. Descriptive analysis of the frequency in this research was conducted on the results of respondent data based on demographic characteristics, variables of knowledge, attitude, and action, products purchased to fulfil the needs of oral hygiene, ATP, and WTP. Cross tabulation analysis in this research was conducted on age characteristics with ATP and WTP variables as well as length of work with ATP and WTP variables.

Table 1 Frequency distribution of study subjects based on demographic characteristics
Table 1 showed the frequency of each demographic characteristic of the respondents in this research. Based on this table, it can be concluded that the number of female respondents was more than male respondents. The latest education frequency analysis showed that the majority of respondents have the latest education at the diploma / bachelor level. Meanwhile, based on the analysis of the frequency of types of work and length of work, it was found that most of the respondents worked as general employees with the majority working experience for less than one year.

Graph 1 Type of product purchased
Based on graph 1, the results showed that most young adults buy toothbrushes, fluoride toothpaste, and mouthwash to fulfil their oral hygiene needs. Meanwhile, products that were rarely purchased are interdental brushes, miswak, and toothpaste without fluoride.

Graph 2 Frequency of knowledge in young adults

Graph 2 showed that most young adults have good knowledge in fulfilling oral hygiene needs, 87%, 13% have sufficient knowledge, and none have poor knowledge.

Graph 3 Frequency of attitude in young adults

Graph 3 showed that most young adults have a good attitude in fulfilling oral hygiene needs, 87%, 12% have a
fairly good attitude, and only 1% have a poor attitude.

Graph 4 Frequency of action in young adults

Graph 4 showed that most of the young adults had good actions in fulfilling oral hygiene needs by 74%, 25% had good enough actions, and only 1% had poor actions.

Based on table 5, respondents with length of work < 1 year to > 3 years were at most willing to fulfil oral hygiene needs at a cost of Rp. 141,000 - Rp. 160,000.

**Discussions**

Oral hygiene is the most significant factor in preventing disease and maintaining oral health. The best way to improve oral hygiene is by practicing oral hygiene using products sold in the market\(^{[11]}\). Along with the development of the dental industry, various dental and oral care products are widely available in the market which include toothbrushes, toothpaste, mouthwash, dental floss, and teeth whitener. Choosing the right product can improve health and prevent diseases of the teeth and mouth. Hence, people must be able to determine products that suit their needs and perform regular maintenance to get maximum results\(^{[11]}\). According to Awais et al. (2019), there are several factors that affect a person’s oral health, including education, employment, social class, and income\(^{[12]}\).

Based on data analysis regarding the knowledge aspect, it was found that 87% of respondents had a good level of knowledge. This can be explained by the theory that the more old a person is, the higher the maturity level of a person in thinking\(^{[13]}\). A person’s age affects their perceptive power and mind-set. As you get older, your perception and mind-set will also develop, thus the knowledge you get will be better\(^{[14]}\).

A high level of knowledge is also followed by good attitudes and actions that the respondents have. This can be seen from the results of data analysis in the attitude domain, where 87% of respondents had good attitude scores. Knowledge and good attitudes are also applied through good actions, where in this study 74% of respondents got good action scores. This is in line with the theory which says that the knowledge that a person acquires will then lead to an inner response in the form of
attitudes towards the object he already knows\textsuperscript{[14]}. Good action is also influenced by socio-psychological factors, one of them is attitude\textsuperscript{[15]}. Attitude is a very important factor because attitude determines a person’s tendency to act. Good knowledge will influence taking the right attitude, thus it will be willing to start taking the right action as well\textsuperscript{[16,17]}

Based on the results of the cross tabulation test between age and ATP and WTP, respondents aged 20-23 years were able to fulfil the needs for oral hygiene maintenance of <50,000, while respondents aged 24-29 years were able to fulfil the needs for oral hygiene maintenance at a cost of Rp. 51,000 - Rp. 100,000. This can be explained by the theory that the more mature a person is, the higher one’s strength at work\textsuperscript{[13]}, thus the higher the income one gets. The amount of income earned certainly affects a person’s ability to fulfil their daily needs, including the need for maintaining oral hygiene.

In regard to the WTP, respondents aged 20-29 years are at most willing to fulfil the needs for oral hygiene maintenance at a cost of Rp. 141,000 - Rp. 160,000. When compared between ATP and WTP, a condition occurs where ATP <WTP, meaning that the respondent’s desire to buy oral hygiene maintenance products is greater than their ability. It is natural for people with low ATP to have a high WTP because the WTP value is determined by the user’s psychological considerations\textsuperscript{[18]}

According to the results of the cross tabulation test between work experience and ATP and WTP, ATP or the ability to pay the costs for those who have 1 year of work experience to>3 years is higher than work experience <1 year. This is because work experience affects the income used in calculating ATP. The higher the work experience, the income earned will increase. Income is directly proportional to ATP. This is as same as the greater the income and the smaller the frequency of purchasing goods, the value of ATP will increase\textsuperscript{[19]}. This means that young adults in all work experiences have the same awareness of the costs they want to spend to fulfil dental health products\textsuperscript{[20]}. Therefore, it is sufficient to fulfil the needs of health and dental hygiene such as toothbrushes, toothpaste, dental floss, and mouthwash at a cost of Rp. 141,000 - Rp. 160,000.

**Conclusions**

According to the research results, it can be concluded that the level of knowledge of young adults in fulfilling the needs for maintenance of oral hygiene is good (87% of respondents). The attitude of young adults in fulfilling the need for maintenance of oral hygiene is good (87% of respondents). Besides that, the action of young adults in fulfilling the need for maintenance of oral hygiene is good also (74% of respondents).

The ability of adolescent adolescents in Ability to Pay (ATP) and Willingness to Pay (WTP) based on age who have a higher level of ability in maintaining oral hygiene is aged 24-29 years. The ability of young adults in Ability to Pay (ATP) and Willingness to Pay (WTP) based on length of work which has a higher level of ability in maintaining oral hygiene is 1 year to> 3 years of work, while WTP in all work experiences is the same.

Dental Health Care for Older Persons with Diabetes by Caregivers in Ubon Ratchathani

Namphet Tungyingyong¹, Ruengsin Thuennadee², Niruwan Turnbull³

¹Doctoral Degree Student, Faculty of Public Health, Mahasarakham University, Mahasarakham, 44150, Thailand, ²National Health Security Office Region 10, Ubon Ratchathani, 34000, Thailand, ³Associate Professor at Public Health, Faculty of Public Health, Mahasarakham University, Mahasarakham, 44150, Thailand

Abstract

Background: Ubon Ratchathani province has seen the phenomenon of the population aging since 2010 and the number of the elderly continues rise each year. According to the assessment of oral health, most of the elderly suffer from Gingivitis and Periodontitis, and have lost their teeth as a result of tooth decay and periodontal diseases. Methods: This study design was a research and development study aimed to explore the process of dental health caregiving for older persons with diabetes by caregivers in Ubon Ratchathani province. Proportional to the estimation of the population, the sample size was 403 elderly patients for contextual study from June 2016 to July 2018. Data was collected using questionnaires with a reliability of 0.8, and analysis was conducted using statistical tools, number, percent, mean, standard deviation, independent sample t-test and paired sample t-test. Results: The finding demonstrated that the participants, similarly, needed care from caregivers, the role of caregivers, health promotion and prevention, while treatment was less of a need. Comparisons of evaluation results from both groups considered impacts on their oral health, on the Daily Performance of their Lives, as well as their Knowledge of and Attitude towards oral care, demonstrated a statistically significant difference (p-value = <0.001). Elderly patients without caregivers suffered largely from loose teeth, showing little knowledge and misunderstanding of tooth brushing techniques, believing that the harder they brush the better it is for their dental health. As for behavior, both groups showed no statistically significant difference (p-value = 0.09) and were rated to be at the same medium level. Conclusion: The finding can be applied for consistency of information from current such as the service was easy to access, the development of the potential and skills of the elderly patients with diabetes and their involved, as well as follow-up for strength and teamwork.

Keywords: caregiver, patients with diabetes, dental health, elderly, oral care model

Introduction

Ubon Ratchathani province has seen the phenomenon of the population aging since 2010 and the number of the elderly continues rise each year. In 2015, the total number of the elderly in the province was 205,698 – or 11.1% of the city’s population. Of this number, 56.2% are in early old age, 30.4% are in middle old age, and 13.3% are in late old age. According to the assessment of Activities of Daily Living (ADL),¹ the samples were divided into three groups: Group 1 (social-oriented, 93.1%), Group 2 (home-oriented, 5.02%), and Group 3 (bed-oriented, 1.86%). Most of the elderly are experiencing chronic diseases: 164,689 of them (80.0%) have diabetes and 162,205 of them (78.8%) have high blood pressure. According to the assessment of oral health, most of the elderly suffer from Gingivitis and Periodontitis, and have lost their teeth as a result of tooth decay and periodontal diseases. This leaves 52.7% of them with fewer than 20 teeth and only 55.8% with at least 4 occlusal pairs: one permanent tooth with another,
or permanent tooth with a denture. This has undermined their ability to chew food and has a negative impact on their quality of life. It was also found that 2.1% of the elderly were experiencing malnutrition. As many of the elderly have chronic diseases such as diabetes that slow down the healing process of wounds and bruises, have a lack of knowledge in self-care, and no caregiver in their families, it is important that caregivers be assigned to help educate the elderly on how to appropriately practice self-care and dental care.

Consequently, Ubon Ratchathani Provincial Health Office has worked to equip local caregivers with the necessary knowledge and skills through a 70-hour training program which includes both lecture and practice hours enabling caregivers to become more capable of taking care of the elderly. However, in practice, different groups of patients with diabetes, such as the home-oriented and the bed-oriented, may pose different challenges leading to the necessity for different methods of care. Therefore, it is asserted that there is a need for oral and dental care from caregivers among elderly patients with diabetes in Ubon Ratchathani province, as well as to compare the impacts of oral health on the Daily Performance of their Lives, knowledge, attitude and behavior regarding oral care among elderly patients with diabetes, with or without caregivers, requires further examination.

**Objective**

The objective of this study was to explore the process of dental health caregiving for older persons with diabetes by caregivers in Ubon Ratchathani province.

**Material And Methods**

**Research model and sample**

This research an action research study was carried out using a purposive sampling to selected elderly with diabetes patients in Ubon Ratchathani province to participated in this study. The participants of this study were examined 164,689 elderly patients with diabetes in Ubon Ratchathani province. Of this number, 43,454 patients had caregivers while 121,235 did not. Proportional to the estimation of the population, the sample size of the elderly patient’s group with a caregiver was 403 patients and there were 245 patients in the elderly patient’s group without a caregiver.

**Data collection**

The model by Kemmis and McTaggart study (Kemmis & McTaggart, 2005) was used to answer the question and explore the new practice of dental health caregiving for older persons with diabetes. The research comprises two phases, each of which consists of 4 phases: 1) planning, 2) action, 3) observation, and 4) reflection. In the first cycle, the planning phase included studying the context of dental health care for older persons, Oral Impact on Daily Performance (OIDP Index), designation of the working team, meeting of the team, and introducing the data into the action phase. The action phase simply followed the plan. The dental health care manual for older persons with diabetes was made. A workshop training was provided to older persons with diabetes, their relatives, and caregivers. The observation phase involved patient visit for enhancing empowerment of the working team. Finally, the reflection phase involved the considering the lesson learned from the above steps. In the second cycle, the working team had a meeting to make a plan and introduced the data into the action phase. In the action phase, the working team followed the action plan and provided a specific skill training program for older persons with diabetes, updated the data, and gave feedback for them on a monthly basis. In the observation phase, the working team visited the patients for enhancing empowerment of the working team. Finally, the reflection phase involved the considering the lesson learned from the above steps in the second cycle. From the implementation of the entire cycle, the key success factors can be summarized into 9 activities as follows: 1) designation of the research team and participant selection, 2) investigation of dental health care situation among older persons with diabetes, 3) introducing the data from the study as the background knowledge in order to determine the dental health care method for older persons with diabetes, 4) the workshop training for making the action plan, 5) trial of the resultant model in the area and developing.
the lesson, 6) development of the data processing system and reflection of the lesson learned, 7) expanding the specific skill training for dental health care, 8) modifying the caregiving system for older persons with diabetes and dental health problems to cover all patients, and 9) monitoring for enhancing empowerment of the working team.

Regarding the key success factors, it was found that having systematic planning and collaboration among the community leader, local administrative organization, and relatives of older persons with diabetes, caregivers, and dental professionals is of paramount important. This includes availability of the updated and complete data on dental health of older persons with diabetes, dental service reorientation, reference system from caregivers, increased access to the service of older persons with diabetes, increased social connection (Line Application), skill and potential development for the relatives of older persons with diabetes so that they can perform self-care, and enhancing empowerment. Community leaders and local administrative organization play a prominent role because they can enhance empowerment of the community for dental health care for older persons with diabetes. According to the qualitative research, the new method of dental health care giving for older persons with diabetes was developed from the key success factors. See Figure 1 for the “DDS CG Ubon Ratchathani Dental Health Care”.

**Human research ethics**

The study has been approved by the Human Research Committee in the University of Mahasarakham. On 7 February 2561, PH002/2017, based on the declaration of Helsinki (Declaration of Helsinki) and good clinical research practices.

**Data analysis**

SPSS version 16 for Winders were used for the data analysis. Descriptive statistics mainly frequency, percent, mean, and standard deviation (SD), max.-min., were used to summarize elderly with diabetes’ demographic characteristics Oral Impact on Daily Performance (OIDP), impact, knowledge, attitude, and behavior between with and without caregivers. Independent sample t-test was used for compared OIDP indices, knowledge, attitude, and behavior between elderly patients with and without a caregiver.

![Figure-1: The method of DDS CG for Ubon Ratchathani Dental Health Care](image)
Results

Data on the demographic characteristics of the participants

Elderly patients in both groups: with and without caregivers demonstrated that most of them are female (68.2% and 66.3% respectively), age ranged between 60 and 69 (72.1% and 68.2% respectively), already married (78.0% and 76.9% respectively), with primary education (89.7% and 88.0% respectively), working on the farm (79.8% and 79.3% respectively), with an income of less than 17,000 baht (95.9% and 95.8% respectively), with an average income of 4,335.92 baht and 4,854.84 baht respectively, have been given care by any caregivers for a year, 63.3% of elderly patients with caregivers have received news and information from public health officials, 95.9% of elderly patients with caregivers and 95.8% of elderly patients without caregivers have had Diabetes for less than 21 years, have no dentures (81.6% and 80.9% respectively), are socially-oriented - 78.4% and 81.1% respectively.

The need for oral care from caregivers to elderly patients with diabetes

Elderly patients in both groups: with and without caregivers demonstrated that most of them needed caregivers to teach them about nutrition and oral health (98.4% and 97.5%), how to maintain oral health (96.3% and 95.5%), and thirdly they needed caregivers to teach them how to conduct oral health check-ups by themselves (94.7% and 93.1%) (Figure 2). In figure 2, the results demonstrated that elderly patients in both groups: with and without caregivers needed the caregivers to conduct oral check-ups on them (82.4% and 81.4% respectively), needed the caregivers to record their oral health for them (63.7% and 61.5% respectively), needed oral care from the caregivers (92.7% and 91.3% respectively), needed to gain more knowledge regarding nutrition for good oral health (98.4% and 97.5% respectively), needed the caregivers to teach them how to clean their dentures (75.5% and 77.9% respectively), to teach them how to correctly brush their teeth (76.6% and 77.4% respectively), needed the caregivers to teach them how to use accessories for oral health care (69.0% and 69.2% respectively), needed the caregivers to teach them how to conduct oral health check-ups by themselves (94.7% and 93.1% respectively), needed to learn healthy cooking from the caregivers (71.4% and 72.7% respectively), needed the caregivers to teach them oral cleaning (96.3% and 95.5% respectively), need implant replacement teeth (46.9% and 48.4% respectively), needed scaling of teeth (60.8% and 58.1% respectively), needed tooth extraction (35.9% and 38.2% respectively), and needed teeth filling (38.4% and 42.9% respectively).

![Figure-2: The need for oral care from caregivers of diabetes elderly patients with or without caregivers](image-url)
Data on the Oral Impact on Daily Performance (OIDP Index)

(Both groups) The group of elderly patients without caregivers showed an average OIDP index at the medium level (Mean = 2.06, S.D. = 0.39), which was higher than that of the group with a caregiver – which stood at a low level (Mean = 1.08, S.D. = 0.16). The group without caregivers also experienced a greater incidence of loose teeth and had more difficulty taking in food than the group with caregivers. Thus, the latter had experienced a better quality of life than the former.

Data on knowledge level

Oral health care data showed that elderly patients both without and with caregivers, have a medium level such as knowledge (11 – 15 points) at 43.67% and 66.94% respectively. It was also noted that the former was at the low-to-medium level of such knowledge while the latter was at the medium-to-high level. This is partly because caregivers may have provided advice to the latter group to a certain extent allowing them to have a better knowledge of oral care than the group without a caregiver.

Data on attitude

Both groups regarding oral care by the type of activity, showed that both elderly patients without and those with caregivers have an appropriate Attitude with average points standing at the medium level (Mean = 1.73, S.D. = 0.36; Mean =1.83, S.D. = 0.48, respectively). The types of activity that saw a better Attitude from both groups, than other types of activity were eating, smoking, and chewing. Both groups agreed that they should brush their teeth after eating, while smoking and chewing a betel nut may pose a health risk to their gums (Mean = 1.86, S.D. = 0.66; Mean = 1.96, S.D. = 0.59, respectively).

Data one behavior

Data regarding Oral Care by type of activity, showed that both groups of elderly patients without and those with caregivers had a medium level result (Mean = 2.10, S.D. = 0.67; Mean = 2.33, S.D. = 0.46, respectively). The reason for the type of activity that saw better behavior from both groups, than other types of activity, is the risk of catching oral diseases (Mean = 2.35 and S.D. =0.33; mean = 2.43 and S.D. = 0.45, respectively). For all types of activity, elderly patients without caregivers scored lower than the elderly patients with caregivers.

Comparisons of Oral Impact on Daily Performance (OIDP) as well as knowledge, attitude and behavior regarding Oral Care

Among elderly patients with diabetes, it was shown that those patients with a caregiver had a better quality of life than those without, with a statistically significant difference of 0.01 and the difference between average points of both groups was 8.11 points (95% CI=7.69-8.52). Those patients with a caregiver also had a better Knowledge of Oral Care than those without, with a statistically significant difference of 0.05 and the difference between the average points of both groups was 0.58 points (95% CI=0.03-1.13), as well as a better attitude towards Oral Care with a statistically significant difference of 0.01 and the difference between the average points of both groups was 1.12 points (95% CI=0.42-1.83), they also had better behavior’s in Oral Care with a statistically significant difference of 0.05 and the difference between the average points of both groups was 0.72 points (95% CI=0.13-1.58) as shown in the table 1.

Oral Impact on Daily Performance (OIDP Index) and comparison between OIDP indices, knowledge, attitude, and behavior of older persons with diabetes who have caregivers and those who do not have caregivers.

The study revealed that older patients with diabetes who do not have caregivers have the OIDP Index at medium level (mean=2.06 and S.D=0.39) while those who have caregivers have the OIDP Index at low level (mean=1.08 and S.D=0.16). The former group suffered more oral impact on daily performance than the latter group. Those who do not have caregivers have odontoseisis problem which affects their chewing more than the other group. It is safe to say that older persons with diabetes who have caregivers have better quality of life than those who do not have as shown in tables 2.

Comparision between OIDP indices, knowledge, attitude, and behavior of older persons with diabetes who have caregivers and those do not have caregivers

As a result of comparison between OIDP indices, knowledge, attitude, and behavior of older persons with diabetes who have caregivers and those do not have caregivers, it was found that the former group have a better quality of life than the latter with the significance level of 0.01 with the mean difference of 8.11 (95% CI = 7.69-8.52). In addition, it was also found that the former group have better knowledge on dental health care than the latter at the significance level of 0.05 with the mean difference of 0.58 (95% CI = 0.03-1.13), the former group have better attitude toward dental health care than the latter at the significance level of 0.01 with the mean difference of 1.12 (95% CI = 0.42-1.83), and that the former group have more proper dental health care behavior than the latter group at the significance level of 0.05 with the mean difference of 0.72 (95% CI = 0.13-1.58) as shown in table 3.

**Discussion**

In terms of the needs for oral care from caregivers among elderly patients with diabetes, it was found that both groups - without or with a caregiver – needed care and health promotion from caregivers, and this showed at a high level, of 53.3% and 79.6% respectively. This finding was confirmed by the study of Jeasoh study which claimed that the elderly usually needed a lot of health services – ranging from annual check-ups and appropriate physical activity, to memory exercises which should be delivered and/or monitored closely by caregivers. Moreover, the elderly need special care and home visits from caregivers. They need intimate care, especially within the family, which will help mitigate the feelings of abandonment, isolation, or neglect, that elderly people suffer from, while enabling them to become motivated and stay positive with all aspects of the health services being provided – i.e. health promotion, prevention, treatment and rehabilitation – to give them a chance to improve both their physicality and mentality. The Oral Impact on Daily Performance between the two groups, it was illustrated that the group with a caregiver had less Oral Impact on Daily Performance or a better quality of life than the group without a career, with a statistically significant difference of 0.01 (p-value = <0.001). Eating as a type of activity has the most effect of all types of activity. This finding was confirmed in a study with Watthanasan study et al. study, which claimed that daily performances of their sample – such as talking and working – are affected by oral ill health, and that many patients are experiencing difficulty in chewing their food nearly every day. Charoentanyarak et al. found that the prevalence of Oral Impact on Daily Performance was most obvious when elderly people experienced toothache with severe or extremely severe pain during eating and while conducting oral hygiene. The most common causes of such pain are toothache, tooth loss, and loose teeth, which may result from diabetes. This places patients at greater risks of being diagnosed with Periodontitis. Patients suffering from these causes of pain should be treated quickly to prevent any further complications that may also cause them to lose more teeth. Suksang et al. study found that the way that patients ate, talked, expressed their feelings through their faces, as well as the OIDP index, before and after surgery were different suggesting that corrective jaw surgery could help to improve the oral health of the patients. Turk et al. suggested that if patients could effectively control their diabetes they would have a better quality of life than those who could not. Laiteerapong et al. study argued that low levels of blood sugar in patients with diabetes may be related to a lower quality of life. In 2015, Wändell posited that patients with diabetes who have received appropriate and continued care will have a better quality of life while, suggested that the overall
quality of life may be partly improved by appropriate oral care. Comparisons of knowledge, an attitude, and behavior regarding oral care between both patient groups with diabetes showed that the group with a caregiver had better knowledge than the group without a caregiver, with a statistically significant difference of 0.05 (p-value = 0.03) and a better Attitude with a statistically significant difference of 0.01 (p-value = <0.001). But in terms of oral care behavior there was no statistically insignificant difference and no significant differences in behaviors r between them. This may result from the factors that determine everyday behaviors which include not only the level of Knowledge and Attitude, but also feelings, habits, and convenience, for instance.

Therefore, it can be assumed that elderly people with better knowledge and attitude may not have better corresponding behaviors for oral care, given that most of them (approximately 90%) showed a medium-high level of knowledge and attitude, but only 77.2% (relatively low) of them brushed their teeth twice a day. It can also be assumed that the level of knowledge is not related to eating habits that may cause tooth decay, which means that an inverse variation exists between the level of knowledge and behavior, with a statistical significance \( r = -0.164, p = 0.001 \), and that the Level of knowledge and attitude are independent to the oral care behaviour in students, which argues against the study of Muksing et al. claiming that the level of knowledge and attitude regarding self-care have a positive relationship at a low level with self-care behavior in students, with a statistical significance \( r = 0.28, p\text{-value} < 0.01 \). Watthanaasen et al. also added that the level of knowledge in oral care has a positive relationship at a low level with oral care practice, with a statistical significance \( r = 0.13, p\text{-value} = 0.046 \) while Uthon confirmed that the Level of Knowledge and Attitude have a positive relationship with oral care behavior, with a statistical significance \( r = 0.124, p\text{-value} = .019 \) and \( r = 0.172, p\text{-value} =0.001 \). Pulthong et al. claimed that when elderly people become more knowledgeable of oral care their oral care behavior improves as well, with a statistical significance, while Jitaram and Makboon study found that the level of knowledge and attitude regarding oral care for children between the ages of 3 and 5 years is related to the parents’ behavior in taking oral care of their children with a statistical significance at 0.05. Based on the relevant literature, the Level of Knowledge and Attitude may not be directly related to the behavior as there might be other factors that have come in to play in determining the behavior – including feelings, personal habits, and awareness of self-care importance.

**Conclusion**

This study concluded that both patient groups with diabetes: one with and one without a caregiver, are mostly socially-oriented (86.6% and 82.8% respectively) and require a high level of care from caregivers (53.3% and 79.6% respectively). Comparisons between these two groups have shown that in terms of Knowledge and Attitude they are different with a statistically significant difference of 0.05. However, in terms of oral care behavior they are different with a statistically insignificant difference of 0.05. In terms of oral impact on daily performance there is a statistically significant difference of 0.01. It can be implied that the socially-oriented groups have the potential to take good care of their oral health if they are taught, trained, and inspired to do so. As a result, the development of capacity and better practice of caregivers is the key to the improvement of such care for the elderly. As the findings of this research demonstrates, elderly patients with diabetes still have low levels of oral care behavior, they should be trained on how to better perform oral self-care, and their relevant medical records should be initiated, summarized, and then returned to them so as to make them better aware of the importance of oral self-care performance.

**Suggestion**

1. The administrators of the Ubon Ratchathani Provincial Public Health Office, Ubon Ratchathani, Thailand who take care of and perform all aspects of this work, such as providing support in exchanging knowledge with other agencies, encourage a mentor to supervise and monitor the operation, budget support, sufficient personnel for the operation, coordination
with relevant network parties, as well as providing various social welfare for older persons with diabetes by caregivers.

2. Executives should encourage health officer to have a forum to showcase their works or organize public benefit activities. Networking partners from all sectors join as mentors, support and advisor in organizing activities of the older persons with diabetes by caregivers.

Endodontic Retreatment in Underfilled Root Canal of Maxillary First Molar with Chronic Periapical Abscess: A Case Report

Nanik Zubaidah¹, Kun Ismiyatin¹, Cinitra Anindya², Nindhira Puspita Sari², Singgih Harseno², Ahmad Afif Dzulfikar², Dian Dwi Pratiwi²

¹Staff, ²Resident of Conservative Dentistry Department, Faculty of Dental Medicine, Universitas Airlangga

Abstract

Background: The failure of endodontic treatment commonly caused by imperfect obturation, periodontal-periradicular lesions, untreated root canals, and some other factors. The failure may trigger the occurrence of secondary infections due to persistent bacteria. One of the abnormalities that appear after endodontic treatment is a periapical abscess. Endodontic failure can be overcome by endodontic retreatment, apical surgery, or extraction. During an endodontic retreatment, endodontic instruments are used to remove the root canal filling material and to repeat the steps of endodontic treatment to achieve the apical patency.

Purpose: This case report presents management to overcome the failure of previous endodontic treatment with nonsurgical endodontic retreatment.

Case: A 66 years old male patient came with a dull pain of tooth no 16 and uncomfortable when used for chewing since 2 months after endodontic treatment. The episodic swelling appeared since 3 months ago which then deflated. The objective examination showed a positive response to bite test and percussion test. Intraoral periapical radiograph confirmed an underfilled root canal, and a periapical radiolucency with a diffuse border on palatal root.

Case Management: Based on the patient’s history taking, radiographic, and clinical examination, endodontic retreatment was done and followed by porcelain fused to metal crown restoration.

Conclusion: Endodontic retreatment is the appropriate treatment option to overcome the failure of the previous endodontic treatment that accompanied with a periapical lesion and to preserve its function in stomatognatic system.

Keywords: endodontic retreatment, endodontic failure, chronic periapical abscess

Introduction

There are many causes of endodontic treatment failure including imperfect obturation, root perforation, external root resorption, periodontal-periradicular lesions, overfilling, the presence of a left root canal, periapical cysts, the lagging of broken instruments in the root canal, perforation of the nasal foramen and coronal leakage.

The main differences between endodontic therapy and endodontic retreatment are the necessity to remove filling materials from the root canals. A good retreatment procedure required no visible debris observed on the instrument flutes. Cases of retreatment always begin with a careful examination of the endodontic morphology of the involved tooth on pre-operative radiographs, because many times the failure of the first performed therapy is caused by a missed and untreated root canal. To be able to find all the canals of a tooth root and biomechanically treat and obturate, a knowledge of root canal morphology is needed.
Persistent microbiological infection plays an important role of endodontic failure. One of the abnormalities that appear after endodontic treatment is a chronic periapical abscess. Chronic abscesses may not cause pain or only cause mild pain. Radiographic examination often shows a diffuse area of rarefaction of bone and thickened periodontal ligament.

This case report presents management to overcome the failure of previous endodontic treatment with nonsurgical endodontic retreatment in underfilled root canal with a chronic periapical abscess.

Case Report

A 66 years old male patient came to the dental hospital of Universitas Airlangga with a dull pain of tooth no 16 and uncomfortable when used for chewing since 2 months after endodontic treatment. The episodic swelling appeared since 3 months ago which then deflated. A week ago, the throbbing pain appeared and access opening were done by the previous General Practitioner. The patient has no medical history.

The objective examination showed there was a metal crown on tooth no 16 (Fig 1A), bite test (+), percussion test (+), vitality (-), gingivitis (+). Intraoral periapical radiographic confirmed that the patient had a deficient previous root canal treatment, with inadequate obturation, a radiopaque view on the root canal from pulp chamber to apical third, and periapical radiolucency with a diffuse border on palatal root (Fig 1B).

Treatment planning was endodontic retreatment with balance force preparation technique and single cone obturation technique. The final restoration chosen was fiber post and porcelain fused to metal crown.

Under patient’s consent, endodontic retreatment started with the removal of the metal crown and the threaded post (Fig 2), then rubber dam was placed for isolation. Access opening and rewalling was performed. The removal of gutta percha using retreatment files (Dentsply Maillefer, Baillagues, Switzerland) was done, followed by taking the radiographic image to evaluate the result of the gutta percha removal. After Glide path using K-Files #10 (Dentsply Maillefer, Baillagues, Switzerland) was established, a combination of electronic apex locator (Root ZX, J. Morita Corp, Tustin, California, USA) and periapical radiographs were used.
to estimate working lengths. Biomechanical preparation was performed using Reciproc R40 (VDW, Munich, Germany) on the palatal root canal; Reciproc R25 (VDW, Munich, Germany) on the mesiobuccal and distobuccal root canals. The motor used for reinstrumentation of the root canals was the VDW Silver Reciproc (VDW, Munich, Germany). The canals were irrigated with 2.5% NaOCl and aquadest throughout these processes. Gutta point trial radiographic image was taken (Fig 3), followed by the final irrigation with 2.5% NaOCl, 17% EDTA, and 2% Chlorhexidine Gluconate. Each time the irrigation solution was replaced, it was irrigated with sterile aquadest and activated using the EDDY system. The root canal was dried with sterile paper points. Intracanal medication (calcium hydroxide paste) was applied.

Fig 2. Clinical image after the metal crown was removed (with threaded post)

Fig 3. Radiographic image

A week after the first visit, the clinical examination showed palpation test (-), percussion test (-), swelling (-), normal periodontal tissue and temporary filling was in good condition. The tooth was isolated using rubber dam, then the canals were irrigated with 2.5% NaOCl, 17% EDTA, and 2% Chlorhexidine Gluconate. Each time the irrigation solution was replaced, it was irrigated with sterile aquadest and activated using the EDDY system. The root canal was dried with sterile paper points. Single cone technique was used to fill the root canals using R40 and R25 gutta-percha (VDW, Munich, Germany) and resin based sealer (Dentsply Maillefer, Ballaigues, Swiss. The radiographic image was taken to confirm the result of the obturation on the root canals (Fig 4).

Figure 4. Obturation

On the third visit, a week after the second visit, the clinical examination showed palpation test (-), percussion test (-), normal periodontal tissue and temporary filling was in good condition. Rubber dam was placed to isolate the tooth during the removal of the gutta percha for preparation of fiber post insertion. After the fiber post was inserted, preparation for the crown was performed, and the impression of mandibular and maxillary teeth were made. Bite registration were made, and the shade selection was performed using shade guide, (Vitapan3D master, Vita Zahnfabrik, Bad Sackingen, Germany). The shade chosen was 3M-3, then the provisional crown was inserted.

Six months after the third visit, the clinical examination showed percussion test (-), normal periodontal tissue and the provisional crown was in good condition. The provisional crown then removed and replaced with the porcelain fused to metal crown (Fig 5A) using luting cement (Fuji I Glass Ionomer Luting Cement, GC Europe). The occlusion and articulation were checked using articulating paper.
Fig 5. A : Porcelain fused to metal crown insertion (Buccal view); B : Post operative radiographic image

Follow up was performed six months after endodontic retreatment, the clinical examination showed no abnormality, percussion test (-), normal periodontal tissue and the porcelain fused to metal crown was in good condition. Radiographic examination showed healing of the periapical lesion (5B).

Discussion

There are many factors that affect the success of endodontic treatment. All this time, endodontic failure has been associated to persistent infection of canals 8. Cleaning and shaping technique, and also the measurement of the working length is the key of successful endodontic retreatment 9. An inadequate obturation or overextended filling often plays a role in endodontic failure. Success rates are naturally lower for obturations which are under or overextended 10.

Based on several studies, in different European countries, there is a large number of teeth needed to be retreated because of periapical lesion appeared from poor root-canal treatment. In 2004, Friedman reported healing rates of nonsurgical retreatment range between 74% and 98% 11.

In this case report, the persistence of bacteria in the root canal occur because of inadequate obturation, resulting a periapical lesion, which was a periapical abscess. Chronic abscesses may not cause pain or only cause mild pain, which sometimes, the patients is unaware to the symptoms. Therefore, non surgical endodontic treatment is needed to overcome the failure of the previous endodontic treatment.

Since the first-line treatment option for previously treated tooth is nonsurgical retreatment 12, in this case report, those treatment was chosen. The function of retreated tooth can be maintained for a long time, even for a lifetime 9.

The reciprocating, alternating or oscillatory movement in Reciproc file system (balanced force), is a system with a single-use file 13,14. Using the reciprocal file system to remove the previous root filling materials is the most rapid method compared with other retreatment instruments 9.

Conclusion

Endodontic retreatment is the appropriate treatment option to overcome the failure of the previous endodontic treatment that accompanied with a periapical lesion and to preserve its function in stomatognatic system.

Harlequin Ichthyosis is the Most Severe Form of the Congenital Ichthyosis; A Case Report Study

Nasim Talebi-Azar¹, Mayam Rasouli², Babak Choobi Anzali², Rasoul Goli³, Jaizeh Karimi Johani⁴, Navid Faraji³, Amireh Hassanpour⁵, Aynaz Bagherzadi³

¹Assistant Professor, Psychiatrist, Urmia University of Medical Sciences, Urmia, Iran, ²Assistant Professor, Department of Emergency Medicine, Urmia University of Medical Sciences, Urmia, Iran, ³MSc, Department of Medical-Surgical Nursing, School of Nursing and Midwifery, Urmia University of Medical Sciences, Urmia, Iran, ⁴MSc, Department of Community Health Nursing, Tabriz University of Medical Sciences, Tabriz, Iran, ⁵MSc, Department of Critical Care Nursing, School of Nursing and Midwifery, Urmia University of Medical Sciences, Urmia, Iran

Abstract

Harlequin ichthyosis (HI) is a rare and the most severe form of the congenital ichthyosis with an autosomal recessive inheritance. At birth, the HI phenotype is striking with thick hyperkeratotic plate-like scales with deep dermal fissures, severe ectropion, among other findings. Although HI infants have historically succumbed in the perinatal period related to their profound epidermal compromise, the prognosis of HI infants has vastly improved over the past 20 years. The disease might be lethal at birth and the affected babies are often premature. The present study reports a new case with HI and adds to the collective knowledge of this rare skin disorder.

Keywords: Harlequin ichthyosis, Gene, Mutation, Autosomal recessive, Case report, Iran

Introduction

Harlequin ichthyosis (HI) is a genetic disorder that results in thickened skin over nearly the entire body at birth.¹ The skin forms large, diamond/trapezoid/rectangle-shaped plates that are separated by deep cracks. These affect the shape of the eyelids, nose, mouth, and ears and limit movement of the arms and legs.² Restricted movement of the chest can lead to breathing difficulties. These plates fall off over several weeks.³ Other complications can include premature birth, infection, problems with body temperature, and dehydration. The condition is the most severe form of ichthyosis, a group of genetic disorders characterized by scaly skin.²

HI is caused by mutations in the ABCA12 gene. This gene codes for a protein necessary for transporting lipids out of cells in the outermost layer of skin. The disorder is autosomal recessive and inherited from parents who are carriers.⁴ Diagnosis is often based on appearance at birth and confirmed by genetic testing.⁵

Before birth, amniocentesis or ultrasound may support the diagnosis.⁴ Newborns with HI present with thick, fissured armor-plate hyperkeratosis. Sufferers feature severe cranial and facial deformities.⁶ The ears may be very poorly developed or absent entirely, as may the nose.² The eyelids may be everted (ectropion), which leaves the eyes and the area around them very susceptible to infection. Babies with this condition often bleed during birth. The lips are pulled back by the dry skin.⁷

Joints are sometimes lacking in movement, and may be below the normal size. Hypoplasia is sometimes found in the fingers. Polydactyly has also been found on
In addition, the fish mouth appearance, mouth breathing, and xerostomia place affected individuals at extremely high risk for developing rampant dental decay.\(^2\)

Patients with HI are extremely sensitive to changes in temperature due to their hard, cracked skin, which prevents normal heat loss. Respiration is also restricted by the skin, which impedes the chest wall from expanding and drawing in enough air.\(^8\) This can lead to hypoventilation and respiratory failure. Patients are often dehydrated, as their plated skin is not well suited to retaining water.\(^3\)

There is no cure for the condition. Early in life, constant supportive care is typically required. Around half of those affected die within the first few months; however, retinoid treatment can increase chances of survival.\(^9\) Children who survive the first year of life often have long-term problems such as red skin, joint contractures and delayed growth.\(^7\)

**Case presentation**

A 26-year-old woman, gravida 3, was admitted to Kosar Hospital in Urmia, Iran at 29 weeks of gestation because of oligohydramnios. There was no family history of harlequin ichthyosis. Ultrasound examination showed a 28 gestational weeks fetus with oligohydramnios. A male baby with HI was born via normal spontaneous vaginal delivery. Her birth weight, length, and head circumference was 2.4 kg, 43 cm, and 28 cm, respectively [see Figure 1]. Parents had a distant relation and had two other normal healthy children. Thick skin with deep fissures, general hyperkeratinization, cyanosis, flat fontanels, ectropion, immature eyes and auricles, eclabium, bradycardia, bradypnea, and moaning were noted in the physical examination. Antibiotic therapy and conservative treatments were started after admission to the neonatal intensive care unit. However, the newborn died after two weeks.

![Figure 1: The newborn with open wide mouth, abnormal eyes, and flatted nose and e](image-url)
Discussion

HI is a rare and extremely severe form of congenital ichthyosis, with an incidence of about 1 in 300000 births. Prenatal diagnosis is usually difficult because of nonspecific signs in the ultrasonographic examination and rareness of the disorder. Delivery of a child with congenital ichthyosis identifies a family at risk, and for subsequent pregnancies prenatal diagnosis can be offered. This report is a typical example of all of these issues.

Mutations in the ABCA12 gene have been reported in the majority of HI patients. This gene plays a major role in transporting lipids to cells that form the epidermis and the normal development of the skin. At birth, infants are covered with hard hyperkeratonic armor, composed of large, thick, yellowish brown, and very sticky plates. After birth, deep red fissures occur on these hard and inflexible plates that extend to the dermis, resulting in a joker-like skin. Infants with HI might have microcephaly, ectropion, and eclairbium.

External auditory meatus and nostrils appear rudimentary and immature. In addition, patients with HI have respiratory failure as a result of restricted chest expansion and skeletal deformities. Feeding problems may result in low blood sugar, dehydration, and kidney failure. In addition, temperature instability and infection would be common. Almost all these clinical features were observed in the current case.

The mortality of HI is high and most of the victims die within a few weeks of birth because of secondary complications such as infection and dehydration. However, survival contributes to the type of mutations; victims with the compound heterozygote mutation survive more than those with the homozygote mutation. In addition, advances in the postnatal treatments and cares improve the prognosis of the disease. The survival rate increases to more than 50% with early prescription of oral retinoids. The patients’ quality of life improves with supportive cares. In addition to the routine care such as checking vital signs, patients should be kept in a warm and humid incubator. Hydration should be performed. As accessing to the peripheral vessels can be difficult, an umbilical venous catheter might be needed. Taking shower twice per day, saline compresses and gentle emollients must be used to keep the skin soft and to accelerate the desquamation. Water and electrolyte disturbances must be managed as well. Environment must be cleaned up to prevent infection; hence, repeated cultures of the skin would be essential to detect the hazardous microorganisms.

Abstract

Background: The Investigator conducted a study to Assess the Effectiveness of Breast Crawl Technique on selected, Maternal and neonatal Outcomes Among Mothers Admitted in Labour Ward at selected hospitals of Kheda-anand District Gujarat. was carried out by researcher. The objectives of the study were: (1) To assess the effectiveness of breast crawl technique on maternal and neonatal outcome among experimental group and control group. (2) To find out the association between maternal and neonatal outcomes and selected demographic variables in experimental group. Research Design: A quasi experimental research approach was used with non-equivalent control group post test only design. The researcher used non-probability purposive sampling technique for selecting the 40 samples. Tools: Latch scale was used to assess the initiation of breast feeding, Visual analogue pain scale was used to assess the intensity of pain, and APGAR score was used for newborn assessment. Validity was assessed by 7 experts. Reliability of latch scale, Visual analogue pain scale and APGAR Score was ascertained by using Karl Pearson’s co-relation coefficient formula. Data Analysis & Results: The data will be analyzed by descriptive statistics such as Mean, Standard deviation, Frequency, Percentage. The mean score of effectiveness of breast crawl technique on initiation of breast feeding, intensity of pain, newborn assessment was higher in experimental group than the control group. So it was revealed that there was significant difference between experimental group and control group. For comparison of effectiveness of breast crawl technique on initiation of breast feeding, intensity of pain, newborn assessment in that mean score was higher and calculated “t” test value is 4.83 which is greater than tabulated value 2.09. So, that the research hypothesis is accepted and proved that there will be significant association between initiation of breast feeding, intensity of pain, newborn assessment between the experimental group and control group. The finding of the study also revealed that there was significant association between the initiation of breast feeding, intensity of pain, newborn assessment with selected demographic variables.

Key Words: Breast Crawl Technique, DF, Labour, Latch Score, Partograph, WHO, SD

Introduction

“With baby’s small head pillowed against mother’s breast and milk which is warming baby inside, Her baby knows closeness to her.”

The woman may experience stress and physical pain and danger may lurk around the corner. The goal of maternity care is a healthy pregnancy with a physically safe and emotionally satisfying outcome for mother, infant, and family. The uterus and the placenta have provided warmth, protection, nutrition, and oxygen as
well as close and continual proximity to the mother's heart and voice. After birth, the mother's body and breasts take over the function of the uterus and placenta in providing warmth, protection, nutrition, and oxygenation.

Being skin to skin with the mother is the newborn infant’s "natural habitat" - the one place where all his needs are met. Breast crawl is the most natural spontaneous and logical method of initiating breastfeeding. It is the simplest method that provides prolonged skin to skin contact and will start the first feed. Every newborn, when placed on mother’s abdomen soon after birth, has the ability to find its mother’s breast all on its own and to decide when to take the first breast feed. Breast crawl also helps mother to have good uterine contraction and fastens expulsion of placenta, decreases maternal blood loss, and prevents anemia. The promotion of early initiation of breast feeding has great potential; 16% of neonatal deaths could be saved if all infants were breastfeed from day 1 and 22% if breastfeeding was started within the first hour after birth. Improving initiating rates, breast feeding success, and reducing neonatal, infant, and under-five mortality rates and morbidity by early initiation of breastfeeding.

Need of Study

The first hour after birth has a measure influence on the survival, future health, and wellbeing of a newly born infant. The best time to start breast feeding is within 20-30 minutes of the new-born’s birth, if there are no complications with delivery. It helps to promote mother-infant bonding and immune protection to the newborn by the first breast feed. The basic needs of a baby at birth are warmth, normal breathing, mother’s milk, and protection from infection. Early initiation of breast feeding serves as the starting point for a continuum of care for mother and newborn that can have long-lasting effect on health and development.

WHO and UNICEF recommended early initiation of breast feeding which results in lower neonatal mortality. Each year approximately 4 million newborn die, mostly from preventable causes. Deaths in the neonatal period accounts 41% of all deaths in children below five years and almost 99% of neonatal deaths takes place in low and middle income countries. In which India is leading with 28% of global neonatal deaths. Evidence shows that early initiation of breast can prevent 22% of all deaths among babies below one month in developing countries. About 16% of neonatal deaths could be prevented if all infants were breastfed from day 1 and 22% if breastfed within 1st hour after birth.

Dr. Sarah Buckley studied that during breast crawl technique immediately after birth benefit the mother who release high level of oxytocin which help the uterus to contract and help in preventing excessive bleeding. Moreover, maximum benefits of early initiation of breast feeding are best achieved with breast crawl.

Objective of The Study

1. To assess the effectiveness of breast crawl technique on maternal and neonatal outcome among experimental group and control group.

2. To find out the association between maternal and neonatal outcomes and selected demographic variables in experimental group.

Hypotheses

• H1 – There will be significant difference between the breast crawl technique on maternal and neonatal outcomes in experimental group at 0.05 level of significance.

• H2 – There will be a significant association between the maternal and neonatal outcomes among mothers with selected demographic variables at 0.05 level of significance.

Material and Methods

— Research approach: Quantitative approach.

— Research design: quasi-experimental research approach, Non-Equivalent control group post-test-only design.

— Target population: mothers who are in labour in selected hospital of Kheda-Anand district, Gujarat.
— **Accessible population:** mother who deliver full term neonate without any complications.

— **Sampling technique:** non probability purposive sampling technique

— **Sample size:** 40 mothers (20 experimental group and 20 control group)

— **Data collection tool:** standardized tool was used.

1. **LATCH SCALE**” for assessment of initiation of breast feeding,

2. **VISUAL ANALOGUE PAIN SCALE”** for assessment of intensity of labour pain

3. **CLINICAL OBSERVATION CHECKLIST”** for assessment of uterus involution

4. **VIRGINIA’S APGAR SCORING SYSTEM”** for newborn assessment .

— **Data analysis:** Descriptive statistics and Inferential statistics

— **Criteria measure:** Maternal Outcome (initiation of breastfeeding, intensity of labor pain, assessment of uterus involution and neonatal outcome (APGAR Score)

**Results and Discussion**

1. Findings related to demographic variables of samples

   majority samples for age 8(2Q0%) sample were of 18-20 years, 12(30%) sample were of 21-23 years, 14(35%) samples were of 24-26 years, 6(15%) were of 27-30 years. In the stream of education 10(25%) samples were from primary education, 17(42.5%) samples were from higher education, 10(25%) samples were graduated and above, 3(7.5%) samples were illiterate. In occupation 3(7.5%) samples were government employee, 6(15%) samples were private employee, 31(77.5%) samples were housewife, 0(0%) samples were in business. In religion 23(57.5%) samples were Hindu, 6(15%) samples were Christian, 11(17.5%) samples were Muslim. In type of family 21(52.5%) samples were from nuclear family, 19(47.5%) samples were from joint family, 0(0%) samples were from single parents. In parity 17(42.5%) samples were from first parity, 16(40%) samples were from second parity, 7(17.5%) samples were from third parity, 0(0%) samples were from more than three parity. In duration of 1st stage of labour 13(32.5%) samples were from 4-6 hours, 8(20%) samples were from 7-9 hours, 16(40%) samples were from 10-12 hours, 2.5% samples were from 13-15 hours. In duration of 2nd stage of labour 21(52.5%) samples were from ½-1 hour, 15(37.5%) samples were from 1½-2 hours, 4(10%) samples were from 2½-3 hours. For gender of baby 17(42.5%) samples have male child, 23(57.5%) samples have female child. For birth weight of new born 24(60%) samples have 2500-3000 grams of child, 13(32.5%) samples have 3100-3500 grams of child, 3 (7.5%) samples have 3600-4000 grams of child.

2. Mean, mean difference, standard deviation, ‘t’ test value of experimental and control group on initiation of breast feeding

<table>
<thead>
<tr>
<th>Initiation of breast feeding</th>
<th>Mean</th>
<th>Mean difference</th>
<th>SD</th>
<th>Calculated ‘t value</th>
<th>Table ‘t’ value</th>
<th>DF</th>
</tr>
</thead>
<tbody>
<tr>
<td>Experimental group</td>

<tr>
<td>Control group</td>
<td>6.35</td>
<td>0.74</td>
<td>8.68</td>
<td>2.09</td>
<td>19</td>
<td></td>
</tr>
</tbody>
</table>
Above table, reveals that the mean score of the experimental group is significantly greater than the mean score of the control group. The calculated ‘t’ value (t=8.68) is greater than the tabulated ‘t’ value (t=2.09). Therefore, the null hypothesis H01 is rejected and research hypothesis H1 is accepted and it reveals that breast crawl is effective in reducing the initiation of breast feeding among the sample.

3. Mean, mean difference, standard deviation, ‘t’ test value of experimental and control group on intensity of pain.

<table>
<thead>
<tr>
<th>Intensity of pain</th>
<th>Mean</th>
<th>Mean difference</th>
<th>SD</th>
<th>Calculated ‘t’ value</th>
<th>Table ‘t’ value</th>
<th>DF</th>

<td>8.1</td>
<td>0.04</td>
<td>0.94</td>
<td>4.83</td>
<td>2.09</td>
<td>39</td>
</tr>
<tr>
<td>Control Group</td>
<td>6.65</td>
<td></td>
<td>0.98</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Above table, reveals that the mean score of the experimental group is significantly greater than the mean score of the control group. The calculated ‘t’ value (t=4.83) is greater than the tabulated ‘t’ value (t=2.09). Therefore, the null hypothesis H01 is rejected and research hypothesis H1 is accepted and it reveals that breast crawl is effective in the newborn outcome among the sample.

5. Findings related to association between maternal outcome with the selected demographic variables of samples

The findings of the study revealed that there was no significant association between maternal outcome with selected demographic variables. The calculated Χ² values of the demographic variables was less than the tabulated Χ² values of the demographic variable at 0.05 level of significant. It reveals that there was no significant association between the maternal outcome with selected demographic variables in experimental group.

6. Findings related to Association between neonatal outcome with the selected demographic variables of samples

The findings of the study revealed that there was no significant association between neonatal outcome and selected demographic variables. The calculated Χ²
values of the demographic variables was less than the tabulated $X^2$ values of the demographic variable at 0.05 level of significant. It reveals that there was no significant association between the neonatal outcome with selected demographic variables in experimental group.

**Conclusion**

The following conclusions can be drawn from the present study findings:

To mark a good beginning, the process and experience of labour should not be a misery for a mother. There are variety of discomfort that women will experience during the labour. Reducing the discomfort is an important part of good nursing care. Breast crawl enhances the initiation of breast feeding early. Nurse should have a vital role in early initiation of breast feeding, reduction of labour pain and newborn assessment.

The findings indicated that the breast crawl technique was effective method in early initiation of breast feeding, reduction of labour pain and newborn assessment of mother admitted in labour at selected hospital of Anand-Kheda district, Gujarat.

**Ethical Clearance:** Taken from institutional ethical committee, DPCN, and got permission from superintendent of selected hospitals of Kheda –Anand District, dated 30/1/2020

The Effect of Capitation Value of Healthcare and Social Security Agency on Service Quality at Primary Clinics

Neny Nurlaily¹, Titik Ernawati¹, FaraValeyria Irma Zain¹, Chomariyah²

¹Student of Master of Law Program, Hang Tuah University, Surabaya, Indonesia, ²Associate Professor, Faculty of Law, Hang Tuah University, Surabaya, Indonesia

Abstract

Indonesia started to apply the National Health Insurance System on January 1, 2014, and the legal entity formed to administer this program is the Healthcare and Social Security Agency. Funding for the Healthcare and Social Security Agency at primary clinic uses the capitation system where the funds are mostly used for services and operations. The use of capitation funds at the primary clinic is fully managed by itself based on the agreement. This actually creates the potential for fraud because of the lack of regulations on using the capitation funds. Fraud at the primary clinic does not really appear on the surface like a fraud in hospitals. It can be in the form of insufficient resources, facilities and service discrimination. Many studies have shown a link between capitation funds and health services. A primary clinic needs to have an audit team to evaluate whether the use of capitation funds is following the expected targets and needs.

Key Words: Healthcare and Social Security Agency, Fraud, Capitation, Primary Clinic, Quality, Services.

Introduction

Health development is integral and most important part of national development, as stated in the 1945 Constitution. Implementing health development aims to increase awareness, willingness, and ability to live a healthy life for everyone to achieve an optimal degree of public health. The success of health development plays an important role in improving service quality and competitiveness of Indonesian human resources.¹ ²

The National Health Insurance System has been implemented in Indonesia since January 1, 2014, and is planned to achieve universal health coverage by 2019. Act No. 40 the Year 2004 on the National Social Security System defines as a procedure for administering social security programs by the social security administering agency. A legal entity established to administer the health social security program is the Healthcare and Social Security Agency.³

The Healthcare and Social Security Agency has the authority to make contracts with healthcare facilities that provide individual health services, both promotive, preventive, curative, and rehabilitative, carried out by the government, regional government, and/or the community. The agency also has the duty to pay the benefits and/or costs of health services based on the provisions. ⁴

Authorized Primary Care Facilities provide non-specialized personal health services. This includes the needs for observation, diagnosis, treatment, treatment and other health services. Health service facilities as a media to carry out health efforts for the community.⁵

One of the Authorized Primary Care Facilities provided by the government is community health centres, while private services such as clinics and independent practice doctors.⁶ The Healthcare and Social Security Agency has 28,000 health service facilities tied in contracts, including 237 main clinics and 6,535 primary clinics.² The clinic receives funding from The Healthcare and Social Security Agency on a capitation basis.
Capitation is the amount of payment per month paid in advance to the Authorized Primary Care Facilities based on the number of registered participants regardless of the type and number of health services provided. The capitation rate is strongly influenced by the utilization rate of health services, and the types of health insurance packages (benefits) offered and unit costs service. The formula for calculating capitation is “the utilization rate multiplied by the unit cost”. The utilization rate is the utilization of health service facilities owned by Authorized Primary Care Facilities, expressed in percent. The utilization rate is influenced by the characteristics of the population, the service system’s nature, the benefits offered and the insurance policy. Utilization is the number of visits per 100 people in a certain population or number of visits/total population x 100%. 

Capitation is given to authorized primary care facility or Authorized Primary Care Facilities based on the number of participants served in an area. The capitation model allows the doctor or Authorized Primary Care Facilities management to clearly calculate the income, based on the number of dependent participants in the area. Research shows that the use of capitation funds in clinics is mostly to pay for services and the rest for operations.

Capitation funds for authorized primary care facilities are generally insufficient, especially for drugs and laboratory costs. The use of capitation funds by Authorized Primary Care Facilities is to provide health services, both preventive and curative services. This article aims to review the effect of the BPJS capitation value on Primary Clinic services’ quality.

**Discussion**

**The Healthcare and Social Security Agency and Capitation Fund**

Indonesia began to apply the The National Health Insurance System system in 2014 and is targeted to reach Universal Health Coverage by 2019. The legal entity established to implement this program is the Healthcare and Social Security Agency. The Healthcare and Social Security Agency has a task to pay for each benefit and/or costs of health services based on the provisions. The development of the Healthcare and Social Security Agency services must have a service quality control system and payment system for the efficiency and effectiveness of health insurance.

National Health Insurance is one part of the National Social Security mandated by the Constitution. The 5th precept of Pancasila is the reason for the birth of the amendment to the 1945 constitution article 28H, which outlines special provisions regarding the social rights of citizens which the state must guarantee, including the right to health. 

The Healthcare and Social Security Agency is to collect contributions paid by participants, then distributed on a capitation basis to optimize services. Capitation is one of the models used in payments to Authorized Primary Care Facilities in the The National Health Insurance System era. Capitation funds are distributed to contracted Authorized Primary Care Facilities by the Healthcare and Social Security Agency. The use of capitation funds at the Primary Clinic is fully managed by itself. This actually creates the potential for fraud because of the lack of regulations on using the capitation funds.

The capitation system does not rule out the fraud, for example, the primary clinic, is not following statutory provisions, manipulates claims on non-capitally paid services, receives commissions for referrals to Authorized Primary Care Facilities, charges fees from participants that should have been guaranteed in capitation fees and/or non-capitation by the stipulated standard rates, making patient referrals only to obtain certain benefits; and/or other The National Health Insurance System fraudulent actions.

The primary clinic’s standard capitation rate is Rp. 8,000.00 (eight thousand rupiahs) to Rp. 10,000.00 (ten thousand rupiahs) per participant per month. The capitation rate calculation then considers the criteria for human resources, completeness of facilities and
infrastructure, service scope, and service commitment.

The average number of capitation received by the Primary Clinic in Siswoyo’s study was 39.4 million rupiahs, increasing the number of capitation funds by 9%. This made the Primary Clinic the Authorized Primary Care Facilities with the highest increase in capitation value. The utilization of capitation funds in terms of services at Primary Clinics generally tends to be higher than doctor/dentist practices. The ratio between operational costs and services at the Primary Clinic is 45%: 55%.15

Payment for health services obtained by health workers (doctors) is based on the number of capitation funds at the primary clinic. Primary Clinic, with large capitation funds, provides health services based on attendance and performance. Primary Clinic, with a small capitation fund, provides health services on a per-patient visit basis.16

Most non-health workers get paid for services below the Regional Minimum Wage. This is influenced by education, length of work, and the number of capitation funds the clinic receives. If the amount of capitation funds is large, health and non-health workers’ salaries will also be large. The capitation funds received by Primary Clinic are also used to support health operational costs.16

Primary clinics with no collaboration with pharmacies are generally required to have pharmaceutical services with the pharmacist as the person in charge and procure drugs. In contrast, clinics with pharmacies services can use capitation funds to purchase medical devices and other health services.

Ghana is one of the countries that first introduced the capitation payment method in 2012, but there is a lot of resistance due to people’s perception of poor service quality. There are three regions have a good perception of health services, while one region has a poor perception. The regions with good perceptions are areas with large capitation funds, while one other, with poor perception, is small capitation fund area.17

**Overview of the Quality of Health Services**

Service quality is an approach to running a business to maximize organizational competitiveness through continuous improvement or its products, workforce, processes and environment. A customer-focused marketing work strategy, satisfaction assurance, teamwork and employee empowerment is required.18

The influence of service attitudes on patient interest in using health care facilities. Measurement of service quality to obtain the best reliability response where Authorized Primary Care Facilities always provides the best physical appearance services (tangibles), responsiveness, assurance, and empathy through a dynamic attitude as an overall service evaluation.19

The availability of resources, patient cooperation, and collaboration among health workers can support health service quality improvement. Supportive leadership, proper planning, education and training and effective management of resources and processes also improve medical services quality.20

Patient satisfaction is closely related to the quality of health service providers.21 Trust is an important factor for the service industry to maintain customer satisfaction. Medical service is a type of intangible product with more than one service to involve. Both medical care workers and general service workers must develop trust with patients to increase patient satisfaction.22

The four main factors contributing to the quality improvement process are leadership, including the leader’s awareness and attitude towards quality improvement, the involvement of the leader in the quality improvement process, and decision-making in budget allocation for quality improvement. The second factor is staff enthusiasm and multidisciplinary collaboration, followed by organizational culture as the third factor. The last factor is the standardization process.23

The success of improving quality in Indonesia’s existing decentralized system requires action at four levels. At the individual level, leadership tools can
create an internal quality environment and foster an organizational culture to change. Staff enthusiasm and collaboration can be sparked at the team level by involving and assigning everyone in the quality improvement process and having a shared vision of what quality should be. At the organizational level, the quality improvement must be integrated into planned activities, ensuring financial and human resources.²⁴

Quality improvement is carried out by improving the medical and non-medical aspects. Some medical aspects have a significant role in improving quality services such as waiting time, communication, clear information, straightforward administration, additional services such as a comfortable room, and drinking water. Medical aspects include training and education for health workers.²⁵

**Overview of Service Quality Based on Capitation Funds at Primary Clinic**

The capitation funding system used by the Healthcare and Social Security Agency for health financing at the Authorized Primary Care Facilities causes the number of funds received by the Primary Clinic to match the number of participants at the clinic. The more participants, the greater the capitation funds the Clinic will receive. ²⁶

The disparity in The National Health Insurance System membership occurs due to The National Health Insurance System participants (Contribution Assistance Recipients) according to the area where they live and the percentage of poor people as the The National Health Insurance System participants. This is consistent with the results of the Ministry of Health evaluation in 2015. It was said JKN participants registered at the Authorized Primary Care Facilities are not ideal.²⁶ Each Participant is entitled to receive Health Insurance Benefits in health services, such as medical benefits, accommodation and ambulance.

The capitation fee for the Primary Clinic is Rp. 8,000 (eight thousand rupiahs) to Rp. 10,000 (ten thousand rupiahs). This calculation is not influenced by how many patients go to Primary Clinic, so capitation may not be sufficient if the Primary Clinic serves patients repeatedly within a month.

The Primary Clinic’s various obligations as above are as if the Primary Clinic was being forced to carry out heavy obligations with low capitation. Doctors do have a clear legal basis in determining their service definition, but according to article 53 of Act No. 29 the Year 2004 on Medical Practice, patients who have received medical practice services have an obligation to provide compensation for the services they receive.²⁹

For example, fees can be completely waived or reduced if medical expenses are too heavy for patients with economic difficulties. This condition is not a problem for private practising doctors. Still, it is certainly different for Primary Clinic because its status is a business entity with many employees and operational needs; of course, capitation funds are vital for the survival of the Primary Clinic.

The ratio of doctors to The National Health Insurance System participants is 1: 6,765, still higher than the national standard of 1: 5,000 participants, even higher than the national average of 1: 6,708 participants. The high ratio of participants results in a decrease in the quality of service time. The number 1: 5,000 is obtained if 1 doctor serves the patient for 10 minutes per patient, with examinations for 5 hours and 25 working days, then if the length of time the doctor checks each patient who visits, ideally 15-20 minutes or 18-20.9 minutes.²⁶

Ideally, doctors’ ratio to participants is a maximum of 1: 2,500 participants if it is taken for just 20 minutes, with 15% participant visits. Clinics or Authorized Primary Care Facilities with large capitation funds have more flexibility in managing them, whereas those with small capitation funds have limitations in allocating their capitation funds. This will lead to neglect of service to some people.²⁶

Opportunities for fraud that could harm The National Health Insurance System participants in terms of the limitation of health services and access, including
discrimination to health services for participants and non-participants of JKN, limited basic service facilities, an improper work system leading to detrimental to The National Health Insurance System participants and very complicated procedures for participants to get health services.27

Weak internal controls facilitate fraud to grow and develop rapidly beside an inadequate external monitoring system. It makes fraud detection is not optimal. There are two mechanisms to prevent fraud. The first is to implement pre-employment screening, and the second is to implement mechanisms (internal controls) during the service time. An internal control system is clearly necessary for business success. A business needs to have some control to eliminate the element of opportunity.27

Discrimination is an unfair and unbalanced treatment to distinguish between individuals or groups, based on criteria, usually categorized or differentiating attributes. Theoretically, discrimination sometimes occurs through policies to reduce, destroy, conquer, move, protect legally, create cultural pluralism and assimilate other groups. In this regard, the differentiation of services and types of time for The National Health Insurance System participants is one example of discrimination.27

The service sharing system is considered valuable to employees, and it gives a positive perception of the service sharing system. Employees with the perception that the benefits they receive are not sufficient generally will try to find a better-rewarded place to work. Incentives can also affect the performance and presence of health workers at a primary clinic. Research in Banda Aceh showed that the distribution of capitation funds affects health workers’ performance in providing services. As the researchers suggest, Authorized Primary Care Facilities management can increase the distribution of capitation funds to each health worker to achieve better performance and provide health services as well as possible.28 This can be a form of service discrimination and fraud at the Primary Clinic.

Human resources are the potential to realize their role as adaptive and transformative social beings who can manage themselves and all the potentials around them to achieve balanced and sustainable life welfare. An effort to support productivity and activities needs competent and quality human resources to achieve the goals of a country or organization successfully.

Human resource skills play an important role in managing community service. The quality of human resources is one of the important factors for the continuity and progress of an organization since it can directly affect the organization’s performance. The main focus of human resource management is to contribute to organizational success. In clinics, unreliable human resources become a form of fraud.

The key to improving public and private health organizations’ performance is ensuring human resource activities support organizational efforts on productivity, service, and quality. Human Resource performance appraisal plays an important role in improving organizational performance. It is essential, especially for the services provided by human resources which support holistic health services.

Table 1. Difference capitation funds use by Hasan (2017)
Most of the primary clinics have constraints in infrastructure development. It is because infrastructure development costs a lot. Funds for supporting health operational costs are mostly used for infrastructure development. It is known that the unit cost of health services and medicines is a major component in calculating the amount of capitation.

The use of too-high operational costs can reduce the share of other costs utilization. For example, the use of operational costs taken from drug costs can cause the primary clinic to experience a stock out of the drug, disrupting the health service process for BPJS participants. Some small capitation fund primary clinics without pharmacies may experience losses and require bailouts to meet drug needs.

Inadequate facilities and infrastructure led to fraud; for example, The National Health Insurance System participants were sent to private laboratories for examining process. Public health facilities must provide minimum health services in a standard way. Facilities must include a general examination room, a treatment room, family planning and immunization, a dental and oral health room, a nursing room, a health promotion room, a pharmacy room, a birthing centre, a laboratory, and others. Other supporting facilities include waiting/registration rooms, consultation rooms, administration rooms, treatment rooms, action rooms, breastfeeding rooms, bathrooms, etc.

Activating internal controls can prevent the occurrence of fraud in the primary clinic. Active internal control is the most widely applied internal control applied. It is like a fence preventing thieves from entering people’s yards; however, a strong fence can still be penetrated by clever and brave thieves. Internal audit is beneficial to prevent the occurrence of greater fraud so that health services can run effectively, efficiently and integrated. The primary clinic must make clear policies and funds in conducting audits based on positive actions.29

Conclusion

The Healthcare and Social Security Agency has tasks to collect contributions paid by the participants, and then distribute it on a capitation basis to optimize services. Capitation is one of the models used in payments to Authorized Primary Care Facilities in The National Health Insurance System. Capitation funds are distributed to Authorized Primary Care Facilities which have collaborated with The National Health Insurance. The capitation system does not rule out the fraud, for example, the primary clinic, is not following statutory provisions, manipulates claims on non-capitally paid services, receives commissions for referrals to Authorized Primary Care Facilities, charges fees from participants that should have been guaranteed in capitation fees and/or non-capitation following the stipulated standard rates, making patient referrals only to obtain certain benefits; and/or other The National
Health Insurance System fraudulent actions. An internal audit team needs to be formed to oversee the use of capitation funds at the primary clinic. The capitation fund currently given to the primary clinic is considered insufficient to run the primary clinic’s operations and infrastructure, especially clinics with limited facilities, such as pharmacies and laboratories.

Abstract

Background: Patients’ satisfaction is a person’s feeling of pleasure or disappointment resulting from a service’s perceived performance or outcome to his or her expectations. As this definition makes it clear, satisfaction is a function of perceived performance and expectations. This study was undertaken to evaluate patients’ satisfaction level with the hospital services and health care providers among four government hospitals in Sulaimani city. The data from 311 inpatients admitted to and stayed in the hospital for any medical condition were collected by a face-to-face interview from November 2019 to February 2020. Standardized 4-point Likert scales ranging from satisfying to dissatisfying (1 to 4 points) were used for all the 24 items in the questionnaire. Data analysis was performed using a statistical package of Stata (14. version). A frequency analysis was used for demographic data analysis. A person Chi-square test was employed to determine the association between the categorical independent variables. The participant’s mean age was 37.9 SD 13.5 years with ages ranged from 14-85 years. The majority (86.5%) of the study participants were satisfied with the hospital services and environment while a small number 42 (13.5%) of them were dissatisfied with the issue. Almost 275 (88.4%) of the patients were revealed excellent nurse care and a very small number 36 (11.6%) was showed dissatisfaction. Also, 245 (79.1%) of the patients were satisfied with doctor care. Only 65 (20.9%) of them have a negative aspect of doctor care. A significant difference was found between the level of education and patients’ satisfaction with doctor care (coefficient 0.88, \( p<0.05 \)). Besides, a significant association was found between residence and hospital services (coefficient 0.63, \( p =0.05 \)). In general, we have discovered a satisfaction level among our sample is considered high and indicates good care provided by health facilities in all hospitals. Further study required seeking the least satisfactory factor regarding doctor care.

Keywords: Satisfaction, Shar hospital, nurse, Sulaimani, patients, physician

Introduction

Patient satisfaction has been described as the value and reaction of patients towards the care they received in the hospital and the medical care was performed (1). Patient satisfaction is a central indicator of health care quality and reflects the ability of the provider to meet the patients’ needs (2). So, it is a process as much as an attitude, so it must be, monitored continuously, and frequently measured. Patient satisfaction is essential and must be taken into account in assessing the quality of health care delivered particularly when decisions are being made about changes and enhancement in services. It also is used as an instrument in determining payment rates, especially in the context of a competitive healthcare atmosphere and consumerism (3, 4). Gradually, patients’ satisfaction became an essential component of health care services quality monitoring and improvement.

processes (5). Patient satisfaction with nursing care is of great importance to any health care agency because nurses comprise most health care providers and they provide care for patients 24 hours a day (6). Assessing to what extent patients are satisfied with health services is clinically relevant, as satisfied patients are more likely to comply with treatment, take an active role in their care, continue using medical care services, and stay within a health provider (where there are some selections to be made) and maintain with a specific system (7). Nurses are the frontline people that patients most likely meet up with, spend the highest amount of time with and rely upon for recovery during their hospitalization. Nursing care plays a prominent role in determining the overall satisfaction of patients’ hospitalization experience (2). Furthermore, maintaining good technical as well as interpersonal skills is essential for doctors to satisfy their patients (8). Besides, the demonstration of professionalism and ethical practice are also required to meet the expectations of patients. The technical expertise of physicians is regarded as consisting of maintaining an appropriate level of experience, ability to diagnose, the performance of clinical procedures, prescribing medicine, and learning about the latest medical developments. Moreover, the success with technical procedures, treatment, and medication depends upon favorable communication with patients (9, 10). Unlike developed countries, doctors are not made to comprehend the importance of ethical practice and communication skills during medical training. Physicians working in public hospitals deal with patients of a lower socio-economic class with negligible health awareness and poor hygiene. Understanding the patients and making them understand is the big challenge with which physicians are confronted in public outpatient clinics in developed countries (10, 11). Patients’ satisfaction of their relation with their doctors is a key element in the efficiency and usage of health services and varies depending on patient characteristics. Each patient has expectations when meeting a doctor and the difference between these expectations and what he obtains represent the perception of the satisfaction (12). Many previous studies have developed and applied patient satisfaction as a quality improvement tool for health care providers. Thus, patient satisfaction is an important issue both for the evaluation and improvement of healthcare services (13). The aims of the study: first, to analyze patient satisfaction with doctor and nurse-patient interaction and relationship. Second: to determine patient satisfaction with the quality of hospital and services performed to patients during their hospital stay in Sulaimani.

**Methodology**

This cross-sectional study was conducted from November 2019 to February 2020. The study population consisted of all patients admitted to four government hospitals (Shar Hospital, Shahid Hemen Hospital, Teaching Hospital, and Maternity Teaching Hospital) during the period of study. The four hospitals are located in the center of Sulaimani City. Shar, Shahid Hemen, and Teaching hospital are provided a wide range of care and treatment to adult people. Maternity Teaching Hospital is provided a wide range of care and delivers to women. In this study, the participation of the patients was voluntary. The data from 311 inpatients admitted to and stay in the hospital for any medical condition were collected. Convenient sample size was chosen because this is conservative and adequate when the proportion of participants is unknown. Patients selected for the study included those who were at least 2 days of experience of hospitalization and aged 14 years and over. The patient was interviewed when they were in a good situation and conscious. Accompanying patients were excluded from the study. The authors personally visited the hospitals and all of the respondents (patients) after informed consent was taking were told about the aim of the study and they were encouraged to contribute. Furthermore, the authors guaranteed the privacy of the responses of the participants. However, face-to-face interviews were conducted with patients with no education and education. Each interview session took about 10 to 15 minutes and the data collection process was conducted over a period of 16 weeks.

The questionnaire was originally developed in Kurdish for a better understanding of the local people.
The questionnaire was shared with the experts to ensure face validity, revised and a pre-tested questionnaire was used in this research. A pilot study was done before administering it to a representative sample. The aim was to find out if the questions are clear enough, clearly understood, in the right order and the provided answers are sufficient and detailed enough. The fill-in time was also determined. The questionnaire consists of four sections, the first section include Sociodemographic characteristics (age, gender, residence, occupation, marital state, and education), the second section consists of 11 items on the hospital services and environment, third and fourth section each consist of 7 items on physicians and 6 items for nurses care. The study was approved by the ethics committee of the Technical Institute of Sulaimani and permission was also taken from Sulaimani Directory of health and all hospitals.

Data analysis was performed using a statistical package of Stata (14 version) after the data was entered into the Epidata (3.1). A frequency analysis was used for demographic data analysis. A person Chi-square test was employed to determine the association between the categorical independent variables. Standardized 4-point Likert scales ranging from satisfying to dissatisfying (1 to 4 points) were used for all 24 items. Internal consistency was tested using Cronbach’s alpha coefficient. Scales 1, 2, and 3 were interpreted as being satisfied Patients’ and 4 dissatisfied. Binary logistic regression was subsequently conducted to predict the factors which influence the level of satisfaction.

Results

A frequency analysis was used for the demographic data analysis and general information about the survey participants. The results of the frequency analysis or demographic assessments are presented in Table 1. This includes age, gender, education, residence, marital status, occupation, and education of the participants. One-third of the participants (83.3%) aged 25 and over. The mean age was 37.9 SD 13.5 years with ages ranged from 14-85 years. The majority of the study participants were women (81.1%). A very slight difference was found between inside and outside participants (49.8% and 50.1%) respectively. Of (80.1%) the participants were married while the rest (19.9%) was unmarried. The larger part of respondents had no employment (20.3%). However, most of them were educated (60.1%).

The distribution of the participants of four hospitals was presented in Figure 1. There was a similar number (32.2%) of the patients who participated from Shar and Teaching hospital. While (25.6%) was from Maternity teaching hospital and fewer patients have participated from Shahid Hemen hospital was (9%).

3.1- Patient satisfied with hospital services and environment

Analyses of patients satisfied with hospital services and environment were shown in Table 2. A large number of the patients were satisfied with four hospital services 280(90%) out of 311 patients. We noted most of the respondents were satisfied with the patient’s ward and bedding (61.1%), ward cleanliness (91%), ward comfortable and calmness (71.4%). Of (81.7%) participants were satisfied with providing medical requirements by the staff while only a small number were dissatisfied (18.3%). One–third of the respondents (84.6%) answered that hospital departments (laboratory, radiology, and pharmacy…) can be easily found by the patients. Over half (68.8%) of the patients were satisfied with ward water facilities and sanitary while (31.2%) have a negative aspect. The majority of the patients (89.4%) were satisfied with the patient’s system registration. More than half (59.5%) of the patients were satisfied with the availability of medical requirements (drugs and medical items). A large number of the participants (92.3%) were satisfied with the doctor’s performance for medical procedures at the time needed. A high percentage (90% vs 91.6%) of the respondents was satisfied with the time patients examine by the physician and the finding of laboratory results respectively.

3.2- Patient satisfaction with nurse care

Regarding patients satisfied with nurse care was shown in Table 3. The majority (90.7%) of the respondents were satisfied with nurse behavior and patient respect. Of (89.7% vs 91.6%) were satisfied with nurse responsibility at any time. We noted a participant (92.3%) recorded that nurses have implemented each medical procedure adequately, (89.4%) of them providing a good explanation about the situation to the patients, and (87.5%) of respondents were answered that nurses were medically qualified.

3.3- Patient satisfaction with physician care

The study findings showed that (91%) of the 282 patients were satisfied with the doctor’s behavior and dealing respectfully with patients during an examination. (87.8%) respondents during visiting hospitals were strongly satisfied with the doctor responded to the patient’s condition and hear them. Also (84.2%), were mostly satisfied with doctors providing a good explanation about the disease condition and the best medical care requirements. Of 90% of the patients were satisfied with the time of examination by the physician. The majority of the patients (91.6%) were satisfied with the easy access to the physician as needed at night shift. Of these (87.5%) were satisfied with physician clarity of drug use and dose. We noticed that (75.6%) of patients were satisfied with the physician’s exam, while (24.4%) of the patients were unsatisfied.

The score level of patients’ satisfaction with the study subject was presented in Figure 2. The satisfaction score was ranged from 0-10 on a scale of 10. Two hundred ninety-six (86.5%) of the study participants were satisfied with hospital services and environment, while a small number 42 (13.5%) of them were showed dissatisfied with a mean score of 9.5, SD ±1.8. The majority of patients 275 (88.4%) were revealed excellent nurse care while a very small number 36 (11.6%) was dissatisfied, a mean score of 5.4, SD ± 1.3. Patients’ satisfaction with doctor care was 245 (79.1%) and a negative aspect was found among a small number of 65 (20.9%) with a mean score of 4.5, SD ± 1.7.
Chi-square analysis was performed to find the correlation between socio-demographic factors and patient satisfaction level with hospital services and health care (doctors and nurses) Table 5: We found no significant correlation between the participant’s age, gender, marital state, and occupation with the level of satisfaction. Except significant association was found between participant’s residence with hospital services (P-value= 0.04) and between education level with doctor care (P-value= 0.002).

Multiple logistic regressions for the level of satisfaction with hospital services and health care providers with socio-demographic factors (residence, age, gender, marital state, occupation, and education) were presented in Table 6. A residence was found significantly associated with hospital services satisfaction the coefficient 0.68, P= 0.05, and level of education was found significantly associated with doctor care satisfaction the coefficient 0.88, P= 0.01, while no significant association was found with remained factors.

Discussion

This study examined the level of patient satisfaction with a health care provider (nurses and physicians) and services performed in the non-private hospitals in Sulaimani city. We evaluated 311 patients among whom were highly satisfied with the nurse’s care (88.4%), physician’s care (79.1%), and hospital services (86.5%). The findings of our study are corresponding with the Saudi experience study and the study of Lagos University Teaching Hospital reported that patients with high levels of satisfaction with nurse care (2, 14) and the study of Southern Saudi Arabia (15). A lower number of patient’s dissatisfaction with hospital services and health care was recorded in this study. Such a low perception of satisfaction with staff care and hospital services by patients may create problems in the health system by decreasing trust and less utilization of services as well as delayed health-seeking with subsequent poor health outcomes of the public. We found the study participants were more satisfied with nurse care compared to doctor care. The result of this study appeared consistent with the study done by the Kingdom of Saudi Arabia (16) while inconsistent with the study reported by Southern Saudi Arabia (15). The study discovered that there were no significant differences between patients’ satisfaction and age and gender. Indeed, older respondents did not affect satisfaction values. However, several studies indicated that older participants are generally more satisfied with the health care provider and hospital services compared to younger respondents (17, 18). More females were participated in this study (81%) but no relationships were found between gender and level of satisfaction. Our results are similar to the study that reported patient gender did not affect satisfaction values (18). The Ha’il City, Saudi Arabiastudy also reported no relationships were found between gender and patient satisfaction levels (19). The results of this present study indicated that there was a significant difference between the level of education and patients’ satisfaction. Patient with a lower level of education was more satisfied with doctor care services than the higher education the P=0.002. The finding of this study is similar to some studies that reported that lower education level was greater satisfaction with health care service (20, 21) and also is consistent with a study that reported a higher level of education was less satisfied with health care (22). This can occur because patients with high educational levels possess more information about treatment alternatives and expect higher care standards and therefore are more critical in this regard. In regression analysis, significant associations between place of residence and patient satisfaction were identified, respondents in the rural area remained significantly associated with respect to satisfaction with hospital services the coefficient 0.63, p=0.05. The result of this study is in line with the study (23). This may be due to that some of the rural places they don’t have large hospitals and if they found, the quality of the services may be at the lowest level compared to urban a place. Our study has much strength including the use of validated measures of patient satisfaction, nurses and physician’s care, hospital services, and environment across four large government hospitals. The study has limitations as well. Data from both health care providers and hospital services are cross-sectional, thus limiting causal inferences about the associations found. The open bedside interview we use to collect data might also influence the participants’ responses to some extent even if the data collectors were not part of the treating team. According to our knowledge, this is the first quantitative study to determine the level of patient satisfaction with health care providers (nurses and doctors) and hospital services in Sulaimaniyah city.

Conclusions

In general, the study revealed that patients were highly satisfied with hospital service and health care providers in Sulaimani city. The proportion of patients satisfied with nurse care was found to be higher than the proportion of patients satisfied with doctor care and those with a lower level of education was more satisfied with doctor care than a higher level of education because the second group have adequate treatment information and predicted adequate care they received. Besides, respondents with rural residents are more satisfied with hospitals’ quality and services because some of the
respondents living in rural areas have a lack of large hospitals and inadequate health system services. If we improve the quality of hospital services and health care, it is clear that evaluating patients’ satisfaction should be constant to reformulate the baseline and regulation and to be able to assess interventions and changes in the health system. Further study is suggested on patient satisfaction with doctor care to find factors that influence low patient satisfaction compared to nurse care if we must improve the quality of health.

Acknowledgments: We would like to extend our gratitude to the Sulaimani directorate of health and Sulaimani polytechnic university for their permission. Furthermore, our gratitude also goes to all participants who voluntarily agreed to participate in this study and helping to complete this study.

Conflict of Interest: The authors declare that there was no conflict of interest.

Abstract

Introduction and Background: Healthcare-acquired infections [HCAI] account for 10-30% of all hospital admissions, according to the World Health Organization [WHO]. An estimated 1.4 million people are infected with HCAI at any given time.1 As the burden of health-care-associated infections grows, so does the seriousness of disease and treatment difficulty, which is exacerbated by multi-drug-resistant pathogens.2 Health care providers are reverting to the fundamentals of infection control by employing common steps such as hand hygiene.3 The WHO’s global initiative on patient safety programmers has made “Clean Care is Safer Care” a top priority. It is time for developing countries to formulate the much-needed policies for implementation of basic infection prevention practices in health care set-up.4

Nurses, the “nucleus of the health-care system,” spend more time with patients than any other health-care worker, and their adherence to hand-washing protocols appears to be more important in preventing disease transmission among patients. Hand hygiene is thought to be the most important factor in preventing healthcare-associated infections (HAI). Hand hygiene programmes with a variety of components have been shown to increase compliance among healthcare workers and, as a result, minimise infections. One such initiative is the World Health Organization’s implementation of an evidence-based definition called “My five moments for hand hygiene.”5

The investigator seeks to study the compliance to hand hygiene practices among staff nurses, working in the obstetrical and gynaecological wards. The research is an endeavour to increase the awareness and educate nurses about the need for compliance to hand hygiene practices.

Aim: A. The aim of this study was to see how well health care workers in the intensive care unit kept their hands clean (ICU)

B. To determine the causes of noncompliance, and

C. To investigate the effectiveness of a multimodal intervention approach in enhancing compliance.

Methodology: This Quasi experimental one group pre-intervention and post intervention study compares the compliance to hand hygiene practices before and after a multimodal interventional strategy

Setting: The study was conducted in ICU ward in hospital

Result: The study needed a sample size of 64 nurses to achieve an 80 percent power and a 5% error rate. A t test was used to compare the mean pre- and post-test scores. ANOVA was used to examine the relationships between the baseline variables. Hand hygiene enforcement among staff nurses increased dramatically from 45.31 percent to 65.78 percent following multimodal intervention strategies. (P<0.0001) Hand hygiene techniques have improved significantly (hand wash technique mean score increased from 5.97 ± 1.284 to 8.16 ± 1.158 (p<0.05) and hand rub technique score increased from 4.52 ± 0.992 to 6.69 ± 1.489 (p<0.05)). The private wards had considerably better hand hygiene than the general wards.

XI. Conclusion: The results of this study show that when multimodal interventional interventions were used, hand hygiene compliance improved.

Introduction

If there is an abundance of foreign matter in the air, it is referred to as air pollution. This can be harmful to both the person and the environment. The phenomenon known as “pollution” is an unavoidable result of man’s existence and behavior. The word “air pollution” refers to the presence of pollutants (e.g., chemicals, mixtures of gases, and particulate matter) in concentrations in the atmospheric (surrounding) environment that are harmful to human health. Chemicals join the food chain or are found in drinking water, constituting an additional source of human exposure, whether for safety or comfort, or because they are harmful to plants and animals. The direct impact of air pollution on plants, animals, and soil can have an impact on the structure and function of the eco system, including its ability to self-regulate, lowering quality of life.

Pollution is the introduction of pollutants into an atmosphere that cause the ecosystem, i.e. physical structures or living organisms, to become unstable, disordered, harmed, or uncomfortable. Pollution may take the form of chemical compounds or energy in the form of noise, heat, or light. Pollutants, or pollution elements, can be foreign substances or energies, or they can occur naturally; when they do, they are called pollutants when their quantities exceed natural levels. Pollution is often classified as either point source or nonpoint source. A variety of pollution-related diseases and health problems, such as respiratory infections, heart disease, COPD, stroke, and lung cancer, are all linked to air pollution.

Breathing difficulties, wheezing, coughing, asthma, and worsening of chronic respiratory and cardiac conditions are all possible health consequences of air pollution. Increased drug usage, increased doctor or emergency department visits, further hospital admissions, and premature death are all possible outcomes of these results. Bad air quality has a wide range of health consequences for humans, but it mostly affects the respiratory and cardiovascular systems. Individual responses to air pollutants are influenced by the type of pollutant, the degree of exposure, as well as the person’s health and genetics. Particulates, ozone, nitrogen dioxide, and sulphur dioxide are the most important sources of air pollution. In terms of overall deaths due to indoor and outdoor air pollution, children under the age of five years in developed countries are the most affected group.

Multi Modal Intervention Strategies:

XIII. The following multimodal intervention techniques were used in this study:

XIV. 1. Educational Initiatives: Demonstration and lecture focused on WHO’s Your Five Minutes of Hand Hygiene: Before patient touch, before the aseptic task, after the danger of body fluid exposure, after patient contact, and after contact with the patient’s surroundings

XV. 2. The HICC protocol is being reinforced.

XVI. • Signs throughout the nurses’ station and in the wards to serve as visual reminders.

XVII. • Verbal reminders to use a hand hygiene product

XVIII. • Hand hygiene solutions and services are readily available.

XIX. 3. One-on-one instruction and community discussion

Methods and Materials

Instrument: Three parts make up the data collection method.

Section A: Demographic data interview schedule includes age, years of experience, education, and field of employment.

Section B: Hand hygiene specific enforcement observation form Section B: Observation check list (WHO).

Tool for data collection
The researcher obtained written permission from the consent authority of prior of data collection. Data collection date waseldon. The purpose of the study was explained to the sample sand written informed consent was obtained. Their response was assessing.

Individual explanation was given regarding structured Knowledge questionnaires to assess the knowledge regarding effects of air pollution on health. Knowledge test was checked. The average time taken 60 minutes. All people gave good cooperation during data, investigation, analyzed the data and made findings.

**Study participants and size:** Sample size determine by power analysis calculated based on previous studies.

\[
N = \frac{4pq}{L^2}
\]

Where \( p = 0.087 \), \( q = 0.913 \)

\[
= \frac{4 \times 0.087 \times 0.913}{0.017 \times 0.017} = 0.317 = 1097
\]

Calculation sample size for this study was 1097, due to time constraint and global pandemic situation investigator consider 64 participants for the study.

**Result**

**SECTION 1: Distribution of Nurses according to the demographic variable**

</tbody>
</table>

* Significant
Table II shows that the pre-test and post-test scores for hand washing techniques vary significantly. Before intervention, the mean pre-test score was 5.97; after intervention, it was 8.16. At the 0.05 stage, the obtained t value is meaningful.

With a t value of 0.05, the data in Table II c shows that there is a substantial difference in hand hygiene technique (hand rub) before and after intervention. Thus, at the 0.05 stage, Hypothesis 1 is accepted: there is a substantial difference in hand hygiene practise enforcement before and after multimodal interventional strategies among staff nurses.

A - ANOVA, t- independent t test:
Table III Demonstrates that there is a strong link between hand hygiene enforcement and the type of job (private room). At the 0.05 stage, the obtained t value is meaningful. Some baseline variables have no meaningful relationship (Age, Years of Experience and Education). At the 0.05 stage, Hypothesis 2 is agreed for the work field.

Discussion

The current research included 64 staff nurses between the ages of 21 and 24 years old. The majority of them (53.1 percent) have a nursing degree. Staff nurses were employed in obstetrics and gynaecology general wards by 48 (75%) of them, and 37 (57.8%) of them had clinical experience of up to two years. The age group of 21-24 was found to have the highest level of hand hygiene compliance in the sample. The baseline characteristics were close to those of a previous descriptive cross-sectional analysis on nurse compliance with hand hygiene procedure and expertise conducted in the intensive care units of a hospital in Kuala Lumpur. There were a total of 84 nurses on board. It revealed that the majority of people (53.6%) agreed with the statement the staff nurses ranged in age from 21 to 30 years old. The respondents had 1 to 5 years of work experience (34.5%), and the majority of them had a Diploma as their educational qualification.

The results of this study show that after multimodal interventional interventions, there is a substantial difference in pre-test and post-test scores in hand hygiene enforcement and practises. Compliance improved (p<0.001) from 45.31±10.23 to 65.78±9.22. Hand rub techniques improved from 4.52±0.99 to 6.99±1.48 (p<0.001), while hand wash techniques improved from 5.97±1.28 to 8.16±1.16 (p<0.001). In a tertiary care hospital in northern India, a similar prospective study was performed in the adult ICU. Hand hygiene compliance was initially measured over a 6-week span, with pre-intervention hand hygiene compliance of 21.48 percent and post-intervention hand hygiene compliance of 61.59 percent (p<0.0000).

Before and after the introduction of a multimodal interventional strategy, hand hygiene enforcement was 40 to 55 percent before patient contact and 42 to 62 percent after patient contact in the current report. Hand hygiene enforcement increased from 40 to 53 percent before patient contact in a neonatal ICU before the introduction of a multimodal implementation programme, and from 39 to 59 percent after patient contact, according to a report by Lam. They came to the conclusion that a good education programme could help people keep their hands clean.

Hand washing agents cause irritations and dryness, sinks are inconveniently located, shortages of sinks, always too busy, insufficient time, patient needs take priority, wearing of gloves, beliefs that glove use obviates the need for hand hygiene, low risk of infection from h. influenza Other studies have shown that non-compliance is due to a lack of understanding of guidelines/ procedures, a lack of rewards/ motivation, and a lack of a role model from a colleague.

Conclusion

The results of this study show that when multimodal interventional interventions were used, hand hygiene compliance improved. In order to improve hand hygiene practises among hospital staff nurses, formal communication and hand hygiene education, promotion, and leadership support are needed. As a result, the investigator is confident that this will be a reliable piece of knowledge for health-care professionals, allowing them to offer thorough patient care while also improving nursing practise efficiency.

Antimicrobial Peptide Cathelicidin and Vitamin D Receptor Gene Polymorphism in Oral Health

Nireeksha 1, Mithra N Hegde 2, Suchetha Kumari N 3
1 Lecturer, 2 Vice Principal, Head of the Department, Department of Conservative Dentistry and Endodontics, A.B.Shetty Memorial Institute of Dental Sciences, Nitte University (deemed to be) Deralakatte, Mangalore, 3 Professor, Department of Biochemistry, K.S.Hegde Medical Academy, Nitte University (deemed to be) Deralakatte, Mangalore

Abstract

Background: Anti-microbial peptides and vitamin D levels in saliva, GCF play an important role in oral health and its maintenance. The peptide levels are regulated by the Vitamin D cathelicidin pathway and their association and influence on oral health is of utmost importance. The aim of the present review article is to establish the aim is to establish a relationship and possibly the role of Cathelicidins and Vitamin D receptor gene polymorphism in relation to oral health.

Methodology: The preferred reporting items for systematic review ad meta analysis (PRISMA) were used for reporting this systematic review. The study protocol has been approved by all co-authors. The study has been registered at the National institute for health research (NHR) under the Prospero ID: CRD42020200946.

Results: A total of 102 articles were retrieved through electronic database search. After evaluating the title, abstract and full text of these articles only 7 were selected for the present systematic review. However 3 articles were excluded because they were classified as high risk of bias according to PRISMA guidelines. Out of 7 studies selected, 4 were classified as low risk bias and 3 were classified as moderate risk bias.

Conclusion: The current evidence suggests anti-microbial peptide LL-37 and vitamin D receptor gene polymorphism plays an important role in caries prevalence and periodontal health.

Highlight: Understanding the role of antimicrobial peptides in saliva helps in enhancing focus on the effect of these components on oral health and its maintenance.

Keywords: Saliva, Anti-Microbial Peptide, Vitamin D, Dental Caries, Periodontitis.

Introduction

Organisms possess very strong defence system to combat the invading pathogens and micro-organisms. One of the principal defence system which plays a major role against microorganism is innate immunity system. The anti-microbial functionality of innate immunity modulates the disruption of gram negative, gram positive, fungi and virus principally by disruption of bacterial cell membrane. Anti-microbial peptides enhances the chemical and physical barrier in mucous membrane and skin. Various recognized anti-microbial peptides are highly conserved and expressed in organisms such as insects (drosophila) rabbits, mice, crabs. They are expressed in response to inflammatory conditions by phagocyte cells like monocytes, macrophages and granulocytes.

Oral cavity inspite of these numerous bacterial colonies and has high chances of invasion to the body through GIT, epithelium, gut, surgical procedure rarely leads to infection. Thus, indicates a strong and efficient host defensive mechanism that is in action. Production of antimicrobial peptides from neutrophils, salivary gland makes saliva rich in its anti-microbial, anti-fungal and anti-bacterial properties. They perform various functions...
like stimulation of epidermal growth factor thereby promotes wound healing, stimulates keratinocytes, chemotaxis and immune activation. The binding ability of LL-37 to lipopolysaccharides and neutralizing its activity facilitates a strong positive correlation between inhibition of lipopolysaccharides induced cytokine secretion. LL-37 influence epidermal growth factor levels, migration of keratinocytes and mediates angiogenesis. This quality of these AMP’s make them an area of interest and they are also extensively studied².

These anti-microbial peptides destroyed by attraction, attachment and insertion. Attraction is electrostatic attraction between cationic and anionic moieties on bacterial membrane, these antimicrobial peptides attach in parallel/perpendicular manner to the membrane thereby stretching the bacterial membrane further thinning it down leads to pore formation, further insertion of these antimicrobial peptides takes place by three different model systems barrel stave model, carpet model leading to bacterial dissociation. Several types of anti-microbial peptide adverse in their sequence and structure are identified. Among them cathelicidins are peptides which are crucial in inflammatory conditions.

Cathelicidins are transcribed from a single gene CAMP with a N-terminal [30 amino acid residues] a highly conserved pro-sequence and mature antimicrobial peptide name LL-37 at the C-terminal domain. It has been observed that LL-37 play a role in oral inflammatory conditions, few studies show their association of these peptides. The peptide has anti-microbial activity against gram positive and negative bacteria specifically on clinically relevant pathogens such as Pseudomonas aeruginosa, Escherichia coli, Staphylococcus aureus, Salomonella typhimium at a mic of <10µg/ml also has an effect on lowering release of pro-inflammatory mediators. This peptide is located in azurophil granule, immature neutrophils, NK cells, monocytes, mast cells, squamous epithelium, airway, mouth, tongue, oesophagus, intestine, cervix and vagina. Widely produced in salivary glands, acinar cel of submandibular glands and minor glands⁵. This systemic review will focus on Cathelicidins [LL-37] and its role in oral inflammatory conditions.

### Materials and Methods

The preferred reporting items for systematic review ad meta analysis (PRISMA) were used for reporting this systematic review. The study protocol has been approved by all co-authors. The study has been registered at the National institute for health research (NHR) under the Prospero ID: CRD42020200946.

#### Systematic search strategy:

Electronic search strategy consisted of two stages: Stage 1 included studies that specifies antimicrobial peptide levels and vitamin D receptor gene polymorphism, Stage 2 included systemic search to identify various studies evaluating these levels in association with oral health and disease [Dental caries and Periodontitis].

Focused question: For identifying various studies the below mentioned focused questions were adapted using PICO criteria (Miller and forest 2001)

“What is the role of anti-microbial peptide LL-37 (Cathelicidins) in oral health and the association of vitamin D receptor gene polymorphism and dental caries”

**POPULATION:** Younger adolescence and middle aged with dental caries and periodontitis.

**INTERVENTION/EXPOSURE:** Salivary antimicrobial peptide levels and its protective anti-inflammatory effect on oral health.

**COMPARISON:** Control group with Good oral hygiene (Low caries index and good periodontal health) Case group with poor oral health status (High caries index and poor periodontal health).

**OUTCOME:** Effect of LL-37 levels and vitamin D receptor gene polymorphism on caries prevalence and periodontal health.
Scope:

Clinical studies which involved estimation of LL-37 and vitamin D receptor gene polymorphism conducted in human subjects. Comparison done between healthy individuals and study subjects with dental caries and periodontitis. Animal studies, abstracts, letter to editors, narrative reviews and case reports were excluded.

Sources:

Electronic search was performed in Pubmed medline, ISI web of science and medline database applying Mesh terms “dental caries”, “periodontal disease” “Cathelicidins” “LL-37” “Vitamin D” “VDR receptor gene polymorphism” “saliva”. The search system reviewed the article published between 2009 to 2019. Also a hand search of references and related articles were performed.

Study Selection:

Controlled observational studies comparing and evaluating dental caries and periodontitis with LL-37 and vitamin D levels were selected. Studies concerning permanent dentition individuals with any other systemic disease and under medication that effect the salivary composition were excluded. Case report, review articles were excluded. Studies which presented at least 8 of evaluating criteria were considered as low risk bias and 4 to 7 criteria were considered “moderate risk” less than 3 criteria it was considered as high risk bias and excluded from the study due to low evidence.

| 1. Definition of inclusion criteria |
| 2. Definition of exclusion criteria |
| 3. Dental caries diagnosis criteria |
| 4. Periodontal condition and evaluation criteria | 5. Saliva collection description |
| 6. Statistical analysis description | 7. Risk of Bias |
| 8. Level of evidence |

Chart 1: Quality assessment criteria

Result

Electronic search retrieved 102 no-duplicate records. However, after checking the titles, abstract and full texts, 9 studies were selected for this systematic review. Two of them [Davidipoulou et al and Putsep K et al] were excluded because they were classified as high risk bias leaving a total of 7 for systematic review, from the selected studies. 4 classified as low risk and 3 classified as moderate risk bias. Table 1 shows quality assessment, table 2 gives description of study group.

Simon Sara included 33 children’s grouped based on caries at baseline and developing caries were further evaluated. Turkaglu et al conducted a study including 4 participants with gingivitis and healthy periodontal tissue were included and presence/absence of caries was not of concern. Another study conducted
by Davidopoulu included 49 systemically healthy individuals evaluated for Decay index, periodontal index and gingival index and were divided into 3 groups based on caries experience7.

Takeuchi conducted a study among 69 patients, comparison between them was done based on probing depth, clinical attachment levels, Bleeding on probing, Plaque record. No comparison with healthy individuals was done9. Turkoglu in 2009 evaluated IL-18 and LL-37 in 18 healthy 41 individuals with chronic periodontitis and comparison of these levels was done10. BsmI and Folk gene role in VDR receptor gene polymorphism was analyzed by Yu M et al and Kong YY among 400 and 380 consequently. Both the studies included caries free group for comparison11,12.

Based on the results of selected studies 5 studies showed statistical difference between groups with/without caries and with/without periodontitis. Two of the studies showed association between BsmI and Folk gene polymorphism and dental caries.

Discussion

The selected studies were those which satisfied the minimum criteria that would be able to evaluate the role of LL-37, Vitamin D in caries and periodontal conditions. Rolf Kotsmann in 1956 first reported condition called morbus Kostmann syndrome (infantile genetic agranulocytosis) with a missing serum factor. These patients were highly susceptible to repetitive infections primarily gingivitis and periodontitis persisted even after antibiotic treatment. Later absence of LL-37 in saliva and load were reported. LL-37 is tested as an anti-biofilm compound, due to its broad spectrum effect, rare resistance development by bacteria’s, bacterial growth inhibition and bactericidal activity. These Anti-microbial peptides help in maintaining oral health by allowing more resistant non-pathogenic bacteria to dominate the colonization. The conducive factor for anti-microbial activity is the low ionic strength of saliva. Therefore evaluation of LL-37 plays a major role in caries risk assessment and development of treatment strategies.

Majority of studies showed relationship between salivary LL-37, periodontitis and dental caries. In a study microbial composition was compared with LL-37 levels in children significant increase in LL-37 levels in healthy individuals throughout the study. This longitudinal study concluded that both antimicrobial composition of saliva and bacterial composition predispose development of dental caries. In another study LL-37 levels were evaluated in different age group in patients with gingivitis showed that inflammation of gingiva as an increasing effect on LL-37 levels, independent of individual agegroup.

Caries experience and LL-37 were evaluated in relation to age, gender, type of dentition i.e. primary, mixed and permanent in a study which showed that there is low peptide at early childhood and 100 fold increase in adolescence in ng/ml. Variation in gender was served based on differences in immuno-competency. Thus suggested that LL-37 may serve as prognostic tool for disease and efficient therapeutic agent. A study compared LL-37 in chronic periodontitis shows increase in LL-37 which may be attributed to response of innate defense mechanism against peri-odontopathic bacteria.

In contrast LL-37 was elevated in chronic periodontitis compare to healthy individuals, suggesting an important role of LL-37 in pathogenesis of chronic periodontitis they concluded that LL-37 in gingival crevicular fluid was sufficient to decrease or prevent periodontal destruction. IL-18 was evaluated to identify whether both LL-37 and IL-18 contribute to innate immunity in periodontal destruction. IL-18 is a pro-inflammatory cytokine stimulates mediator’s of inflammation and activate neutrophil’s thus a part of host defense it was showed that LL-37 can stimulate production of IL-18. But in this study there was no correlation between the LL-37 levels and IL-18 in chronic periodontitis.

These peptides being one of the important effector molecules of innate immunity is produced by the circulating cells, bone marrow progenitor cells, various epithelial surfaces, inflamed gingival tissues. Vitamin D is critical for regulation of CAMP gene and DEFB4 gene which codes for cathelicidin and defensins in both normal and hematopoietic cells. Therefore, vitamin D boosts innate immunity system and helps in wound healing and infection control. Presence of pathogen stimulates toll-like receptor’s (TLR) of macrophages inducing expression of CYP27B1 (25- hydroxyvitamin D-1α-hydroxylase) which, in turn, leads to the production of bioactive 1,25(OH)2D from circulating inactive 25(OH)D. Locally increase in 1,25(OH)2D activates CAMP gene which codes for cathelicidin. The release of cytokines are also mediated through stimulation of toll-like receptorsthrough vitamin D. Thus, Vitamin D levels play a major role in modulating immunity.

Kong YY and Yu m et al studied the possible correlation between genetic polymorphism of vitamin D receptor and occurrence of dental caries. Vitamin D regulates the calcium metabolism and promotes calcium depositing on enamel, also in a meta-analysis they mentioned that supplementation with vitamin D decreases he occurrence of caries by 40%. Both these
studies showed correlation between vitamin D and caries pattern even though the specific mechanism is not understood. A single variable like LL-37 is difficult to establish as a marker because dental caries is multifactorial as a maker in nature. Understanding the complexity of peptide and their role in innate immunity makes it complex to understand the role of these LL-37 peptides in dental caries. They target a broad spectrum of microbial activity, the ease of synthesis they are ideal for formulation of peptide based oral health care products along with routine maintenance of oral hygiene methods. Since they help to kill bacteria selectively in mixed culture, they can be used as an adjuvant to standard hygiene care in immune-compromised patients, control biofilms, progression of caries, biofilms on implants also prevention of plaque mediated dental diseases. These Anti-microbial peptides can be idealized has biomarkers for dental caries assessment, the up regulation and down regulation of these peptides may help in monitoring treatment outcome pre and post treatment. They are highly conserved and show relatively lower potential to resistance against microbes.

**Conclusion**

The selected studies showed a significant variation in LL-37 levels in dental caries, periodontitis, gingivitis and vitamin D polymorphism with dental caries. Still the complexity in mechanism of action of LL-37 and its relationship with Vitamin D levels makes it difficult to conclude. Only with more evidence and analysis we will be able to establish vitamin D and L-37 have a major role to play in occurrence and progression of dental caries.

Primary Closure after Open Common Bile Duct Exploration in Comparison to T-tube Drainage. Our Experience in a New Medical College of Assam

Nirmal Kumar Agarwal¹, Jon Bordalai¹, SantanuSarma¹
¹Asso. Prof. of Surgery, Tezpur Medical College, Tezpur

Abstract

Background: Traditionally T-tube drainage of CBD is most commonly done. However T-tube has its own problems mainly longer hospitalisation, longer absence from work and many complications. This study done to assess outcome of primary closure of CBD after open CBD exploration.

Methods: This retrospective study was done in Tezpur Medical College which is a new medical college in Assam. All the patients who underwent CBD exploration in our unit were analysed to compare the results. All together 38 patients underwent CBD exploration of which in 18 primary closure of CBD was done.

Results and Conclusion: Our results indicate lesser complications for primary closure, much shorter hospital stay in comparison to T-tube drainage.

Primary closure of CBD after choledocholithotomy is safe, much simple and effective and has lesser complications in comparison to T-tube drainage.

Keywords: Common bile duct (CBD), primary closure, T-tube, choledocholithotomy

Introduction

Gallstone disease is very common prevalence in population and along with Gall bladder(cholelithiasis), stones are present in 5-15% of gallstone patients in common bile duct(choledocholithiasis). Surgical intervention is necessary for CBD stones. Management options are- either endoscopic sphincterotomy in case of smaller stone or surgery is required in case of ERCP failure and in case of larger CBD stones. After surgical exploration of CBD i.e. choledocholithotomy, traditionally common bile duct is closed over a T-tube. The purpose of using T-tube drainage after open CBD stone removal is to decompress the CBD and to allow for oedema at sphincter of Oddi to subside. It also allows radiological visualisation of CBD in post-operative period and a potential route for stone extraction of any retained stones. T-tube is kept for about 10-28 days and a T-tube cholangiogram is usually done at 10-14 days to look for any retained stones. Traditional CBD closure over T-tube carries potential complications. These include bacteremia, dislodgement of tube, obstruction and/or fracture of tube. Further leakage of bile may be encountered after removal. Patients may have to carry it for several weeks before removal. All of these lead to prolong length of hospital stay and increased cost. The role of T-tube has been challenged...
and primary closure of CBD after exploration has been described more than a century ago. Primary closure of CBD has been described in literature to overcome adverse consequences of T-tube\(^9\). Traditionally it is thought T-tube has definitive role after CBD clearance, but many authors found no significant difference in the complication rate or mortality between primary closure and T-tube drainage\(^10,15\). Others found higher morbidity in terms of more biliary infection, discomfort from tube, delayed discharge from hospital\(^11\)-\(^19\). However still there are apprehensions in the minds of surgeons and primary closure is not performed routinely.

This study was conducted to assess the outcome of primary repair of CBD in terms of patient comfort, duration of hospital stay and post-operative complications.

**Materials and Methods**

This retrospective study was conducted in department of surgery of Tezpur Medical College which is a new medical college in Assam. All together 38 patients of common bile duct stones were analysed from January 2017 to February 2020. Out of 38 patients 20 underwent T-tube closure (group I) while 18 patients (group II) underwent primary closure of CBD. The patients were investigated with required blood investigations for operative procedure like haemogram, blood sugar, renal function test, liver function test, PA view x-ray chest, E.C.G., prothrombin time, thyroid status and viral markers. Ultrasonography of abdomen was done to see dilatation of CBD, stones in CBD and MRCP done in selected cases. Contrast enhanced CT was done in selected cases to rule out malignancy, pancreatic diseases causing jaundice and other conditions like renal failure and these patients were not included in study. The studied patients underwent open cholecystectomy through moderate size subcostal incision followed by supraduodenal CBD exploration between stay sutures. Stones were removed from CBD with Desjardin forceps and CBD was irrigated with normal saline ensuring no stone is left. Also patency of CBD checked with 10F feeding tube and Bakes dilator passing readily into duodenum. Intraoperative choledochoscopy could not be done because of nonavailability. This is also a reason for not doing primary closure in many cases. T-tube was inserted in 20 cases (group I) and primary closure was done in 18 cases (group II). Primary closure of CBD was done with 3-0 vicryl interrupted sutures. 12F size T-tube was inserted in group I patients and opening in CBD around T-tube was made watertight with 3-0 vicryl sutures.

![Figure 1-Primary closure of CBD after choledocholithotomy](image)

In all patients a subhepatic tube drain was inserted which was removed after 3-6 days. T-tube was removed after 3 weeks after a satisfactory T-tube cholangiography after 10-14 days. The other options of CBD stone management like choledochoduodenostomy, transduodenal sphincterotomy/sphincteroplasty which are necessary in selected cases of CBD exploration for stone are not discussed in this study. All patients were given standard post-operative care with IV fluids. Antibiotics, analgesics and followed up at 3 weeks, 3 months and 1 year. Primary closure was done in those patients with few stones (up to 2 wholesome stones) not breaking easily while holding with Desjardins forceps. T-tube was given in those patients with large number of stones of different sizes, easily crushable stones, CBD much inflamed.
Results

Out of 38 patients who underwent CBD exploration 28 were females (73%) and 10 (27%) were males. Age group varied from 32 to 67 years. In group I average duration of hospital stay was 12 days (8-16) and in group II, hospital stay ranged from 4-7 days average 5 days. In group I, one case (5%) had tube dislodgement on 4th post-operative day which was again inserted operatively and another patient developed bile leak about 200ml which was managed conservatively by drain. In group II, one patient developed bile leak about 300ml on 2nd post-op day which subsided by 4th post-op day. In group I one patient had residual stone which was referred for ERCP removal. Other complication were superficial wound infection one in each group. No postoperative haemorrhage, biliary peritonitis, acute pancreatitis were found. However one patient with residual stone developed pain and jaundice which was persistent. Size of CBD ranged from 8-17mm. average operation time was 65-85 minutes more in T-tube group. Serum bilirubin level ranged from 1mg(normal) to 9.6mg/dl.

Discussion

The current standard protocol for the treatment of CBD stones is to clear CBD by means of Endoscopic retrogradecholangio-pancreatography(ERCP), followed by laparoscopic cholecystectomy in today’s minimally invasive era. However, these minimally invasive approaches are not widely practised in many developing countries including ours due to the lack of equipment and trained endoscopists. Even in the developed world, in rural setting there is lack of equipment for these techniques. In many studies, ERCP was less successful compared with open surgery in CBD stone clearance and was associated with a higher mortality rate. There is also an increased incidence rate of CBD stones after endoscopic removal. Post ERCP pancreatitis, chance of ascending cholangitis, haemorrhage and very rare possibility of increased chance of malignancy cannot be ignored. Traditionally after exploration of CBD, t-tube is placed. The T-tube drainage is helpful to prevent bile stasis, decompress the biliary tree, allows spasm or oedema of sphincter of Oddi to settle after the trauma of exploration and acts as a stent in CBD and minimises the risk of biliary drainage. A T-tube has also provided an easy access for cholangiography and extraction of
Indian Journal of Forensic Medicine & Toxicology, October-December 2021, Vol. 15, No. 4

2021

retained stones. Despite these potential advantages, morbidity rates related to T-tube have been reported to be at a rate of 4-16.4%. The T-tube related complication includes accidental T-tube displacement leading to CBD obstruction, bile leakage, persistent biliary fistulas and excoriation of the skin, cholangitis from exogenous sources through the T-tube, and dehydration and saline depletion. Additionally, CBD stenosis has been reported as a long term complication after T-tube removal. After discharge, indwelling T-tube becomes uncomfortable, requiring continuous management, thus restricting patient’s activity because of the risk of dislodgement and prolonged absence from joining work. As T-tube drainage is associated with these significant disadvantages, therefore, primary repair of CBD has been advocated in literature. The four requirements for a safe and successful primary closure are patent ampulla of Vater, complete removal of all intraductal calculi, absence of pancreatic pathology and meticulous suture of the duct. This study shows that hospital stay in the T-tube group (8-16) days versus 4-7 days in primary group was longer than primary closure group which is in agreement with studies conducted by Zhang et al, Ambreen et al, and KywinTah Noe et al. In our study in T-tube group there were complications like bile leak, infection and dislodgement of T-tube which required replacement operatively. The main drawback of T-tube was that it was uncomfortable, require continuous management and it restricts patient’s activity because of risk of dislodgement. It also affects the patient’s quality of life. Retained stones following CBD exploration remained a significant complication and it was reported in up to 10% of cases in relevant studies. In present study in T-tube group, one patient (5%) had retained stones and these were removed by ERCP. Post-operative hospital stay was much shorter in primary closure group and hospital expenses were also lower than in the T-tube group. After discharge from hospital there is no effect on patient’s quality of life and they can join their jobs early. Biliary complications are considered to be major consequences after primary repair of CBD. However their overall frequency are not higher than T-tube closure. In this study one patient in each group had bile leak which subsided with conservative management. The use of primary closure was limited in the treatment of patients with severe acute biliary pancreatitis, acute pyogenic cholangitis or ampullary stenosis because they required CBD decompression and biliary drainage or other preferable therapeutic options. A small diameter CBD (8mm) may be a contraindication for primary closure because this might increase the risk of bile duct stricture. To minimise post-operative complications, the indications for T-tube must be strictly followed, such as CBD stones secondary to intrahepatic duct stones or if there is undefined residual stone in the intrahepatic or extrahepatic ducts, vague patency of the Oddi’s sphincter or failure to pass bae’s dilator through Vater’s ampulla due to oedema or obstructed stones, acute suppurative cholangitis with severe oedema of the CBD wall.

Results of our early experience with primary closure did not increase the risk of bile leak after the operation. Post-operative hospital stay and operation time (75min) were shorter and lower hospital expenses. With primary closure, we could surely avoid T-tube related complications.

Therefore we can conclude that primary closure without T-tube drainage after cholecystolithotomy is safe, much simpler and cost effective. Post-operative primary closure should be preferred in most cases after CBD exploration wherever possible. However larger randomised trials with longer follow up are necessary to find whether there is stenosis or any other problems after primary closure.

Conclusion

From the study we can conclude that primary closure without external drainage (T-tube) after cholecystolithotomy is safe, feasible, much simple and effective. It reduces the hospital stay and cost, can be done in many cases of CBD exploration and is much comfortable for the patient. However randomised trials on a larger scale of patient and a longer follow up are necessary to address the issue.

Detection of Mn – Dependent Chitinase for Wheat Root Rot Disease Control by Real time PCR

Noor Maath Ahmed¹, Akeel Hussian Ali Al-Assie¹, Abdullah Abdulkareem Hassan²

¹Researcher, Department of Biology, University of Tikrit, College of Science, ²Prof. Department of Plant Protection, University of Tikrit, College of Agriculture

Abstract

The use of some mineral salts with concentrations of 10, 30 and 50 mm Muller led to the inhibition of the activity of the enzyme chitinase, but to varying degrees. Manganese chloride MnCl₂ showed more effect in stimulating the activity of the enzyme, as the effectiveness reached 74.87% in addition to calcium chloride CaCl₂, which had a stimulating effect for the enzyme as well. The salts EDTA and NH₄Cl had an inhibitory effect on the enzyme activity. The field experiment was conducted for the purpose of inducing systemic resistance of wheat plants with the fungus T. longibrachiatum under conditions of infection with the pathogen Fusarium oxysporum and evaluating the efficacy of the chitinase enzyme in improving plant growth for three varieties of wheat, which are Iba 99, Sham 6 and July 2 for 45 days, after which the vegetative characteristics were taken. For cultivated plants and the efficacy of the chitinase enzyme for the shoot and root system, the induction treatment (pathogenic fungus + T. longibrachiatum + MnCl₂) proved its role in the highest reduction of the severity of infection with the pathogen fungus of wheat, reaching 18.05% and the high vegetative and root growth indicators under conditions of pathogen infection and for all the studied varieties. The results of induction were due to the increased expression of the chitinase enzyme gene. RT - PCR technique was used. It showed that all the studied cultivars with 99, Sham 6 and July 2 had higher expression than the control treatment.

Keyword: Wheat, chitinase, MnCl₂, Trichoderma, RT-qPCR

Introduction

Wheat Triticum L. belongs to the Poaceae family, and it is one of the oldest agricultural crops known to man, as it is grown on a large scale and produced in large quantities. Many of the economic losses in agricultural crops are due to its infection with fungi, and the fungi of roots rot the largest share, and at the forefront of these crops is wheat and barley. The symptoms of field infection are the absence of plants from some areas or the presence of scattered areas in the field of yellowish or wilted plants due to infection with the fungi of root rot, and the infection of different wheat plants with different types of fusarium, which affects the wheat yield. The severity of the disease was inversely related to the plant height. It also significantly contributed to reducing the number of heads and their infestation with mold[1].

There are many problems facing the process of growing the wheat plant, which cause a significant reduction in its production and quality, including the pathogens that afflict it in all stages of its growth and attack its various parts, causing the deterioration of its production in terms of quantity and quality and the occurrence of economic losses, especially when the appropriate conditions are available, including disease of seed rot, roots and death. Wheat seedlings caused by the fungus Pythium spp., Rhizoctonia solani, Fusarium spp. and other fungal species [2]. The fungus Fusarium sp. Fusarium head blight (FHB) for wheat is the most important problem in cereal cultivation, which leads to large quantitative losses and deterioration of the quality of grain fields and their products. Crop losses due to FHB can be excessive and in maximum cases up to 70% [3]. Fusarium head blight (FHB) mainly caused by F. graminearum is one
of the most destructive fungal pathogens of wheatgrass and very important economically\cite{4}[5].

Many studies have emphasized the importance of enzymes in biological control, including chitin degradation enzymes, as they received great attention in this regard and were developed as biopesticides or chemical defense proteins in genetically modified plants or microbial biological control agents. The biological control of the fungal diseases that carry the soil is interrelated with the production of chitinase, as the fungi and bacteria producing the enzyme chitinase are more virulent in inhibiting the growth and killing of pathogenic fungi \cite{6}. The chitinase enzyme is one of the hydrolysis enzymes secreted by the plant when stimulating its resistance, and its secretion to this enzyme gives it protection from pathogens and increases its resistance to pathogens at different levels as it works to release N-acetyl glucosamine upon infection \cite{7}[8].

Some enzymes show an absolute need for a specific inorganic ion for their catalytic activity, while other enzymes show increased activity when certain cations are added to the reaction medium. Some divalent cations can replace each other, but sometimes one of them competes with the other, while inhibitors reduce the activity Catalytic enzymes\cite{9}. Found Lee\cite{10} that the purified chitinase from Penicillium sp. LYG0704 was inhibited by (79 and 81)% in the presence of iron ions (Fe + 2) and mercury (Hg + 2). Respectively, while the magnesium ions (Mg + 2) and molybdenum (Mo + 2) had an inductive effect on the activity of the enzyme by (26 and 22)%, respectively, at a concentration of 1 mmol at a temperature of 37 C for an hour. Told Yi\cite{11} that zinc ions (Zn + 2), calcium (Ca + 2) and iron (Fe + 2) had an effect on the activity of the enzyme beta 1 - 3 clokinase purified from the fungus Trichoderma viride TP09. Due to the spread of wheat root rot disease and its increase in recent years And the importance of the chitinase enzyme in biological control and the role of T. RT-PCR cannula in detecting enzymatic activity. The study aimed:

1 - Use of RT - PCR technique to determine and quantify the expressivity of the chitinase gene.

2 - The effect of mineral salts in activating and inactivating the enzyme chitinase induced by wheatgrass, class Iba 99.

3 - The effect of the mineral inhibitor MnCl2 and the chitinase enzyme on pathogenicity of Fusarium oxysporum on the wheat plant.

Materials and Methods of Work

The Effect of Mineral Salts on the Effectiveness of chitinase

This experiment was conducted on pure chitinase induced from wheatgrass type Iba 99 bioavailable using the fungus Trichoderma longibrachiatum\cite{12}. The salts have prepared Na₂MoO₄, MgCl₂, K2SO₄, ZnSO₄, FeCl₃, LiCl, (NH₄)SO₄, MgSO₄, CoCl₂, MnCl, FeSO₄, Na₂SO₄, MnSO₄, NH₄Cl₂, CaCl₂, KCl, LiF, CuSO₄10, CaCl₂, KCl, LiF, CuSO₄, 3-D, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, CaCl₂, KCl, LiF, Cu 50) Milli-Muller and add 1 ml of each concentration to 1 ml of enzyme chitinase. Then incubate in a water bath at a temperature of 35 C for an hour, then take 1 ml of it and add 1 ml of pure chitin solution to it, then put it in a water bath at a temperature of 35 For an hour, then 1 ml of DNS was added and then placed in a boiling water bath at a temperature of 100 ° C for 5 minutes. After that, the tubes were cooled with tap water. The readings were taken on a spectrophotometer with a wavelength of 540 nm and then the enzymatic activity of chitinase was estimated.

Estimate the Efficacy of the Enzyme Chitinase

The method has been folloled by Tweddell\cite{13} for the determination of the chitinase enzyme, as the reaction mixture consisted of adding 0.5 ml of a solution of chitin (1%) and 0.5 of the enzyme extract and incubated in a water bath at a temperature of 37 C for two hours. After which 1 ml of DNS was added and the mixture was placed in a water bath at a temperature of 100 M for 5 min, the tubes were cooled and the absorbance was measured in a Spectrophotometer at a wavelength of 540 nm. The standard curve for n-style glucose amine was adopted in estimating the enzymatic activity. The
enzymatic activity was defined as the amount of enzyme required to release 1 micromol of n-stylet glucose amine per minute and according to the reaction conditions.

**Effect of mineral inhibitor MnCl₂ and chitinase enzyme on pathogenicity of Fusarium oxysporum on wheat plant.**

The potting experiment was carried out in the 2019-2020 season. Mixed soil was cleaned and sifted well, then sterilized with 5% formalin, then covered with nylon for 10 days. Then the nylon was lifted to perform a 3-day aeration of the soil. Soil was distributed in the pots at a rate of 3 kg per pot and the experiment included 5 treatments of three varieties and three replications to produce 45 experimental units as follows:

**Field experiment parameters**

The experiment included three varieties of wheat (Sham 6, Tamuz 2, Iba 99). The experiment also included the following treatments:

- 1 Treatment of healthy plants only.
- 2 Treatment of the pathogen F. oxysporum only.
- 3 Treatment of the pathogen F. oxysporum + Trichoderma longibrachiatum (T1).
- 4 Treatment of the pathogen F. oxysporum + MnCl₂.
- 5 Treatment of the pathogen F. oxysporum + Trichoderma longibrachiatum (T1) + MnCl₂.

A suspension of F. oxysporum spores was added at 1 x 10¹⁰ colony forming units (CFU) / ml at 100 ml per pot. After 3 days, a suspension of Trichoderma longibrachiatum (T1) was added at 1 x 10¹⁰ CFU / ml at 100 ml. For each pot, 15 seeds of each variety of wheat were planted separately for each pot. As for the treatment of manganese chloride MnCl₂, 100 ml of it was added at a concentration of 10 mmol per pot after planting the seeds. The plant service was carried out from bush hoe (if any) and the irrigation was carried out according to the plant’s need.

**Studied traits**

The studied traits were taken after 45 days of germination, except for the efficacy of chitinase, which were tested after two weeks of germination

**Germination Rate**

It was calculated by dividing the number of plants growing in pots for each variety of wheat by 3 replications for each treatment by the total number of seeds planted.

**Chlorophyll Estimate**

The percentage of chlorophyll in wheat plant leaves was estimated in the morning using a Chlorophyll meter, as three plants were taken from each repeat randomly for all varieties and treatments.

**Weights Estimate for Dry and Wet Root and Vegetable Masses**

Samples were taken randomly from the pots from all the duplicates, then the plants were cleaned and washed with water to get rid of soil residues on the roots. Then the weights were measured for the vegetative and root system (wet), after that, the plants were dried on sunlight until the weight stabilized and according to the dry weight (in grams) using the sensitive balance.

**Estimate injury severity**

According to McKinney’s equation\(^{[14]}\), the percentage of injury severity was calculated in all treatments depending on the appearance of the injury and according to the pathological evidence adopted by it\(^{[15]}\).

**The degree appearance of the injury**

0 The plant is healthy, the root system is large, and the roots are white

1 slight brown discoloration on the roots and yellowing of a specified number of leaves

2 Full coloration of the roots, with a complete
yellowing of leaves

3 The coloration extends from the roots to the bases of the stems

4 general death

The severity of the injury was estimated according to the following equation:

\[ \text{Severity of injury} = \frac{\text{Number of plants in grade } 0 \times 0 + \text{number of plants in degree } 1 \times 1 + \text{number of plants in degree } 4 \times 4}{\text{Total examined plants}} \times 100\% \]

**The Effectiveness of Chitinase in the Root System**

The efficacy of the chitinase enzyme was estimated by the root group of the three varieties after two weeks of germination, as the plant was uprooted and washed well with sterile distilled water. After which the root group was separated from the vegetative and weighed 1 g per portion and placed in a ceramic mortar each part separately and 10 ml of acetate buffer solution was placed on top pH 5.6. The parts were crushed with the solution inside an ice bath until the plant part was well crushed and the plant cells were ruptured. After that, the solution was filtered and the solution was centrifuged at 5000 revolutions / minute for 10 minutes for the solution to get rid of the plant parts, the scent which represented the raw chitinase enzyme was collected and kept in the refrigerator at a temperature of 4°C until use, then the chitinase activity was estimated.

**Extraction of RNA**

The RNA was isolated from fungi and wheat plants of the three varieties using the GENEzol™ TriRNA Pure Kit provided by the Taiwanese company Geneaid, to extract the ribonucleic acid according to the instructions of the supplier.

**Measurement of RNA Concentration and Purity**

The concentration and purity of the extracted RNA was measured using a nucleic acid concentration and purity meter (NANO DROP). RNA purity was measured by dividing the RNA absorbance at length 230 by the absorbance product at 280, while the purity was calculated using the following equation: Concentration (µg / ml) = OD 260 x dilution factor x 40 µg / ml.

**Converting RNA into cDNA**

The conversion process was performed using the AccuPower RocketScript™ RT PreMix kit prepared from the Korean company BIONEER. The cDNA reaction mix includes 18 µl of template RNA (100pg), 2 µl of Oligo dt20 (50 pmoles), after that, the reaction mixture was transferred to transparent white tubes of 0.2 ml, and the mixture was mixed with the Vortex device for 3 minutes at a speed of 3000 rpm. The reaction conditions as follow: Primer annealing (Oligo dT 20) at 37°C for 10 min, cDNA synthesis at 42°C for 60 min and heat inactivation at 95°C for 3 min.

**Real Time PCR reaction**

**Prepare the qPCR mixture**

The reaction mixture was prepared using the AccuPower GreenStar™ qPCR PreMix prepared from the Korean company BIONEER and according to the company’s instructions, 5 ml of cDNA and 3 ml of the initiator (F + R) were added at a concentration of 10 pmole and 12 l DEPC - distilled water and then the mixture was applied in opaque white tubes of 0.2 ml for the kit and the Real Time PCR machine, then all the tubes were transferred to the Vortex machine to mix the mixture.

**Prefixes used in the Reaction**

The primers for the chitinase gene for wheatgrass were designed by Dr. Ahmed Abdul-Jabbar Sulaiman, prepared from Macrogen; the first primer was Wheat
Primer “F: 5’-CTACACGTACGCCTCCTA-3’” and “R: 5’-TGCCCTTGCTTATCTCTCC-3’” whose annealing temperature was 58 and it’s produced band was 194 bp. The second primer was ADP “F: 5’-CCTCATGGTCGGTCTCGATG-3’” and “R: 5’-GGATGGTGGTGACGATCTCT-3’”. the annealing temperature of ADP was 59 and it’s produced band was 80 bp.

The prefixes were dissolved with Nuclease Free Water to obtain a final concentration of 100 pmole as a storage solution and kept at a temperature of -20 ̊C. Upon reaction, 10 pmole of the storage solution was prepared by taking 10 ml of the storage initiator and adding to it 90 ml of Nuclease Free Water to obtain a final volume of 100 ml that was involved in the qPCR.

The program used to amplify the prefixes in a real-time polymerase chain reaction (qPCR) is shown below:

Statistical Analysis

The laboratory experiments and the CRD were carried out and the data were analyzed using the SPSS program, and the averages were compared according to the Least Significant Differences LDS at a probability level of 0.05 [16].

Results and Discussion

Inhibition and Activation of Minerals on the Effectiveness of Chitinase

The results indicated that if Manganese Chloride recorded the highest activity of the enzyme, the percentage increase in activity was (74.82, 71.11, 66.33) %, followed by CaCl2 (43.76, 57.63, 73.98%). The lowest activity of the enzyme was recorded when using K2SO4, as the percentage increase in activity was (12.23, 7.03, 4.22%) for the concentrations used respectively.

The results also indicated that there is an inhibitory effect for all EDTA concentrations, as the percentage of chitinase reductase activity was (22.75, 34.12, 56.43), followed by the salt NH4Cl, as the percentage of enzyme reductase was (18.87, 33.51, 42.32)%. These results were in agreement with Haider [17], who mentioned there is an induced effect of manganese chloride on the activity of the chitinase enzyme, but for calcium chloride the result was opposite to what appeared to us as it had an inhibitory effect on the enzyme activity. The results are also in agreement with those found by Adrangi [18] showed that manganese ions had an effect on the two forms of the intracellular enzyme (chi-56 and chi-64) purified from Massilia timonae. As for the effect of EDTA on decreasing the enzyme’s effectiveness, it was identical to what Al-Fakihi [19] found in his study on the effectiveness of purified alpha amylase from malt type Iba 99, as it was also found a decrease in the
activity of the enzyme by increasing the concentration of EDTA, but its results were opposite to what we found with regard to manganese chloride. The activity of the enzyme decreased when incubated with this salt.

The higher activity in the presence of Mn ions may be attributed to the enzyme’s need for this ion in the form of co-factor. The evidence for the enzyme’s requirement for this ion is the lower activity when using the EDTA chelating agent. The decrease in activity when incubating the enzyme with the mineral salts under study may be attributed to the effect of these salts on the enzyme synthesis or at the enzyme’s active sites on the one hand or in the base material on the other hand through the formation of complexes that impede the enzyme’s attachment to the base material. The mechanism by which the positive and negative ions activating the enzyme works is also different, as the ion may change the interstitial direction of the protein in order to allow the correct association between the enzyme and its base material[20].

Effect of mineral inhibitor MnCl₂ and chitinase enzyme on pathogenicity of Fusarium oxysporum on wheat plant.

The Effect of Treatment with the Fungus T. longibrachiatum T1 and Manganese Chloride on Shoots Weight

The results listed in Table (1) show that the highest shoots weight at the level of treatments was when treating the fungus Tricho. + Mncl2 in the presence of the pathogen F. oxysporum, which reached 0.82 g, followed by the Trichoderma treatment in the presence of the pathogen, which reached 0.67 g compared to the weight of the shoot in the treatment of healthy plants (control), which amounted to 0.66 g. Whereas, the lowest weight of the shoot total was recorded in the MnCl₂ treatment with the presence of The pathogenic fungus was 0.25 g, which did not differ significantly compared to the treatment of pathogenic fungi only (0.21 g). As for the average of the varieties, cultivar Iba 99 showed the highest weight of the shoot total, which reached 0.56 g, while the lowest weight of the shoots was 0.49 g in the Sham 6 cultivar. As for the interaction, the cultivar showed a positive 99 with the highest shoot weight of 0.86 g in the treatment of the pathogen + Tricho. + MnCl₂ without significant differences with the control treatment compared to the minimum shoot weight of 0.17 g in the cultivar Cham 6 in the treatment of pathogenic fungi only.

Table (1) Effect of Treatment with the fungus T. longibrachiatum T1 and manganese chloride on shoots weight (gm) of three varieties of Iraqi wheat under conditions of infection with the pathogen F. oxysporum.

The Effect of Treatment with the Fungus T. longibrachiatum T1 and Manganese Chloride in Root Mass Weight

The results listed in table (2) show that the highest weight of the root group at the level of treatments was when treating the fungus Tricho. + MnCl2 in the presence of the pathogen F. oxysporum, which reached 0.53 g, followed by the treatment of Trichoderma in the presence of the pathogen, which reached 0.43 g compared to the weight of the root total in the treatment of healthy plants (control), which amounted to 0.4 g, while the lowest weight of the root group was recorded in the treatment of MnCl2 with the presence of the pathogenic mushrooms, which amounted to 0.15 gm, did not differ significantly compared to the treatment of pathogenic fungi only (0.13g).

As for average cultivars, cultivar Iba 99 showed the highest root total weight of 0.372 g, while the lowest root total weight was 0.29 g in Sham 6. With regard to the interaction, the cultivar showed a test of 99 with the highest root total weight of 0.59 g in the treatment of the pathogen + Tricho. + MnCl2, compared to the minimum root weight, was 0.11 g for the cultivar Cham 6, in the treatment of pathogenic fungi only.

Table (2) the effect of treatment with the fungus T. longibrachiatum and manganese chloride on the weight of the root system (gm) of three varieties of Iraqi wheat under conditions of infection with the pathogen F. oxysporum.

The Effect of Treatment with the fungus T. longibrachiatum T1 and manganese chloride on the efficacy of the enzyme ketinase radical total.

The results listed in Table (3) show that the highest efficacy of the enzyme chitinase is in the area. Radical on the level of transactions was the treatment of Tricho mushrooms. + MnCl2 in the presence of the pathogen F. oxysporum, which reached 1.92 units / ml, followed by the treatment of Trichoderma in the presence of the pathogen, reaching 1.75 units / ml, compared to the effectiveness of the enzyme in the treatment of healthy plants (control), which amounted to 0.07 units / ml, while the lowest activity of the enzyme was recorded. Chitinase, MG. Radical treatment of MnCl2 in the presence of the pathogen, reaching 1.26 units / ml, which was not significantly different compared to the treatment of pathogenic fungi only (1.08 units / ml).

As for the average of the varieties, class Iba 99 showed the highest efficacy of the enzyme chitinase Mg. Radicals of 1.36 units / ml, while the lowest activity of
the enzyme chitinase was mg. Radical was 1.03 units / mL in the Sham 6 cultivar. As for the interaction, the cultivar showed 99 highest efficacy of the enzyme chitinase Mg. Radicals amounted to 2.07 units / ml in the treatment of pathogenic fungi + Tricho. + MnCl₂ compared to the lowest efficacy of the Mg chitinase enzyme. Radicals amounted to 0.07 units / mL in the Sham 6 cultivar in the control treatment.

The Effect of Treatment with the Fungus T. longibrachiatum T1 and Manganese Chloride on Pathogen Severity

The results listed in Table (4) show that the highest severity of pathogen infection at the level of treatments was when treating the pathogen only. As it reached 75.44%, followed by MnCl₂ treatment in the presence of the pathogen, reaching 73.94%, compared to the severity of pathogen infection in the treatment of healthy plants (control), which amounted to 0 %. While the lowest pathogen severity was recorded in Tricho treatment. + MnCl₂ in the presence of the pathogen, reaching 18.05%, which does not differ significantly compared to the treatment of the fungus Trichoderma with the presence of the pathogen (23.71%). This is confirmed by the study of Hasan & Aldoury [21], that there is a significant superiority in the severity of infection within the treatment of pathogenic fungi only compared to the rest of the treatments.

As for the average of the varieties, the Sham 6 variety showed the highest pathogen severity, which was 40.0%, while the lowest pathogen severity was 36.22%, in the IBA class 99. As for the interaction, the cultivar Sham 6 showed the highest pathogen intensity, which was 78.40% in the treatment of pathogenic fungi only, compared to the lowest pathogen severity, which was 17.05%, in the cultivar, Ibb 99, in the treatment of the pathogen + Tricho. + MnCl₂.

It was noticed from the results of the experiment that the treatment with the pathogenic fungus only gave the lowest values for the rate of germination, chlorophyll, plant height and dry weight for both vegetable and root parts; as well as, the experiment gave the highest rates for the dead cells, highest harshness and infection rates; this indicates that the virulence of the pathogenic fungus and the occurrence of damage in the plant, Pathogenic fungus enzymes such as cellulose, pectinase and protease cause degradation of the root and components of plant cells; as well as, the production of pathogenic fungus for fungal toxins that directly effect on plant growth, inversely the low vegetative growth traits and high indicators of injury[22]. The treatment
with MnCl2 alone did not positively affect on the characteristics of vegetative growth nor did it affect in the reduction of plant diseases and this was laboratory proven by Ahmed[23]as it may provide Mn element to the pathogen, while the treatment with *Trichoderma* improved the proportions of seed germination and all the characteristics of vegetative growth and reduced the incidence and severity of the infection due to the mechanisms’ action of *Trichoderma* and their significant role in vital resistance such as antibiosis, competition, Mycoparasitism, Enzymes, resistance induction, production of plant hormones, increased readiness of elements and tolerance of external stress. In case of treating *Trichoderma* with MnCl2 treatment, it is observed that there is a significant superiority statistically to all the characteristics of vegetative plant growth and a decrease in infection indicators, which due to the role of *Trichoderma* and its direct and indirect mechanisms against the pathogen. It should be mentioned that the important factor is activation of Chitinase, which is well known as Mn dependent enzyme.

**Real Time PCR Gene Expression Results**

RT-qPCR was used to detect and estimate the level of gene expression for the gene (Primer Chitinase Wheat) responsible for producing the enzyme chitinase in wheat plant. The ADP gene was used as a reference gene, and the relative quantitative expression method was used where data are presented for the reference gene where the expression is expressed. For reference genes in all cells of the organism under normal and pathological conditions, and although some reference genes are expressed at constant levels in most cases. There are genes whose expression may change depending on the situation, the interval (Ct) where Ct is the number of cycles required for the fluorescence to be emitted from the dye to reach the threshold level to detect the reaction.

The results listed in Table (5) show the gene expression values represented by the value of Cycle threshold (Ct), which indicates the degree of gene expression inversely (as the lower the value of Ct, the more the gene expression process increases), as well as the Fold Fold, where the results showed the high gene expression of the chitinase gene. In wheat plants, class Ibaa 99 for treatment No. 4 (pathogenic mushrooms + Tricho. + MnCl2), which amounted to 1184.449 compared to the control treatment, in which the value of the volt was 1, followed by treatment No. 2 for the same variety (pathogenic mushrooms + Tricho), reaching 9.78, i.e., it increased by approximately 9 times for the Control treatment, which equals 1.

As for the variety Sham 6, the results showed that the highest gene expression for treatment No. 4 (pathogen + Tricho) was 3956.475 compared to the Fold value for Control (1), followed by treatment No. 2 (pathogenic fungus + Tricho), reaching 92,411 compared to A control transaction.

As for the July 2 variety, the results of its gene expression showed that the highest value was recorded for treatment No. 4 (pathogenic fungus + Tricho), reaching 19.027, followed by treatment No. 2 (pathogenic fungus + Tricho), which reached 7, which increased by 7 times over the control treatment (1).

It is evident from the results shown above that the gene expression increased for the three cultivars by the last treatment No. 4 (pathogenic fungus + Tricho), but the highest gene expression was for type Sham 6. The reason for the high gene expression of the chitinase gene in Treatment No. (4) and for the three varieties is due to the treatment of plants with the fungus *Trichodrema*, which stimulates biological resistance and thus stimulates induced systemic resistance (ISR) in addition to the presence of salt (MnCl2), which acts synergistically with the fungus and leads to increased stimulation. The production of the enzyme chitinase and thus leads to the stimulation of acquired systemic resistance (SAR) in the plant, which lies in the stimulation of genes encoding some pathogen-related proteins such as the enzyme chitinase, which has a high activity in analyzing the cell wall of pathogenic fungi and improving plant growth[24][25]. This has been demonstrated in our previous experiments in induction of chitinase enzyme biosynthesis in 12 varieties of wheat plants, as the mushroom-induced
varieties showed the highest efficacy of the chitinase enzyme compared to the enzyme activity of the varieties without the inducement factor. As well as what was demonstrated in the experiment of steroids and enzyme inhibitors of a group A wide range of salts and three concentrations, as the MnCl2 salt recorded the highest activity of the enzyme and of the three concentrations. In another experiment on the effect of Mineralogenerator MnCl2 and the enzyme chitinase extracted from wheat induced by Trichoderma fungus on some pathogenic fungi. The results proved that the presence of the salt and enzyme mixture in the middle of the development of pathogenic fungi inhibits the growth of these fungi compared to the control plate. Thus, the salt and enzyme mixture inhibited the growth of pathogenic fungi due to the maximum effectiveness of the enzyme Manganese ions. The results of the gene expression were consistent with the findings of Al-Jassani [26] in his study of three varieties of date palms treated with salicylic acid and hydrogen peroxide. Which led to an increase in the gene expression of the gene responsible for the enzyme Superoxide SOD dismutase (which is considered one of the defense enzymes to reduce the damage caused by exposure to The plant under saline stress conditions). As the variety Burhi gave the highest gene expression when treated with salicylic acid 500 mg, when the value of Folding (3.36) was reached. As for the crescent variety, the highest value of gene expression in the treatment of salicylic acid was 250 mg, as the value of Folding (5.09) and the unknown variety gave the highest an expression value in the treatment of hydrogen peroxide at a concentration of 6%, as it reached (2.82).

On Health Care Sector, What External Environment that Important? : A Review Literature

Noor SyamSidiq Himawan¹, Nur Wening²

¹Doctoral Student, ²Associate Professor, Post Graduate Program of Management, University of Technology Yogyakarta

Abstract

This Paper is a literature review related to various studies that discuss macro environmental analysis (political, economic, socio-cultural and technological) in the field of health care. The purpose of this study is to explore and connect theories from various studies related to macro business environment factors that are important in the field of health care, how much research is related and what are the opportunities for future research. This paper identifies 21 articles that discuss the analysis of the business environment in the health care sector. In this study, the criteria for selecting literature were applied, namely the selected literature must be in the form of articles not handbooks, in English, discussing business environmental analysis, especially in the field of health services and published for a maximum of the last 10 years. The research related to political factors was 31.25%, economic factors 18.75%, socio-cultural factors 18.75% and technological factors 31.25%. Research related to environmental analysis (political, economic, socio-cultural and technological factors) in the health sector is still very minimal, especially in the economic and socio-cultural sectors so that this can actually become an opportunity in developing research on the business environment in the health sector.

Keywords: PEST analysis, health sector, political factors, economic factors, socio-cultural factors, technological factors, external environment, strategic management.

Introduction

Analysis of external environmental factors is an important thing in the formulation of strategies for improving the performance of health organizations ¹². Based on research, business environment analysis can have a significant impact on a company p value 0.025 ³. Macro environmental conditions are conditions outside a company and cannot be controlled by a company but must be analyzed to adjust the company’s strategy to changes in the business environment. The main strengths of the macro environment are political, economic, social, technological, legal, ecological, demographic, ethical and regulatory aspects. The macro environment can be analyzed by various methods such as PEST, PESTEL, PESTLE, STEEPLE, STEEPLED ⁴. The challenge faced by health services today is how to be able to control patient care costs efficiently and adapt to policy changes that occur quickly ⁵. Economic and political instability are also factors that affect the health service system ⁶. In addition, the socio-cultural condition of the organization also plays an important role in health services ⁷. The term PESTLE has been used regularly in the last 10+ years and its true history is difficult to establish. The earliest know reference to tools and techniques for ‘Scanning the Business Environment’ appears to be by Francis J. Aguilar (1967) who discusses ‘ETPS’ – a mnemonic for the four sectors of his taxonomy of the environment: Economic, Technical, Political, and Social. Shortly after its publication, Arnold Brown for the Institute of Life

Corresponding author:
Noor SyamSidiq Himawan.
Post Graduate Program of Management, University of Technology Yogyakarta,
Email: noorsyamsh@gmail.com+623815249295
Insurance (in the US) reorganized it as ‘STEP’ (Strategic Trend Evaluation Process) as a way to organise the results of his environmental scanning. Thereafter, this ‘macro external environment analysis’, or ‘environmental scanning for change’, was modified yet again to become a so-called STEPE analysis (the Social, Technical, Economic, Political, and Ecological taxonomies). In the 1980s, several other authors including Fahey, Narayanan, Morrison, Renfro, Boucher, Mecca and Porter included variations of the taxonomy classifications in a variety of orders: PEST, PESTLE, STEEPLE etc. Why the slightly negative connotations of PEST have proven to be more popular than STEP is not known. There is no implied order or priority in any of the formats. Quite who and when added what elements to the mnemonic is a mystery, but what is known is that the actual order and words contained are common to certain parts of the world and streams of academic study.

**Literature Review**

Macro environmental conditions are conditions outside a company and cannot be controlled by a company but must be analyzed to adjust the company’s strategy to changes in the business environment. The main strengths of the macro environment are political, economic, social, technological, legal, ecological, demographic, ethical and regulatory aspects. The macro environment can be analyzed using various methods such as PEST, PESTEL, STEEPLE, STEEPLED. The explanation of these methods is as follows:

- **PEST**

  PEST is an external environmental analysis using approaches political, economic, social, and technological.

- **PESTEL**

  PESTEL is an external environmental analysis using approaches political, economic, social, technological, environmental and legal.

- **STEEPLE**

  STEEPLE is an external environmental analysis using social, technological, economic, environmental, political, legal and ethical.

- **STEEPLED**

  STEEPLED is an external environmental analysis using the social, technological, economic, environmental, political, legal, ethical, and demographics dimension.

The explanation of the above components is as follows:

**Political**

This factor looks at the extent to which the government can influence a particular economy or industry. Political factors are generally in the form of various national policies taken by the government that affect an industry. Such as: various policies (tax, fiscal, trade, evil that support certain industries), licensing, processes and services, laws and regulations. These factors determine the extent to which a government may influence the economy or a certain industry.

**Economic**

Factors are factors of economic performance that directly impact the company and have a long term impact. Such as: local economy, international economy, economic trends, inflation, corporate taxes, market and trade cycles, GDP, consumer purchasing power, interest and exchange rates. Economic factors include inflation rate, interest rates, foreign exchange rates, economic growth patterns etc. It also accounts for the FDI (foreign direct investment) depending on certain specific industries who are undergoing this analysis.

**Social Factor**

Are conditions that affect market and consumers. These factors include: Demographics, lifestyle psychology, consumer perceptions of brands, consumer purchasing behavior, influence of advertising and public relations, influencers /role models, influence (race, ethnicity and religion). The sociological factor
takes into consideration all events that affect the market and community socially. Thus, the advantages and disadvantages to the people of the area in which the project is taking place also need to be considered. These factors scrutinize the social environment of the market, and gauge determinants like cultural trends, demographics, population analytics etc. An example for this can be buying trends for Western countries like the US where there is high demand during the Holiday season.

**Technological Factors**

This is a technological innovation that can affect industry and the market. Such as: technology in product design, production, distribution, price and consumption, machines or software that support business processes. These factors pertain to innovations in technology that may affect the operations of the industry and the market favorably or unfavorably. This refers to automation, research and development and the amount of technological awareness that a market possesses. This factor takes into consideration all events that affect technology. Since technology often becomes outdated within a few months after it is launched, it is important to consider this. This factor could also take into consideration all barriers to entry in certain markets and changes to financial decisions.

**Legal**

This factor takes into consideration all legal aspects like employment, quotas, taxation, resources, imports and exports, etc. These factors have both external and internal sides. There are certain laws that affect the business environment in a certain country while there are certain policies that companies maintain for themselves. Legal analysis takes into account both of these angles and then charts out the strategies in light of these legislations. For example, consumer laws, safety standards, labor laws etc.

**Environmental**

These factors include all those that influence or are determined by the surrounding environment. Factors of a business environmental analysis include but are not limited to climate, weather, geographical location, global changes in climate, environmental offsets, ground conditions, ground contamination, nearby water sources, etc. 8,9

Based on previous research conducted on health facilitation research in the Lubin area, the environmental analysis obtained is as follows:

Method

This research is a review of literature related to various studies that discuss the analysis of the business environment, especially the macro environment (political, economic, cultural-cultural and technological) in the field of health services. The collection of articles is done using search engines such as mendeley, google and google scholar. In this study, there were 21 articles discussing the analysis of the business environment in the field of health services. In this study, criteria were applied in the selection of literature. These criteria are that the selected literature must be in the form of articles not handbooks, in English, discussing business environmental analysis, especially in the field of health services and published for a maximum of the last 10 years. Furthermore, the literature obtained was analyzed related to components in important political, economic, socio-cultural and technological factors in the health sector, research that had been carried out for each of these factors, conclusions and future research opportunities.

Results and Discussion

Based on important factors in the above PEST analysis. Several studies have been conducted to
examine each factor in the analysis of the business environment as follows:

Sources\(^{2,5,18–21,7,10,12–17}\)

Research related to environmental analysis (political, economic, socio-cultural and technological factors) in the health sector is still very minimal, especially in socio-culture, demography, epidemiology so that this can actually be an opportunity development of research on the business environment in the health sector, even though careful analysis of environmental factors important for improving the performance\(^2,10\)

**Conclusion**

Analysis of external environmental factors is an important thing in the formulation of strategies for improving performance health organization. The main strengths of the macro environment are political,
economic, social, technological aspects. Political factors that are important to note in the health sector include (the role of the government in terms of promoting the quality of health services, government initiatives in the health sector that can change, government strategies in the health sector, health care reform, changes in health care policies, volatility in regulations and legal norms). Economic factors include (government investment targets in the health sector, priority setting, economic situation, inflation, equality of population income, availability of loans). Socio-cultural factors include (age of the population, changes in lifestyle, community expectations regarding health services, changes in work practices). Technological factors (latest health intervention technology, telemedicine, scientific evidence in health, changing health regulations). For each of these facilitators, very little research has been carried out so that it can become an opportunity for future research, especially related to the economic and socio-cultural sectors.

The Effectiveness of Dayak Song Art as a Media for Increasing Mother’s Knowledge about the Health and Development of Toddler

Noordiati
Lecturer of Midwifery Department, Polytechnic of Ministry of Health, Palangka Raya, Center of Kalimantan, Indonesia

Abstract

The Dayak song serves as a medium or medium for conveying various development messages, physical development, health, and mental and spiritual development. The Dayak song is very appropriate if used as an innovative medium in conveying the information given to the Mother Toddler class’s implementation. Every mother in Palangka Raya City can easily accept and remember the material given. This type of research is a quasi-experimental study with a two-group comparison pretest-posttest design. Samples were selected based on inclusion and exclusion criteria and were taken by a consecutive sampling of mothers who have children aged 0-60 months. The results of the statistical test p-value of 0.000 (p <0.05), it can be concluded that there is a significant difference in increasing the knowledge of mothers with children under five years about health and growth between the group using the Dayak song media and the flipchart group on the first pre-test and post-test. The results showed a significant difference in the pre and post-test knowledge scores in the Dayak Song and flipchart groups. The knowledge scores between the Dayak song groups and flipcharts shows that Dayak songs are more effective as a medium for delivering information with an increase of 77.41 compared to the increase in knowledge using flipcharts 39.59.

Keywords: Dayak song, knowledge, mother, health and development, toddler

Introduction

Most causes of infant mortality are due to neonatal problems such as low birth weight 11.1%; respiratory disorders 35.9%; prematurity 32.4%, sepsis 12%, hypothermia 6.3%; blood / jaundice disorders 5.6%; post matur 2.8% and 1.4% congenital abnormalities. Infectious diseases are the most common causes of under-five mortality with diarrhea 12.3%, ARI 12.8%, pneumonia 4.8%. Toddlers who experience malnutrition 3.8% and malnutrition are still high, namely as much as 11.4%. Early initiation of breastfeeding (EIB) and exclusive breastfeeding, which plays a major role in reducing neonatal mortality, infants and toddlers can reduce morbidity as diarrhoea and pneumonia. Although the coverage shows an increase, which based on The Indonesian Basic Health Research 2018, the EIB coverage has become 58.2% and the coverage of breastfeeding alone in the last 24 hours is 74.5%, efforts still need to be optimally increased. Immunization can also reduce infant and child mortality due to preventable diseases by immunization. Complete immunization coverage for children aged 12-23 months has decreased from The Indonesian Basic Health Research 2013 of 59.2% to 57.9% in 2018.

The variables that can affect the incidence of infant mortality in Indonesia during the period 1984 to 2012 are Gross Regional Domestic Product (GRDP) per capita, total fertility rate (TFR), female labor force participation rate, and female literacy numbers. Of these variables,
TFR is the determinant that has the greatest influence on infant mortality. One of the strategic efforts to increase the independence of families and communities in maintaining and caring for maternal and child health is using the MCH Handbook. In order for the MCH book to be used properly and its benefits will be felt by the community, it is necessary to provide an understanding of the MCH book through a communication platform that exists in the community which is then referred to as the mother class. The mother class is one of the important activities in increasing the use of the MCH Handbook in the community and as a learning effort for mothers, husbands, and families to understand the MCH Handbook’s contents through the method of collective learning activities facilitated by competent health workers. The mother class was developed for two targets, namely pregnant women through the pregnant mother class and mothers who have toddlers through the mother toddler class. Both are implemented to increase the coverage and use of the MCH Handbook in maternal and child health services. The pregnant mother class activities aim to prepare pregnant women for safe, comfortable and safe delivery, as well as for babies to be born healthy and smart. While the toddler mother class activities aim to realize optimal toddler growth and development.

In several community health center in Palangka Raya City, almost every community health research already has a mother class facilitator, the implementation of the pregnant women class at the community health center has been implemented, but it is different from the maternal toddler class, almost all community health center have not implemented it due to the unavailability of operational funds, ignorance health workers that the implementation of the mother under five class can be integrated with integrated healthcare center services and planning at the community health center level does not yet know technically that this activity is an indicator and priority activity of the ministry of health.

Considering the importance of the mother’s class for toddlers as an effort to realize optimal health and development of toddlers, the researcher intends to contribute in the form of cultural-based learning media innovation to complement existing media, namely in the form of song lyrics containing health material for toddlers in Dayak language songs. One of the functions of the Dayak Song is as a means or medium for conveying various messages of development, both physical development, health and mental and spiritual development, so the Dayak song is very appropriate if it is used as an innovative medium in conveying information given to the implementation of the Mother Toddler class, so that every mother is Palangka Raya City easily accepts and remembers the material given. In addition, families and communities can easily find out children’s health messages under five through Dayak Songs.

**Materials and Methods**

This type of research is a quasi-experimental study with a two-group comparison pretest-posttest design. The research was conducted in two sub-districts of the working area of Community Health Center Kereng Bangkirai, where the mothers with children under-fives used Dayak language daily. This study’s population was all mothers who have children under five aged 0-60 months in the family. Samples were selected based on criteria of ink warp and exclusion and taken with consecutive sampling as follows.

The inclusion criteria in this study were:

a. Have children under the age of 0-60 months.

b. Willing to take part in mother-to-child classes which are held 3 times in a row every month.

c. Residing in the village area which is the place for the mother’s toddler class to be held.

The exclusion criteria are:

a. Not attending all mother-to-child class meetings

b. Have taken a mother class before

c. Not following the post-test.

The difference in the average change in the expected
knowledge score from mothers of children under five is 1.70, the sample obtained for each group is 52 people, in anticipation of missing the sample during the study added 10% so that each group to 58 people. The variables in this research include independent variables, namely the knowledge of mothers under five about the health and development of children under five. The dependent variable, namely the Dayak language song media and flipcharts, and confounding variables are the mothers’ education age who have toddlers. Data analysis was descriptive and analytic (univariate and bivariate).

Findings and Discussion

</table>

Based on table 1, the results of the statistical test with the p-value of 0.000 (p <0.05), it can be concluded that there is a significant difference in increasing the knowledge of mothers under five about health and growth and development between the groups using the Dayak song media and the flipchart group on the first pre-test and post-test. The increase in the group’s knowledge score that received the Dayak song intervention by 73.34 was higher than the increase in the knowledge score of the group that received the flipchart intervention by 43.66. In the pre and post-test II, increased knowledge score intervention group that received Dayak songs of 77.41 is higher than the increase in knowledge scores intervention group receiving a flip chart at 39.59. The increase in knowledge of the group that received the Dayak song media intervention was higher than the group that received the flipchart intervention, so it can be concluded that the intervention using the Dayak song media was effective in increasing maternal knowledge compared to the flipchart media intervention, and the results of the increase in knowledge were greater in the second pre-test compared to the first pre-test.

The results showed a significant difference in the pre and post-test knowledge scores in the Dayak Song and Flipchart groups. The difference in knowledge from the pre and post-test of each group shows that both the Dayak song median and the turning sheet used as a medium for conveying information in the toddler mother class implementation can improve knowledge.

The mother toddler class is held in a participatory manner, it means that mothers are not positioned only to receive information because the passive position tends to be ineffective in changing behaviour. Therefore, the
mother toddler class is designed with a participatory learning method where mothers are not seen as students, but as learning citizens. In practice, mothers are encouraged to learn from others’ experiences, while the facilitator acts as a guide to correct knowledge. Facilitators are not teachers or lecturers who teach, but they can be a source of learning in a limited scope.5

In the implementation of the Toddler Mother Class program based on the Indonesian Ministry of Health, flipcharts are used as a medium for delivering information that aims to increase the MCH books’ use. The flipchart used contains pictures related to children’s health and development under five, then the facilitator explains what is on the flipchart. For the Mother Class Toddler group using the Dayak song media, the participants and the facilitator sang Dayak songs whose lyrics were adjusted to the material to be delivered according to the age group, after which the facilitator explained the material contained in the song lyrics using the lecture or question and answer method. The knowledge obtained from the resource persons is inseparable from the experience and knowledge they already have, the facilitator helps the learning community bring back this knowledge to what is happening around them.

Behavioural change in the adult education process (andragogy) is generally more difficult than behavior change in children’s education (pedagogy), because adults already have prior knowledge, attitudes and skills, so that media and learning methods are wrong. A component in the learning process plays a very important role, because these two aspects are interrelated. The choice of a particular teaching method will affect the appropriate type of learning media, although other components must still be considered in selecting instructional media.6

The results of statistical tests show an increase in the knowledge of mothers under five who follow the mother toddler class using Dayak Songs and Flipchart. The increase in knowledge of mothers under five was higher in the group that used Dayak songs than in the Flipchart group so that Dayak songs were considered effective in increasing maternal knowledge compared to Flipchart.

This study’s results are in line with research in West Africa, which shows that music has an important role in improving the health and well-being of people in Sierra Leone. Health messages attract listeners when the existing rhythm is used to be heard by the community.7 The effectiveness of Cirebon tarling culture (regional music) on increasing the knowledge of pregnant women in Cirebon Regency, West Java showed that the change in the knowledge score of pregnant women was higher in the group using Cirebon art media than using flipcharts. The use of local culture in increasing knowledge is one form of creative media that has contextual meaning.5

In Uganda states that by combining scientific knowledge about health and distinctive music as cultural heritage, messages/information will be more able to enter into life to become a culture that is commonly practised. Health messages will attract listeners if they are packaged in the form of a song, especially if the song is well known and has important meaning for the listener. Messages/information can be conveyed through songs to the wider community.7

In this study, the Dayak song lyrics were taken from the material contained in the Facilitator’s Handbook module and then translated into Dayak to easily remember the lyrics sung because they used the language they used daily as a means of communication. The culture-based learning approach can provide opportunities for students to create meaning and achieve an integrated understanding of the scientific information they obtain, as well as the application of scientific information in the context of the problems of their cultural community.8

Health promotion efforts must be carried out most effectively and efficiently to achieve the goals. Various educational strategies, including audiovisual entertainment such as storytelling and videos, are valuable tools in increasing people’s knowledge and attitudes in health promotion. Many health promotion programs use music to increase health promotion, increasing knowledge, social, and building behaviour. In yet another example, traditional song in Laos has proven
effective in imparting knowledge about HIV/AIDS, teaching prevention skills and motivating listeners to change their behavior regarding disease prevention.9

Conclusion

1. There are differences in the level of knowledge of mothers with children under five before and after receiving intervention using the Dayak song media in the implementation of the toddler mother class from a knowledge score of 46.97 to 74.47.

2. There are differences in the level of knowledge of mothers with children under five before and after receiving intervention using flipchart media in the implementation of the toddler mother class from a knowledge score of 48.19 to 63.76.

3. Comparison of the increase in knowledge scores between the Dayak song groups and flipcharts shows that Dayak songs are more effective as a medium for delivering information with an increase of 77.41 compared to the increase in knowledge using flipcharts, namely 39.59.

**Abstract**

**Introduction:** Pregnancy is the golden period to prepare children for the future. Stimulation is needed during pregnancy, one of which is brain stimulation. This can be done with Al Qur’an Murrotal Surah Ar-Rahman stimulation. This study aims to analyze expression of *synapsin 1* in the *cerebrum* of newborn *Rattus norvegicus* when given murrotal Surah Ar-Rahman stimulation by qari, qariah, and not given any stimulation during pregnancy.

**Methods:** Experimental with post-test only control group design. Sampling in this study was considered homogeneous because it met the inclusion criteria. The samples obtained were distributed randomly to each experimental group and randomized into 3 groups, including control group, group stimulated by qari, and group stimulated by qariah. The treatment was given on the 6th day of pregnancy for 1 hour in a soundproof room with an intensity of 65 dB.

**Results:** The highest mean expression of *synapsin 1* in the *cerebrum* is qari group (6.96 ± 2.59), then qariah group (5.84 ± 2.90), and the lowest is control group (5.74 ± 2.32). There is no significant difference in expression of *synapsin 1* in the *cerebrum* between control and qari groups (p = 0.306), control and qariah groups (p = 0.932), qari and qariah groups (p = 0.347).

**Conclusion:** The highest expression of *Synapsin 1* in the *cerebrum* of newborn *Rattus norvegicus* is the group stimulated by qari.

**Introduction**

Pregnancy is the golden period to prepare children for the future. In that pregnancy, most women focus on filling their pregnancy with activities that make the fetus healthy and smart, to prepare quality human resources. Report from the World Economic Forum Indonesia’s competitiveness position in 2019 was at level 50, down compared to 2018 which was in 45th position. The lowering of this competitiveness ranking is due to the low quality of human resources(1). Intelligence is related to the quality of the brain which states that stimulation will increase the potential for intelligence if it is done during pregnancy and early in life. Lack of brain stimulation during pregnancy can lead to the child’s
inability to learn and adapt to the demands of society\textsuperscript{(2)}.

Efforts to improve the quality of human resources through the First 1000 Days of Life program continue to be voiced in Indonesia. At 1000 HPK, there is a rapid rate of proliferation, migration, differentiation, synaptogenesis, myelination, and apoptosis\textsuperscript{(3)}. Good brain development will affect cognitive and motor skills to prepare for the development of future generations. The brain consists of the cerebrum which plays a role in cognitive function. This process is supported by synapsin 1 as a marker for synaptogenesis. Synapsin-I (Syn-I) is the main isoform in neurons which is a phosphoprotein that binds to synaptic vesicles\textsuperscript{(4)}.

Dr. Al Qadhi, the main director of the Islamic Medicine Institute for Education and research in Florida, United States, said that 97\% of Al-Qur’an murattal therapy reduces reflective nerve tension and these results are recorded and measured quantitatively and qualitatively by computer-based tools. The most frequently used Murattal of the Koran is the Surah Al-Rahman\textsuperscript{(5)}. Research on the spectrum analysis of the human voice based on gender has been carried out. The results showed that the frequency ranged from 120 - 150 Hz for men and 200 - 280 Hz for women\textsuperscript{(6)}. Murottal sounds certainly have their respective sound characteristics based on the frequency and intensity values of the sound source. From the description above, a study was carried out on qari (male voice) increase higher expression of synapsin 1 than qariah (female voice) in the cerebrum newborn Rattus norvegicus.

**Materials and Methods**

This researched was a laboratory experimental study with a post-test-only control group design. The samples of this studied were white adult female rats (Rattus norvegicus) aged 2-3 months of 6 days of gestation with an initial body weight of 120-160 grams with three groups were randomized, including control group (K1), qari (K2) and qariah (K3). On the 18th day of pregnancy, Rattus norvegicus was sacrificed, then expression of synapsin 1 was calculated using immunohistochemical methods and analyzed with the appropriate statistics. In the expression of synapsin 1 variable, each subject was assessed according to the Remmele method. The data normality test was performed using the Shapiro Wilk test. Normally distributed data will be analyzed using one-way ANOVA followed by the Least Significant Differences test between groups.

**Results**

Expression of synapsin 1 in the cerebrum Rattus norvegicus which is the variable of this study. The table 1 shows the mean and standard deviation of expression of synapsin 1 in the cerebrum of Rattus norvegicus which was highest in the Ar-Rahman voice treatment group by Qari (K2).

<table>

Note: K1: Control group  
K2: Qari group  
K3: Qariah group

The figure 1 shows the expression of synapsin 1 in the cerebrum uses immunohistochemical methods. Red arrows indicate the expression of Synapsin 1 in the brain which indicates the presence of a chromogen brown color. The tissue was observed under a light microscope at 5x the field of view at 400X magnification.
The results of the normality test using the Shapiro-Wilk test showed that the distribution expression of synapsin 1 data in the cerebrum in each group was normally distributed. The ANOVA test results with a significance value of 0.519. Then the Analysis Least Significant Difference further test.

Table 2. Test Results LSD Against Expression Of Synapsin 1 In Cerebrum Rattus norvegicus

The results of the Table 2 LSD advanced test showed no significant difference between the control group (K1) compared to the Ar-Rahman voice treatment group by Qari (K2), there was no significant difference between the control group (K1) compared to the Ar-Rahman voice treatment group by Qariah (K3), and there is no significant difference between the Ar-Rahman voice treatment group by Qari (K2) compared to the Ar-Rahman voice treatment group by Qariah (K3) with a significance value of more than 0.05.

Discussion

The cerebrum of the newborn Rattus norvegicus showed that the mean expression of Synapsin 1 which was given muotton surah Ar-Rahman stimulation by the qari during pregnancy was higher than that qariah and control group, but there were no significant differences in expression of synapsin 1 in the cerebrum. During this period the fetus can deliver information in the form of sound waves to the brain. The sound waves activate a specific area of the bacillary membrane according to the frequency of the vibrations\(^7\). The qari used in this
research is the voice of Muzammil Hasbalah. A qari who reads every word of the surah in a good and easy way can make a person concentrate on listening and can provide a more pleasant stimulus. listening to soothing sounds can increase, reduce pain perception, and provide sound stimulation that will affect physiological functions (8).

The advantages of learning Al Quran with audio visual media by Hj wafiq azizah. Audio visual media that are more varied can increase the activeness and learning outcomes of students. Murottal surah Ar-Rahman stimulation by qariah which is given during the prenatal period from an early age is expected to improve the intellectual function and emotional function of children as they grow and develop in the future (9).

Surah Ar-Rahman has a duration of 13 minutes 55 seconds with a tempo of 79.8 beats per minute, a tempo of 79.8 bpm is a slow tempo. The slow tempo has a range between 60-120 bpm. The slow tempo itself is a tempo that is in line with the human heartbeat, so the heart will synchronize the beat according to the tempo of the sound (10). Music that is rich in high frequency and has a high rhythm (similar to the rhythm of the fetal heartbeat), which can be associated with simulation and energizing functions. Mozart’s music has the best combination with mellow sound colors dominated by violin instruments which help mothers to relax, there are no minor tones, the number of beats in the rhythm is around 60-80 times/minute which corresponds to the mother’s heart rate (11).

Likewise with the murottal Surah Ar-Rahman by the qari has a frequency that can be associated with fetal stimulation.

At 26-28 weeks’ gestation, the fetal hearing function begins to respond and process to auditory stimulation through stimulation of the auditory cortex located in the cerebral cortex and brainstem. 30-35 weeks of gestation, the fetus can hear and respond to the mother’s voice and begins to distinguish between sounds around it. At 42 weeks, the lines of the auditory system with the central nervous system undergo a process of maturity and will then develop after the baby is born (12). In this study, the murottal element that can be adjusted is the intensity where all types of murottal that are presented have been adjusted to an intensity of 65 dB using a sound level meter and analyzed using Cubase 5, it was found that it was murottal qari around 15,400 Hz and the murottal qariah around 13,000 Hz. This difference in frequency will be captured differently by the tonopy of the cochlea, so the response to the brain will be different (13).

From the recorded sound spectrum, the basic frequency is determined. The results showed that there were fewer males than females. The mean formant value of boys was slightly higher than that of girls, including 525 Hz for girls and 512 Hz for boys, respectively (6). This is to support that the mother’s voice, which is higher in frequency, is received by the fetus. Auditory stimulation of the mother’s voice has been applied in several studies. This is in line which states that the ability to receive auditory stimulation and memorization has begun since the fetus in the womb has a permanent impact on brain development (14).

The initial male frequency was smaller than the female initial frequency, the male final frequency was smaller than the female final frequency, the highest male frequency was smaller than the female high frequency, the lowest male frequency was smaller than the lowest frequency girls. Broadly speaking, it can be said that the male voice frequency is smaller than the female voice frequency (15). From this study, it is related to the current research that the results of the analysis show that the voice frequency of male voice is higher than that of female voice. Therefore, it is obtained a higher expression in the voice of the qari than the voice of the qariah.

**Conclusion**

The highest expression of Synapsin 1 in the cerebrum of newborn Rattus norvegicus is the group stimulated by qari, but there is no significant difference among control, qari, and qariah groups.

Evaluation of Root Canal Morphology of Maxillary 2nd Premolars Using Cone Beam Computed Tomography in Chennai Population

Nur Qistina Binti Ahmad Fauzi¹, Mahesh R²

¹Undergraduate Student, ²Reader, Department of Pedodontics, Saveetha Dental College and Hospital, Saveetha Institute of Medical and Technical Sciences, Chennai

Abstract

Background: Using the CBCT, this technique has the ability to identify the root canal morphology as detailed as using the root canal staining and other clearing techniques that in the past have been of higher value to the other conventional techniques that can be implemented to give a three-dimensional perspective of the complete morphological details. With this, analysing the variation in root canal morphology of human maxillary second premolar between different gender in Chennai population can be done.

Methods: One hundred Cone Beam Computed Tomography (CBCT) images from different patients are selected randomly from Department of Oral Radiology of Saveetha Dental College and Hospital, India. All the CBCT images of patients are examined for the inclusion criteria in maxillary second premolars between different genders based on Vertucci classification. All root canal configurations of maxillary second premolars between different genders are investigated and compared with Vertucci Classification.

Conclusion: Of all the 100 maxillary second premolars, the most common type of canal configuration for both the genders is Type I (41%), Type III (22%), and Type V (22%). In females, the most common type of canal configuration discovered is Type I (35%), Type III (63.6%) and Type V (83.3%). In males, the most common type of canal configuration determined is Type I (65%) and Type III (36.4%).

Keyword: Root Canal Morphology, maxillary second premolar, Cone Beam Computed Tomography, Vertucci’s classification.

Introduction

An endodontic procedure can be deemed successful depending on the cleaning and shaping, the disinfection process and the filling of the root canal system. Each tooth has their own anatomical feature and if variations are present, it could pose as an important issue during a root canal treatment.¹ In cases when there are missing root canals, there could be a possibility of the presence of necrotic tissues and microorganisms. As time goes by, these microorganisms can proliferate and thus resulting in a periapical periodontitis. With that reason, clinicians should be aware of the complexity surrounding different root canal structures in order to provide proper treatment techniques and protocols allowing for an increase in the rate of success of the treatment.²

Premolars are generally considered as a challenging tooth when a root canal treatment is involved. For a
maxillary first premolar, there could be either be two roots and two canals (56%) or one root with two canals (40%). In some studies, it was found that both maxillary and mandibular premolars more than often could have additional roots and canals.3-7 Based on a study made by Vertucci and Gegauff, it was concluded that there were three root canals seen on approximately 5-6% of maxillary premolars. 6 On the other hand, a study made by Caliskan et al found that there was no three-seperate-rooted first maxillary premolars as a result. Second premolars will more than often have one roots with a single oval-shaped canal. 8 Based on a study made by Ok et al. it was established that one canal second maxillary premolars were seen in 59.7% of their cases while there were two canals in 40% of the cases and three canals in 0.30% of their cases. 9 Constant to this finding, Vertucci et al. even concluded that there was an incidence where there was 1% of three-rooted-plus-three-canal in second maxillary premolars. 10

When the root canals are classified, various types of classification can be used which comprises of Weine, Vertucci and Gulabivala classifications. In describing the root canal morphology, Vertucci’s classification is known to be the most commonly used classification and it comprises of eight categories: Type I (1), Type II (2-1), Type III (1-2-1), Type IV(2), Type V (1-2), Type VI (2-1-2), Type VII(1-2-1-2) and Type VIII(3).

In investigating the root canal anatomy of the tooth, various methods have been proposed which includes that of in vivo and in vitro methods. In vivo methods comprise of the basic clinical evaluation of the root canal treatment, the retrospective assessment of the patient records, any conventional radiographic evaluation, and advanced radiographic techniques like cone-beam computed tomography (CBCT).11-13 In vitro methods comprise of the root canal staining and tooth clearing,14,15 root sectioning, microscopic examination, examination of conventional radiographs and using three-dimensional modalities such as microcomputed tomography.16,17,18 Using the CBCT, this technique has the ability to identify the root canal morphology as detailed as using the root canal staining and other clearing techniques that in the past have been of higher value to the other conventional techniques that can be implemented to give a three-dimensional perspective of the complete morphological details.2

With these in mind, the purpose of this study is to analyse the variation in root canal morphology of human maxillary second premolar between different gender in Chennai population.

**Materials and Methods**

One hundred CBCT images of Saveetha Dental College patients (53 females and 47 males) which are aged between 16-60 years old, with an average of 45 years, whom were seeking the routine dental diagnosis for further dental treatment. These patients were referred to the Radiology Department of Saveetha Dental College between the years 2017-2018.

The samples that were collected and analysed were purposive where at the very least there was either one maxillary second premolar with fully developed roots; which was taken as the inclusion criteria. When determining which samples to examine, unclear or distorted CBCT images, beforehand endodontically initiated or treated teeth, teeth with posts or crowns, periapical lesions, and any physiological or pathological process such as immature apex was excluded. The final sample that was collected was 100 including both right and left second maxillary premolars, was further screened for the number of roots and root canal configuration. The total data observed and collected were then evaluated and classified under Vertucci’s classification. Other additional data that was collected also included the number of canals, the distance between the occlusal pit to the pulp chamber, the distance between pulp floor to the furcation as well as the distance between the CEJ to the pulp chamber. The genders of each patients were also recorded in order to be analysed.
The collected CBCT samples were retrieved and assessed at the Radiology Department of Saveetha Dental College, Chennai using the Galileo software used for viewing the CBCT that are taken.

**Results and Discussion**

The results of the study are presented in Tables 1-5 and the overall data has been graphically represented in Graph 1. Based on Table 1, of all the 100 maxillary second premolars, the most common type of canal configuration for both the genders is Type I (41%), Type III (22%), and Type V (22%). In females, the most common type of canal configuration discovered is Type I (35%), Type III (63.6%) and Type V (83.3%). In males, the most common type of canal configuration determined is Type I (65%) and Type III (36.4%).

Based on Table 2, when the number of canals for each tooth were evaluated, female patients showed a mean value of 1.708 with a standard deviation of 0.470 while in male patients, the mean value is 1.888 with the standard deviation of 0.471. When both the genders were compared in terms of the number of canals, there was no significant difference (p-value: 0.9835).

To achieve a successful treatment in endodontics, a proper comprehension of both the root canal anatomy and the morphology is of utmost importance. A proper endodontic treatment involves procedures where all the canals are properly debrided, disinfected, shaped and obturated completely. When an endodontist come across failures in an endodontic treatment, the main cause to this is either because of an untreated canal, incomplete debridement or incomplete obturation. Because of these possible scenarios, a cautious clinical and radiographical examination should be of importance and essential criteria for a successful prognosis.

Another study that was done presented an intricate investigation on the root canal morphology of maxillary second premolars in Chennai population using Cone Beam Computed Tomography (CBCT). With various techniques being introduced and used till this day for the purpose of assessing the root canal morphology and configuration like macroscopic sections, transparent samples and polyester resin impressions, CBCT is considered as the most excellent technique for a proper three-dimensional assessment of the root canal morphology.

Overall, there are various studies that have attempted to fully investigate the root canal morphology and the root numbers of the maxillary second premolar. In terms of the number of canals present in the maxillary second premolar, a study that was made by Pineda and Kuttler\(^2\) showed that there was one canal in 55% of the obtained sample while there were two canals in 45% of the total samples. Vertucci et al, on the other hand discovered that 48 of the maxillary second premolars have one canal while there were two canals in 51 of the premolars and three canals in 1 premolar. Similar to the latter study, a study made by Bellizi and Hartwell reported that there were 40.3% of premolars that have one canal while 58.6% have been discovered to have two canals and 1.1% have three canals.\(^2\)

In regard to the root canal configurations based upon Vertucci’s classification, in the Turkish population, it was reported that the most common type of canal configuration is Type IV (60%) and Type I (38%). On the other hand, in females, the most common type of canal configuration is Type IV (63%) and Type V (34%). Based upon a study made by Ok et al. on the
Turkish population, for the maxillary second premolar, the frequency of canals is that of one canal (59.7%) and Type I (54.5%) of Vertucci’s root canal configuration.\(^9\) (PM 1). Comparing these studies to a study made by Abella et al. the most frequently seen canal configuration if of Type I (47.2%); which is seen in the Spanish population.\(^{23}\) Additionally, in the Pakistani population, commonly there were 84% of premolars that were single rooted with a Type I (53.4%) canal configuration.\(^{24}\)

In the current study that was made, out of all the 100 maxillary second premolars, the most common type of canal configuration for both the genders is Type I (41%), Type III (22%), and Type V (22%). In females, the most common type of canal configuration discovered is Type I (35%), Type III (63.6%) and Type V (83.3%). In males, the most common type of canal configuration determined is Type I (65%) and Type III (36.4%).

In terms of the number of canals, female patients showed a mean value of 1.708 with a standard deviation of 0.470 while in male patients, the mean value is 1.888 with the standard deviation of 0.471. When both the genders were compared in terms of the number of canals, there was no significant difference (p-value: 0.9835). These results are consistent with our study.

**Conclusion**

Within the limited number of samples available, it is proven that the Chennai population have maxillary second premolars with a root canal morphology of one canal and a Type I Vertucci’s classification. In addition to that, there some instances when there is more than one root with various canal configurations that have been identified. In order for a proper generalization of results to be produced, future studies should include even larger sample sizes.

Application of Berry’s Index in the Analysis of Bite Mark

Nur Qistina Binti Ahmad Fauzi¹, Gheena S²
¹Undergraduate Student, ²Reader, Department of Oral Pathology, Saveetha Dental College and Hospital, Saveetha Institute of Medical and Technical Sciences, Chennai

Abstract

Background: This study was done to evaluate the importance of applying Berry’s index in bite mark analysis. With that, it is able to highlight the usefulness of Berry’s index in aiding the analysis of bite mark of an individual.

Methods: The study was conducted among 60 students between the ages of 18-30 from Saveetha Dental College, Chennai. The data that was obtained was then tabulated and statistically analyzed.

Conclusion: The results of the study revealed that the widths of both maxillary central incisors and the bizygomatic width were higher in males when compared to females. A positive correlation can be found in males compared to females in regard to both of the widths obtained. Berry’s index is a useful tool of high forensic value and can be used to help in the identification of an individual’s facial proportions based on the calculated width of the central incisors. Thus, it can be of correlation to that of forensic facial reconstruction.

Keywords: Berry’s formula, bitemark analysis, incisal width, bizygomatic width

Introduction

Dentistry is a form of science that can be applied in various legal applications. In regard to legal matters, if the detailed aspects of dentistry including the facts, experience and knowledge is used, it is then terms as Forensic Odontology. In today’s Forensic Dentistry, it has flourished and developed into applying evidence-based methods and procedures allowing for a more accurate result.¹

The identification of an individual through human remains is considered to be one of the most difficult tasks whenever an evidence is presented. Several methods have been used; one of the many being the analysis of the human bitemark.²

The significance of using bite marks was initially brought to light in the year 1937 where its application helped in securing an ongoing murder conviction.³ The bitemark evidence that was put forward gave proof of the victim’s struggles during the assault.⁴ Ever since that moment, bite mark analysis has progressed in terms of the techniques that are used making it more reliable and allowed a more reproducible result to be achieved.⁴,⁵

The human teeth can be considered a weapon whether it being a form of assault or a self-defense act against an assailant. For a bitemark to be of good forensic value, there should be specific characteristics that it should possess. Structurally, incisors have rectangular outlines, canines have triangular outlines and premolars have double triangles. Distinctive characteristics like missing teeth, fractures, etc. has even higher forensic
values. More than often, bite marks are seen as an elliptical or round shape of contusion or abrasion, which is significantly linked with indentations. When a person’s dentition needs confirmation to that of a set of bite marks, the procedure will include that of measuring the size, shape and the position of a specific individual’s teeth.

As a result of the human skin’s distortional property, the stiffness of tissues serves as a problematic thing during bite mark analysis. In instances where the teeth indent the skin especially loose tissues like the breast and the thighs, the teeth mark distance would be increased mesiodistally, the angle of rotation would be flattened, and there would be an increase of intercanine distance. On the opposite note, when the indents are made on areas like the forearm and the shoulders, the exact opposite characteristics would be produced.

In a typical bitemark analysis, it begins with photographic records of the injury including a universal measurement scale in order to record the measurements. Following that, it also requires the impressions for both the model of the injury as well as to represent the perpetrator’s dentition. In present days, advancement in technology has allowed a more accurate way of tracing the outlines of the bitemark for a more proper comparison.

In prosthodontics, the application of the width of the anterior teeth and the form selection is considered to be essential in order to provide the patient with a natural form of aesthetics. In relation to this, the maxillary central incisors are necessary to maintain a satisfying appearance. One of the methods that can be used is known as Berry’s Biometric Index. This index provides an overall compatible aesthetics during tooth selection in the instance that the pre-extraction of the patient is absent.

**Berry’s formula**

The formula used for this index includes the calculation of the width of the maxillary incisor in relation to the bizygomatic width:

\[
\text{Width of the maxillary central incisor} = \frac{\text{Bizygomatic width}}{16}
\]

When various available literatures where observed through PubMed, there has been a number of articles about Berry’s Index in regard to forensic odontology. With that in mind, this study was made to explore the correlation between these two. The obtained results would help provide great inference to the significance between that of the mesiodistal width of the central incisors and the bizygomatic width of the participants both males and females. This finding can further prove that Berry’s index could serve as a useful tool in the identification of damaged remains in forensics.

**Materials and Method**

This study was conducted among 60 students between the ages of 18 -27 from Saveetha Dental College, Chennai. Out of 60 subjects, 30 of the subjects were males and the other 30 were females. The objective as well as the procedure involved in conducting this study was explained beforehand to all of the subjects. An informal consent was also agreed upon by the participants before any steps where taken.

When this study was conducted, the inclusion criteria that was followed included:

- No missing maxillary and mandibular teeth
- Absence of any gingival and periodontal pathology
- Absence of anterior restoration
- Absence of interdental spacing and crowding

In order to measure the width of each participant’s incisor, bite registration was taken on a modeling wax.
For each participant, they were asked to sit on the dental chair in a position where their heads where upright and rested on the headrest, allowing them to face forwards into the horizon. The participant was then instructed to bite onto the modelling wax sheet with the occlusal plane of the maxillary teeth parallel to that of the floor. The distance between the disto-proximal surface indentation to the mesio-distal surface on the indentation of the maxillary right central incisor was measured and tabulated.

In order to measure the bizygomatic width of the participants, a face bow was used to determine the extent and a millimeter ruler was then used to measure the extent.

The data received was tabulated and analyzed using Statistical Package of Social Sciences (SPSS). Based on these values, the mean and standard deviation (SD) were calculated. The $P$ value of 0.05 or less was considered as statistically significant.

**Results and Discussion**

Once the data was calculated, Table 1 and Graph 1 reveals both the mean values and the standard deviation of the width of upper central incisors and bizygomatic width of both genders.

When the width of the upper central incisors was calculated, the mean value obtained was 0.7613cm and 0.7433cm respectively. On the other hand, the mean value of the bizygomatic width for both males and females were 12.32cm and 12.31cm respectively. After analyzing the obtained data, the t-test showed that there was a statistically significant difference in terms of the width of the upper central incisors between both genders. However, there was no statistically significant difference between males and females for the bizygomatic width.

Table 3 exhibits the Pearson’s correlation between that of the upper central incisor width and the bizygomatic width of both males and females individually. The data obtained revealed that there was a negative correlation between the two values in terms of female participants (r =0.0267). On the other hand, there was a moderate positive correlation between the two mentioned values when compared to in males (r = 0.4318).

Discussion

As a forensic odontologist, the identification of human carcasses is helped with the ability to identify the dental records at a particular crime scene. Through the analyzation of various dental records, the possible cause (physical abuses or injuries) can be identified. It should be noted that the offender’s gender and age can also be determined thus allowing more evidence to be used during the court of law. Various evidences collected for example like tooth prints and radiographs are often used for forensic odontology. 14

Compared to other bones in the body, teeth are a structure that can be conserved for a longer period of time when compared to the latter. The earliest usage of teeth for a method of identification was utilized for the case of Lollia Paulina during the Roman times, which was aided by the distinctive arrangement of her teeth. 4When having to deal with an extremely decomposed body and other methods of identification is not an option, the dental records can be of good use even if additional information is needed. 15, 16

Bite mark analysis to this day has been an indispensable tool during a forensic investigation. 17By definition, it can be described as a representative pattern which is left in tissue or an object by the dentition of a human or an animal. 18On the contrary, even though it is said that bite marks of each individual are unique, the human skin is not an ideal material to which a proper bite registration can be obtained. 19When a bite mark is left on the skin, the pressure is either made against a cloth or wire grates or by the presence of cloth between the culprit’s teeth and the victim’s skin. In some cases, partial bite marks can also be seen in instances where when the bite was made, the victims was moving, resulting in a bitemark that is either partial or incomplete. In certain individuals, when there is a missing tooth, it
can be presented as a result of uneven pressure on the area. However, it is proven that whether it is the dead or living, bite marks can alter as time goes by.  

Berry’s biometric ratio was presented for the first time in 1906. He determined that the upper central incisor tooth is proportional to that of an individual’s face proportions. The maxillary central incisor is a definite item to produce an esthetically pleasing frontal profile for each person. Therefore, a proper selection of the teeth is definitely important to restore the anterior portion of completely or partially edentulous patients during a prosthodontic treatment. Even though this index is of very much use in prosthodontics, its application has yet to be fully examined in as a tool of identification. Thus, this study was made for the sole purpose of demonstrating the usefulness of Berry’s Index for bite mark analysis.

Based on this study, it was found that the bizygomatic width and the widths of the maxillary central incisors were more in males. The results of the bizygomatic width are in correlation with the study done by Anthony et al. in 2015 but is in contrast to that of the value of the width of the incisors. According to a previous study made by Hasanreisoglu et al, it was noted that the correlation between the width of the maxillary incisors and the bizygomatic width is more relevant in females than in males. However, in this study males are of more relevant in correlation compared to females. Compared to the same study, the results show that there is a positive correlation between the bizygomatic width and the width of the central incisors in males rather than in females while based on the later study both of the genders exhibited the positive correlations. The importance of this correlation can be used to aid in the determination of the facial characteristics of the victim as well as the culprit. At the same time, it allows a proper formula to be constructed in the determination of the facial width of destructed human bodies.

**Conclusion**

Even though the significance of bite mark analysis is impossible to be dismissed, it definitely cannot fully achieve a certain evidence. The reason behind this is because there are still drawbacks to this method. Using Berry’s Index enables the measurements that is collected during bite analysis to be utilized and aid in receiving details about a specific individual. Overall, based on the study that was conducted, utilizing the incisal width that is calculated from a bite mark has a possibility to achieve a proper impression in regard to the facial width of an individual. With the results of studies, it is of good use to apply Berry’s index as a subsequent method in bite mark analysis and thus making it a valuable forensic tool.

Mesiodistal Width of Mandibular Central Incisors between Different Genders in Chennai Population Using Cone Beam Computed Tomography

Nur Qistina Binti Ahmad Fauzi¹, Mahesh R²
¹Undergraduate Student, Saveetha Dental College and Hospital, Saveetha Institute of Medical and Technical Sciences, Chennai, India, ²Reader, Department of Pedodontics, Saveetha Dental College and Hospital, Saveetha Institute of Medical and Technical Sciences, Chennai

Abstract

Background: Using the CBCT, this technique has the ability to identify the proper dimensions of the mesiodistal width of the tooth and other clearing techniques that in the past have been of higher value to the other conventional techniques that can be implemented to give a three-dimensional perspective of the complete morphological details. With this, analysing the mesiodistal width of mandibular central incisors between male and female based on CBCT can be accomplished.

Methods: One hundred Cone Beam Computed Tomography (CBCT) images from different patients are selected randomly from Department of Oral Radiology of Saveetha Dental College and Hospital, India. All the CBCT images of patients are examined for the inclusion criterias in the mesiodistal width of the mandibular incisors between different genders. All mesiodistal width of mandibular central incisors between different genders are investigated and compared.

Conclusion: When both the genders were compared in terms of the number of canals, there was a significant difference seen (p-value: 0.000002208). With the p-value calculated, it was found that there was a significant difference between the genders in terms of the distance between the occlusal pit to the pulp chamber (p-value: <0.0000001). Overall, there is no significant difference between the two genders at the level of the cervical third (p-value: 0.6554).

Keyword: Mesiodistal width, mandibular central incisor, Cone Beam Computed Tomography.

Introduction

The ratio of an individual’s tooth size is a reasonable diagnostic method to enable a proper treatment prognosis and outcome to be anticipated. In instances where there are complex cases, this will allow the limitation of requirements of any diagnostic setups. The relationship of the mesiodistal width of mandibular central incisors and other dentitions especially the opposing maxillary dentition will produce a proper treatment outcome preferably in correcting occlusion. In cases where an excellent orthodontic treatment wants to be achieved, the mesiodistal tooth size of both maxillary and mandibular arches should be of an ideal relationship.

plan, it should consist of the identification of tooth size, both local and general, overbite, overjet as well as the occlusion. 4

Various studies have been done to display the differences of the tooth size in relation to a specific group. In a study made by Bolton, the relationship between the tooth size disharmonies and the treatment of malocclusions became the main focus in 55 patients; to which have excellent occlusions. With this, the ratios for the mesiodistal sizes of the maxillary and mandibular teeth were obtained. 5 A number of clinical cases were included in order to obtain the viability of the diagnostic aid and with thorough analysis, found that the need for a diagnostic aid was not necessary. 6 Using only the rough measurement of the labial portion of the teeth and the calculations made with Bolton’s ratio were identified to be enough to deliver a better and exact option of occlusal goals for a specific patient. 5,6

On the other hand, Arya et al. made a study in 1974 on the relationship of the tooth size with different genders. In addition to that, the study also included the presentation of how tooth size affects different types of malocclusions; which was not a success. Based on the study that was made, the calculated and recorded tooth size of each dentition for each specific group was differentiated. However, the differences for each of the individuals were not experimented on. 2 Lavelle in the year 1972 in contrast to the previous studies, determined that in different tooth dimensions there are various sexual dimorphisms related to it. 7 Similar to that of the study made by Arya, the ratio of both maxillary and mandibular arch tooth size was measured in relation to the different form of malocclusion. To oppose of the result obtained from Lavelle’s study, Nie and Lin in 1999 concluded that there an absence of any significant sexual dimorphism for both anterior and posterior tooth size ratio in relation to various types of occlusion. 8

Materials and Method

The data for this study were obtained from the records of Saveetha Dental College, Department of Oral Radiology, Chennai, India. The sample selection was collected based on the dental age of the patient with a permanent dentition specifically the presence of lower anteriors.

The total collected sample was 100 Cone Beam Computed Tomography (CBCT) which was sorted based on the gender of each individual. The following criteria were used:

1. No apparent loss of tooth substance due to attrition, caries or fillings.
2. Presence of at least one lower central incisor in each CBCT sample.

Once the sample CBCTs were collected, the mean, range and standard deviation were calculated in terms of the mesiodistal width of the teeth. The calculation is further divided into the incisal, middle and cervical third of the crown. In each division, the p-value was calculated and the significance in terms of gender of each of the divisions are determined.

Results and Discussion

The results of the study are presented in Tables 1-3 and the overall data has been graphically represented in Graph 1. Based on Table 1, when the mesiodistal width in the level of the incisal third were evaluated, female patients showed a mean value of 5.676 with a standard deviation of 0.304 while in male patients, the mean value is 5.167 with the standard deviation of 0.626. When both the genders were compared in terms of the number of canals, there was a significant difference seen (p-value: 0.000002208).

</table>

Based on table 2, when the mesiodistal width of the incisor in the level of the middle third was analysed and recorded, female patient showed a mean value of 5.405 with a standard deviation of 1.501 while in male patients, the mean value is 4.726 with a standard deviation is 0.470. With the p-value calculated, it was found that there was a significant difference between the genders in terms of the distance between the occlusal pit to the pulp chamber (p-value: <0.0000001).

Based on the table 3, in female patients in terms of the mesiodistal width of the incisor in the level of the cervical third, the mean value that was gathered was 3.943 with a standard deviation of 0.622 while in male patients, the mean value is 4.092 with a standard deviation of 0.582. Overall, there is no significant difference between the two genders at the level of the cervical third (p-value: 0.6554).

</table>
A number of literatures regarding orthodontic studies have compared tooth size proportions in relation to that of various ethnics and malocclusion groups. With that in mind, as a result of the lack of knowledge in regard to gender, Angle’s classification as well as the mesiodistal width of the tooth serves a setback for these studies. In order to fully comprehend this topic, more added information should be obtained.  

When the tooth size discrepancy ratio is implemented as a diagnostic method, the main motivation to do so is to enable a proper view into how the both the functional and aesthetic outcome can be produced in instances when no diagnostic set-up is available. In relation to this, the most common use of this diagnostic method is in the evaluation of tooth size discrepancy in regard to different dental arches. 

The mesiodistal width of the crown is a criteria that is known to be a determining variable when we are in search of factors that can be related to the development of occlusal irregularities, the probable effects of the discrepancies in interdigititation, as well as the isolation of discrepant teeth with minor malocclusion that can be attended to through selective mesiodistal grinding and minor tooth movement. When this specific topic needs to be determined, the clinician has the ability to analyse various probable number of crown size relationships; which in this case is the relative size differences between a single tooth and a group of teeth, despite not knowing their location in the dental arch. 

In certain clinical settings, the Bolton’s analysis is known to be a useful method in order to guide the orthodontist whenever they come across cases where the tooth size discrepancies are extreme. However, this analysis has some setbacks and limitations. The reason behind this is because, Bolton’s estimates of variation at first was underestimated as a result of being obtained from samples of perfect Class 1 occlusion. On top of that, the population and gender composition using Bolton’s sample was not specific, which in results in it being a probable selection bias. With this finding, this index is considered not to be a universal acceptable index to be used in all population groups. Moreover, this analysis only identifies with either an anterior or overall ratio, meaning that it cannot identify each mesiodistal individual tooth size like smallness or excessiveness.
If there is a presence of tooth size discrepancy, this results in the prevention to achieve a proper occlusion. When there is a case of mismatched size between that of maxillary and mandibular dentition, this can result in a generalised spacing or crowding or even deviations from a Class 1 occlusion particularly in the posterior region. In order to fix the malocclusion, it is commonly specified only to that particular affected arch. 12

In recent studies, in regard to the gender difference, there have been reported to be a clinical relevance to the mesiodistal width. In a study done by Seipel, when the primary and the permanent dentition was compared, there was found to be less differences in terms of gender. When each individual tooth was evaluated, the maxillary canine and maxillary central incisors exhibit the greatest gender differences, while in another study, the upper lateral incisor and the lower central incisor showed to be the most homogenous.13 Based on this current study, there showed to be a significant difference between genders when an individual mandibular incisor was evaluated.

Conclusion

Within the limited number of samples available, it is proven that the Chennai population there is a significant difference between males and females when the mesiodistal width is compared. Although at the cervical region, both males and females exhibit the similar measurements, at the middle and the incisal edge, there is much significant difference between the two genders. In order for a proper generalization of results to be produced, future studies should include even larger sample sizes.

Abstract

Background: Coronavirus disease 2019 (COVID-19) pandemic affects many aspects of society, including the quality of life (QoL) of children with type 1 diabetes mellitus (T1DM). This study analyzed predisposing factors that affect QoL of children with T1DM during the COVID-19 pandemic, mainly the socioeconomic factors.

Methods: Cross-sectional study was conducted in the Pediatric Endocrine Outpatient Clinic of Dr. Soetomo General Hospital, Indonesia, from March to October 2020. Children with T1DM were assessed using Pediatric Quality of Life Inventory 3.2 diabetes module. Socioeconomic characteristics were presented; correlation between variables were analyzed using Pearson and Spearman tests and \( p < 0.05 \) was statistically significant.

Conclusion: This study included 33 subjects (18 boys and 15 girls; mean age, 11.97 ± 2.91 years). Worry and treatment barrier for the child report correlated to the parent’s educational background (\( r=0.35; p=0.022 \)) and income (\( r=0.29; p=0.049 \)). Worry, treatment barrier, and diabetes aspects for parents’ report correlated to age group (\( r=−0.38; p=0.014 \)), parents’ educational background (\( r=0.37; p=0.015 \)) and income (\( r=0.29; p=0.049 \)). There’s correlation between diabetes aspect of parent’s report and age group (\( r=−0.38; p=0.014 \)).

Keywords: children, COVID-19, HRQOL, type 1 diabetes mellitus

Introduction

The World Health Organization Emergency Committee declared the coronavirus disease 2019 (COVID-19) pandemic as a global health emergency1. Its existence affects not only the health aspect but also the social and global economic aspects. In just 4 weeks, the lockdown conducted in New York cost an estimated $1.1 billion, which is 1% of the country’s gross domestic product2. In Indonesia, the losses incurred during the first quarter of 2020 amounted to 320,000,000,000 rupiahs3. Separately, the occurrence of social restrictions, independent isolation, restrictions on long-distance travel, dismissal, and closed schools led to multidimensional crisis2,4.

Type 1 diabetes mellitus (T1DM) is the most common chronic disease, with approximately 70,000 children diagnosed each year worldwide. The incidence was reported to be lower in Asia5. This century, the
prevalence of diabetes mellitus worldwide is increasing. In 2002–2014, there were 70 children with T1DM with 40% increment lately in 2020 in Surabaya, Indonesia. As of August 2020, the Chinese Center for Disease Control and Prevention reported 2143 infections in children aged below 18 years. Moreover, a report from the COVID-19 task force in Indonesia indicated that the infection rate in children is 11.4%, with 3.2% of deaths. This mortality rate is relatively the highest compared with other countries.

A multidisciplinary approach was very important in children with T1DM. Previous studies have reported that individuals with low socioeconomic status (SES) tend to have inadequate treatment; thus, they are at risk to develop complications. Alfian et al. stated that patient’s low compliance may result in a lower QoL. In addition, the International Society for Pediatric and Adolescent Diabetes (ISPAD) guidelines said that depression and anxiety affect patients with T1DM, resulting in bad glycemic control.

Parent education, parent income, and parent employment may influence the QoL of patients with T1DM, mainly because of the COVID-19 pandemic. The reduced capacity for contact with physicians owing to fear of going to the hospital may lead to a further decrease in QoL of patients with T1DM in pandemic conditions. This study aimed to analyze factors that affect the quality of life (QoL) of children with T1DM during the COVID-19 pandemic; the components assessed were diabetes, treatment barrier, treatment adherence, worry, and communication.

Material and Methods

Sample

This study involved children and adolescents diagnosed as having T1DM according to the ISPAD guidelines registered at the Pediatric Endocrinology Outpatient Clinic of Dr. Soetomo General Hospital, Surabaya, Indonesia, and their parents. The inclusion criteria were patients aged 5–18 years, who were diagnosed as having T1DM, and who already started their treatment. A total of 33 patients aged between 5 and 18 years (18 boys and 15 girls) were included in this study.

Socioeconomic factor

Socioeconomic factors such as parents’ education, parents’ income, child’s age, and children’s education were obtained. The educational background was classified based on the government program of 9-year compulsory education; hence, we divided it into 3 groups: <9 years, 9–12 years, and >12 years. Based on the regional minimum wage, we classified SES into 3 groups: low, medium, and high. The ages of children were then grouped into 5–7 years, 8–12 years, and 13–18 years.

Nutritional status

Nutritional status was classified according to the World Health Organization (body mass index for age) values defined for children and adolescents (5–18 years old): severe malnutrition (z < −3), moderate malnutrition (−3 < z < −2), normal (−2 < z ≤ 1), overweight (1 < z < 2), and obesity (z > 2). We grouped the subjects into severe malnutrition, moderate malnutrition, normal, and overweight or obese.

Pediatric Quality of Life Inventory (PedsQL)

The patient’s QoL was assessed using the PedsQL 3.2 diabetes module by Varni et al. for children based on the patient’s age. The PedsQL questionnaire that was used to assess the QoL of the children with T1DM has been translated into Bahasa Indonesia by a credible sworn translator. It assessed the aspects of diabetes, which assessed the diabetes symptoms (15 items); treatment barriers, which evaluated the obstacles or problems during treatment (treatment I) (5 items); treatment adherence (treatment II) (6 items); worry (3 items); and communication (4 items) with the items reverse scored. A 5-point scale (0 [never], 1 [almost never], 2 [sometimes], 3 [often], and 4 [almost always]) and a 3-point scale (0 [not at all], 2 [sometimes], and 4 [a lot]) were used for the Child Report for Young Children (ages 5–7 years).
These scores were transformed to a 0–100 scale: 0 = 100, 1 = 75, 2 = 50, and 4 = 0. Lower scores indicate more diabetes symptoms and management problems. In a study by Varni et al., the validity and reliability were tested in this PedsQL, showing good results15. Validity is assessed based on predicting the morbidity and disease burden of the patient and his parents. Reliability indicates consistent results from several repetitions of the test14. Moreover, the validity and reliability of the PedsQL questionnaire have been tested by the Statistics of Universitas Airlangga. The questionnaire was shared online to the participants by the same team during the study.

**Evaluation of data**

A comparison test was used to analyze our data using the SPSS 17.0 software (IBM SPSS). For the baseline and clinical characteristics, the mean and standard deviation of each element were used. Normality test was done for each data using the Shapiro-Wilk test because the study sample was >50, the correlation test was done using the Pearson test for parametric data and the Spearman test for nonparametric data, and the chi-square contingency was used for the nominal data to test their correlation. We considered \( p < 0.05 \) as statistically significant.

**Ethical permission**

This study’s ethical approval was granted by the ethics committee overseeing health research team at the Dr. Soetomo General Hospital, Surabaya, Indonesia (ref. no:0123/LOE/301.4.2/IX/2020).

**Results and Discussion**

This cross-sectional study involved 33 children with T1DM (18 boys and 15 girls; age, 11.97 ± 2.91 years). The socioeconomic characteristics of the patients with T1DM are presented in Table 1. Most of them have a good nutritional status (90.9%) and are active in teaching and learning activities. Most of the parents’ income was in the group of middle income (54.5%). The parent’s educational background was mostly 9–12 years (63.6%).

The average data of each aspect on the QoL assessment results of children and parents are presented in Fig. 1. The best value was obtained in the adherence treatment, whereas the worst was the worry score.

The results of the correlation between socioeconomic factors and QoL are presented in Tables 2 and 3. The correlation test revealed significant results in parent’s education with child’s worry ($r = 0.35; p = 0.022$) and parent’s worry ($r = 0.37; p = 0.015$). Moreover, the age group had a significant value on the diabetes score of the parents ($r = -0.38; p = 0.014$). Parent’s income significantly correlated to the treatment barrier ($r = 0.29; p = 0.049$).

Our study findings from the constituent components of SES indicated that parent education significantly correlates to the worry aspect of QoL in both parent and child. This finding is consistent with the findings of Costa and Vieira, who reported that parental education correlated with QoL, especially in the worry’s domain. In particular, it was reported that patients who have parents with higher education backgrounds will have better QoL and lower levels of anxiety and depression than those who have parents with lower educational backgrounds.

This study also found that parental income significantly correlates to treatment barriers. This finding consistent with the study of Costa and Vieira, who reported that parent’s income has a role in better QoL results in the satisfaction component and worries, which was also linked to happiness, which can then play a role in better compliance and self-management. T1DM is a disease that is closely related to the environment and lifestyle, in which lifestyle and environment are related to the SES of a family, which consists of parents’ education, parents’ income, and parents’ occupation. Other studies also reported that QoL was better in males than females.

Another finding indicated that older children with T1DM had a lower QoL, especially in the diabetes aspect. This can happen because when children are getting older, they have more personal opinions, and it becomes more difficult to control their treatment. This finding is also consistent with that of Abdul-Rasoul’s study, which showed that the 13–18 age group had the lowest QoL compared with the younger age group.

In this study, most of the subjects aged 8–12 years (51.5%), were male (54.5%), and had normal nutritional status (90.9%). This study is consistent with that of Abdul-Rasoul et al., who reported that most of the age group is 8–12 years.

Nevertheless, there is a limitation in this study. It was conducted at a referral hospital in East Indonesia, where the number of T1DM cases was lower than in Caucasians. Moreover, because of limited resources, the
management of T1DM is quite complicated in Indonesia. Besides maintaining routine control in the Pediatric Endocrine Outpatient Clinic, some factors, such as the socioeconomic and educational background of parents, can affect QoL.

We could not conclude whether there is any different T1DM QoL before and during the pandemic. There are no studies that evaluated factors affecting QoL during the COVID-19 pandemic. To the best of our knowledge, this is the first study on children with T1DM that evaluated the determining factors that affect QoL during the COVID-19 pandemic.

**Conclusion**

This study included 33 subjects (18 boys and 15 girls; mean age, 11.97 ± 2.91 years). Worry and treatment barrier for the child report correlated to the parent’s educational background (r = 0.35; p = 0.022) and income (r = 0.29; p = 0.049). Worry, treatment barrier, and diabetes aspects for parents’ report correlated to age group (r = −0.38; p = 0.014), parents’ educational background (r = 0.37; p = 0.015) and income (r = 0.29; p = 0.049). There’s correlation between diabetes aspect of parent’s report and age group (r = −0.38; p = 0.014).

The Effect of Collagen-Chitosan-Sodium Hyaluronates Intrastromal Implantation on Corneal Clarity and Transforming Growth Factor (TGF-β) (Experimental Study On New Zealand Rabbit)

Nurul Fitri Shabrina¹, Reni Prasetyani², Prihatini Widiyanti³

¹Researcher, ²Researcher/Tutor, Department of Ophthalmology, Faculty of Medicine Universitas Airlangga, Dr Soetomo General Hospital Surabaya, ³Researcher/Tutor, Department of Biomedicine, Faculty of Science and Technology Universitas Airlangga

Abstract

Background: Stromal haziness due to various diseases could results in permanent blindness. Currently, many biomaterials are developed to help aid the healing, so, haziness does not occur. This study aims to examine the effect of the collagen-chitosan-sodium hyaluronic (Col-Chi-NaHa) as an alternative to healing the corneal stroma so that corneal haziness does not occur.

Method: A total of 30 New Zealand male rabbit eyes were divided into three groups. The first group was not treated at all. The second group performed intrastromal injuries by making a stromal pocket with the aid of a crescent knife. The third group carried out implantation of the Col-Chi-NaHa biomaterial which was inserted into the stromal pocket. On day 14, the corneal haziness level was examined using an eye microscope and handheld slit lamp. Immunohistochemical staining of the cornea was carried out using anti-TGF-β antibodies.

Result: After 14 days post-treatment showed that there was more significant haziness between the Col-Chi-NaHa composite implantation group and the control group (p = 0.00, \( \alpha > 0.05 \)). There were also lower TGF-β levels between the Col-Chi-NaHa implantation group and the control group (p = 0.00, \( \alpha > 0.05 \)).

Conclusion: Corneal clarity in the implanted group was lower than that of the control group but this was due to the short observation period which causing biomaterial not completely degraded. The TGF-β level in the implanted group was lower than control.

Keyword: Corneal clarity, stroma, TGF-β, biomaterial, Collagen, Chitosan, Sodium hyaluronic

Introduction

Corneal damage is the second leading cause of blindness worldwide. According to WHO, there are 36 million people who suffer from blindness worldwide, and 217 suffer from vision damage, 2.4% of the total blindness is caused by corneal disorders¹. The cornea is a transparent avascular tissue that functions protect the eye from infection and trauma. Due to its transparent
nature, the cornea has a refractive role in absorbing light and accounts for 2/3 of the eye’s total refractive function\(^2\). Corneal damage to the stromal layer due to corneal surgery, refractive surgery, trauma, or infection will cause corneal haziness due to extracellular matrix and imperfect collagen fibers arrangement. Haziness in the stroma will reduce the cornea’s clarity so that its refractive function will decrease, resulting in blindness\(^3\).

Until now, corneal transplantation is the only way to correct blindness due to corneal loss of transparency, but there is an imbalance between the donor and the need for a corneal transplant. There are currently only 40,000 people who receive corneal donor annually in the United States, with conditions that may worsen in developing countries. Due to this imbalance, many artificial corneas and biomaterials are developed to help heal the cornea properly so that corneal scar that reduces the clarity does not occur. Biomaterials are currently widely studied to treat corneal defects by reducing mechanical stress and reducing pro-inflammatory cytokines. Biomaterials that are widely studied for use in aiding corneal healing include chitosan, hyaluronic acid, silk fibers, and polyarginins\(^4\). Biomaterials to be implanted on the cornea must be non-toxic, non-immunogenic, transparent, flexible to adjust during implant insertion surgery, and must be able to support the growth of corneal cells. One of the biomaterials being developed is a combination of collagen-chitosan-sodium hyaluronate (Col-Chi-NaHa) discovered by Chen in 2005 fulfils the biomaterial criteria for the cornea because these three materials are similar to the extracellular matrix of the cornea\(^5\).

Collagen is the largest component of the extracellular matrix of the cornea. The extracellular matrix allows organogenesis and reconstruction during the wound healing process, so collagen is good for corneal repair and regeneration. Collagen is biodegradable, has low antigenicity, and has good biocompatibility due to its low toxicity and immune reactions. Collagen is widely used in ophthalmology for thread materials, bandage contact lenses, punctual plugs, and viscoelastic fluids during surgery. Collagen is also used for corneal reconstruction with good results because it has been shown to facilitate corneal cell and nerve regeneration in vitro. When implanted into the cornea, collagen has a brittle consistency, so it should be mixed with other ingredients to improve its strengths\(^6\). Chitosan is a linear polysaccharide consisting of glucosamine and N-acetylg glucosamine and is a deacetylated derivative of chitin. Chitosan is biocompatible, biodegradable, inert and non-toxic\(^7\). Chitosan also have anti-fungal, anti-bacterial, and hemostatic properties so it is suitable for use as a material for tissue engineering\(^29\). Sodium hyaluronate is a glycosaminoglycan in the extracellular matrix, which has a vital role in wound healing and inflammation. In the eye plane, sodium hyaluronate has viscoelastic properties, so it is often used to protect the corneal endothelium and maintain the anterior chamber’s depth during cataract surgery. Animal studies have also shown that sodium hyaluronate supports corneal epithelial wound healing by stimulating corneal epithelial migration, adhesion, and proliferation\(^8\). The addition of chitosan to collagen can improve its stability and structural integrity so that it can be implanted in the eye\(^9\) and the addition of sodium hyaluronate improves light transmission\(^28,29\). This study attempted to evaluate the differences in Collagen-Chitosan- sodium hyaluronates (Col-Chi-NaHa) intrastromal implantation to the corneal haziness level TGF-\(\beta\) expression in stromal injury on New Zealand rabbits eye.

**Methods**

**Animal**

Thirty New Zealand male albino rabbits weighing 2–3 kg were used. Ethical approval was given by the animal care and Use Committee of the Faculty of Veterinary Airlangga University (Surabaya, Indonesia). Animals were given at least one week for acclimatization. The rabbits then divided into three groups, with each group consists of 10 rabbits. The first group are the treatment group which was given a circular complex of Col-Chi-NaHa biomaterial intrastromal implantation. The second group is the positive control group who was given injuries by making the stromal pocket in the cornea. The
third group is a negative control group where rabbit eyes were not treated at all.

**Collagen-chitosan-sodium hyaluronates (Col-Chi-NaHa) membrane preparation**

Collagen-Chitosan-Sodium Hyaluronic (Col-Chi-NaHa) membrane was made at the biomaterial laboratory at the Institute of Tropical Disease (ITD) Airlangga university. Collagen 20% solution was mixed with 0.1 M acetic acid using a magnetic stirrer for 60 minutes. Then the solution was cross-linked with hydroxypropyl methylcellulose (HPMC). 10% w/v DD 95% chitosan is then dissolved in 13.4 M acetic acid. Collagen and chitosan, which had been wholly dissolved were mixed using a magnetic stirrer for 1 hour. Sodium hyaluronates with a concentration variation of 0.6% were then added to Col + Chi solution and stirred for 30 minutes. The homogeneous Col + Chi + NaHa solution was cast on a Perspex plate and heated using an incubator for 24 hours at 35°C until the membrane dries. After that, the membrane was immersed in PBS until the pH became neutral. The biomaterial membrane was then cut with a diameter of 3 mm and a thickness of 0.2 mm. Sterilization is carried out by rinsing thoroughly in distilled water, then rinsing again with 75% ethanol. The final stage was sterilization with UV for 30 minutes and immersed in sterile PBS buffer liquid, and the biomaterial was ready to be applied intrastromal to the rabbit’s cornea.

**Intrastromal implantation**

The corneal stromal pocket was created at 2 mm from the superior limbus with a diameter of 4 mm and a thickness of 0.2-0.3 mm using crescent knife. The first group was given a circular complex of Col-Chi-NaHa biomaterial intrastromal implantation of 3 mm and a thickness of 0.2 mm, and the stromal pocket was closed without suturing. The second group is the positive control group who was given injuries by making the stromal pocket in the same way as stated above. The third group is a negative control group where rabbit eyes were not treated at all. Each group consists of 10 rabbits with a total population of 30 rabbits. Levofloxacin 0.5% and fluorometholone 0.1% eyedrops were applied six times daily for 2 weeks. The rabbits were examined 2 weeks post op using eye surgery microscope and handheld slit lamp for corneal clarity grading. All the animals were euthanized, the eye were enucleated, and the samples were fixed in 10% NBF (BBC chemicals, Mount vernon, USA) and processed for light microscopy.

**Histopathology**

Immunohistochemical staining was performed on the corneal surface of the enucleated eye tissue in the second week after corneal stromal injury treatment was given. Paraffin-blocked tissue was cut with a thickness of 3µm and placed on a glass polylysine object, then incubated at 45°C for one night. The preparations were paraffinized and washed with flowing distilled water, then incubated with H₂O₂ for 3 minutes and washed with flowing distilled water. The preparations were incubated with citrate buffer pH 6 at 95°C for 45 minutes, then cooled for 30 minutes and washed with PBS 2x for 3-5 minutes. The preparations were then incubated with a blocking serum for 15 minutes and drained. Subsequently, immersion was carried out in alcohol with levels of 70%, 96%, 100%, and xylol. The tissue is then cooled for 15 minutes at room temperature and rinsed in phosphate-buffered saline (PBS) for at least 5 minutes. Tissues to be incubated in anti-TGF-β were given 0.5% casein in PBS for 10 min to block non-specific binding sites. The primary antibody incubation with rabbit polyclonal antibody TGF-β (1:50 Serotec MCA797, Oxford, UK). was carried out for 30 minutes. The tissue was rinsed in water, and 0.5% cobber sulfate in PBS was added to increase the staining intensity. The stained tissue was observed using a light microscope with a magnification of 400x.

**Corneal haze grading**

Corneal haze was graded using Sonoda and Streiler grading at two weeks post-op using ophtalmic surgery microscope and handheld slit lamp. The opacification observed and scored according to an established grading system as follows: 0, completely transparent cornea; 1, minimal corneal opacity, iris vessels easily visible; 2, moderate corneal opacity, iris vessels still visible; 3,
moderate corneal opacity, only pupil margin visible; 4, complete corneal opacity, pupil not visible.

**TGF-β immunoreactivity grading**

The level of TGF-β expression to assess the healing process of the corneal stroma was analyzed by semiquantitative histopathological examination using the Allred scoring method. Immunoreactive-score (IRS) can be assessed quantitatively by adding the results between proportion score (PS) and Intensity score (IS). Proportion score is the proportion of positive cells that are immunoreactive (scored on a scale of 0-5). Intensity score is staining intensity (scored on a scale of 0-3) from light brown to silver brown. The IRS scores range from 0-8, with the scores attached to table 1. Each sample’s data is the average IRS scores observed at 5 Fields of View at 400x magnification.

**Statistics**

The groups’ distribution was analyzed using the Shapiro-Wilk normality test. The comparison of variables between groups was analyzed using Anova if the variables were normally distributed or Kruskal-Wallis if the variables were not normally distributed. All the statistical tests are carried out with the help of SPSS 23 software.

**Results**

**The Effect Of Col-Chi-NaHa Intrastromal Implantation On Corneal Haze**

In the negative control group, all samples had clear corneas on the 14th day after surgery. In the positive control group that was given intrastromal injury, the mean corneal haze level was 0.30 ± 0.949, with the lowest corneal haze on a scale of 0 and the highest corneal haze was on scale 3 which was found on one rabbit. In the treatment group given the Col-Chi-NaHa implant, the mean corneal haze level was 1.80 ± 1.033 with the with the lowest corneal haze scale of 0 in two rabbits, a scale of 3 in two rabbits and a scale of 2 in the remaining six rabbits. The Kruskal-Wallis statistical test showed that there were significant differences between groups (P=0.00, P<0.01).

Discussion

The cornea is a transparent avascular tissue that functions as a protective and refractive structure for the eye and responsible for transmitting light. The corneal stroma is a structure that makes up almost 90% of the total thickness of the cornea, so it is imperative to maintain the transparency of the stroma in order to be maintained. Changes in the corneal stroma structure due to disease, trauma, or scarring can cause the loss of corneal transparency. Corneal stromal abnormalities cause millions of cases of blindness worldwide and currently there is an imbalance between corneal donors and the needs of corneal donors that are needed. A synthetic stromal substitute that can replace the endogenous regeneration ability of the stroma, however, until now there has not been found a synthetic material that can replace the corneal stroma because of the complex structure of the stroma consisting of the extracellular matrix, stromal cells and proteoglycans which are difficult to replicate in vitro. Therefore, research on synthetic materials is currently directed at helping stromal regeneration so that scar tissue that causes corneal haziness does not occur. Synthesis materials currently being researched are corneal tissue donors or other tissues such as lip mucosa, acellular corneal scaffold with bioengineering, adhesive tissue, 3-dimensional bioprinting and stromal stem cell therapy. Currently, many biomaterials are developed to help heal the cornea. Biomaterials have the advantage of inducing less immune reactions and can be fabricated in the laboratory, so the availability is relatively fast compared to waiting for donors’ availability. Good biomaterial can also function as a scaffold for additional cells and medication which are expected to accelerate healing even further.

Implantation of intrastromal biomaterials in rabbit eyes with fish scales as the main ingredient showed no biomaterial degradation until 54 weeks after surgery, and there were minimal corneal opacities around the implant site. In vitro biomaterials with fish scales can support the growth of stromal and epithelial cells. So that biomaterials that are difficult to degrade are more suitable for use to help stromal healing rather than replace the corneal stroma as a whole. Implantation of rabbit intrastromal biomaterials with collagen and Hydroxypropyl methylcellulose (HPMC) shows a mild inflammatory reaction two weeks post-op and neovascularization one-month post-op, which disappeared one week after. Furthermore, observations for seven months showed that the implanted biomaterial was well received without implant extrusion and the corneal condition was clear.

Thus, higher corneal haziness result in the treatment group is due to the short time of observation that causing implanted biomaterial to not fully absorbed and causes corneal haziness.
In this study, we also found 1/5 of the population in the treatment group had completely absorbed biomaterials resulting in transparent corneal condition after 14 days of implantation. The rate of degradation of the Col-Chi-NaHa biomaterial has been previously investigated in vitro by immersing the Col-Chi-NaHa biomaterial in 5 ml PBS and 0.05-gram collagenase for one week. With the results of biomaterial degradation of 0.68% per week\textsuperscript{16}. There has been no research on the degradation rate of the Col-Chi-NaHa biomaterial implanted intrastromally, further research is still needed on the timeline of Col-Chi-NaHa biomaterial degradation in vivo.

The lower corneal clarity in the treatment group could also occur because, in the second week postoperatively, the corneal wound healing phase was still in the remodelling phase. In general, the timeline for wound healing in the corneal stroma is that apoptosis of cells around the wound and neutrophil infiltration begins at six hours post-injury and reaches a peak at 24 hours after injury. Activation of keratocytes started at two days after injury and fibroblast and myofibroblast differentiation occurred 3-5 days after the injury occurred. Myofibroblasts also produce an extracellular matrix whose fibre direction is irregular, causing cloudiness in the cornea. Myofibroblasts have the contractile ability to go to the corneal wound and close the wound. The fibrosis expression gene will be detected within two weeks after injury, and remodelling and scar tissue deposition will occur 14-28 days after the first wound occurs\textsuperscript{17,18}. If the healing goes well and the wound is completely closed, the number of myofibroblasts in the stroma will decrease. In clinical conditions, this is characterized by the disappearance of corneal opacities and this occurs an average of 30-40 days after the injury occurs\textsuperscript{11}. We suggest more extended observation to assess the effect of Col-Chi-NaHa implantation on corneal healing.

Transforming growth factor (TGF-\(\beta\)) is a cytokine that has a significant role in healing corneal stromal wounds. TGF-\(\beta\) will activate the cornea’s wound healing pathway, including differentiate keratocytes into fibroblasts and myofibroblasts, induce changes in the extracellular matrix, and support the proliferation and migration of corneal epithelial cells. However, overexpression of TGF-\(\beta\) also negatively affects the cornea by causing the accumulation of myofibroblasts in the stroma and producing an irregular extracellular matrix leading to post-injury corneal opacification. Inhibition of TGF-\(\beta\) results in more transparent cornea after corneal alkali burn\textsuperscript{19}. Mice wounded by corneal alkali burn and given TGF-\(\beta\) inhibitor also had less inflammatory cell infiltration and myofibroblasts than the control group and had more transparent corneas and less neovascular at day 20 observation\textsuperscript{20}.

The primary ingredient of this biomaterial is collagen, a natural protein found throughout the body. Collagen is brittle and needs to be cross-linked with various ingredients. Mixing collagen with other ingredients can increase mechanical strength and defend collagen from enzyme degradation\textsuperscript{21}. Collagen-chitosan composites are reported to have good mechanical strength and clarity and can regenerate epithelial cells, stroma, and eye nerves after being implanted for 12 months in pig eyes\textsuperscript{21,22}. Chitosan is mixed with collagen to improve mechanical strength so that the biomaterial does not degrade quickly before the wound closes. Clinically, chitosan and its derivatives have been shown to aid in eye healing and are cytologically compatible with various cells in the eye. Administration of chitosan to rabbits with keratoconjunctivitis due to alkaline trauma can decrease symblepharon formation and increase collagen formation in the conjunctiva\textsuperscript{23}. Chitosan also accelerates the proliferation of epithelial cells and inhibits the proliferation of stromal cells in rabbits whose corneal epithelium is damaged due to chemical trauma. The cornea that is given chitosan treatment is more transparent due to rapid wound closure, and the stroma is still regular in structure\textsuperscript{24}. Chitosan also aids in corneal healing by inducing extracellular signal-regulated kinases (ERK) pathway\textsuperscript{27}. Another ingredient in this biomaterial is sodium hyaluronic that...
is present naturally in the extracellular matrix in various organs so that it has non-toxic and non-immunogenic properties. Hyaluronic acid can accelerate corneal healing by reducing pro-inflammatory cytokines, including CD44, IL-1β and MMP9\(^{26}\). Combining these three materials in the form of a biomaterial composite in this study was shown to reduce TGF-beta levels on day 14 compared to the control group, which is thought to occur because it accelerates healing and reduces pro-inflammatory cytokines.

**Limitation**

This study limitation is the short observation period and was not conducted serially to compare the level of corneal opacities at each phase of wound healing. This study also requires many other variables to be investigated to evaluate the chol-Chi-NaHa biomaterial composite’s effectiveness and investigate the inflammatory pathways this composite can inhibit.

**Conclusion**

In this article we reported on our study of Col–Chi–NaHA composite and its effect on corneal clarity and TGF-β level. After 14 days after stromal wounding, the results of the study showed that corneal clarity in the implanted group was lower than that of the control group, but this was due to the short observation period which causing biomaterial not completely degraded. The long-time effects of this biomaterials in cornea still need to be studied. TGF-β level in the implanted group was lower than control. Examination of other parameters, especially other pro-inflammatory cytokines and pro-inflammatory cells count can evaluate the effectiveness and further understand how the Col-Chi-NaHa composites work.

Review on Mobile Apps for Toxicovigilance

Nurul Syafika Nadiah Mohd Zabarudin¹, Sharifah Mashita Syed-Mohamad², Yulita Hanum P Iskandar³

¹Student, ²Lecturer, School of Computer Sciences, ³Lecturer, Graduate School of Business, Universiti Sains Malaysia, 11800 USM, Pulau Pinang, Malaysia

Abstract

Toxicovigilance is the active process to detect, validate and follow up with poisoning occurrence within the community. The collection of data on poisoning occurrences over the years has been compiled into a poison information database that is accessible by users initially through a computer software and later as a web application. With mobile technology evolving rapidly, mobile apps have transformed and benefitted users in many areas including toxicology. This study conducted a review of existing mobile apps in the marketplace to find out available mobile apps for toxicovigilance and to evaluate its features and functionality to gain insight into the current trends in that area. Secondly, the objective of this study is to find out whether those apps are embedded with learning functionalities for health care professionals and examine its learning features. This study adopts a systematic searching method for apps selection in the marketplace through pre-determined keywords. A total of 22 apps were selected with a majority from the reference and information gathering category. The learning features in the apps focus on self-assessment and examination. The findings show that there are limited number of mobile apps for toxicovigilance and more features can be introduced such as patient monitoring and management or learning features for continuous learning, in addition to the assessment and evaluation features.

Key words: mobile applications, toxicovigilance, health care professionals.

Introduction

Toxicovigilance is an approach in medical toxicology concerned with the active process of detection, validation and follow-up for toxic exposure within the community (¹). It involves the identification and evaluation of toxic risk in the community and the evaluation of measures taken in eliminating and reducing the risks. This process is done by monitoring the occurrence of poisoning cases and identifying the cause that contributes to the occurrence with the intention to reduce the toxicological risk by analysing the inquiries reported to the poison centre (²) (³).

The poison centre received inquiries mostly from health care professionals (HCPs) and the public about toxic exposure. Experts or toxicologist in the poison centre will help to assess if the exposure is harmful and needs further actions. Especially in cases reported by the health care professionals, the experts will consult and give detailed information on the diagnosis and treatment management. From these inquiries, poison centres are able to create databases and repositories that can provide useful information on poisoning occurrence trends and risks which is a part of the toxicovigilance process.

Over time, the poison centre is able to create their own information databases and information management system from their analysis. The compiled information is organized into more structured information that better facilitates information retrieval and information sharing. For example, TOXBASE is a first generation poison information database developed by the National Poisons Information Service (NPIS) in the UK (⁴). The registered users in TOXBASE can easily access the information on poisoning management or products and substances. This database started as computer software, then moved to a more compatible system that utilized internet
access. This conversion enabled users to get access to information easily at anytime and anywhere.

The use of mobile device and apps is becoming increasingly common in the health-related area. On various devices and operating system platforms, there are various free and paid apps offered to aid and provide easy access to specific users or the public. The databases or information systems that previously can be accessed only through the web or stand-alone devices, can now be acquired through the mobile devices. Specifically, in the case of the HCPs, these databases and information systems give them quick access to information in assisting their jobs and also for their learning and education especially when using the mobile devices (5).

There are many existing mobile apps developed for various health purposes. The apps are typically more general-purpose like for diabetes, pregnancies, or smoking. Other apps are developed for more specific health areas such as emergency medicine, pharmacology or pediatrics. These apps could be used by general users, healthcare providers, students or healthcare professionals (6). Mobile apps benefit HCPs in terms of information management, time management, health record maintenance and access, communications and consulting, reference and information gathering, clinical decision making, patient monitoring and medical education and training (5).

This study aims to review available mobile apps related to toxicovigilance or toxicology and evaluate its features and functionality to gain insight into current trends in that area. Secondly, the objective of this study is to find out whether those apps are embedded with learning functionalities for HCPs and examine the learning features of the apps if it is present. Hence, this study conducted a review of available toxicovigilance mobile apps in the market.

**Methods**

**Systematic Review Design**

This review adapts a systematic search method by Kim (7) as this method is mainly used for studies that focuses on a specific domain and is applicable to this study as the review is focused on the context of toxicology. Two research questions are formulated for this review; (1) What are the available apps in the market that are for toxicovigilance, and (2) What are the features offered by those apps. These research questions set the baseline for designing app searching strategy.

**App Search Strategy**

The search was been conducted in June 2020 in two marketplaces, Google Apps Store for Android and Apple iTunes Store for iOS. Before the search, the researchers developed a set of related and relevant keywords to optimize the search process and identify related apps. The keywords are 1) Toxicovigilance, 2) Poison, 3) Toxicology, 4) Toxic, 5) Drug. Any apps related to toxicology or human poisoning will be included while excluding any games, entertainment, non-toxicology, and animal poisoning apps. The apps that are described in English or which the description could be translated to English are also reviewed. The apps that comply with all the pre-determined criteria will be reviewed. In Google Apps Store, the search was conducted in the Apps category by using the pre-determined keywords. Similar to the Apple iTunes Store, the search was conducted in the search box by using the same set of keywords. The researchers also viewed the recommendation of similar/related apps and reviewing the apps under the medical category that contain any of the keywords.

**App Selection**

The apps that are selected will be reviewed based on the description and screenshot provided. Relevant information such as general information, app description, and features were extracted and compiled into a spreadsheet file for analysis.

**Data Analysis**

The information that was compiled is analysed. The apps will be further classified based on the features and usage. The usage of mobile device and apps could be classified into eight (8) categories (5); 1) information management, 2) time management, 3) health record
maintenance and access, 4) communications and consulting, 5) reference and information gathering, 6) clinical decision-making, 7) patient monitoring, 8) medical education and training.

Following this classification, in order to answer the second research question, the selected apps are classified into five (5) categories that are relevant to our scope and the features for each category in the bracket: Information Management [write notes, dictate notes, record audio, take photographs, organize information and images, use e-book reader, access cloud service], Communication and Consulting [voice calling, video calling, texting, e-mail, multimedia messaging, video conferencing, social networking], Reference and Information Gathering [medical textbooks, medical journals, medical literature, literature search portals, drug reference guides, medical news], Patient Management and Monitoring[monitor patient health, monitor patient location, monitor patient rehabilitation, collect clinical data, monitor heart function], and Medical Education and Training[continuing medical education, knowledge assessment tests, board exam preparation, case studies, e-learning and teaching, surgical simulation, skill assessment tests].

**Results and Discussion**

The first aim for the study is to review the existing mobile apps for toxicovigilance to gain insight on the current trends. There are a lot of applications developed to assist HCPs for their tasks, learning and have become essential tools (8) for them. However, the findings shows that there are still limited number of mobile apps for toxicovigilance compared to the existing number of applications for health. From the review, there are a total of 30 apps that fit the criteria, with 19 apps (67%) on Android and the rest on iOS with 11 apps-37% (Refer Table 1, and Figure 1).

There are 8 apps offered on both platform: 1) 5 minute toxicology consult - poisoned patients (Android)/ 5 Minute Toxicology Consult Rapid Access Guide (IoS), 2) Austin Health Clinical Toxicology Guideline (Android) / Austin Health Toxicology – Clinical Toxicology Guideline (IoS), 3) TOXBASE, 4) Tox Handbook, 5) Poisoning - First Aid for Children (Android) / Poisoning - First Aid First Aid for Children (IoS), 6) Poisoning & Drug Overdose Info, 7) Poisoning and Drug Overdose and 8) Poisoning & Drug Overdose Ref. (Android) / Poisoning & Drug Overdose Quick Reference (IoS). These apps offer the same features and same company/developer on both platforms. In the marketplace, the apps are grouped into certain categories to help users browse existing apps or discover new ones. 18 apps (82%) are labelled in the “Medical” category, while two apps (9%) in the “Education” category and another two (9%) are in the “Book & Reference” category. 17 (77%) of the apps are in English, while 4 apps (18%) are offered in Spanish and 1 app (5%) in French. 18 apps (90%) are available as free, while another 2 (10%) are paid apps. 6 free apps offered in-app purchases. For Poisoning and drug overdose by MobiSystem, it is offered as a free android app with in-app purchases and paid apps in iOS. Poisoning - First Aid for Children by Kigorosa UG, it is free with no in-apps purchase in Android while it is a paid app in iOS.

While reviewing the description, the researchers try to find out whether the apps mention its targeted users (in specific HCPs). 11 apps (50%) mentioned their apps are targeted for HCPs (Refer Figure 2). Other apps either do not state any specific targeted users. It is beneficial to state the targeted users as part of the material or if the features included in the apps are very specific to the purpose of the targeted users.
To learn the features and functionality of the apps, the 22 apps are further classified into 5 categories: Information Management, Communication and Consulting, Reference and Information Gathering, Patient Management and Monitoring, and Medical Education and Training based on their features (Refer Table 2, and Figure 3). 20 apps contain the features that are defined under the category of reference and information gathering, making this category the most popular category for toxicology apps. Most of the applications developed for toxicology purpose are reference books and guide and it is consistent with Aungst (9) who stated that the mobile device has been transformed into a medical tool for clinical reference and decision making. From 20 apps in this category, 7 apps (35%) are considered as medical textbooks.

**Figure 3:** Classification of Mobile Apps by Usage and Features
There are 3 apps that match the features for medical education and training (Refer Table 3). “Official ABT Exam Practice” is a self-study app that provides practice tests in two modes: simulation, and study. Questions are reviewed by subject-matter-experts and the content is aligned with actual exams and provide answer explanations for each question. It provides result analysis and examination history. It allows users to customize study sessions and exam requirements to suit their needs. Users can choose total questions, enable timers, and filter examination content. It also has study reminders and exam day countdowns. However, the feature may be different based on the free version or paid version. The free version has limited features, such as limited number of questions, limited exam builder and only provide examination information. The free version provides only 30 practice questions and explanations while there are more than 400 questions for the paid version. The exam customization is available only in the full paid version in addition to answer explanations, references, progress tracking, support and update. This app can be used without internet connectivity.

These apps are designed with sections and books chapters that replicate the textbook in a mobile form. 13 apps (65%) are drug reference guide that provides guideline or gives recommendation (Refer Table 3). 3 apps have features for medical education and training (refer Table 4). Some of them include a search feature to help users easily find information that they require. Another interesting feature is the barcode scanner which allows users to scan products to retrieve information.

“Poisonology Exam Prep 2017 Edition” is a self-study and examination preparation app by breaking materials into smaller sets. Each set contains flashcards, matching games, true or false, and multiple choice. It can filter questions by detecting and separating the most difficult questions for user. It keeps track of the user learning process for each set and exam. For the free version, users are given access to hundreds of practice questions & terms, 5 free exam builders, a free matching game and the ability to filter the hardest and weakest questions. For the paid version, users have unlimited access to the exam builder and simulator, including all practice questions & terms prepared by experts for the most current exam. Questions are automatically filtered based on users and progress is tracked for each question and exam. It also encompasses support and update.

“Poisoning and drug overdose” helps users in learning by introducing and expanding vocabulary through a “Word of the day” features. The description of the apps that include learning feature show that it specifically focuses on the self-assessment and exam. It can be a tool for exam preparation and evaluating current skills. Beside the assessment and evaluation, continuous learning is also necessary for HCPs to ensure highly skilled staff and ensure their knowledge is maintained and improved, though there might be difficulties or limitation for the HCPs to attend lectures. Continuous learning using e-learning that includes interactive content could enhance the learning experience of HCPs.

2 apps namely “Poisoning and drug overdose” and “5 Minute Toxicology Consult” in the category of information management have features like writing and dictating notes, audio recording and information and image organization. As for now, the apps include
features for information organization like note taking, creating bookmarks or set favourites to the learning material. For taking notes, the users can input text or use voice. Annotation in the form of a scribble, doodle or text are also the features that could be discovered. These features are useful for reading and revision.

It is notable that none of the selected apps offer features for communication and consulting or patient management and monitoring toxicology. The patient management and monitoring apps are quite common in other health areas. Patient management and monitoring include features such as monitoring patient health, location, rehabilitation or collecting clinical data. Toxicology is an multi-disciplinary area and the study of poison (11), while toxicovigilance is an approach in managing poisoning occurrence. The important step in managing poisoning occurrences is to record and monitor the poisoning cases that happened. Collecting poisoning case details is important in determining the case risk and treatment. These databases are very useful for the reference and guidance or learning material as there are always new products or new toxic from time to time.

Implications and Future Work

Toxicology as any other health area, is a very specific domain. It is a challenge to develop an application that could fit the specific needs of the related HCPs. As shown in the review, in terms of education or training, the available apps are more focused on preparation for exam boards. Although there are many textbooks and drug references available, however it is an opportunity to explore expanding learning features like e-learning and teaching. Simulation or case studies could be offered to promote ongoing, continuous learning for HCPs with the flexibility of using mobile phone. This is where e-learning and mobile apps can be used as the medium to utilize learning delivery or so-called m-learning (12). Developing any type of apps is possible, but the bigger question is to come out with appropriate apps. There is a need to study their requirements in terms of content development and presentation, learning style or features requirement. As emphasized by Lazzara (6), HCPs should be involved in the development process to ensure the correctness and the reliability of the mobile apps as errors in the apps could contribute to the ineffectiveness of the apps and create risks to users.

It is also interesting to explore patient monitoring for poisoning cases. There are many user self-monitoring apps or patient monitoring apps in other health areas. Having this feature in mobile applications will improve accessibility of HCPs to manage and monitor their poisoning cases in the future.

Conclusion

As a conclusion, this paper reviewed 22 toxicology mobile apps in the categories of information management, reference and information gathering, and medical and training. It shows that there is a lack of mobile apps developed for HCPs in this area. As the review has shown, there are many studies that could be conducted for the development of mobile apps that is appropriate for HCPs in area of toxicovigilance especially for HCPs.

Stimulation of Male Voice during Pregnancy Results in Higher Expression of Brain Derived Neurotrophic Factor in Cerebellum of Newborn Rattus norvegicus

Nurvy Alief Aidillah¹, Hermanto Tri Joewono², Widjiati³

¹Final year Master of Reproductive Health Science, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia ²Lecture, Department of Obstetrics and Gynecology, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia ³Professor, Department of Veterinary Science, Faculty of Veterinary Medicine, Universitas Airlangga, Surabaya, Indonesia

Abstract

Background: Recent studies in the field of Fertomaternal Medicine show that stimulation in the uterus can support brain growth and development. If in previous studies stimulation using several types of music, this study uses human voice which aims to analyze the effect of stimulation of male and female voices on differences in the expression of Brain Derived Neurotrophic Factor (BDNF) in cerebellum of newborn Rattus norvegicus. Methods: This type of research is true experimental with post test only control group design. Rattus norvegicus was given stimulation of men voice and women voice on 6th day until 17th day of pregnancy. The expression of BDNF was examined using immunohistochemistry. Results: The mean ± standard deviation of the expression of BDNF in the cerebellum is 4.20 ± 1.75 (without stimulation), 6.04 ± 1.58 (male voice stimulation), and 5.60 ± 2.43 (female voice stimulation). The results of statistical tests show that there is a significant difference on BDNF expression between the control group and the group stimulated with male voice with a significance value <0.05 of 0.045 Conclusion: Giving stimulation using the male voice during pregnancy shows a significant increase in the expression of BDNF in cerebellum of newborn Rattus norvegicus.

Key words: Stimulation, Pregnancy, Male and female voice, Rattus norvegicus, Cerebellum, BDNF

Introduction

One way to measure the progress of a country, is not only dependent on indicators of economic growth. The Human Development Index (HDI) measures the progress of a country based on its human development dimensions; healthy and long-lived humans, knowledge, and a high standard of living. In 2019, Indonesia was ranked 111. Even though UNDP has classified Indonesia as a country with high HDI, this condition still deserves our attention, because we are still left behind with several developing countries such as the Philippines (106), Thailand (77), and Malaysia (61). Some of these countries outperformed Indonesia in their education indicators so that their human development index scores were better than Indonesia according to UNDP (1).

The high index of education is influenced by the quality of a country’s generation. Several recent findings in the field of fetomaternal medicine state that to obtain a smarter generation, one of which is by enriching the environment during the gestation, especially the development of the fetal brain. Giving stimulation can support brain growth and development by stimulating the formation of synapses or connections between nerve cells and also inhibiting apoptosis or cell death. Apoptosis peaks at around 36-40 weeks of gestation, therefore it is highly recommended to provide optimal and routine stimulation during pregnancy (2–4).
Cerebellum is the second largest part of the brain after the cerebellum; several findings show the cerebellum has a more complex function. Most of the cerebellum is connected with brain association areas related to intelligence, social cognition, and emotional control (5). Brain Derived Neurotrophic Factor (BDNF) is the main neuronal growth factor in the brain that regulates neurogenesis, neuron maturation, survival, and synaptic processes. Although neurogenesis in the hippocampus occurs until adulthood, most neurogenesis occurs in the prenatal and early postnatal periods. The main factor of Neurotrophin that plays a very important role in the learning process, memory, and behavior in the hippocampus is BDNF (6).

A frequency of about 8,000 Hz is very useful for filling (charging) cells in the brain. Music that is rich in high frequencies and has a high rhythm that is similar to the rhythm of the fetal heartbeat and can be linked to simulation and energizing functions (7). In the sound production system in humans, the lungs produce air pressure which then passes through the windpipe (trachea). The pressure then vibrates the vocal cord that is located above the windpipe. The vibration of the vocal cord (opening and closing) produces sound which is then pronounced by mouth. The voice characteristics of each person are different because they are influenced by variations in the shape, length, and thickness of the vocal cord. Therefore, the sounds that sounded are significantly different in each person. The length of the vocal cord for a human is usually between 12 and 24 millimeters (mm), while the thickness is 3 to 5 mm (8).

In music theory, humans have different types of voices, both male and female. The types of voices in male are divided into tenor, baritone, and bass. Meanwhile, female voices are divided into soprano, mezzo-osopran, and alto (9). The results of the study using the Backpropagation Neural Network as a system for identifying the types of human voices show that the algorithm used is very weak to detect the type of alto voice and tend to be good for detecting the type of tenor voice (10).

In recent years, there have been several issues regarding the brain development of infants that are given stimulation during pregnancy, such as a significant increase in the number of cerebral neuron cells of Rattus norvegicus after stimulation of Mozart music (11); Similar studies on BDNF expression obtain a significant increase in BDNF expression with stimulation of Mozart’s music (12). The study uses two different types of human voice characters, namely male voice and female voice as stimulation during pregnancy in experimental animal, Rattus norvegicus, which aims to determine the effect of Ar-Rahman murottal stimulation on the expression of BDNF in cerebellum of newborn Rattus norvegicus.

Materials and Methods

This type of research is the experimental laboratory (true experimental) with a post-test only control group research design. Ethical eligibility was obtained from Research Ethics Committee of the Faculty of Veterinary Medicine, Airlangga University. The research was conducted at the Animal Experiment Cage and Pathology Laboratory of the Faculty of Veterinary Medicine, Airlangga University, Surabaya, from January to March 2021. The research subjects used were 30 pregnant Rattus norvegicus mothers who were divided randomly into 3 groups, namely the non-stimulated group (P1), the group stimulated with Surah Ar-Rahman by male voice (P2), and the group stimulated with Surah Ar-Rahman by female voice (P3). Stimulation was started from 6th until 17th days of pregnancy in a soundproof box with a sound intensity of 65 dB for 60 minutes at night. Inclusion criteria: Rattus norvegicus mothers who had never been used for previous studies, healthy, body weight of 120-160 g, and give birth 5-9 pups, newborn Rattus norvegicus born surgically in healthy condition. Meanwhile, the criteria for drop out were Rattus norvegicus which was stillborn and had anatomical abnormalities.

Two newborn Rattus norvegicus were selected from each mother with the heaviest and lightest weights. Then sacrificed, the head was weighed and preserved in 10% formalin solution which was then prepared for examination
of BDNF expression by immunohistochemical methods. Antibodies used were primary antibody, anti-BDNF and DAB (3,3-diaminobenzidine tetrahydrochloride). BDNF expression of each subject was assessed according to the modified Remmele method (13), where the Remmele scale index (Immuno Reactive Score / IRS) is the result of the multiplication of the percentage score of immunoreactive cells and the color intensity score of the immunoreactive cells. Data of each subject represented the mean IRS value observed at 5x the field of view (LP) at 400x magnification. The data obtained were then statistically tested using the data normality test with the Shapiro-Wilk test. The data that normally distributed were analyzed using one way ANOVA followed by the Least Significant Difference (LSD) test among the three groups.

Results and Discussions

The results of the normality test using the Shapiro-Wilk test on body weight after treatment are obtained a significance value (p-value) in the control group of 0.712, the group stimulated by male voice of 0.971, and the group stimulated by female voice of 0.958. These results indicate the distribution of parent body weight data in each group is normally distributed. The results of the homogeneity test of variety using the Levene test on data on body weight after treatment are obtained a significance value of 0.237. These results indicate that the variance among the three groups is homogeneous. The results of the normality test using the Shapiro-Wilk test on the treatment group are obtained a significance value (p-value) of fetal head weight in the control group is 0.083, the group stimulated by male voice is 0.243, and the group stimulated by female voice is 0.124. These results indicate that the distribution of data on fetal head weight data in each group is normally distributed. It can be seen in Table 1.

</tbody>
</table>
The results of the homogeneity test of variance using the Levene test on BDNF expression data in the cerebellum are obtained a significance value of 0.060. These results indicate that the variance among the three groups is homogeneous. Based on the results of the normality test and the homogeneity test of variance, the data analysis to test whether there are differences in the treatment groups on BDNF expression in the cerebellum used the Analysis of Variance (ANOVA) test with the advanced Least Significant Difference (LSD) test.

<td>0.121</td>
</tr>
<tr>
<td>Male Voice</td>
<td></td>
<td>0.619</td>
</tr>
</tbody>
</table>

The results of LSD test show a significant difference in BDNF expression in the cerebellum of newborn Rattus norvegicus between the group stimulated by male voice and the non-stimulated group (Control). Meanwhile, the control group compared to the group stimulated by female voice shows a less significant difference, it means that there is less significant difference in BDNF expression in the cerebellum of newborn Rattus norvegicus. In the next group, the group stimulated by male voice compared to the group stimulated by female voice, the result is less significant. Although the result in the group stimulated by male voice is higher than the group stimulated by female voice, the difference is less significant or insignificant. Among the three groups, it is known that the group stimulated by male voice is obtained the highest expression results in BDNF expression in the cerebellum of newborn Rattus norvegicus.

Gender affects the size of the vocal cords. The length of the female vocal cords is approximately 12.5 mm to 17.5 mm, whereas in male voice it is from 17.5 mm to 24 mm (14). Because the vocal cords are longer, the pitch of the male voice is lower, therefore the male voice sounds heavier than the female voice. Heavy voices contain more sound intensity. Based on research on the voice identification system using Backpropagation Artificial Neural Network (ANN), the results of the voice identification system tend to be better at detecting the type of tenor voice compared to the type of alto voice, in which the tenor voice is one of male voice types, whereas alto voice is one of female voice types (9). Research with similar results proposing a new feature for automatic gender detection using modified voice contour (MVC), found that the area under the MVC for male speakers is greater than for female speakers (15). This is because male speakers have a higher intensity than female speakers.

Automatic gender detection applications have actually been widely used in the health world, for example in the health care monitoring system (16,17); and the detection of abnormalities in the vocal cords (18,19). Various researches on automatic gender detection (AGD) applications that have been developed have proven that male voices are easier to identify. Therefore, this study proves the theory that male voice is known to have a higher effect as a form of stimulation performed on experimental animal during pregnancy.
The red arrows in Figure 2 show the BDNF expression in the cerebellum which is indicated by the presence of a brown chromogen on the immunohistochemical examination which is observed at 5x the visual field (LP) at 400x magnification.

Figure 2 Comparison of BDNF expressions in the brain of the control group (P1), the group stimulated by male voice (P2), and the group stimulated by female voice (P3).

Conclusion

The stimulation of male voice during pregnancy has a significant effect on increasing the expression of BDNF in cerebellum of newborn Rattus norvegicus because the highest BDNF expression is shown in the group stimulated by male voice. Similar research in other parts of the brain needs to be more developed because this research is the first experiment of giving stimulation using the type of human voice in experimental animal.

Effect of Thunbergia Laurifolia Lindl. on Oxidative Stress and Blood Cholinesterase in farm Workers Exposed to Pesticides in the Mae Chai District of Phayao Province

Orapin Insuan, Padchanee Sangthong, Pennipat Nabheerong, Surachat Buddhisae, Peerawan Kengsangunsi, Suntorn Prompao, Benchaluk Thongchuai

Abstract

Thunbergia laurifolia Lindl. or Rang Chuet is a plant traditionally used in Thailand for the treatment of toxicity and as an antidote for many poisons. This study aimed to investigate the effect of Rang Chuet capsules on blood chemistry in 39 agricultural workers (21 males, 18 females) during an intensive 8-week spraying program. The following tests were performed: serum butyrylcholinesterase (BChE) and serum malondialdehyde (MDA) levels before and after Rang Chuet capsule supplementation. The results indicate that serum BChE levels were unchanged in male and female workers. However, the levels of serum MDA in male and female workers decreased significantly at p < 0.001 and p < 0.05, respectively. In this study, the phylogenetic relationships within the large tropical and subtropical family Thunbergia were studied using genomic DNA from the fresh leaves of sampled plants. The results showed 99% homology with Thunbergia coccinea. This study indicates that Rang Chuet presents antioxidant activity and could be promoted as a health supplement.

Key words: Rang Chuet, butyrylcholinesterase, malondialdehyde

Introduction

In recent years, many insecticide chemicals have been widely used to increase agricultural production in Thailand. However, many agricultural workers do not understand the correct way to use insecticides; as such, these pesticide chemicals may be deposited in the environment, resulting in health and environmental problems. Cantaloupe, watermelon and lychee are the most common fruits that are widely planted, especially in the north of Thailand. In this study, survey data showed that the farm workers in the Mae Chai District of Phayao Province use many pesticides to control agricultural pests on their farms.
Organophosphate (OP) and carbamate (CB) pesticides are the main pesticides sprayed over this agriculture area. The contamination of pesticide residue may remain on soil particles, water or in food after farm workers have applied it to crops. Many of these chemical residues accumulate in tissues and could build up with harmful effects on the body. Toxic effects are observed with acute and chronic toxicity. OP and CB pesticides are acetylcholinesterase (AChE) inhibitors. During the metabolism of both pesticides, they are converted to an oxon intermediate through an oxidative desulphurization reaction mediated by cytochrome P450 in the liver. The oxon intermediate is a reactive metabolite that binds tightly to the hydroxyl group of the serine residue present in the esteratic region of the cholinesterase active site, located on the post-synaptic membrane. Inhibition of AChE results in the accumulation of acetylcholine, the neurotransmitter acting at cholinergic synapses and neuromuscular junctions in the central and peripheral nervous systems. Some studies have revealed that oxidative stress could be an important component of the mechanism of OP and CB pesticide poisoning. Pesticide exposure over a long period could change molecules and damage DNA, resulting in gene mutation or cancer [1,2]. In addition, some studies have revealed that oxidative stress and lipid peroxidation also occur, leading to DNA single strand breaks caused by reactive oxygen species; this induces apoptosis [3].

*Thunbergia laurifolia* Lindl. (laurel clock or blue trumpet vine) is interesting to study with regard to oxidative stress induced by insecticide exposure. The leaves of this plant have been used in traditional herbal medicine for the treatment of symptoms such as fever and rash [4]. In addition, the reported therapeutic properties include antioxidant, antimicrobial, antiproliferative, hepatoprotective and anti-inflammatory activities, as well as detoxifying properties [5]. The antioxidative properties of *Thunbergia laurifolia* Lindl. and its active compounds have been reported using in vitro and in vivo test systems. Kosai et al., 2015 reported that *Thunbergia laurifolia* Lindl. has anti-inflammatory and antioxidant activity and could repair hepatocellular cells [7]. Moreover, Chan et al., 2011 found the *Thunbergia laurifolia* Lindl. showed excellent antioxidant capacity and reduced hepatocellular damage [8]. *Thunbergia laurifolia* Lindl. contains many active ingredients such as delphinidin-3, apigenin, apigenin-7-O-β-D glucopyranoside, rosmarinic acid, iridoid glucosides, alkaloid, flavonoids, phenolic acid and chlorogenic acid, which also have excellent antioxidant effects [9]. Many reports have revealed that *Thunbergia laurifolia* Lindl. reduces pesticide toxicity in rats. The aim of this study was to evaluate the effect of *Thunbergia laurifolia* Lindl. on cholinesterase activity and its antioxidant activity on pesticide intoxication.

### Materials and Methods

#### Participants

This study was conducted on farm workers in the Mae Chai District of Phayao Province in the north of Thailand during the period from December 2017 to April 2018. The study included the rural population of 39 cantaloupe farm workers (21 males, 18 females). Farmworkers had to be 20-70 years old.

#### Data collection

Participants were interviewed by the research staff using a questionnaire. The information collected included personal formation, occupational history and behaviours at work and at home.

#### Administration of Rang Chuet

Rang Chuet capsules were purchased from Ouay Un Osoth Co., Ltd. The participants were treated with Rang Chuet capsules (two 250 mg capsules), before meals three times per day. They were treated with Rang Chuet capsules for 60 days.

#### Sample collection

After overnight fasting, 3 mL of whole blood with EDTA and 7 mL of clotted blood were collected. Serum was separated for malondialdehyde (MDA) assessments. Clotted blood samples were centrifuged for 15 minutes.
at 3,000 rpm at room temperature, then the serum was separated and stored at -20°C until analysis.

**Determination of butyrylcholinesterase in serum**

Butyrylcholinesterase (BChE) was measured in serum following a modified method described by Ellman et al., 1961 [10]. First, 3,000 µL of 5, 5-dithiobisnitrobenzoic acid solution was used for setting zero, then 20 µL of diluted sample was added and mixed gently. After that, 5% butyryl thiocholine iodide (50 µL) was added and mixed. The absorbance of the solution was measured at 405 nm. BChE was calculated and reported in U/L.

**Thiobarbituric acid reactive substances (TBARS) assay**

Lipid peroxidation levels in serum were measured following a modification of the methodology described by Santos et al., 1980 [11]. The sample (80 µL) was mixed with 0.2% BHT in in 240 µL 0.44 M methanol, then H₃PO₄ and 160 µL 0.6% TBA were added. After heating for 30 minutes at 95-100°C and cooling, the absorbance of the solution was measured at 540 nm.

**Plant molecular evaluation using the NucleoSpin® Plant II kit**

Genomic DNA of fresh leaves of Rang Chuet and the powder of Rang Chuet capsules were extracted using the NucleoSpin® Plant II kit and the extracted DNA was used as the DNA template for PCR amplification. The PCR products were amplified using designed primers. These primers were universal primers complementary to the chloroplast DNA of *Thunbergia laurifolia* Lindl. The PCR products were visualised by agarose gel electrophoresis containing 3 µL ethidium bromide in 1% (w/v) under a UV transilluminator. The PCR products were purified using a NucleoSpin Gel and PCR clean-up kit before sequencing. Finally, the sequences were aligned using the database in GenBank® (http://www.ncbi.nlm.nih.gov/genbank/).

**Statistical Analysis**

Graph Prism Version 8 was used to assess the levels of cholinesterase and MDA in farm worker sera.

**Results**

**Butyrylcholinesterase levels in serum**

The blood BChE levels were slightly decreased in female farmworkers and considerably increased in male farmworkers (Figure 1). The BChE levels before Rang Chuet treatment were 5,012 ± 1,364.0 U/L and 5,299 ± 1,381.0 U/L in female and male sprayers, respectively. The BChE levels after Rang Chuet treatment were 4,605 ± 668.8 U/L and 5,490 ± 1,395.0 U/L in female and male sprayers, respectively. The results demonstrate that BChE activity was not significantly impacted in sprayers.

**Malondialdehyde levels in serum**

The MDA levels after Rang Chuet treatment were significantly lower in both male and female farmworkers at p < 0.001 and p < 0.05, respectively. The MDA levels before Rang Chuet treatment were 5.69 ± 2.81 mM and 8.80 ± 3.61 mM in female and male sprayers, respectively. The MDA levels after Rang Chuet treatment were 5.13 ± 2.14 mM and 6.58 ± 2.24 mM in female and male sprayers, respectively (Figure 2).
Figure 2: Malondialdehyde levels before and after Rang Chuet treatment in male and female farmworkers (*p<0.05, **p<0.01, ***p<0.001).

Plant molecular identification

The purified PCR products from fresh leaves Rang Chuet and the powder of Rang Chuet capsules were analysed (Figure 3) and the nucleotide sequences of the trnL-trnL intergenic spacer and trnL-trnF intergenic spacer were determined using the dye terminator technique (First BASE Laboratories Sdn Bhd, Malaysia). The nucleotide sequences were analysed by a biological sequence alignment editor program (BioEdit). The results illustrate that the sequence analysis of the trnL-trnF intergenic spacer from fresh leaves Rang Chuet and the powder of Rang Chuet capsules compared with the reference data in the NCBI database showed 99%, 99%, 99% and 98% homology with *Thunbergia coccinea* (GenBank® accession number KT075030.1), *Thunbergia grandiflora* (GenBank® accession number KT075034.1), *Thunbergia laurifolia* (GenBank® accession number KT075036.1) and *Thunbergia erecta* (GenBank® accession number KT075032.1).
Discussion

In this study, the objective was to investigate the effect of *Thunbergia laurifolia* Lindl., commonly known as Rang Chuet in Thailand. It has several therapeutic effects, especially as an antidote for many xenobiotic poisons. OP and CM insecticides are well-known to have toxic effects by inhibiting cholinesterase activity in plasma, red blood cells and brain tissue. This study demonstrated that OP and CM insecticides result in a significant increase in MDA formation, which may be associated with the chemical structure of organophosphate pesticides [12].

In addition, OP insecticides, as inhibitors of AChE and BChE, induce the production of ROS and oxidative tissue damage [13]. In this study, the activity of AChE and BChE were not significantly increase. Tayeh et al., 2018 illustrated that Rang Chuet has antioxidant activity and neuroprotective activity in animals exposure to OP insecticides [14]. The data from this study show unchanged cholinesterase enzyme levels after treatment with Rang Chuet. However, the levels of cholinesterase were in the normal range in all participants, possibly due to uncontrolled factors such as subject performance when spraying, personal hygiene and frequency of spraying by each farm worker. In this study, treatment with Rang Chuet did not affect cholinesterase levels. OP pesticide exposure causes oxidative stress resulting in MDA generation, as well as decreased glutathione levels [15,16]. There is also a significant decrease in catalase...
and superoxide dismutase\textsuperscript{[17]}. People who are exposed to insecticides show evidence of DNA damage via lipid peroxidation reactions and significantly increased MDA levels\textsuperscript{[18]}. In this study, the blood MDA levels in male and female participants were significantly decreased after Rang Chuet treatment. \textit{T. laurifolia} leaves contain phenolic compounds, caffeic acid, apigenin and flavonoids, which are rich in antioxidant activity\textsuperscript{[6]}. Interestingly, blood MDA levels in farmers using chemical pesticides have been found to be significantly increased when compared with farmers using organic pesticides\textsuperscript{[19]}. Our research team suggests initiating a campaign to reduce the use of chemical pesticides or provide information for individualised health intervention, in order to reduce health effects in farmers.

The results of plant identification from the fresh leaves of Rang Chuet in the local area and the powder of Rang Chuet capsules using the NucleoSpin® Plant II kit found that the nucleotide sequences on the \textit{trnL-trnF} intergenic spacer regions showed 99\% homology with \textit{Thunbergia coccinea} (GenBank® accession number KT075030.1) and \textit{Thunbergia grandiflora} (GenBank® accession number KT075034.1). In addition, Wongakson et al., 2015 elevated the phytogenic relationships within the \textit{Thunbergia spp.} using sequences from the chloroplast \textit{psbA-trnH}, \textit{trnL-trnF} intergenic spacers and second nuclear internal transcribed spacer (ITS2)\textsuperscript{[20]}. Therefore, the utilisation of fresh leaves of \textit{T. laurifolia} yield a comparable result as a capsule supplementation processed from the plant.

In conclusion, Rang Chuet supplements significantly reduce blood MDA levels and did not affect the daily life of participants. Prospective studies are needed on a larger sample of farm workers to improve the statistical power and measure more biomarkers in the antioxidant system.

Dental Panoramic Radiographs as Early Signs of Osteoporosis in Pre and Post Menopausal Women – An Observational Study

P.E. Chandra Mouli1, Madhavan Prasad2, T. Gopalakrishnan3

1Professor and Head, Department of Oral Medicine and Radiology, 2Reader and Incharge, Department of Pedodontics, 3Reader, Department of Oral Pathology And Microbiology, Sri Venkateswara Dental College and Hospital, Thalambur, Chennai. Tamil Nadu

Abstract

Osteoporosis is defined as “a skeletal disorder characterized by low bone mass and micro architectural deterioration of bone tissue leading to enhanced bone fragility, with consequent increase in fracture risk”. An osteoporotic fracture is an outcome of trauma to bone of compromised strength, commonly first occurring in the vertebral bodies and distal radius, both sites composed predominantly of medullary (trabecular) bone.

Osteoporosis is an extremely common disease affecting most women during their lifetime. Osteoporosis reduces bone density, affecting the bone mass and strength without altering the basic chemical composition. Declining estrogen levels during and after menopause lead to increase bone resorption and increased urinary excretion of calcium. Thus, estrogen deficiency plays a primary role in osteoporosis, accounting for up to one half of the bone lost during a women’s lifetime.

Oral signs of osteoporosis might be manifested by excessive alveolar ridge resorption, tooth loss, chronic destructive periodontal disease, referred maxillary sinus pain, or fracture.

Radiographic evaluation of post-menopausal women and patients with advanced renal failure demonstrated the loss of cortical bone at the mandible.

The purpose of the study is to evaluate relationship between various oral signs the probability of this relationship excising in certain patients and to access cortical bone thickness measurements using panoramic radiographs.

Keywords Osteoporosis · Panoramic radiography · Bone density · Fragility fracture · Mandible

Introduction

In human beings, the loss of bone mass with increasing age is a universally observed phenomenon. Human bones decrease in density and increase in porosity beginning at about third decade of life. Osteoporosis is a term used to describe a significant age-related deficiency in the bone mass with a potential or structural failure.

Osteoporosis is defined as “a deficiency of bone tissue, per unit volume of bone”1. Osteoporosis is a generalized disease in bone mass, is a public health problem of middle aged and elderly women2. Although it may effect as a result as many different metabolic bone disorders, the disease dramatically accelerates after the age of menopause and in women whose ovaries have been removed. Therefore, evaluation or dental radiographs for osseous changes might be useful measures to screen for osteoporosis. Osteoporosis reduces bone density, affecting the bone mass and strength without altering the basic chemical composition. Declining estrogen levels during and after menopause lead to increase bone resorption and increased urinary excretion of calcium.

Thus, estrogen deficiency plays a primary role in osteoporosis, accounting for up to one half of the bone lost during a women’s lifetime.

Oral signs of osteoporosis might be manifested by excessive alveolar ridge resorption, tooth loss, chronic destructive periodontal disease, referred maxillary sinus pain, or fracture.

Postmenopausal osteoporosis is usually evaluated in the region of the lumbar and thoracic spine. Thoracic spine fractures are reported to comprise 50% to 70% of all spinal fractures. Thoracic spine fracture can be related to certain oral signs; the possibility of latent osteoporosis might prompt dental practitioners to refer these for medical evaluation. The fracture risk assessment tool FRAX was developed by the World Health Organization (WHO) to evaluate fracture risk in men and women.

Radiographic evaluation of post-menopausal women and patients with advanced renal failure demonstrated the loss of cortical bone at the mandible. The purpose of the study is to evaluate relationship between various oral signs and to access cortical bone thickness measurements using panoramic radiographs.

Skeletal mass in old age is proportional to the skeletal mass at maturity, indicating that infant and childhood calcium intake may play an important role in the occurrence and severity of the disease in later years. Measurement of the mandibular inferior cortical width is made bilaterally on panoramic radiographs at a site below the mental foramen.

Dentists may be able to refer postmenopausal women with suspected spinal osteoporosis for bone densitometry on the basis of dental panoramic radiographs with diagnostic performance similar to that of osteoporosis screening tools based on questionnaires.

Aims and Objectives

Assessment of osteoporosis in mandible in pre and postmenopausal women with history of estrogen use, hysterectomy, oophorectomy and without history of estrogenic use, hysterectomy, oophorectomy.

Materials and Methods

This is a cross sectional hospital-based study conducted in the outpatient Department of Oral Medicine and Radiology, which was designed to assess Osteoporosis in mandible in pre and postmenopausal women with history of estrogen use, hysterectomy, oophorectomy and without history of estrogen use, hysterectomy, oophorectomy.

Includes premenopausal and postmenopausal women patients reporting to Dental Hospital, seeking dental treatment. The study consists of 105 patients and is divided into 3 groups. Group A consists of 35 post-menopausal women with history of hysterectomy, oophorectomy and estrogen use. Group B consists of 35 post-menopausal women without history of hysterectomy, oophorectomy and estrogen use. Group C is the control group and consists of 35 pre-menopausal women.

Measurement of Mandibular Cortical Width:

Measurement of mandibular cortical width was made bilaterally on the radiographs at the site of the mental foramen according to the study (Fig.1). We drew a line parallel to the long axis of the mandible and tangential to the inferior border of the mandible and constructed a line perpendicular to this tangent intersecting the inferior border of mental foramen, along which the mandibular cortical width was measured with a calliper. The mean cortical width on both sides of the mandible was used in this study.

Usefulness of the MCW in screening for osteoporosis

In osteoporotic patients, bone resorption occurs chiefly in the Haversian and Volkmann canals, which are the nutrient canals of the cortical bone. The cortical bone becomes thinner when adjacent canals finally conglutinate. This phenomenon is clearly detected in the mandibular inferior cortex on panoramic radiographs. The mandibular angle and the area below the mental foramen are reported to be useful sites for measuring...
the inferior cortical width of the mandible. However, the MCW is considered to be a simpler and more useful indicator given the magnification of panoramic radiographs, the reproducibility of the measurement, and the attachment of the masseter and medial pterygoid muscles which may influence the results.\(^7\)

A detailed history of the patient and thorough clinical examination was done and findings recorded in the enclosed proforma. Selected patients’ blood was estimated for Serum Calcium, Serum Phosphorus and Serum Alkaline Phosphatase. Chi square test, P value, and ANOVA analysis were made for the statistical purpose.

**Results**

105 female subjects were included in the study. **Group A** consists of 35 post-menopausal women with history of hysterectomy, oopherectomy and estrogen use. **Group B** consists of 35 post-menopausal women without history of hysterectomy, oopherectomy and estrogen use. **Group C** is the control group and consists of 35 pre-menopausal women. (TABLE 2, TABLE 3, GRAPH 1 AND GRAPH 2)

\[ \chi^2 = 79.09 \quad p \text{ value} = 0.001 \quad F = 75.7 \]
Discussion

The number of teeth missing increases as age increases in both Group A and Group B and there was no significant change in Group C.

Shape of cortex shows significance in both Group A and Group B, cortex was severely eroded between 51-60 years in Group A and between 61-70 years in Group B.

Cortical width was reduced below the normal(3mm) in Group A; but not in Group B although p value was significant in both groups. This is due to inadequate number of subjects in Group B and unavailability of subjects between 71-80 and above 80 years.

The number of teeth missing, Shape of cortex, Cortical width are useful parameters for assessment of osteoporosis. This coincides with the previous studies by Harry V. Daniel⁸

Cortical erosion is severe with subjects who are underweight in group A.

The number of missing teeth was significant in group A and not significant in group B.

Cortical shape showed 63% erosion in group B and only 50% in group A. This may be due to unavailability of subjects in group A.

Cortical width was significant in group A and not significant in group B. This is due to unavailability of patients in group B who are underweight.

Serum calcium, phosphorus and alkaline phosphatase levels were on the lower side of normal limits and were not useful in our study. This may be due to limited sample size and laboratory standards. John L. Stock et al have also proved this in his study⁹.

In our study, The bone density and the mineral levels are normal for pre menopause women and for post menopause women both the serum mineral levels and the bone density was less than the normal, because of which the general dental health of the post menopause women will not be good¹⁰,¹¹,¹²,¹³.

Cortical width was clearly significant in group A and is not significant in group B. This may be due to unavailability of subjects with time since menopause between 21-30 years in group B¹⁴,¹⁵,¹⁶.

Administrative Factors and Organization Climate Affecting the Performance of Health Personnel at the Emergency Department in Community Hospital

Padcharin Phomdonko¹, Prachak Bouphan², Nuttapol Yotha³, Surachai Phimha⁴

¹Master of Public Health Student in Public Health Administration, Faculty of Public Health, KhonKaen University, Thailand, ²Associate Professor in Department of Public Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, KhonKaen University, Thailand, ³Muang Phon Sub-District Health Promoting Hospitals, KhonKaen Province, Thailand, ⁴Lecturer of Department of Public Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, Khon Kaen University, Thailand

Abstract

This is a cross-sectional analytical study aimed to identify administrative factors and organizational climate affecting the performance of health personnel at the emergency department in community hospital Roi-Et province, Thailand. The study samples selected randomly from Emergency Department were 137 health personnel. Stratified random sampling technique was applied to recruit the respondents from the total of 229 health personnel. Similarly, 12 key informants were selected for the qualitative study. In-Depth interview guidelines was applied to conduct qualitative study. The content validity of the questionnaire was evaluated by three experts yielding an IOC value more than 0.50 in all questions. The Cronbach’s alpha coefficient of the questionnaire was 0.98. Data were collected between 23rd December 2020 to 12th January 2021. Data analysis was performed by descriptive statistics and inferential statistics at a significant level at 0.05.

The study results showed that the administrative factors such as money, organizational climate such as dimension of warmth, a dimension of responsibility and dimension of identity were affecting the performance of health personnel (49.6 % (R²=0.496, p-value<0.001). In conclusion, four factors are affecting the performance of health personnel. Hence those factors should be addressed, and administration should create the climate which can address the budget, working objective and goal for the development of the organization.

Keywords: Administrative factors, Organization Climate, Performance of Health Personnel, Emergency room

Introduction

The standard nursing service is provided to the accident-related victims and patients in emergency who are injured or suffering from critical illnesses whose physical and mental systems are affected. It is assessed by the severity of the illness, the decision to provide the first aid, and use medical equipment and pharmaceutical supplies to improve patients’ lives as well as monitoring the parameters of changes in patients after providing nursing services. Moreover, it can help patients in urgent situations safely, and reduce illnesses from complications. The standard of ambulance and emergency service consists of 8 standards: 1) Nursing Therapeutic in Emergency Medical Service2) Nursing Therapeutic in Emergency Department3) Continuing Care4) Health Promotion5) Protection of health conditions and risk prevention6) Providing information

Lecturer, Department of Public Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, KhonKaen University, Thailand.
E-mail: suraphi@kku.ac.th
and health knowledge7) Protection of patient rights and 8) Nursing Documentation [1]. In order to perform successfully for Health workers in the emergency room, they need to consider many factors to support the jobs; however, one of the most important factors is a management factor which affects the optimal use of resources and provides smooth work and achieve the objectives. It consists of 6 compositions which are 1) Man 2) Money 3) Material 4) Management 5) Time and 6) Technology [2]. Moreover, the atmosphere in the organization is considered to be important to the performance of the health workers in emergency accident organization. It also influences and inspires behavior, and able to perceive the organizational atmosphere both directly and indirectly. It has 9 dimensions which are 1) Structure 2) Responsibility 3) Warmth 4) Support 5) Reward 6) Conflict 7) Standard 8) Identity and 9) Risk [3].

Nowadays, there are 19 community hospitals in Roi Et province, Thailand and there are 229 public health professionals are working under the nursing department working in the accident-emergency room at community hospitals in Roi Et. The Emergency Accident Unit is one of the most high-risk units of the hospital as well as having lots of workload. In the past studies, the Nursing Therapeutic in Emergency Medical Service standard found that some personnel with less than three years of working did not attend the Resuscitation Competency Development Program in order to have the skills and confidence in helping patients and injured patients properly. For the Nursing Therapeutic in Emergency Department still faces some problems with insufficient manpower in some emergency departments and inconsistent with the calculation of workload Full Time Equivalent (FTE) [4-5]. From the mentioned problem, the researcher is interested in the management and atmosphere factor in the organization which affect the public health workers in the emergency accident unit at community hospitals in Roi Ed in order to ensure safety and reduce risk for the personnel. The result of this research will be used as a guideline for planning the development of service quality to reach the needs of the people in order to create confidence and satisfaction in the service sustainably.

**Research Objective**

The aim of the study was to investigate administrative factors and organization climate affecting the performance of health personnel at the emergency department in community hospital Roi-Et province.

**Research Methodology**

This study was an analytical Cross-sectional Study.

**Population and sample size**

The study population was 229 health personnel at the emergency department in community hospital Roi-Et Province [4-5]. Calculating the population size for multiple linear regression analysis to test the hypothesis by using the formula of Cohen [6] as follow

\[
N = \frac{\lambda(1-R_{AB}^2)}{R_{AB}^2-R_{AB}^2} + \frac{w}{\lambda} \\
\text{when} \quad \lambda = \lambda_L \quad \left(1/v_L - 1/v_U\right) \quad (\lambda_L - \lambda_U) \\
\text{Formula} \quad ..........(1)
\]

A total of 137 study respondents were identified.

**Sampling method**

Stratified random sampling method was used by dividing the population into groups of 19 community hospitals and comparing the sample sizes to the population of registered nurses and Advanced Emergency Medical Technician who were providing the service at
the emergency department in community hospital Roi-Et Province. Finally, a total of 137 respondents were recruited.

**In-depth Interview random sampling**

A group of people who provided information in an in-depth interview to verify quantitative data were chosen from health personnel at the emergency department in community hospital Roi-Et Province. 12 Key Informants were selected.

**The research tools**

Two types of data collection tools were used:

**Set one** was a questionnaire that consists of 5 parts:  **Part one** was the question of personal characteristics consisting seven questions.  **Part two** was the question of administrative factors which consists of 30 questions.  **Part three** was the question of organization climate with 45 questions.  **Part four** was the question of performance of health personnel at the emergency department that consists of 41 questions. Use of rating scale five levels in part two, three and four.

The scoring criteria for comments are as follows: The highest level, high level, intermediate level, low level, and lowest level are five point, four point, three point, two point, and one point, respectively. Part five is a question about problems, and suggestions about performance of health personnel at the emergency department in community hospital.

**Set two** was an In-Depth Interview Guideline based on the information from the quantitative research. The least average questions are used for in-depth interviews to confirm, support and explain the quantitative data. The researcher defined the issue in three parts:  **Part one** was an in-depth interview guide about administrative factors.  **Part two** was an in-depth interview guide about Organization climate.  **Part three** was an in-depth interview guide about performance of health personnel at the emergency department in community hospital in Roi Et province.

**Quality of research tools**

Both sets of tools were approved by three experts in terms of content validity then Item Objective Congruence: IOC was analyzed. It was found that all of items had IOC at the level of 0.67-1.00. The questionnaires were pretested in 30 health personnel at the emergency department in community hospital in Khon Kean Province, Thailand. The Cronbach’s Alpha Coefficient was 0.95 for administrative factors, 0.97 for the organizational climate, 0.97 for the performance at the emergency department and the overall questionnaire reliability was 0.98 respectively.

**Data Analysis**

The researcher analyzed the data by using descriptive statistics; frequency, percentage, mean, standard deviation, median, minimum and maximum value, and inferential statistic; Pearson’s correlation coefficient, and stepwise multiple regression analysis.

**Research Results**

1. Personal characteristics and the performance of health personnel at the emergency department in community hospital

Personal Characteristics and the performance of health personnel at the emergency department in community hospital Roi-Et province Thailand were as follows: Most of the sample were female, 120 people (87.6%), aged between 21-30 years, 65 people (47.4%) with an average age of 34.36 years (SD = 9.94 years, Min = 22 years old, Max = 58 years old). Most of them graduated with a bachelor’s degree or equivalent, 84 people (61.3%), married 68 people (49.6%), and most of them were registered nurses, 106 people (77.4%). There were 92 respondents working for 10 years or less (67.1%) with a median of 7 years (Min = 1 year, Max = 35 years), and 105 (76.6%) emergency accident workers had received on-the-job training.

2. Administrative factors and organizational climate affecting the performance of health personnel at the emergency department in community hospital
The analysis results showed that independent variable that affects the performance of health personnel at the emergency department in community hospital Roi-Et Province Thailand. That is selected into the equation is the variables that were statistically significant at level 0.05 and independent variables that were not selected into the equation were variables that were statistically significant greater than 0.05 with variables selected into the sequencing equation as follows: organization climate: warmth (p-value <0.001), organization climate: responsibility (p-value = 0.002), organization climate: identity (p-value = 0.005) and administrative factors: money (p-value = 0.048). Therefore, four independent variables can predict the performance of health personnel at the emergency department in community hospital at 49.6% (Table 1).

Study results: Multiple Linear Regression equation which is a prediction equation of the performance of health personnel at the emergency department in community hospital as follows:

\[
Y = 1.559 + (0.286) \text{(Organization climate: warmth)} + (0.257) \text{(Organization climate: responsibility)} + (0.229) \text{(Organization climate: identity)} - (0.123) \text{(Administrative factors: money)}
\]

**Conclusion and Discussion**

The Stepwise Multiple Regression Analysis found that independent variable affecting the performance of health personnel at the emergency department in community hospital were organization climate; Warmth, Responsibility, Identity, and administrative factors; Money can predict 49.6% for the performance of health personnel at the emergency department in community hospital.
The organization climate in warm dimension of emergency department of community hospital can reduce stress and anxiety which are definitely important to the workers. The warmth needs to be able to support the energy and the relationship to build the great rapport, and it will affect the better organization climate. This result of the study is related to the previous study of the performance of health personnel at the emergency department\(^{[10-11]}\). The organization climate in responsibility dimension is the performance of health personnel at the emergency department in community hospital. It can be responsible with working freely, responsible to themselves, and make a strong decision to solve problems which can create learning on their own working. This result of the study is related to the previous study of the performance of health personnel at the emergency department\(^{[10-14]}\). The organization climate in identity dimension of health personnel at the emergency department is important to the part of supporting energy and relationship in the workers and it importantly emphasizes being a part of the organization. Therefore, it will lead to the rapport and influence on efficiency perform. This result of the study is consistent with the previous study of the performance of health personnel at the emergency department\(^{[10,13,15-17]}\). However, the situation of emergency department and individual of Health Personnel which is different in each hospital, the result of this study inconsistent with the results of the study found that the organization climate; warmth, and identity can’t predict the performance of health personnel\(^{[12]}\).

The administrative factors in terms of money play an important role to manage manpower, materials and necessary equipments which are the prerequisite for the creative environment of the management. The budget is the crucial of factor for the performance to reach the objectives\(^{[2]}\). However, the result of the study found that the coefficient regresses in this factor has a negative value, and it can explain that the money budget affects the performance at the emergency accident unit inversely. It may be, because of the administrative factor’s money is under the control of hospital accounting which have to pass many checking processes. This result is related to the previous study of the performance of health personnel at the emergency department\(^{[17]}\). However, the budgeting support depends on the needs and policies of organization, the result of this study inconsistent with the results of the study found that the administrative factors in money can’t predict the performance of health personnel at the emergency department in community hospital\(^{[18-19]}\).

The in-depth interviews found that the performance of health personnel at the emergency department, it found that the emergency accident unit performance is one of the standards which assess the public health workers’ performance. Besides competencies in each profession to assess the standard of the emergency accident unit, moreover the studied hospital has been set the individual criteria for assessing which is able to assess the individual performance. Therefore, the patient will reach the standard and safety service due to the fact that the performance of the staff is more effective.

In conclusion, the organization climate; warmth, responsibility, identity, and administrative factors; money affect the performance of health personnel at the emergency department in community hospital, so they should be supported and developed the organization climate with mostly considering the budget, work objective and goal, moreover should encouraging by giving rewards and certifying the performance’s ability including having the criteria for clear judgement to encourage the motivation and confidence for working.

Abstract

Aims and Objectives: The aim of the study is to assess the knowledge, attitude, and practice of forensic odontology among undergraduate dental students at Kabul university of medical science, Kabul, Afghanistan after adding this subject in their curriculum

Material and Methods: This cross-sectional study is conducted among 150 undergraduate dental students of Kabul University of medical sciences aged 18 and 23 years during the period from December 2020 to February 2021. A questionnaire of Abdul et al. (2019) study was used; the questionnaire consisted of 19 questions that assessed the knowledge, attitudes, and practice of the participants. The questionnaire is divided into three parts: knowledge, attitude and practice. The collected data were analyzed using SPSS-24 software, chi-square test.

Results: Ninety percent of the participants were aware of the branch of science called forensic dentistry. All the included participants welcomed the idea of adding a module on forensic odontology to the current undergraduate curriculum. Almost 88.7% of the participants were aware that dental record help for identification of deceased person’s age however, The most of undergraduate dental students (90.7%), claim that they have lack of the knowledge related forensic odontology. Most of participants were willing to maintain dental record in their future clinics.

Conclusion: Our study showed that the knowledge, attitude, and practice in undergraduate dental students are better since it’s added into curriculum of Kabul University of medical science. However, there are no workshops, seminars, and continuing dental education programs for dental students. There is a need for further exposure and formal training to bring awareness among all health-care providers.

Keywords: Knowledge and Attitude, Forensic odontology, Students

Introduction

Forensic odontology can be defined as a branch of dentistry by the Federation Dentaire International (FDI) which in interest of justice, deals with the proper manipulation and examination of dental evidence with the proper evaluation, and presentation of dental findings(1).

Forensic odontology is a challenging and attractive branch of forensic science that includes the use of dental science in identifying deceased people by comparing
pre- and post-mortem records. Forensic odontology focuses largely on the teeth and involves assisting in the identification of deceased individuals and criminals and the specialists should have basic skills and knowledge about forensic odontology and be aware of how to manage dental records, dental DNA analysis, radiography, dental morphology and anatomy.

Teeth are resilient to conditions such as high temperatures, immersion and decomposition and are classified as one of the primary identifiers by Interpol. Moreover, teeth are the cheapest, quickest, and easiest methods of human identification when compared to fingerprinting and DNA.

Dental records play an important role in cases where corpses have been severely damaged, impossible, or difficult to identify. This is attributed to the fact that dental tissues and dental restorations are resistant in nature, which make them the most reliable source of DNA, that will help for any individual identifying case. Despite the importance of this field in criminal justice, the literature shows that forensic odontology has been underestimated in many countries. Furthermore, there is no universal acceptance path for forensic odontology education and requirement in each country.

The aim of this study was conducted to assess undergraduate dental students’ knowledge, attitude, and practice of Kabul University of medical science in Kabul, Afghanistan after adding this subject in their curriculum.

**Materials and Methods**

This cross-sectional study is conducted among 150 undergraduate dental students of Kabul University of medical sciences aged 18 and 23 years during the period from December 2020 to February 2021.

A questionnaire of Abdul et al. (2019) study was used; the questionnaire consisted of 19 questions that assessed the knowledge, attitudes and practice of the participants. The questionnaire written in English and Persian language distributed among 150 undergraduate dental students. All included participating was willing to participate in the research process. Males 60 (40%) and females 90 (60%) were included. Information was collected from demographic data of participant following: age, gender, education level. The questionnaire is divided into three parts: knowledge, attitude and practice. The collected data were analyzed using SPSS-24 software, chi-square test.

**Results**

A total of 150 undergraduate dental students, Males 60 (40%) and females 90 (60%) aged between 18 and 23 years were included. The questionnaire was self-administered by a convenience. According to descriptive findings, 58% of respondents were over 21 years old and 42% were under 21 years old.

Question 1-9 were knowledge-based, questions on forensic odontology. (Table 2)

Q1: In our study, 90% of the participants were aware of the branch of science called forensic dentistry and about 10% of the participants were unaware of it.

Q2: 69% of undergraduate dental students were aware that teeth serve as a source of DNA.

Q3: Ninety-six percent of the participants were aware that forensic dentistry helps to investigate criminals and dead persons.

Q4: 76.6% of the participants were aware of age estimation in children and adults by an eruption pattern of teeth. The remaining participants answered that histological and biochemical methods were used to identify the dental age.

Q5: Almost 88.7% of the participants were aware that dental record help for identification of deceased person’s age. However, 10.7% of the participant were thinking fingerprint can help in this situation.

Q6: Nearly, 46.7% of the participants were not aware they mark don’t know option, only 26.7% of participants were able to mark the correct answer.

Q7: Most of the study participants (73.3%) were aware of teeth bite mark pattern significance.

Q8: Proportion of this study participants marks the source of their knowledge book and internet respectively.

Q9: The most of undergraduate dental students (90.7%), claim that they have lack of the knowledge related forensic odontology.

**Discussion**

This study was conducted to assess undergraduate dental students’ knowledge, attitude, and practice of Kabul University of medical science in Kabul, Afghanistan and gives an insight into the significance of this field in reducing the crime rate, illegal birth rates, illegal immigrants, and identification of individuals in mass disasters and pilgrimages in Afghanistan.

There are many studies carried out on forensic odontology in other countries, but no study was conducted in the Afghanistan among dental students. Therefore, this is the first study of forensic odontology in Afghanistan, which targets undergraduate dental students. However, the limitations of this study should
be considered when interpreting the findings; the sample utilized was drawn from one educational institution, therefore, it does not represent all dental students in Afghanistan.

Our study showed that the knowledge, attitude, and practice in undergraduate dental students are better since it is added into curriculum of Kabul University of medical sciences. These findings were consistent with the results of Al-Azri et al (10) in Australia showed that knowledge Students and dentists are well versed in forensic dentistry and many of them are aware of the field of work and the type of specialization in this field.

In the present study revealed that 90% of the participants were aware of the purpose of dentists in mass disaster, which, in contrast to other studies that showed only 31.6% and 59.4% awareness in this expression the adding forensic accounting course to their curriculum. However, the participants were reported their lack of seminars and workshops regards forensic odontology. Furthermore, the poor information regarding Lipology and Cheiloscopy could be due to a lack of awareness and insufficient knowledge about the aspects and use of these techniques.

Dental records are considered as an essential aid in identification of persons who are victims of an illegal act. The dental record might act as a future reference for the dentist when needed, but unfortunately, it is not constantly preserved for a forensic purpose (11). In the current study, most of dental students agreed that maintaining dental records is an essential component in human identification. This insufficient knowledge highlights the necessity for proper education and further training (12). Dentists should know not only the importance of preparing an accurate dental record but also the importance of preserving these records. Almost half of the students reported that their source of information in forensic odontology is from the Media. Media plays a definitive role in creating awareness among the public (13). The same holds true for the present study. Additionally, journals and seminars continue to remain as one of the most reliable and correct sources of this knowledge. However, the focus should be on the worrying finding that the majority of students in this study think that they do not have adequate knowledge or confidence in handling forensic dental cases. However, 100% of the students welcomed the idea of adding a module on forensic odontology to the current undergraduate curriculum.

This study provides a baseline for the upcoming studies in the Afghanistan. Findings from this study might be considered as a reference for endorsing the area of forensic odontology in the undergraduate training of dental students. Thus, the undergraduate program must be improved by including preclinical lectures on forensic odontology, followed by clinical training and a field slips to forensic departments. This suggests that These recommendations might have a positive impact on students’ knowledge and awareness concerning forensic odontology and Students should be aware of this specialty and be encouraged to participate in research and identification teams and consider it as their specialty. Further studies should be carried out at other dental colleges in Afghanistan.

**Conclusion**

Our study showed that the knowledge, attitude and practice in undergraduate dental students are better since it’s added into curriculum of Kabul University of medical science. However, there are no workshops, seminars, and continuing dental education programs for dental students. There is a need for further exposure and formal training to bring awareness among all health-care providers.

Menstrual Blood Stem Cell Preservation

Parul Saini1, Bharti Sachdeva1

1Assistant Professor, Faculty of Nursing, SGT University, Gurgaon

Abstract

Unlike past days menstrual blood has been considered as the rich source of self-rejuvenating stem cells. These cells can multiple rapidly and helps in various cosmetic and regenerative surgeries. They can easily be used same as that of stem cells derived from umbilical cord and bone marrow.

Key Words: Menstrual Blood Banking, Stem cell, Regenerative capacity.

Introduction

Menstrual blood stem cell banking has been established as an important field of research and is progressing day by day. Earlier menstrual blood was considered as unsanitary waste of human body but latest researches have shown that menstrual blood is rich in stem cells and they have the ability to multiple and differentiate into any kind of cells.

Over the years menstrual stem cells are used in various regenerative and cosmetic surgeries.

Stem cells derived from menstrual blood are rich in mesenchymal stem cells. These cells have high survival rate after transplant as they are immunologically immature and can successfully contribute in cell cycle. Menstrual stem cells have same regenerative capacity as that of umbilical cord blood and bone marrow. They are considered as powerful tools for repairing as they can multiply rapidly and can differentiate into many other types of cells such as cardiac, neural, bone, fat and cartilage. They can easily be collected non-invasively without ethical concerns.

Sources of stem cells:

There are two main sources of stem cells are embryonic stem cell and adult stem cells. Embryonic stem cells can be collected from human embryos whereas adult stem cells can be derived from bone marrow, umbilical cord, menstrual blood cells, placental tissue, endometrium, peripheral blood stem cells.4 Adult cells found in bone marrow collected through invasive painful procedure.5

Collection and storage:

Menstrual blood cell collection procedure is hassle free and can be done easily at home. It can be collected using a medical-grade silicone cup instead of a sanitary pad or tampon. On the heaviest flow day, a silicone cup is inserted into the vagina for collecting 20 millilitres of blood. 15 ml to 20 ml of menstrual blood could easily yield between 10 million to 100 million Mesenchymal Stem cells. After that collected blood is poured into collection kit and sent to menstrual blood bank laboratory where it is processed, frozen and stored. It is completely painless and non-invasive procedure. The menstrual stem cells are cryogenically preserved in overwrapped vials which is closely monitored all the times for its safety and future usage.6

Advantages:

- Easily accessible, non-invasive and painless procedure.
- Highly potential to replicate into bone, skeletal, cartilage muscle cells
- More proliferative and multiply for longer duration without damaging DNA.
Can be administered easily through a standard IV line.

It can be preserved multiple times at any age.

**Uses:**

Menstrual stem cells are used in Heart Failure & Post Myocardial Infarction as they help to secrete certain angiogenic and trophic factors that assist in activation and regeneration of cardiac stem cells. They can also be used in treatment of stroke as these cells migrate to the infarct site and secrete neurotrophic factors. They are also beneficial in several other conditions like atherosclerosis, Diabetes, Rheumatoid arthritis, Parkinson’s disease and Alzheimer’s disease etc. As the chances of immune rejection are minimal as female patients are using their own cells hence it has broad scope in the near future.

**Menstrual blood stem cell banks:**

In India, stem cell banking services are mainly provide by Privately- held banks, Government- owned (Public) banks and Community stem cell bank. Life cell international Pvt. Ltd. is the first community stem cell bank in India. It has two high-tech labs located at Chennai (Tamil Nadu) and Gurugram (Haryana). It has dual storage facility.

**Conclusion:** Menstrual derived stem cells have shown regenerative properties in prevention and control of various disorders like stroke, diabetes, Myocardial infarction and many other neuro degenerative diseases. Diverse therapeutic research on mesenchymal stem cells would greatly contribute to treat variety of diseases. In summary, more clinical research on menstrual derived stem cells preservation and its clinical use can make these cells a preferred type of stem cells over umbilical cord and bone marrow stem cells.

**Discussion**

Stem cells are used to treat variety of diseases and disorders. Menstrual derived stem cells are considered to have tremendous therapeutic potential. Naoko Hida et al (2008) stated that menstrual derived mesenchymal stem cells have potential to restore impaired cardiac functioning. Ian A White et al (2016) have also stated Mesenchymal stem cells are capable of differentiation into cardiac cells. In another study Borlongan et al. concluded that menstrual derived stem cells successfully improved ischemic stroke among rats in vitro.

**Ethical Clearance** - Not applicable

Psychoeducation on Adherence to Treatment of Schizophrenia Patient During Covid-19 Pandemic Era

Patria Yudha Putra1, Izzatul Fithriyah2

1General Practitioner, Psychiatry Resident, Faculty of Medicine, 2Psychiatrist, Assistant Professor, Department of Psychiatry, Faculty of Medicine, Universitas Airlangga/ Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Abstract

Background: The outbreak of Covid-19 is really disrupting people’s thought and their ability to face the problem clearly and their mental health could be disturbed. They will go under their circumstance of fear, start to panic, and leads to poor decision making. This fear and anxiety could affect and lead to any negative behavioural changes of patients to the belief of being infected by avoiding going to the hospital as a source of contagion place.

Methods: Case study from an inward patient, adult woman that suffered from schizophrenia for more than 10 years and got injection of antipsychotic routinely once a month. During the early time of Covid-19 pandemic, the patient and her family are afraid of coming to the hospital to get her injection. After one month of not getting the injection, she started to relapse again and hospitalized for 10 days.

Results: The difficulty faced in handling this case is to provide an understanding of the patient and family about adherence on her continuity treatment. Therefore, by giving a psychoeducation using a telemedicine is considered to the most suitable way to handle this patient to gain more insight about her willingness back to get the monthly treatment during the pandemic situation.

Keywords: Schizophrenia, Covid-19, Adherence of Treatment, Psychoeducation, Telemedicine, Telepsychiatry

Introduction

Schizophrenia is part of a psychotic disorder which is mainly characterized by a loss of understanding of reality and a loss of insight. (1) consisting of a complex, heterogeneous group of cognitive and behavioural syndromes, which may originate from brain development disorder caused by genetic or environmental factors, or both. (2) Schizophrenia occurs all over the world, affects about 1 percent of the global population that lasts along their life. (3)

The incidence rate of Schizophrenia is about 1.5 per 10,000 people and the onset of people getting schizophrenia is around 18 to 25 years old for men and around 25-35 years old for women to be diagnosed with. (4)

According to Diagnostic and Statistical Manual of Mental Disorders, 5th Edition (DSM-5), there are specific criteria for schizophrenia over a period of 1 month such as delusions, hallucinations, unorganized speech, unorganized or catatonic behavior and...
negative symptoms. Patients with schizophrenia also experience cognitive impairment like patients have poor performance to control their cognitive functions. 

World Health Organization (WHO) declared that 2020 is a year of Coronavirus disease 2019 (Covid-19). The spreading of this virus contributed globally in just some weeks, the Covid-19 epidemic had spread to over 100 countries that matched to the definition of pandemic.

Coronavirus comes from a family of *Coronaviridae* virus and contains four structural proteins: spike (S), envelope (E), membrane (M) and nucleocapsid (N). The spike glycoprotein will infect the human body by attaching the membrane of the host cell and started to make symptoms like common cold or attack respiratory organ. This family of virus also responsible to the other global pandemic virus such as, Severe Acute Respiratory Syndrome (SARS) and Middle East Respiratory Syndrome (MERS). 

The mode of transmission of the Covid-19 virus is mainly spread via respiratory droplets. Basic reproduction number of the human transmission of Covid-19 is more contagious than other viruses such as SARS, MERS, H1N1 or Ebola and the value of reproduction number of Covid-19 reported is 3.6 compared to the other pandemic virus is 2.7. Thus, it proved that Covid-19 is highly contagious. This basic reproduction number could be reduced by encouraging people to restrict travel that are not essential and do the physical distancing. To prevent the spreading of Covid-19, people are asked to maintain their standard of hygiene. The public health authorities strongly advised people to wear a face mask wherever they go and do the physical distancing by not taking activities outside their houses if is not very necessary during the outbreak. Also, the government has done several non-pharmaceutical interventions by closing some places that people could gather in a large number, such as shopping centres, public areas, or restaurants. They also minimizing the office hours to minimize the spreading of the virus.

The outbreak of Covid-19 is really disrupting people’s thought and their ability to face the problem clearly and their mental health could be disturbed. Their reaction could be varies, some believe their life is in a danger situation, some believe it is just a theory conspiracy or they will believe the misleading rumours. With this outbreak happens, most people will react with confusion and anxiety. They will go under their circumstance of fear, start to panic and leads to poor decision making.

People with fear of Covid-19 are afraid to go outside their house, especially people with poor mental health and living in region with high reported Covid-19 cases. Their ability to think clearly is disturbed so they will become afraid to go to the hospital and this will ruin their long-term treatment. The long-term medication and hospitalization for patients with psychotic symptoms could decrease their motivation. They take medication pills or get an injection day by day passively in the hospital in a long time aimlessly could lower their adherence of medication, especially in the patients with schizophrenia, they usually have a lower insight than other patients. It is difficult to gain an insight of the patient especially with schizophrenia about their adherence of medication and stay continue with her treatment.

This review is aimed to give a management to the patient with mental health illness during Covid-19. They have to be provided with a very clear about information, situation, strategies to face the unstable living condition in order to fulfil their treatment on time. Psychoeducation is one of the methods to improve the adherence of the treatment given to psychotic patients.

**Case Report**

The patient was a 28-year-old female. Patient was angry 2 days before admitted to the hospital. The patient was late getting the treatment because the patient was forbidden by her husband to come to the hospital for fear of the spread of the Covid-19 virus which was increasingly widespread. The patient could tell that
she was taken to the hospital because suddenly she could not control her anger, the patient felt unable to control her emotions so that the patient was angry both to her husband as well as to her mother, felt restless and slammed things nearby. She also could not sleep well for 2 days before being admitted to the hospital, became restless and paced around the house. She was taken by his family to the emergency room Dr.Soetomo General Hospital Surabaya because her mother saw the patient getting angry and agitated. The patient also said that she was the Guardian of God to save the world that was currently sick and through her, the patient wanted to prevent human from going into hell. The patient also said that she had many similarities with famous Indonesian artists.

The patient said she had to go home soon because the patient has many thousands of employees who are waiting for her to return to work. She said that currently she was working on the making of protective gown project in the Covid-19 pandemic season and had donated a large set of them to many hospitals in East Java that made her contacted directly by the president and given a grand prize of Holy pilgrimage program in 2025. The President contacted patients through direct message on Instagram. She also heard a whispering voice that emerge clearly in the left ear which says that the voice of whisper said that the patient must die, the patient feels that the voice is the voice of the devil and she did not know before. Besides that, she also heard a different whispering voice that arises from her right ear. The voice from the right ear says that the patient is in good health, and the voice that the patient believed that the voice came from of a good genie and wants to save the patient. These sounds appeared continuously in turn at any time during the last 2 days before being admitted to the hospital and disappear when the patient closed her ears. Because these sounds often disturb the patient and make the patient confused and ultimately made the patient unable to control her emotions and the patient became angry.

The patient first experienced a mental disorder since she was in the high school. At that time, she often got bullying by her classmates. Since then, she often had become frightened, often seeing the shadow of the devil and hear of whispering genie. She had previously been treated at MenurMental Hospital for more than 10 times inpatient care because of her mental illness. She had been hospitalized in Psychiatric Ward Dr Soetomo General Hospital 2 times, in 2015 and 2017. Patients routinely got Fluphenazine 25 milligram injection via intramuscular since 2016 and routine given to her every 1 month. The patient never had any serious illness that brought her to the hospitalized. She never had any problems with any substance abuse or using any drugs before and never had smoking any cigarettes.

The patient was diagnosed with Schizophrenia Disorder because her symptoms met the diagnosis of criteria such as unorganized speech, grandiose and bizarre idea, delusion, and hallucinations that persists one month. During hospitalized, patient got several psychopharmacological, Trifluoperazine 2x5mg tablet orally every 12 hour, Depakote 2x250mg tabletorally every 12 hour and Lorazepam 1x1mg tablet orally every 24 hours. For 10 days treatment of psychopharmacology given orally, the patient wet showed better progress of her clinical status. She got injection of Fluphenazine 25 milligram intramuscular again after she was discharged from the hospital.

Discussion

Covid-19 is causing high morbidity and mortality and most of the governments has decided to lockdown almost all the nation’s aspect including economics and politics. People are not able to go to work anymore, many people loses their job and these situations make people started to worry and become fear of their future. (17,18)

The fear and anxiety of being infected to the Covid-19 has increased more since people are exposed to the digital media platform (news, broadcast message, some influencer’s thought, rumoured news), their perception of facing the pandemic and their obsessive thought of being less control from preventing the virus. Having heard about the increasing number of mortality
of Covid-19 made people confused to do their plan and
did not want to work and do activities like they usually
did.(19,20) This fear and anxiety could affect and lead
to any negative behavioural changes of patients to the
belief of being infected by avoiding going to the hospital
as a source of contagion place. (21,22) This condition could
disrupt patient’s understanding and decision-making to
keep on their treatment program. (23)

The adherence of treatment depends on the patient’s
willingness to receive and keep following the doctor’s
suggestions. There are many types of the incompliance
of treatment that patients usually do like, not using the
doctor’s prescribed as advised, the patients missed the
appointments and not attending the follow up sessions.
(24)

Bad adherence of treatment is the main cause of
relapse of the disease and increasing patient’s frequent
hospitalized. Education to the patient’s insight really
could help minimize the relapse and recurrence of the
patient’s disease so does minimize the treatment cost.
Medical employees here, including doctors, nurses and
other hospital staffs need to give psychoeducation to
the patient for being aware of their illness and know
their symptoms further. (24) Besides, the medical staffs
are required to give a nice, improved and secured
hospital environment especially during the pandemic so
it expected to reduce the patient’s fear to come to the
hospital. (25)

The Intervention of psychoeducation for patients
with schizophrenia disorders shows some improvements
outcome to the patient especially for very long-term
inward patient. A Good psychoeducation from a doctor
will determines a great improvement in some areas of
their knowledge and adherence to their psychiatric
medication to ensure that their ongoing medication
after discharge from the hospital. It will become
very important to every doctor to give an explainable
psychoeducation to the patient and family about the
diagnosis and the following treatment. (16)

Medical staffs here need to gain concern about
delivering active psychological and psychiatric
intervention for those who needs help during this
pandemic era of Covid-19. We are all cannot just sit and
wait until this pandemic over. The long-term treatment of
psychotic inward patients must go on and telepsychiatry
and use of digital media believed could be used helping
the treatment to continue during this era. (26)

Telemedicine is one of the healthcare services
methods that gives solution of bringing healthcare
service within distance between patients and doctors
especially during the pandemic era, using digital media
technologies involving information and communication.
In the psychiatry department, this service known as
Telepsychiatry. (27)

Telemedicine is an interesting tool for psychiatrist
because psychiatric care is not necessary to meet the
patients physically. The verbal and visual assessment
could be easily done via telepsychiatry. Doctor and
patient could face to face directly via their digital media
platform such as, laptop, tablet and phones without
any restrictions (28). They are only having to switch on
their camera during the consultation so rapport and
expressed face could be obtained and helping doctor to
determine their treatment. This service is very useful for
both patients and doctors during this pandemic because
doctors can still provide assistance and treatment to
patient in a distance while still maintain to minimize the
risk of spreading infection of Covid-19. (27)

Even telepsychiatry sounds especially useful to
the psychiatrist to continue giving the psychiatric care
during the pandemic but telepsychiatry also have some
difficulties that both doctor and patients feel. Doctors
feel that using this technology they hard to detect non-
verbal cues during their videoconference also they could
not build the relationship between doctors and patients
as good as they meet directly. (27)

The needs of telepsychiatry to the inward patient is
giving the supportive psychotherapy and psychoeducation
by phone or video during the pandemic and to follow
up the condition of the patient. (29) One of the aims of
giving psychoeducation to this patient by telepsychiatry
is to gain more insight about patient’s willingness to
get the monthly treatment. Long-acting injection of antipsychotics that given to the patient is every 4 weeks. Compared to the oral antipsychotics, proven that long acting injection have more stability in the blood system, more consistent bioavailability and more predictable on adherence treatment and also have lower rate of relapse.

This patient was getting better condition since she got long-acting injection of antipsychotics. She never relapsed again of her disorder and always got her long-acting injection once a month from 2018 until 2020. Because of her family’s fear of Covid-19, her adherence getting bad and relapse again. By giving right choice of psychoeducation that is telepsychiatry to this patient, from the moment she was discharged from the hospital and always encouraging and reminding her and her family to keep on her medication by taking long-acting injection on the inward clinic every month and doctor gives the consultation via videoconference to minimize her time in the hospital during time of injection.

**Conclusion**

Patients with chronic schizophrenia disorder that had a treatment with long-acting injection antipsychotics must have a good adherence of obeying the procedure of treatment to stabilize their conditions. There are some psychosocial interventions that recommended, one of them that suggested is psychoeducation. A combination of giving a long-acting treatment and psychoeducation intervention for patients with schizophrenia disorder will improve the patient’s condition especially for very long-term inward patient. During the era of Covid-19, many people are afraid of coming to the hospital like they usually did it before. This is a normal situation, but medical staffs must gain their concerns to the continuation of patient’s treatment. Telemedicine is one of the healthcare services methods that gives solution of bringing healthcare service within distance between patients and doctors especially during the pandemic era by using the digital media technologies.

Key Success Factors and Motivation Affecting the Care of Patients with Tuberculosis of Health Personnel in Primary Care Units

Phatthraphon Chowong¹, Prachak Bouphan², Nakarin Prasit³, Surachai Phimha⁴

¹Master, ²Associate Professor, in Department of Public Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, KhonKaen University, Thailand, ³Sisa Laloeng Health Promoting Hospital, Nakhon Ratchasima Province, Thailand, ⁴Lecturer of Department of Public Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, KhonKaen University, Thailand

Abstract

This research is a cross-sectional descriptive aimed to study key success factors and motivation affecting the care of patients with tuberculosis of health personnel in primary care units Nongbualamphu province, Thailand. The populations were 89 health personnel and 12 key informants. The content validity of the questionnaire was evaluated by three experts with an IOC greater than 0.50 and Cronbach’s Correlation Coefficient was 0.97 and In-Depth interview guidelines for the qualitative. Data was collected between 4th January 2021 and 25th January 2021.

The results of the study showed that five factors including; 1) motivation factor in responsibility 2) Hygiene Factor in policy and management 3) key success factor in the startup in areas that are ready and willing to participation 4) Hygiene Factor in a relationship with supervisors, subordinates, co-workers and 5) Hygiene Factor in salary and compensation affecting and could joint predict the care for tuberculosis patients in primary care at 75.0 percentage (R² = 0.750, p-value <0.001). In conclusion, key success factors and motivation affecting the care of patients with tuberculosis of health personnel in primary care units. Therefore, the health personnel should be developed in terms of work priorities, working process that led to the intention to work, awareness of their roles and responsibilities Including promoting participation in policymaking on tuberculosis work.

Keywords: Key success factors, Care of patients with Tuberculosis, Primary care units

Introduction

Thailand is the center of Southeast Asia and many people are traveling to Thailand. The ASEAN Economics Community leads to people movement into the country, therefore vulnerable to problems of various diseases, including emerging diseases and recurrent disease[1]. It increases the spread of infectious diseases including tuberculosis a serious contagious disease. The World Health Organization(WHO) classifies Thailand as one of 14 countries with a high burden of tuberculosis according to the WHO reported in 2019[2]. In 2018, there were many patients registered for tuberculosis treatment in Thailand (New tuberculosis patients and recurring) 85,029 cases were covered by active case finding and registered for treatment[3]. Tuberculosis is still a major public health problem in Thailand and tuberculosis patient’s care also important.

Taking care of patients with tuberculosis by using Patient-Centered Care (PCC) which is a holistic care service that aligns with the lifestyle of the patient and understands the various contexts of the patient[4]. To ensure the care and treatment of tuberculosis patients from public health personnel at all stages is defined details of measures and requirements into five measures, including 1) prevention and control of tuberculosis, 2) search and screening, 3) treatment, 4) management, and
5) care and treatment of Multidrug-resistant tuberculosis (MDR-TB)[5].

Nong Bua Lam Phu province has 89 primary care facilities comprising 83 sub-district health promoting hospitals and 6 primary care units to provide tuberculosis patients care. The total number of tuberculosis cases in 2017 - 2019 was 505, 482, and 495 cases, representing the incidence at 107.10, 90.65, and 104.15 per 100,000 population, respectively. The problem in tuberculosis care was unable to follow-up, drug resistance. The admission patient has become more severe because most of the registered tuberculosis patients are elderly and having a common disease[6]. It led to the study in key success factorsbase on Supawongtheory[7] and Herzberg’s theory of motivation factors which classify into two main dimensions was motivation factor and Hygiene Factor[8] which affecting the care of patients with Tuberculosis of health personnel in primary care units.

Objective

The study aimed to investigate Key Success Factors and motivation affecting the care of tuberculosis patients of health personnel in primary care units Nong Bua LamPhu province, Thailand.

Research methodology

This research is a cross-sectional descriptive research

Population

The population was 89 health personnel in primary care units who responsible for the care of tuberculosis patients under the public health office of Nong Bua Lam Phu province, Thailand. The researcher studied the entire population.

The sample group for an In-Depth Interview was 12 health personnel responsible for the care of tuberculosis patients under the public health office of Nong Bua Lam Phu province, Thailand.

Research instruments

There were two sets of data collection tools in this research

Set 1: There are five parts questionnaires: Part 1. Personal characteristics, Part 2. Key success factors consist of 30 questions, Part 3. Motivation factor (motivation factor and Hygiene Factor) consists of 59 questions, Part 4. Care for TB patients consists of 24 questions. The parts 2 to part 4 using the approximation scale there is a choice of answers with five scoring levels[9] and Part 5. In the open-ended questions which the respondent proposes problems, and suggestions in caring for patients with tuberculosis.

Set 2: In-Depth Interview, there are three parts: Part 1. key success factors, Part 2. Motivation factors, Part 3. Care for tuberculosis patients of health personnel in the primary care unit.

The measurement: Interpretation of the key success factor rating score, motivation score, and the care for patients with tuberculosis of health personnel in primary care was classified by rating scale in 5 levels which were the most, most, medium, low, and lowest then calculate in average score.

Quality of research tools

Both tools were tested for content validity by three experts who found that each question has a consistency index greater than 0.50. Then, the questionnaire was examined, corrected, and improved by experts and. The questionnaire was tryout with 30 health personnel in Bueng Kan province, Thailand who have similar performance characteristics. The Cronbach’s Alpha Coefficients found that the accuracy value reliability of key success factor variable was 0.93, Motivation factor was 0.95, care for tuberculosis patients was 0.86, and overall was 0.97.

Data Analysis

Data analysis was performed by descriptive statistics: frequency, percentage, mean, standard
deviation, median, minimum, and maximum values, and inferential statistics; Pearson’s correlation coefficient statistics and stepwise multiple regression analysis with a statistical significance level of 0.05.

**Results**

1. **Personal characteristics**

   The population characteristics found that most of the study population was female, 67 people (75.3%), aged between 31-40 years, 44 people (49.4%) with an average age of 36.93 years (S.D. = 8.46, Min=23 years old, Max=60 years old), most of them have marital status (couples) of 49 people, (55.1%). They have education in bachelor’s degree, 73 people (82.0%), most of the income (per month) between 15,001 - 25,000-baht, amount 52 people (58.1%) with an average income of 23,872.47 Baht (S.D. = 11369.30).

2. **Key success factors and motivation affecting the care of patients with tuberculosis of health personnel in primary care units**

   Independent variables affecting care tuberculosis patients of health personnel in primary care unit which selected into the equation is significant variables statistical at level 0.05. The variables selected in the equation were 1) motivation factor in responsibility (p-value <0.001) 2) Hygiene Factor in policy and management (p-value =0.001) 3) key success factor in the startup in areas that are ready and willing to participate (p-value =0.001) 4) Hygiene Factor in a relationship with supervisors, subordinates, co-workers(p-value =0.008) and 5) Hygiene Factor in salary and compensation(p-value <0.030), so five independent variables were affecting and predictable for the care of tuberculosis patients of health personnel in primary care unit at 75.0 percentage(Table 1). The Multiple Linear Regression equation is a prediction equation of the care of patients with Tuberculosis of health personnel in primary care units as follows:

   \[
   Y = 0.410 + (0.315) \text{ (Motivation factor in responsibility)} \\
   + (0.299) \text{ (Hygiene Factor in policy and management)} \\
   + (0.218) \text{ (Key success factor in the startup in areas that are ready and willing to participation)} \\
   + (0.205) \text{ (Hygiene Factor in a relationship with supervisors, subordinates, and co-workers)} \\
   - (0.121) \text{ (Hygiene Factor in salary and compensation)}
   \]

   **Table 1: The key success factors and motivation affecting the care of patients with tuberculosis of health personnel in primary care units by stepwise multiple linear regression analysis**

Conclusion and Discussion

The results of the study showed that 1) motivation factor in responsibility 2) Hygiene Factor in policy and management 3) key success factor in the startup in areas that are ready and willing to participation 4) Hygiene Factor in a relationship with supervisors, subordinates, and co-workers and 5) Hygiene Factor in salary and compensation affecting and could joint predict the care for tuberculosis patients in primary care at 75.0 percentage.

The motivation factor in responsibility is the important factor in the fundamentals of health workers in tuberculosis work. Due to responsibility the satisfaction that arises from being assigned to a new task and having the power to take full responsibility monitored. It is a sequence of work, the intention to perform the job and lead to motivation and responsibility to make the job successful. The results of this research are consistent with the research that has been studied and found that motivation in responsibility incentive factors affect the performance of health personnel in primary care units[10-12].

The Hygiene Factor in policy and management which represent the organizations management, goal setting, and providing opportunities to participate in policymaking to achieve clarity of the policy, rules, and regulations until the operator has a real understanding. The results of this research are consistent with the research was found that the Hygiene Factor in policy and management had an effect on the performance of public health personnel in the primary care unit[13-14].

The key success factor in the startup in areas that are ready and willing is a very important factor for promoting participation for public health personnel to work on tuberculosis in the community area. Tuberculosis patient care needs to build cooperation from the community and various organizations in the community by encouraging people and take part in tuberculosis care with understanding, moreover, having the department of public health as a mentor will support a project plan for tuberculosis implementation. The results of this research are consistent with the research that has been studied and found that key success factors in the startup in areas that are ready and willing affect the performance of public health personnel in the primary care unit[15-17].

Hygiene Factor in a relationship with supervisors, subordinates, and co-workers which is the tuberculosis operations on communication to contact in verbal or non-verbal that express a good relationship with each other, understanding to network partners, stakeholders. The results of this research are consistent with the research that has been studied was found that Hygiene Factor in a relationship with supervisors, subordinates, and co-workers affect the performance of public health personnel in the primary care unit[11, 18].

The Hygiene Factor in salary and compensation, in the primary care unit the other benefits or privileges from tuberculosis work were limit. The disbursement is quite difficult because the process is complicated and requires a lot of paperwork this makes it a problem and obstacle for the operator in making financial disbursement. The results of this research a consistency with research that has been researched and found that Hygiene Factor in salary and compensation affect the performance of public health personnel in the primary care unit[10, 14].

The qualitative data found that the primary care monitoring of tuberculosis work from the district-level authorities limit causing no continuity of operations. The suggestion is there should be supervision and monitoring for TB work from related persons at the mentor hospital level and district level. Continuously, monitoring, supervising, giving advice, providing guidance on the work that is correct as the same standard. They should integration between multidisciplinary teams of each department together, such as making a joint plan or sharing administrative resources, information exchange to those involved.

The health personnel low motivation to work because risk of tuberculosis infection and it cannot drive career advancement. the suggestion is providing special rewards for risks arising from operations to encourage the morale of the working staff.
In conclusion, the motivation factor in responsibility, the Hygiene Factor in policy and management, relationship with supervisors, subordinates, and co-workers, salary and compensation, and key success factor in the startup in areas that are ready and willing to participation affecting the care of patients with tuberculosis of health personnel in primary care units. Therefore, the health personnel should be developed in terms of work priorities, working process that led to the intention to work, awareness of their roles and responsibilities Including promoting participation in policymaking on tuberculosis work.

Acknowledgement: The researcher would like to thank lecturer of Faculty of Public Health KhonKaen University. Thanks to health personnel of tuberculosis prevention and control at the primary care unit under the Provincial Health Office of Nong Bua Lam Phu who allowed the researcher to collect data.

Ethical Clearance: The data collected after being certified by the Human Research Ethics Committee of KhonKaen University on December 19, 2020 number HE632268.

Determination of Learning Styles among Nursing Students

Pooja Gill¹, Parul², Yogesh Kumar³, Jyoti Sarin⁴

¹Nursing Tutor, ²Associate Professor, Department of Mental Health Nursing, ³Professor, Department of Child Health Nursing, ⁴Dean-Principal, Maharishi Markandeshwar College of Nursing, Maharishi Markandeshwar Deemed to be University, Mullana, Ambala, Haryana, India

Abstract

Nursing education furnishes students with the learning qualities required for their profession and also makes students lifelong learners. Aim of the study was to evaluate the learning styles among nursing students. A quantitative approach with descriptive design was applied. A total of 122 students were recruited by purposive sampling from two nursing colleges, selected by convenient sampling. In addition, tools used for the study were structured questionnaire for sample characteristics and Kolb’s Learning Style Inventory. Learning styles were assessed after collecting baseline data. Results indicated that the most preferred learning style was turned out to be Accommodator (35%). Findings concluded that there is a diversity of learning styles among nursing students as the students were having all the types of learning styles.

Keywords: Learning styles, Nursing students, Baccalaureate.

Introduction

The nature of education is in the midst of a transformation. Education has traditionally been viewed as the means to convey information and students as identical empty vessels to fill with information. Nursing education furnishes students with the learning qualities required for their profession. Knowledge and practice are not static always; they are going to change at every step in education.¹

Learning style is defined as “The way each learner begins to concentrate on, process and retain new and difficult information”. Learning style theories assume that all may learn in different ways and at different levels. There are theories and models which focus on aspects such as talents, sensory modalities, cognitive and/or learning and thinking processes.²

Learning styles are not “fixed” and can be modified depending on the teaching styles and teaching methods. Teachers have several options for managing their diversity of learners about learning styles accommodate particular styles provide creative mismatches or provide a variety of instructional approaches so that learners are both accommodated and mismatched at the same time.³

Within the nursing career, realistic and theoretical knowledge need to be distinctly consolidated. Practicing in clinical field may be very critical for undergraduate nursing college students to increase themselves professionally. This is the core responsibility of the teacher to provide an individualized learning environment, so that the students can link up the theoretical knowledge to practical skills. The teacher also acts as a role model for students and is seen as pivotal to student learning in clinical setting.⁴

Knowing students’ learning style preferences enables teachers to use more effective and a wide range of teaching methods and to choose better educational tools for a particular student.⁶

Ms. Pooja Gill,
Nursing Tutor (Mental Health Nursing) Maharishi Markandeshwar Deemed to be University
Mullana- 133203, Ambala- 133001, Haryana, India Ph. No.: 8569827527, Email: gjasmine884@gmail.com
Materials And Methods

The study used quantitative approach with descriptive design. The study was conducted in two nursing colleges. A total of 122 students were selected as study participants by purposive sampling. The tools used for the study consisted of selected variables regarding study participants characteristics, Kolb’s Learning Style Inventory to assess the preferred learning styles. Reliability of the tools was established by split-half method for Kolb’s Learning Style Inventory (0.71-0.89). The data collection was done during the period of November to December 2019. Pilot study was conducted before final study. Data collection was started by collecting the baseline data and then assessment of learning styles. Descriptive statistics were used to analyse the data by SPSS 20 version.

Results

The Kolomogorov- Smirnov test was applied to check the normality of data distribution and it was concluded that the data was normally distributed with the value (p= 0.36). Hence parametric tests were applied for the study.

Sample characteristics

The baseline data was collected from participants through sample characteristics which conclude that variables were homogenous. Nearly half (46.90%) of students were from the age group of 19-21 years. Majority of (73.30%) the students were enrolled in B.Sc. nursing course. More than half (68.80%) of the students were females. Seventy three (73.3%) of the nursing students were belonged to Hindu religion. All (100%) the nursing students were unmarried. More than half (66.7%) of the nursing students had 61-75% marks in previous university examination. Nearly all the nursing students (96.6%) were not having any additional qualification. Majority of the (73.3%) nursing students involved in extracurricular activities. All the nursing students (100%) had previous experience in psychiatric ward. Majority (87.5%) of the nursing students were not having any history of mental illness in their family.

Learning style preferences

The most preferred learning style was found to be Accommodator (34.78%) followed by Diverger learning style (32.60%) and assimilator learning style (32.60%). Astonishingly no students were having converger learning style preference.

Fig.1.Bar diagram showing Frequency Distribution in Terms of Preferred Learning Styles among nursing students.
Discussion

Mismatching of students’ learning style preferences avails better benefit to the students. The study results depicts that there are variety of learning style preferences among nursing students.

In this study, 122 nursing students were enrolled and were homogenous in terms of baseline characteristics. The findings of the study highlighted that there is a wide range of different learning styles among nursing students.

In addition, there has been a predominance among nursing students in gaining knowledge related to learning styles at some point of the years of Bachelor of Science in nursing (Nair MA. 2016). There has been a trend of accommodator and diverging learning style as most preferred learning style in the undergraduate nursing college students.

In addition, understanding learning styles could be considered as a key component of managing classroom teaching strategies (Parul, C. Vikas. 2015). The most preferred learning was reflector followed by theorist; pragmatist and activist preferred learning style. It focussed that nursing students prefer to range between different learning styles.

A research study conducted by (Aina-popoola S, Hendricks CS 2012) also admire that divergers are most preferred learning styles followed by assimilators, accommodators and convergers among first year undergraduate nursing and midwifery university students.

Implications

Nursing Education

Nursing educator on the institutional level need to recognize the variations among college teaching techniques. Nursing students getting aware about their own learning style preference would inculcate better thinkers, hassle-solvers, lifelong newbie’s and skilful in peer and self-assessment. It also helps them to collect skills that aid expert improvement. Educators need to design lectures around a trouble-fixing model or discussion method version and lead the class via the invention method after applying appropriate learning styles.

Nursing Administration

Administrators also can form a climate of utilization of most newly research pertaining of learning styles and teaching methods as it helps tutors/educators in understanding the learning styles. Nursing administrators can provide in-service training programme for the nurse educators on assessing desired studying varieties of nursing college students and also inspire them to apply teaching getting to know techniques consistent with their preferred gaining knowledge of styles that suitable to the unique learner.

Strengths and Limitations

The strengths of the study were that it was conducted in two different nursing colleges and the response rate was high. Almost all the students were included besides who were not present at the time of data collection. As with the strengths, the study lacked few points as the sample size was quite small due to time constraints. A similar design can be govern on large sample. It would be a great breakthrough in understanding the learning styles among nursing students.

Conclusion

In the nutshell, the nursing students possessed different preferred learning styles. It depicts the preference of nursing students varied and not all of them pan out in one learning style only. This emerged as an immense need to inculcate teaching learning strategies that are formulated according to preferred learning styles.

Hepatitis-B Screening among Health Care Worker – a Cross Sectional Study

Praf ul Damor¹, Siddaram Sarate²
¹M.Sc Nursing, Manikaka Topawala Institute of Nursing, CHARUSAT, Gujarat, ²Assistant Professor and HOD, Community Health Nursing, Manikaka Topawala Institute of Nursing, Charusat, Gujarat

Abstract

Introduction and Background: Hepatitis B virus (HBV) is known to be an infectious disease affecting the liver and transmitted through contaminated blood and body fluids. It also poses a huge danger to patients. Health employees are more likely to become infected as a result of interaction with infected patients. It begins with individuals coming into contact with someone who has been infected with a hep-b infection with contaminated blood, exposed, wounds, or body fluids. Hepatitis B infection is typically a self-limiting disease characterized by acute inflammation and hepatocellular necrosis, with a 0.5-1 percent case-fatality rate and a higher rate among health care workers than among the general population.

Objective: The objective of the study is to detect infection of Hepatitis-B among healthcare workers.

Methodology: In the analysis, the design of non-experimental cross-sectional research was used. A total of 100 samples were obtained from the chosen hospital using a convenient non-probability sampling technique. Rapid kit (I-care for HBsAg Rapid Screen Test) was performed among health care workers for the identification of hepatitis B.

Result: Descriptive and inferential statistics were used to interpret the results. The study showed that 5(5%) participants were tested positive for hepatitis B. Chi Square used to find association between attribute variables and hepatitis B infection. There was significance difference found among blood transfusion ($\chi^2=0.718$, p<.000), tattooing on body ($\chi^2=10.809$, p < .004), history of hepatitis –B infection in family ($\chi^2=33.518$, p <.000) at 0.05 level of significance.

Conclusion: The risk of infection with hepatitis B is higher among healthcare staff. While it decreases the risk of infection with the use of hep-B vaccine, there is still considerable potential for change, as many healthcare staff remain unvaccinated. There is also a need for well-planned and consistent HBV screening and vaccination policies for healthcare staff, especially those at higher risk of exposure to blood or other potentially infectious materials.

Keywords: Hepatitis –B, health care worker, detection.

Introduction

Hepatitis B is a significant and growing problem for public health. Hep-B virus is transmitted via the blood, sperm, or other sources of human body fluid to an infected person. It is not spread by sneezing or coughing or sharing needles through sexual contact. HBV spread very rapidly by needles and syringes contaminated with tainted blood. An individual is at increased risk for viral hepatitis through intravenous drug sharing.¹

Viral hepatitis caused 1.45 million deaths worldwide in 2013, reflecting a 63% increase in the mortality burden between 1990 and 2013.² Hepatitis (HBV) is estimated to affect at least 257 million people worldwide and 27 million people living with multiple hepatitis B virus infection (WHO 2016), an estimated 887,000 deaths (WHO 2015). There are 56.6 million people...
(WHO 2016) affected by hepatitis in India.

In India, 40 million people are chronically contaminated with hep-B and between 6 and 12 million people are chronically contaminated with hep-C, according to current estimates. HEV is the most important factor in the spread of viral hepatitis, while hep-B is more common among young children. Most cases reported as acute liver failure are due to hep-B. [4]

Healthcare workers (HCWs) who are often in contact with blood and other body fluids are at greater risk of developing blood-borne infections such as HBV, HIV and hepatitis C infections during their work. Approximately two million HCWs are observed worldwide and approximately 70,000 are getting infected with HBV virus per year. As per WHO global disease burden has shown that 37 per cent of HBV between HCWs is due to serious injuries from occupational experience. More than 90% of this contamination occurs in developing countries. [5]

Preventive hep B obstruction vaccination is common in many countries for clinical workers, but is still not used in a variety of low asset environments. Weak resistance reactions to HBV immunization due to, for example, current viral infections or diabetes have been documented. Therefore, in addition to the compulsory immunization of HCWs, the WHO plans to research immune responses to the vaccine. [6]

In this study, researcher aims to detect hepatitis-B amid health care workers working in selected hospitals.

**Material and Methods**

The cross-section design with a quantitative approach has been used. A total of 100 health care staff between the ages of 18 and 58 were drawn from hospital settings. Data was collected by means of a fast kit and a socio-demographic Performa. Blood samples obtained by means of a syringe and precautions were taken during the process to ensure protection. The reliability of the instrument was tested through a calibration review in the hospital.

The duration of the analysis had been 30 days. Descriptive statistics such as frequency distribution, standard deviations and inferential statistics such as the chi-square test were used to interpret the data, and the purpose of the analysis was clarified to ensure better cooperation during the data collection process.

**Tool for data collection**

- Socio demographic and attribute variable.
- Rapid test kit used to detection of hepatitis-B among health care worker

  - The selection of the sample from the sample population is carried out by syringe and needle and the HBsAg Rapid Test is a direct binding test for the visual detection of hepatitis B surface antigen (HBsAg) in serum, plasma and whole blood.
  - The sample is collected in red tube (vacutioner) blood is collected from the participants and store in cold chain at temperature (between+2 to +8 degree) until the time it is used.

**Study participants and size:** Sample size determine by power analysis calculated based on previous studies.

\[
N = \frac{4pq}{L^2}
\]

Where \( p = 0.087 \), \( q = 0.913 \), \( L = 0.017 \)

\[
= \frac{4 \times 0.087 \times 0.913}{0.017 \times 0.017} = \frac{0.317}{0.000289} = 1097
\]

Calculation sample size for this study was 1097, due to time constraint and global pandemic situation investigator consider 100 participants for the study.

**Ethical Clearance:** Permission was gained from CHARUSAT Institutional Ethical Committee, Charotar University of Science and Technology, Gujarat, India
Result

Table 1 shows Data on detection of Hepatitis B infection among health-care-worker

- The data was analysed by using descriptive and inferential statistics such as Chi-square were used.

</table>
Table2 suggests that there was significance difference found with this attribute variable such as blood transfusion ($\chi^2 = 0.718, p < .000$), (χ$^2$=10.809, p < .004), history of hepatitis B infection in family ($\chi^2=33.518$, p <.000) at 0.05 level of significance. There was no any significance noted in the other demographic variable.

Conclusion

This research was performed only on 100 samples (health care worker). Thus 5(5 per cent) participants were tested positive for hepatitis B. Significant difference was found between attribute variables such as blood transfusion ($\chi^2=0.718$, p<.000), body tattooing ($\chi^2=10.809$, p<.004), history of hepatitis B infection in the family ($\chi^2=33.518$, p<.000) at 0.05 level of significance.

Effect of Air Pollution on Health of Community People–A Descriptive Approach

Praful Damor¹, Abhay Pattan², AmbilyV.Vijayakumar³
¹Lecturer, Community Health Nursing Parul Institute of Nursing, Limda, Wagodia Gujarat, ²Assistant Professor and HOD,Community Health Nursing, Parul Institute of Nursing, Charusat, Gujarat, ³Lecturer, Community Health Nursing, Parul Institute of Nursing Waghodia, Gujarat

Abstract

Background: Air pollution is a global and one of the serious environmental hazards because it causes lot of damage to living and non-living things in the environment. Air pollution is a problem which emitted various gases in the air because of burning of wood etc. Air pollution cause not so serious in the past as it is now because of growing population, rapid industrialization, use of automobiles, modern agricultural activities etc.¹

Objectives:

1. To assess the knowledge regarding effects of air pollution on health among community people Gujarat.
2. To assess the attitude regarding effects of air pollution on health among community people in central Gujarat
3. To find out the association between knowledge score regarding effects of air pollution on health with selected socio demographic variables.

Methodology: A quantitative research approach at survey design was adopted to conduct the study at central part of Gujarat. Sample comprised of 60 community people. Sample was selected by convenience sampling technique. The data obtained was analyzed and interpreted in terms of the objectives of the study. A structured questionnaire was used to assess the knowledge and likert scale was used to assess the attitude on effects of air pollution on health among community people.

Result: The findings of the study show that 53% female and 47% male samples, highest percentage 91% are belongs to hindu,1% muslim,3% Cristian,4% are others, majority of people were age group of 26-35years(33%),15-25years(20%),36-45 years (20%),above 45 years (26.6%),43% people received up to secondary level education,91% people are Hindu, 71% people are self-employed, 18.3% people are living in nuclear family,45% people having less than 5000rs income,70% people living in pakka housing,56.6% get knowledge regarding effects of air pollution on health from T.V . 2. The score of the study is mean (16.1) and standard deviation is (3.46).

Conclusion: Overall knowledge and attitude about the effects of air pollution on health was average which suggested that people having average knowledge regarding effects of air pollution Group.

Keywords: Air pollution, health, descriptive approach

Introduction

The term air pollution can be referred when there is an excess of foreign matter in the air. That can be harm full to the man and his environment, the phenomenon called “pollution” is an inescapable consequence of the presence of man and his activity. the term “air pollution” signifies the presence in the ambient (surrounding) atmosphere of substances (e.g.: gases, mixtures of gases
an particulate matter) generated by the activities of man in concentration that interfere with human health, safety or comfort, or injurious to vegetation and animals another environmental media resulting in chemicals entering the food chain or being present in drinking water and there by constituting additional source of human exposure. The direct effect of air pollutants on plants, animals, and soil can influence the structure and function of eco system, including self-regulation ability, there by affecting the quality of life.3

Pollution is the contaminants into an environment that causes instability, disorder, harm or discomfort to the ecosystem i.e. physical systems or living organisms. Pollution can take the form of chemical substances, or energy, such as noise, heat, or light energy. Pollutants, the elements of pollution, can be foreign substances or energies, or naturally occurring; when naturally occurring, they are considered contaminants when they exceed natural levels. Pollution is often classed as point source or nonpoint source pollution.4 Air pollution is a significant risk factor for a number of pollution-related diseases and health conditions including respiratory infections, heart disease, and COPD, stroke and lung cancer.5

The health effects caused by air pollution may include difficulty in breathing, wheezing, coughing, asthma and worsening of existing respiratory and cardiac conditions. These effects can result in increased medication use, increased doctor or emergency room visits, more hospital admissions and premature death.
The human health effects of poor air quality are far reaching, but principally affect the body’s respiratory system and the cardiovascular system. Individual reactions to air pollutants depend on the type of pollutant a person is exposed to, the degree of exposure, and the individual’s health status and genetics. The most common sources of air pollution include particulates, ozone, nitrogen dioxide, and sulphur dioxide. Children aged less than five years that live in developing countries are the most vulnerable population in terms of total deaths attributable to indoor and outdoor air pollution.

Material and Methods
Researcher overall plan for obtaining answers to research questions or for testing the research statement is referred as the research design.A descriptive design was adopted for the study. In this study the base measure was structured questionnaire method was used to assess the knowledge of the people of the age group between 15 to 45 years.

Tool for data collection
· Socio demographic and attribute variable.
· The researcher obtained written permission from the consent authority of prior of data collection. Data collection date was heldon. The purpose of study was explained to the samples and written informed consent was obtained. Their response was assessing the status of air pollution.

· Individual explanation was given regarding structured Knowledge questionnaires to assess the knowledge regarding effects of air pollution on health.Knowledge test was checked. The average time taken 60 minutes. All people gave good cooperation during data, investigation, analyzed the data and made findings.

Study participants and size: Sample size determine by power analysis calculated based on previous studies.
N = \frac{4pq}{L^2}

Where \( p = 0.087 \)
\( q = 0.913 \)
\( L = 0.017 \)

\[
= \frac{4 \times 0.087 \times 0.913}{0.017 \times 0.017} = 0.317 = 1097
\]

Calculation sample size for this study was 1097, due to time constraint and global pandemic situation investigator consider 64 participants for the study.

SECTION-3: Findings related to association between the knowledge score with demographic variables.

For the age calculated chi square ($x^2$) 1.255 was less than the tabulated value of chi square ($x^2$) 7.82 at the 3 degree of freedom at 0.05 level of significance there for, there was no significant association for the knowledge score among the samples.

For the sex the calculated chi square ($x^2$) 4.218 was less than the tabulated value of chi square ($x^2$) 3.84 at the 1 degree of freedom at 0.05 level of significant there for was significant association for the knowledge score among the samples.

For the education the calculated chi square ($x^2$) 0.426
was less than tabulated value of chisquare \( x^2 \) 7.82 at the 3 degree of freedom at 0.05 level of significant there for, there was no significant association for the knowledge score among the samples.

For the religion the calculated chisquare \( x^2 \) 10.874 was less than tabulated value of chisquare \( x^2 \) 7.82 at the 3 degree of freedom at 0.05 level of significant there for, there was significant association for the knowledge score among the samples.

For the occupation the calculated chi square \( x^2 \) 5.442 was less than tabulated value of chi square \( x^2 \) 7.82 at the 3 degree of freedom at 0.05 level of significant there for, there was no significant association for the knowledge score among the samples.

For the type of house the calculated chisquare \( x^2 \) 3.907 was less than tabulated value of chisquare \( x^2 \) 7.82 at the 3 degree of freedom at 0.05 level of significant there for, there was no significant association for the knowledge score among the samples.

For the family income the calculated chi square \( x^2 \) 3.603 was more than tabulated value of chi square \( x^2 \) 7.82 at 3 degree of freedom at the level of significant there for, there was significant association for the knowledge score among.

For the type of house the calculated chisquare \( x^2 \) 3.535 was less than tabulated value of chisquare \( x^2 \) 7.82 at the 2 degree of freedom at 0.05 level of significant there for, there was no significant association for the knowledge score among the samples.

For the previous information the calculated chi square \( x^2 \) 1.740 was less than tabulated value of chi square \( x^2 \) 7.82 at the 3 degree of freedom at 0.05 level of significant there for, there was no significant association for the knowledge score among the samples.

**Conclusion**

The present studies assess the knowledge and attitude regarding effects of air pollution on health among the community people, on the basis of the study the following conclusion were made: the air pollution among the community people are high rather than other residing people.

And they are getting more respiratory problems due to the air pollution.

Risk Factors of Stunting in Children Aged 6-59 Months: A Case-Control Study in Horticulture Area

Prayudhy Yushananta¹, Mei Ahyanti¹, Yetti Anggraini¹
¹Assistant Professor, Tanjungkarang Health Polytechnic

Abstract

Background. Stunting is a critical public health problem in Indonesia because it affects cognitive and physical development and contributes to child mortality. This study aims to identify risk factors for stunting in children aged 6-59 in the horticultural area. Methods. A case-control study was conducted to compare previous exposure between stunted children and non-stunted children. Measurements and interviews were conducted with 160 participants (120 controls and 40 cases), including mothers or caregivers. SPSS was used for X² statistical analysis, multiple logistic regression, and odds ratios. Results. The study identified four risk factors for stunting: children who were born short (AOR = 17.57; 95% CI: 5.02-61.51), LBW (AOR = 4.35; 95% CI: 1.38-13, 78), and got a low protein intake (AOR = 4.96; 95% CI: 1.22-20.26). Significantly, a relationship between stunting and access to sanitation was also found (AOR = 6.06; 95% CI: 1.25-29.35). Conclusion. The risk factors for stunting in children aged 6-59 are related to nutrition during pregnancy and the child’s quality of food. Nutrition interventions should emphasize improving the nutritional status of pregnant women and children and women empowering to affect access to resources and allocations for children’s nutrition.

Keyword: Stunting, birth length, LBW, horticulture, under-five

Introduction

Malnutrition is a critical public health problem for children under five in developing countries, including Indonesia. Malnutrition is due to many interrelated factors and has detrimental health effects in the short and long term 1,2. Malnutrition will affect children’s cognitive and physical development, increase the risk of infection, and significantly contribute to child morbidity and mortality 3-6. The high indicators of malnutrition in a country reflect children’s low nutritional status and health under five 2,7. Three extensively recognized indicators of children’s nutritional status are stunting, wasting, and underweight, and stunting indicates chronic malnutrition form 1,2,6,8-11. A stunted child if their height for age is more than two standard deviations below the median of the World Health Organization (WHO) 2005 2,12.

Stunting is the best measure of malnutrition in childhood, a predictor for long-term morbidity and mortality, and long-term societal costs 13. Children who suffer from stunting will grow into adults at risk of obesity, glucose tolerance, coronary heart disease, hypertension, osteoporosis, decreased performance, and productivity 2,5,6,10,11,13,14.

Globally, in 2025, malnutrition contributes to at least half of all deaths each year in children under five 7,13,15. In 2025, estimating 127 million will be stunted 16. Prevalence was greater in developing countries, especially in South Asia and Africa 15-17. In Indonesia, the stunting prevalence was 30.8%, consisting of 11.5% very short and 19.3% short.
Many factors are associated with stunting. Several studies reported socioeconomic inequality, geographic differences, practices of feeding, food insecurity, education, and childhood morbidity, infection, and environmental 3–6,11. Stunting is also associated with micronutrient deficiencies, such as protein, iron, zinc, calcium, and vitamins D, A, and C 15. There are limited research reports on risk factors for stunting, especially in horticultural farming areas. In the study area (Liwa City), the risk factors for stunting in children aged 24-59 months have not been studied. It is crucial to identify risk factors for stunting to overcome the problem of stunting and its consequences. The study aimed to identified risk factors for stunting among children under five in horticultural farming areas.

Methods

A case-control study was conducted in Liwa City, West Lampung Regency, to compare previous exposures between stunted children (cases) and non-stunting (controls). This research was conducted after obtaining approval from the Health Research Ethics Committee, Tanjungkarang Health Polytechnic(No.261/KEPK-TJK/V/2020). Guided by the Helsinki protocol, informed consent was taken, and data handling was confidential. No risk of harm would be to the participants, and participants have the right to withdraw during the study. All study procedures were described before the interview.

The study was conducted from July to August 2020. Children aged 6-59 months with a mother or caregiver who lived for at least six months in the study area were included. Children without mothers or caregivers, children who appeared to have physical disabilities, children whose exact age was unknown were excluded from the study. Controls selected from the case’s nearby neighbor who was of the same age. If multiple controls are found, they are randomly selected. The exposure considered was parenting (32.9%). Assuming 95% CI, 90% power, control to case ratio 3:1, the total sample size is 160 (120 controls dan 40 cases).

Data were collected from measurements and interviews using a questionnaire. Data were entered into SPSS (24.0) after checked for completeness, edited, coded. The analysis used the Chi-square, Crude OR, and Multiple Logistic Regression analysis.

## Results

A total of 160 (120 controls and 40 cases) children aged 6-59 months and their mothers or caregivers participated in the study. Nobody dropped out during the study period, so the participation rate was 100%. The number of samples was boys and girls almost equal (Table 1), and most were in the 6-23 month age group (73.13%). The majority of mothers or caregivers have completed junior high school (71.25%), they do not work (60.0%), and the family income is low (81.25%).

Although the majority was normal (Table 2), we found about 19 (47.5%) of children in the case group and 4 (3.3%) in the control group were born stunted. There were also 13 (32.5%) children in the case group and 9 (7.5%) in the control group born with low birth weight. Complete immunization was obtained by about 36 (90.0%) children in the case group and 92 (76.7%) in the control group. Almost all (90.63%) children in the case and control groups received adequate protein intake. However, around 24 (60%) in the case group and 59 (49.2%) lacked parenting.

Only 4 of the 12 variables associated with stunting (p <0.05) were shown from multiple logistic regression analysis (Table 4). Interaction tests were also carried out, but none of them showed interactions between variables. The fit model is shown by the Homers and Lemeshow test obtained (p-value = 0.253).

The proportion of children born shortly was significantly higher in the case group than in the control group. Low birth length (boy less than 46.1 cm, and girl less than 45.6 cm) was found to be a risk factor for stunting (adjusted odds ratio (AOR) = 17.57; 95% confident interval (CI): 5.02-61.51). Birth weight less than 2500 grams was also a risk factor for stunting (AOR = 4.35; 95% CI: 1.38-13.78). The proportion of children with low protein intake was higher in the case group than in the control group (AOR = 4.96; 95% CI: 1.22-20.26). We also found a statistically significant relationship between house access to sanitation and stunting (AOR = 6.06; 95% CI: 1.25-29.35). This study found that the dominant variable related to stunting was the low birth length.

Discussion

Of all the factors studied, the length of birth showed the dominant risk factor for stunting in horticulture farming areas. The results confirm Islam, that low birth length and LBW are relationships with stunting. Birth length is associated with low maternal nutritional intake during pregnancy, which is influenced by low family economic status and food insecurity in the family.

Food insecurity in the family results in a decrease in the variety and the nutritional value of food consumed. It will sustainably affect the family’s nutritional status, including child development. In pregnant women, which impacts stunted babies’ birth, Access and availability of food for the poor combine poverty problems, lack of permanent jobs, low and irregular cash income, and limited purchasing power, and closely related to low education levels.

In addition to impaired motor and verbal development, an increase in degenerative diseases, morbidity, and mortality, a further concern of stunting is the disruption of cognitive development. Most child early malnutrition did not finish high school and work as manual laborers. Impaired cognitive development and learning achievement will reduce work productivity to hinder economic growth, increase poverty, and widen inequality in a country.

Multivariate analysis showed that four variables were significantly associated with the incidence of stunting. If related to the child’s life span, it has caused the mother’s nutritional status during pregnancy. These
results explain the concept of stunting in the first 1000 days of life. The role of mothers is critical in facilitating interventions through strengthening their nutritional status during pregnancy and breastfeeding.

Malnutrition in pregnancy results from a low average intake of protein, fat, total energy, and often insufficient micronutrients such as folate, Fe, Ca, and Zn. Malnutrition in pregnant women affects disruption of intra-uterine growth due to LBW, stuntedness, perinatal mortality. Linear growth failure is mostly caused in the intra-uterine period due to an inadequate diet.

Malnutrition in pregnancy is detected from anemia. Anemia is a condition characterized by an abnormal decrease in the total mass of red blood cells caused by blood loss due to acute or chronic bleeding, destruction of red blood cells, and insufficient red blood cell production. Anemia is a risk for pregnant women in agricultural areas due to the chronic impact of pesticide exposure. Sanitation access is associated with increased exposure to microbes and infectious diseases, especially diarrhea. Fecal-oral pathways are water, food, vectors, and vectors.

Control with a nutrition approach for the first 1,000 days by promoting healthy behaviors, breastfeeding, nutrition during pregnancy includes micronutrient supplementation, breastfeeding, and disease prevention will reducing child malnutrition, especially chronic malnutrition in the form of stunting. Nutrition sensitive interventions must also highlight a fundamentally important factor that indirectly impacts mothers’ and children’s nutrition, namely women’s empowerment. Empowerment of women is a process of improving women’s institutions and status, affecting household access to resources, including allocations for children’s health and nutrition.

**Conclusion**

This study found four factors associated with stunting among children aged 6 to 59 months in horticulture farming areas, length at birth, LBW, protein intake, and access sanitation. Of the four variables, it indicates malnutritional during pregnancy. Therefore, it needs intervention and nutrition programs for pregnant women, including micronutrient supplementation and fortification. It also empowers women in the family to affect household access to resources, including allocations for children’s health and nutrition.

A Prospective Study of Burn Deaths with Special Reference to Manner of Death and Duration of Survival

Priyamvada Kurveti Verma¹, Rajendra Kumar Morya², Dheeraj Singh Verma³

¹Associate Professor, ²Ex-Resident, ³Demonstrator; Department of Forensic Medicine and Toxicology, Gandhi Medical College, Bhopal, Madhya Pradesh, Presently ²Assistant Professor, Department of Forensic Medicine and Toxicology, Government Medical College, Shivpuri, Madhya Pradesh

Abstract

Around 0.2 million people are admitted in hospital due to burns, of which about 5000 people die every year. Extent of Total Body Surface Area involved is an important parameter, that affects the prognosis in case of burn injury. The majority of fire related deaths are accidental, usually due to carelessness. Suicidal burns are mostly seen in domestic situations and in females. Homicidal burns are rare; mostly accomplished to take revenge or to conceal crime. So, this study was carried out with the aim to estimate the total body surface area affected & duration of survival / hospital stay and to find out the manner of death in burn cases.

It was found that 79.00% cases had burn injuries covering 60–100% of the total body surface area (TBSA). Maximum percentage of burns was seen in females (30.00% cases) with TBSA of 80-90%. 95% cases were hospitalized with 75.00% having the hospitalization period of 1 – 10 days and maximum number of cases (33%) survived for a period of 3 to 5 days. In most of the cases (64.00%), the manner of death was accidental followed by suicidal (34.00%), with only 2% cases of homicidal burns.

Keywords: burn deaths, manner of death, total body surface area, duration of survival.

Introduction

Burns are a serious health problem having physical, emotional and psychological impact on sufferers. More than 20 lakhs people sustain burn injuries, nationwide every year. Nearly, 0.5 million people were treated as outdoor patients. Around 0.2 million people are admitted in hospital, of which about 5000 people die every year. Extent of Total Body Surface Area involved is most important parameter that affects the prognosis in case of burn injury. There is marked fluid loss resulting in shock, in case more than 20 per cent of the body is affected and usually more than 50 per cent is fatal. Generally speaking, involvement of about one-third (33%) of total body surface area has grave prognosis and about 50% involvement of total body surface area is expected to be fatal in present Indian circumstances. However, with recent advances in modalities of treatment, prognosis is expected to improve the prognosis of injury.

Deaths from burns are usually accidental but may be of suicidal or homicidal origin. The majority of fire related deaths are accidental and there is typically abundant collateral evidence, from police and fire brigade investigations, to exclude suicide or homicide. These deaths are usually the result of carelessness, in allowing clothing to brush against fires, in manipulating matches or other lighted objects such as cigarettes, maintaining faulty electrical and heating appliances, as well as being unable to effectively combat or escape a fire.

Alcoholics and other individuals under the influence of drink or drugs are at risk. Occasionally a natural
disease such as epilepsy or a myocardial infarction may cause the victim to collapse onto a heater, starting a fire; the same natural disease may explain failure to escape the fire.\textsuperscript{13}

Suicide by burns is mostly seen in domestic situations like bedroom, bathroom or kitchen. Self immolation as protest against some social injustice is also common. It is common in females especially amongst newlyweds because of marital disputes and inflammable material being very much in reach. Generally fuel is poured on head and it reaches other part of body tricking downwards. Hence, the body catches fire all at a time. Smell of fuel will be present particularly in scalp hairs and clothing worn at the time of incidence. Soles may be spared, but the percentage of area involved is generally more than 60%.

Homicidal burns are relatively rare and seen in cases where paraffin or some other inflammable material is thrown over victim and his/her clothing then set alight\textsuperscript{14}. It is not unusual for murderer to try to dispose off the body of the victim by fire to conceal crime. At times, some people may cause burn injuries on a dead body and then produce it before the police to support a false charge of murder against his adversary. In both the cases, care should be taken to distinguish between ante mortem and postmortem burns to show that the victim was or was not alive at the time of fire.\textsuperscript{8}

Hence, this autopsy based cross sectional study was planned with the aim to estimate the total body surface area affected & duration of survival / hospital stay and to find out the manner of death in burn cases.

**Material and Methods**

This prospective study was conducted in the Department of Forensic Medicine and Toxicology, at Gandhi Medical College & Hamidia Hospital, Bhopal for a period of 1.6 years. Cases of burns either admitted or directly brought dead to the institute, cases with proper hospital records and cases of spot death due to burns were included. Out of all those, 100 cases were selected by simple random sampling, for the study.

Detailed information regarding the demographic profile of the cases, date, time and place of incidence, duration of hospital stay, cause and manner of death was gathered using a questionnaire; from the case dairies of police that included the inquest papers and dying declaration of deceased, hospital records, autopsy reports and history given by relatives and police accompanying the body.

To estimate the extent of body surface area affected by burns, \textbf{Rule of Nines}\textsuperscript{15} given by Alexander Wallace (Fig. 1A)\textsuperscript{15} was applied; the body being divided into different areas, each representing nine per cent. Head including face and neck 9%, Chest, front & Back each 9%, Abdomen, front & Back each 9%, Upper limbs, Right & Left each 9%, Lower limbs, right & Left each 18%, External genitalia 01%, Total = 100%. For children (less than 15 years of age) and Infants, \textbf{Lund and Browder chart}\textsuperscript{9} was used (Fig. 1B).\textsuperscript{9}
Results And Discussion

On analyzing the collected data, following observations were made:

Figure-1 depicts Estimation of total body surface area in Adults and Children (A- Rule of Nine and B- Lund and Browder)⁹,¹⁵

I. Distribution of cases according to Total Body Surface Area (TBSA) affected by Burns

Graph-1: Distribution of cases according to Total Body Surface Area affected by Burns
In the present study, majority i.e. 79 (79.00%) cases, had burn injuries covering 60– 100% of the total body surface area (TBSA). Maximum percentage of burns was seen in females i.e. 30 (30.00%) cases with 80-90% TBSA; as compared to males where 20 (20.00%) cases with 50-70 % TBSA were seen. TBSA of 35% (minimum in this study) was seen in males and 100% TBSA seen in females.

This observation was somewhat similar to the study of Harish D et al (2013)\(^7\) where 22% (85) victims had 61- 70% TBSA, followed by 71- 80% TBSA in 17% (64) cases i.e. majority of the victims (about 40%) had burn injuries covering 61– 80% of the total body surface area. Memchoubi and H. Nabachandra (2007)\(^12\) observed that in 73.84% cases, >80% body surface area was involved. Mazumder A and Patowary A (2013)\(^11\) observed in most of the victims the burn injury covers 90-100% of the total body surface area followed closely by 50-60% of the total body surface area involvement.

Chawla R et al (2011)\(^4\) found that in males, maximum 10% cases suffered burns to the extent of 0-50%, followed by 8% to the extent of 81-90% TBSA. In females, maximum 26% cases fell in the category of 91-100% of TBSA. Gowri S et al (2012)\(^6\) reported that 39% of males with total burn surface area <19% whereas in 40% females, total burn surface area was >61%.

Chaudhary BL et al (2013)\(^3\) in their study reported that 96 (46.37%) cases had total body surface area of burn between 90 to 100% followed by 80-90% in 29 (14.00%) cases. Buchade D et al (2011)\(^2\) observed that 51 to 75% burns found in133 (56.12%) cases. Mangal HM et al (2007)\(^10\) noted that 232 cases (77.33 %) had >50 % of body surface area, while in 48 cases (16 %) 40-50 % body surface area was burnt and in only 20 cases (6.67%) the involved body surface area was <40%.

### II. Distribution of cases in accordance with Duration of Hospitalization (Survival)

95 cases were hospitalized (95%), two cases were of spot death and 3 cases were declared brought dead at casualty. Majority i.e. 75 (75.00%) cases had the hospitalization period of 1 – 10 days. 11 (11.00%) cases succumbed to death in less than 24 hours. Maximum duration of hospitalization after sustaining burns was 45 days.
Harish D et al (2013)\(^7\) made similar observation that majority of patients i.e. 102 (24%) surviving for more than a week before succumbing to the death and 31 (8%) cases died within the 1\(^{st}\) 24 hours of sustaining burn injuries. Chaudhary BL et al (2013)\(^3\) observed in their study that 150 (72.46%) cases of burns died in hospital after admission during course of treatment while 57 (27.53%) cases died on the spot and declared brought dead in hospital. In 42 cases (20.28%) period of survival after sustaining burn injury was between 7 to 15 days followed by 39 (18.84%) cases where survival period was 3 to 7 days. The maximum period of survival was 59 days in a single case.

On the contrary, Memchoubi and H. Nabachandra (2007)\(^12\) in their study observed that 49.23% victims died within an hour of sustaining burns whereas 21.53% cases survived for more than 1 week. Chawla R et al (2011)\(^4\) reported that 40% cases died within few minutes to 24 hours of sustaining burns, 24% cases died within a week and 20% cases died within 2 weeks. 12% cases died within 3 weeks and beyond.

### III. Distribution of cases on the basis of Manner of Infliction of burns

![Graph-2: Distribution of cases on the basis of Manner of Infliction of burns](image)

On the basis of history, police investigations and postmortem findings, it was observed that in most of the cases i.e. 64 cases (64.00%), the manner of death was accidental, followed by suicidal in 34 cases (34.00%). Out of 34 suicidal cases, 33 (97.00%) cases had alleged history of pouring of kerosene and then setting fire. Homicidal burns were seen in 2 cases, who were newly married females.

This finding of the present study is similar to Chaudhary BL et al (2013)\(^3\) who observed accidental burns in 72.94% cases, followed by suicidal in 17.39% and homicidal in 9.66% cases. Buchade D et al (2011)\(^2\), also found that most common manner of the burn was accidental in 147 (62.02%) cases, followed by suicidal in 62 (26.16%) and homicidal in 28 (11.82%) cases. Mangal HM et al (2007)\(^10\) conducted their study on 300 cases and observed that in most of the burn victims, the manner of death was accidental in 183 cases (61%), followed by suicidal in 105 cases (35%) and homicidal in only 12 (4%) cases. Similar observations were made by Das KC (1998)\(^5\) and Bangal RS (1995)\(^1\).
It is very difficult to state that a burn injury is accidental or suicidal or homicidal in nature, until and unless an eye witness is there. At times, the only way to prove homicidal nature is the Dying Declaration, which is very difficult to obtain either due to unconsciousness of victim, negligence or lack of knowledge on the part of the police. The higher number of accidental deaths especially in females may be due to their involvement in domestic cooking work responsible for accidental cases; and suicidal incidents might be because of marital mal-adjustment resulting in suicidal or bride burning cases owing to dowry disputes.

**Conclusion**

From the present study, it is evident that maximum number of cases (79.00%), had burn injuries covering 60–100% of the total body surface area (TBSA), with TBSA of 80-90% seen predominantly in females. 75.00% cases had the hospitalization period of 1 – 10 days. 11.00% cases succumbed to death in less than 24 hours. Maximum duration of hospitalization after sustaining burns was 45 days. The manner of death was accidental in majority (64.00%), followed by suicidal (34.00%) and least numbers were homicidal (2%).

Similarly, Harish D et al (2013)\(^7\), Memchoubi and H. Nabachandra (2007)\(^12\), Mazumder A and Patowary A (2013)\(^11\) in their study also reported TBSA of more than 60% in maximum cases. Chawla R et al (2011)\(^4\) and Gowri S et al (2012)\(^6\) also observed maximum % TBSA in females. Chaudhary BL et al (2013)\(^17\) also noted survival/ hospitalization period of 7-15 days in majority of the cases, quite similar to the present study. Buchade D et al (2011)\(^2\), Mangal HM et al (2007)\(^10\), Das KC (1996)\(^3\) and Bangal RS (1995)\(^1\) in their respective studies, also found accidental burns to be the most common manner of death.

With advanced burn care, survival rate in patients less than 60% TBSA of burns and without any significant comorbidities, have improved up to a great extent. But still there’s a long way to go to achieve the targets. Educating masses regarding safety precautions to be taken while handling fire; and counseling by experts to control the in- built aggression in individuals and to inculcate awareness; is the need of the hour.

Knowledge of Oral and Dental Health Impacts the Oral Hygiene Index Simplified (OHI-S) of Primary School Children

Pudentiana Rr RE¹, Tedi Purnama¹, Emini¹, Siti Nurbayani Tauchid¹, Neni Prihatiningsih²

¹Lecturer, Departement of Dental Health Ministry of Health Polytechnic Jakarta I, Indonesia,
²Dental Therapist of Agidental Clinic Modrland Tangerang City, Indonesia

Abstract

Primary school children are a vulnerable group to oral and dental diseases. Less of knowledge on dental health will lead to bad dental and oral hygiene status resulting in debris and calculus. The OHI-S is an ideal dental and oral hygiene check tool for assessing the oral hygiene of primary school children. This study aims to analyze the relationship of knowledge of dental and oral health to Oral Hygiene Index Simplified in elementary school children. Method: this type of analytic observational study with cross sectional design. The research was conducted on the research carried out in class III students of SDN Perigi 03 Pondok Aren, South Tangerang City. Data collection with a questionnaire on dental health knowledge and Oral Hygiene Index Simplified. Data analysis using Chi-Square. Result: Knowledge of oral health to Oral Hygiene Index Simplified indicates that the p-value 0.023 (p < 0.05). Conclusion: there is a significant relationship between knowledge of dental and oral health to Oral Hygiene Index Simplified in primary school children.

Keywords: Knowledge, oral health, oral hygiene index simplified

Introduction

Oral and dental health is a part of body health that cannot be separated from one another because oral health will affect the health of the body. Maintenance of oral hygiene is an effort to improve oral health. The role of the oral cavity is very large for human health and well-being. In general, a person is said to be healthy, not only in a healthy body but also in the oral cavity and teeth. Therefore, oral health plays a very important role in supporting the health of one’s body. Dental and oral health issues are an important concern in health development, one of which is the vulnerability of school-age children to dental health problems.¹–⁵

Several studies in Indonesia prove that the dental and oral hygiene status of elementary school children is in the poor category. Among them, Alhamdaet al proved that the dental and oral hygiene status of students in the 12-year-old SDN Bukittinggi City was included in the medium category with an OHI-S average of 1.52; Research by Mawuntu et al proved the OHI-S index in St. Catholic Elementary School children Agustinus Kawangkoan 60% medium category.⁶,⁷

In other countries it also shows that the dental and oral hygiene status of elementary school children is in the moderate category. This is evidenced Denloye cit. Yohanes et al in Nigeria on children aged 13-15 years as outlined in his journals proved that the Debris Index (DI) was 1.57 and the Calculus Index (CI) was 1.48 with an average Oral Hygiene Index Status (OHI-S), for men reaching 3.09 and for women reaching 2.94 which is classified as mild to moderate.⁸ From the research above, it can be concluded in Indonesia and in the world, it shows that school-age children maintain their oral health and have poor oral hygiene status.

One of the main factors affecting oral and dental hygiene is behavior. Behavior that can influence the
development of caries is about how to maintain healthy teeth and mouth and behavior is strongly influenced by knowledge. Behavior based on correct knowledge will last longer than behavior without knowledge, including knowledge about how to maintain proper dental health will greatly affect the incidence of caries.6,9

This is evidenced by the results of research by Sari et al. (2015) showing that knowledge of oral health is related to the oral hygiene index, where the better the level of knowledge, the better the OHI-S index. Another study, Yohanes et al. (2013) showed that children who had good knowledge had a 2.2 times chance of having good oral and dental hygiene status.8,10

Children 6 to 12 years of age, at this stage, they often show the best in their lives, so dental health for them is one of the things that can motivate learning. This is of course every child’s dream, sometimes they feel embarrassed when a friend taunts them because their teeth are yellow. So at this time, the sense of responsibility for schoolwork and homework will be more visible. Therefore, children can be taught how to maintain oral health in more detail so that it will create a sense of responsibility for their own hygiene.11,12

Method

This research is an analytic observational study with a cross-sectional design. The research was conducted in third grade students of SDN Perigi 03 PondokAren, South Tangerang City. The research sample was taken by total sampling technique, namely as many as 51 respondents. The independent variable in this study was knowledge of dental health and the dependent variable was the dental hygiene status of elementary school children (OHI-S).

Data collection on dental health knowledge was measured using a questionnaire containing 15 questions about knowledge of dental health, while dental hygiene status was measured by standard dental hygiene checks for primary school children, namely Oral Hygiene Index Simplified (OHI-S). The stages of data collection activities were carried out in 3 stages: first the respondents were asked to sign an informed consent. The second provides a questionnaire about dental health knowledge.

The third performs an OHI-S index examination by applying a disclosing solution using a cotton pellet on the index tooth if there is staining on the tooth it means that there is debris on the tooth and if at the time the tooth is examined using a sonde and there is a rough surface it shows the tooth. there’s calculus. Then the results of the examination are recorded on the examination sheet.

Data analysis was performed using the SPSS statistical program for univariate analysis and presented in the form of a frequency distribution. After that was done bivariate analysis with chi-square to measure the relationship of dental health knowledge with the Simplified Oral Hygiene Index in primary school children.

Table 3 results of the chi-square analysis of dental health knowledge against Oral Hygiene Index Simplified indicates that the p-value is 0.023 (p <0.05), which means that there is a significant relationship between knowledge of dental health and Oral Hygiene Index Simplified.

Discussion

The results of the research data were obtained respondents11 children (21.6%) had good dental health knowledge, 27 children (52.9%) had enough knowledge and 13 children (25.5%) had less knowledge. Knowledge is a very important domain for the formation of one’s actions. Knowledge of dental and oral health is very important for the formation of actions to maintain dental and oral hygiene. Maintaining dental hygiene is one way to improve dental health.11,13 The results of this study are not much different from the results of research by Restuaastuti et al regarding knowledge and behavior of dental health among students of SDN 174 Muara FajarPekanbaru, it is known that 25 students (41%) have insufficient knowledge of dental health and as many as
25 students (41%) have bad behavior regarding brushing their teeth.

The results of the research data showed that respondents who had good OHI-S criteria were 9 children (17.6%), respondents who had moderate OHI-S criteria were 40 children (78.4%) and a number of 2 children (4%) had OHI-S bad criteria. This is possible due to the less of knowledge of dental health maintenance, so with relevant research. Research by Mawuntu et al on the description of the dental hygiene status of St. Catholic Elementary School students, Agustinus Kawangkoan. Obtained from 65 children who were examined using the OHI-S index showed that 37% of respondents were in the good category; 60% moderate category; and 3% bad category.

The result research about dental health knowledge against Oral Hygiene Index Simplified indicates that the p-value is 0.023 (p <0.05), which means that there is a significant relationship between knowledge of dental health and dental health Oral Hygiene Index Simplified. The results of this study agree with the research. This is evidenced by the results of research by Sari et al. showing that knowledge of oral health is related to the oral hygiene index. Another study, Yohanes et al. also stated that it showed knowledge of dental and oral health was related to the oral hygiene index of children.

Knowledge of oral and dental health is formed from a person’s behavior. Other studies also show a correlation between knowledge and oral health behavior. Remembering the magnitude of the influence of behavior on the degree of dental and oral health, a special approach is needed in shaping positive behavior towards dental health. A positive attitude will affect the intention to participate in activities related to this and a person’s attitude is closely related to the knowledge he/she receives, especially dental health. Knowledge is the basis for the formation of a behavior. A person is said to be less knowledgeable if he is in a state of being unable to recognize and explain and analyze a situation. If the level of knowledge is higher.

**Conclusion**

Based on the research results, it can be concluded that there is a significant relationship (p <0.023) between knowledge of dental health and Oral Hygiene Index Simplified

The Difference of Plasma Prothrombin Time Value in the Production of Adsorbed Plasma Using Various Concentrations of Barium Sulphate in Dr. Soetomo General Hospital, Surabaya, Indonesia

Putu Devi Oktapiani Putri¹, Paulus Budiono Notopuro²

¹Resident, Clinical Pathology Specialization Program, Department of Clinical Pathology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo General Hospital, Surabaya, Indonesia, ²Lecturer, Department of Clinical Pathology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo General Hospital, Surabaya, Indonesia

Abstract

Detection of a factor deficiency in the case of coagulation prolongation is very important, in this case a factor deficient plasma is required. This research provides a simpler method to produce factor deficient plasma, using barium sulphate as an adsorbent with Prothrombin Time (PT) of more than 60 seconds as a target. The aim of this study is to analyze the difference of PT value in various concentrations of barium sulphate. Pooled normal plasma (PNP) was made from citrated blood and basic PT value was measured. Nine plain tubes were prepared with 1 mL of PNP for each tube. Barium sulphate 200-1000 mg/ml plasma was then added to each tube. Finally, PT value of each tube was measured. The presence of barium sulphate <800 mg/ml plasma made no significant changes in PT. Conversely, the presence of ≥800 mg/ml plasma increased PT more than 5 times compared to normal PT. Adsorbed plasma lack vitamin K dependent factors because barium sulphate binds to α-polypeptide, and removes all vitamin K dependent factors. The barium sulphate concentration used to make adsorbed plasma in this research was different with previous research. It was found that barium sulphate with ≥800 mg/ml plasma can significantly change the PT value, and effectively reach the PT target of adsorbed plasma as a basic reagent for substitution study. In conclusion, different concentrations of barium sulphate used resulted in different PT values. Optimal concentration of barium sulphate to make adsorbed plasma was ≥800 mg/ml plasma.

Keywords: Adsorbed plasma, barium sulphate, plasma prothrombin time.

Introduction

Prothrombin Time (PT) and Activated Partial Thromboplastin Time (APTT) examinations are routine tests performed to evaluate coagulation function. There are more than 40,000 PPT and APTT examinations at RSUD Dr. Soetomo per year with results that extend by 28%¹,². In order to determine whether the coagulation abnormality is caused by a lack of coagulation factors or the presence of an inhibitor, a mixing test with normal pooled plasma can be performed. If a coagulation factor deficiency is found, a substitution test can be performed to identify the deficient coagulation factor³,⁴,⁵.

Currently, several coagulation factor examinations are available, including the examination of VIII factor and IX factor. Both of these tests can provide information on levels of VIII factor and IX factor; however, these tests are quite expensive and cannot be performed in standard laboratories. The substitution test is a promising alternative as a method of examining coagulation factors. To perform a substitution test, two types of plasma are
required, namely aged plasma and adsorbed plasma. The availability of these two types of plasma considerably supports the diagnosis of a coagulation disorder, even in a standard laboratory.\textsuperscript{6,7,8}

Preparation of adsorbed plasma requires a standard method so that the adsorbed plasma obtained can be used in the substitution test. In order to produce adsorbed plasma, citrated blood plasma can be mixed with barium sulphate to achieve a predetermined PT value.\textsuperscript{9} This research examines the concentrations of barium sulphate that can be used for the manufacture of adsorbed plasma with citrated blood plasma.

**Method**

This research was conducted using cross-sectional analysis. The samples of this study were collected from veins of Clinical Pathology Resident, Faculty of Medicine, Universitas Airlangga - Dr. Soetomo General Hospital, Surabaya, Indonesia. Random sampling was done until 20 samples were obtained. This research was conducted in the Clinical Pathology Laboratory, Integrated Diagnostic Center Building, Dr. Soetomo General Hospital, Surabaya, Indonesia. The inclusion criteria were samples from Dr. Soetomo General Hospital, Surabaya, Indonesia which were accommodated in citrate anticoagulant tubes with volume in accordance with the minimum limit of citrate tube filling (2.7 mL). Exclusion criteria were samples with insufficient volume, clotted blood samples, icteric, lipemic, or hemolyzed samples. Independent T-test was performed to analyze the effect of difference of barium sulphate on PPT values. p value <0.05 was considered statistically significant. Data was analyzed using MS excel and SPSS software.

**Results and Discussion**

The preparation of adsorbed plasma in this study used several variations of barium sulphate concentration. An increase in the concentration of barium sulphate can affect the PT plasma value produced. A very sharp increase in the value of PT was found in the plasma with 900 mg/mL of barium sulphate. With barium sulphate concentration of 1000 mg, the PT value that appeared on the device was no coagulation. In this case, the upper limit of the PT value that could be detected by the device was used, namely 130 seconds (Figure 1).

![Figure 1. The value of PT in the preparation of adsorbed plasma with various concentrations of barium sulphate.](image-url)
In this research, several cut-offs of barium sulphate concentrations were chosen to observe how much change in the value of PT would occur when higher concentrations of barium sulphate were used or vice versa. In Table 1, it can be seen that there are 3 cut-offs, namely 600 mg/mL of plasma, 700 mg/mL of plasma, and 800 mg/mL of plasma. A difference test was performed on each cut-off mean value of PT that could be achieved. In the use of barium sulphate <600 mg/mL of plasma, the mean value of PT was only 11.48 seconds with p value of 0.49, which was not statistically significant. When barium sulphate was used at 800 mg/mL of plasma or above, the PT value was statistically significant reaching 86.77 seconds.

The use of barium sulphate in the preparation of adsorbed plasma has been investigated for decades. Hydrophobic materials such as barium sulphate and aluminum hydroxide can absorb certain coagulation factors (especially II, VII, IX, and X factors) when added to plasma. Other studies have shown that the use of aluminum hydroxide can reduce the activity of II, VII, IX, and X factors. Increasing the concentration of aluminum hydroxide used will further reduce the activity of these coagulation factors. Barium sulphate and plasma citrate was used in this research for the preparation of adsorbed plasma. The greater the concentration of barium sulphate used, the higher the PPT value. This suggests the possibility that the coagulation factors involved in the extrinsic coagulation pathway experience decreased activity.

Vitamin K-dependent coagulation factors have one special feature, which is the fact that they have the same polypeptide structure. In Nelsestuen and Suttie’s research, it was found that there was a structure called α peptide in prothrombin. This structure disappears after adsorption process. This α peptide is a vitamin K dependent structure, and is present in all vitamin K dependent proteins.

Adsorption process caused a decrease in the activity of II, VII, IX, and X factors. This study used aluminum hydroxide in gel form as an adsorbent. Each factor showed a different decrease in activity after the adsorption process. This was also influenced by differences in temperature and pH.

A literature stated that the concentration of barium sulphate used for the preparation of adsorbed plasma is 100 mg/mL of plasma. A different literature stated that 33 grams of barium sulphate is mixed with 150 mL of plasma, to which a buffer solution has been added, then stirred at room temperature for 30 minutes. In this study, the use of barium sulphate below 600 mg/mL of plasma did not significantly increase the PT value. The use of barium sulphate at concentration of 600 mg/mL plasma...
produced plasma with PT value of 19.4 seconds (Figure 1). There are several variations in the target value of PT in the preparation of adsorbed plasma, namely 2½ times the normal PT value, or PT >60 seconds\textsuperscript{13}. If the upper limit of normal PT value is 13 seconds, then the use of barium sulphate with concentration of 800 mg/mL of plasma would succeed in achieving the minimum target value of PPT, namely 32.5 seconds.

Several cut-offs were selected to determine the appropriate minimum concentration of barium sulphate in the preparation of adsorbed plasma. Based on the PT values achieved with the use of different concentrations of barium sulphate (Figure 1), several cutoffs for barium sulphate concentrations were taken as a reference to achieve the targeted PT value. Using the most minimum concentration of barium sulphate with the most effective result is very important for the efficiency of materials and processing time.

Table 1 shows some of the cutoffs that can be considered as minimal concentrations that can be used for the preparation of barium sulphate. If a lower barium sulphate concentration could achieve the targeted PT value, it would certainly increase the efficiency and effectiveness of the process in making adsorbed plasma. Barium sulphate levels <800 mg did not reach the targeted PT value (Figure 1), and statistically also did not provide a significant difference in PT values (Table 1). Barium sulphate concentration of ≥800 mg/mL of plasma resulted in the most statistically significant p value (p 0.03) with a PPT value that reached 34.3 seconds.

**Conclusion**

The use of barium sulphate with different concentrations produce plasma with different PT values. Higher levels of barium sulphate increase the plasma PPT value, however the increase is non-linear. Barium sulphate with concentration of ≥800 mg/mL is the most optimal for the preparation of adsorbed plasma as a basic reagent for substitution tests.

Abstract

Background: Rheumatoid Arthritis is a chronic autoimmune disease affects joints and connective tissues where different types of cytokines are involved in its pathogenesis and progression. Biological drugs are considered to be a more targeted treatments for rheumatoid arthritis. Therefore, the aim of current study was to explore the effects of etanercept, a biological drug that inhibits tumor necrosis-alpha, on clinical and immunological variables in Iraqi patients with RA. Methods: A prospective open-label study conducted from February to November/ 2020 at Rheumatology Unit, Baghdad Teaching Hospital/ Medical city, Iraq. The study involved 75 patients with rheumatoid arthritis who underwent a 12-week course of treatment with etanercept monotherapy or combined with methotrexate. Assessments of disease activity and immunological markers (using SDAI and ELISA technique, respectively) were performed for the patients after the course of treatment and compared with healthy controls. Results: Data from current study showed that disease activity was not affected by type of treatment and immunological markers were higher in patients with rheumatoid arthritis than in control subjects regardless of type of treatment. Conclusion: To achieve an effective control of rheumatoid arthritis disease activity, treatment with etanercept (monotherapy or combined with methotrexate) needs to be continued for more 12 weeks.

Keywords: Etanercept, Immunological markers. Methotrexate, Pharmacology, Rheumatoid arthritis, SDAI.

Introduction

Rheumatoid Arthritis (RA) is a chronic autoimmune disease that affects joints and connective tissues with associated vascular, metabolic, bone and psychological comorbidities (¹). RA can begin at any age, but the likelihood increases with age as onset of RA is highest among adults in their sixties (²). Women are 2-3 times more likely to develop RA than men, maybe because oestrogens have both stimulatory and inhibitory effects on the immune system (³). Different factors can contribute to pathogenesis of RA (Figure 1).

Figure (1): Factors contributing to development of RA (⁴).
In RA, T cells infiltrate into the synovial membrane where they induce and maintain activation of macrophages and synovial fibroblasts, transforming them into tissue-destructive effector cells (5). In addition, B lymphocytes play many important roles in the pathogenesis of RA. They are the source of rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPAs) that contribute to the formation of immune complexes and complement activation (6).

Cytokines are molecules that, in cases of inflammation, infection or injury, are secreted by immune cells and allow cell to cell communication (7). In RA, they can be categorized into four groups: pro-inflammatory cytokines (IL-1 and TNF-alpha), joint inflammatory cytokines, anti-inflammatory cytokines (IL-4, IL-10, IL-11, IL-13 and IL-20) and natural cytokine antagonists (IL-1 receptor antagonist, soluble type 2 IL-1 receptor, soluble TNF receptor and IL-18 binding protein (7).

Diagnosis of RA is achieved by reviewing symptoms, conducting a physical examination, and doing X-rays as well as biochemical tests. The latter include rheumatoid factor, anti-citrullinated protein antibodies, erythrocyte sedimentation rate and C-reactive protein (8).

The aims of treatment of RA are achieving the lowest possible level of arthritis disease activity and remission if possible, reducing joint damage and improving physical function as well as quality of life (9). Moreover, treatment options for patients with RA are presented in Figure (2).

![Figure (2): Available treatments for RA (4).](image-url)
Although they are considered to be a more “direct, defined and targeted” treatments, biological DMARDs may cause a range of unwanted effects such as increased risk of infections and neurologic symptoms similar to those of multiple sclerosis and lymphoma (10). In addition, these medications tend to be very expensive and they are often used in combination with other DMARDs, especially methotrexate.

In Iraq, biological agents are imported from international drug companies via Ministry of Health and distributed to registered RA patients in specialized centers, such as the one in Baghdad Teaching Hospital, over specific appointments (in weeks). However, this process can create time-, economic-, as well as health-, related burdens to the patient, his/her family and the health system. These burdens are related to supplementation of biologics by producers, administration bureaucracy, dispensing of the required amounts of these drugs for each patient, the cost of drugs in addition to the potential adverse effects and contraindications related to these agents.

Therefore, clinical and/or immunological evidence(s) are critical to adequately justify the use of these agents in treatment of RA.

Taken together, current study was conducted to investigate the effects of Etanercept, a biological agent that acts as an inhibitor of TNF, on clinical and immunological variables in Iraqi patients with RA.

Methods

A prospective open-label study conducted from February to November 2020 at Rheumatology Unit, Baghdad Teaching Hospital/ Medical city, Iraq.

In current study, 91 subjects (75 RA patients and 16 healthy controls), were recruited. Patients were those known to have RA as defined by the American College of Rheumatology (ACR). In addition, recruited patients were with failed response to methotrexate alone and/or another DMARD. Also, selected patients received biological treatment (Etanercept; 50mg/week subcutaneously) either alone or in combination with oral Methotrexate (MTX; 10-15mg/week) for at least 12 weeks. However, subjects who have chronic disease(s) (renal, hepatic, cardiovascular), those having Juvenile RA and/or history of TB were excluded. Moreover, women who are pregnant or breast feeding were also excluded from the study. Patients who participated in current study were interviewed to assess clinical features of the disease and to obtain medical history.

Clinical evaluation of patients was performed using Simplified Disease Activity Index (SDAI; 11) has been validated for both research and clinical uses. On the other hand, the evaluation of patients’ ratings of general health and pain was performed using 10-cm Visual Analogue Scale (VAS; 12).

Furthermore, blood samples were obtained from study participants (12 weeks after starting treatment) for measurement of serum levels of high sensitive C-reactive protein), tumour necrosis-alpha, Interleukin 1-alpha and Interleukin-6. These markers were measured using ELISA technique.

Statistical analysis was performed using the SPSS software for windows version 20.0. Categorical variables were expressed as percentages and continuous variables were expressed as mean± standard deviation. All P values less than 0.05 were considered significant. The Mann Whitney test and Kruskal Wallis test were used.

Results

Demographic characteristics of participants

Results from current study revealed that there were no significant differences between patients and controls in terms of their mean age, mean body mass index and frequency of gender distribution (P values were 0.824, 0.881 and 0.237, respectively).

Moreover, results from current study showed that the median duration of the disease in RA patients was 10 years and ranged from 1 to 30 years. Also, results showed non-significant association between existence of RA disease in recruited patients and their family history, smoking history or diabetes mellitus (P values
were 0.582, 0.633 and 0.237, respectively). However, hypertension showed significant association ($P = 0.018$).

**Assessment of disease activity**

Patients with RA who participated in current study underwent clinical assessment for their disease activity using the SDAI. The median SDAI scores obtained in current study revealed that 62 patients had moderate – high disease activity and 13 patients had low disease activity (Table 1). However, with respect to treatment strategy and regardless of disease activity, RA patients taking etanercept monotherapy and those on combination therapy (etanercept and methotrexate) were not significantly different in their median tender joint count, visual analogue scale (by patients), visual analogue scale (by physician) and SDAI score ($P > 0.05$; Table 2).

Table 1: Clinical assessment of disease activity in patients with RA

Table 2 Clinical assessment of patients with RA according to treatment strategy
Results from current study showed that in RA patients (those with moderate-high and those with low disease activities), serum levels of Hs-CRP, IL-1alpha and IL-6 were higher than their serum levels in control subjects. Interestingly, these findings were not affected by treatment strategy i.e. Etanercept with or without Methotrexate in the respective patients groups (Tables 3&4).

Discussion

Demographic characteristics of participants

The mean age of RA patients enrolled in current study (51.23 ±10.88 years) was higher than that reported by (13), yet it was comparable to that reported by (14). These data indicated that RA can affect any age group and its prevalence increases with age.

In addition, RA patients who participated in current study were overweight (BMI> 25Kg/m²), similar data were reported by (15). These findings suggested that increased BMI could be a risk factor for development
of RA; yet it might be a strategy for prevention or control of this disease. Moreover, the higher incidence of RA in female patients reported in current study was in agreement with data reported in previous studies (3). These findings could be attributed to hormonal changes that turn females having greater immunoreactivity (3). Also, current study revealed that RA was more frequent in patients having family history of RA, but it did not reach statistical significance \( (P= 0.582) \). Previous studies (16) reported the existence of positive association between family history of RA and risk of the disease.

On the other hand, the weak association between smoking history and incidence of RA in our patients (Table 1) might be due to the small sample size and/ or the probability that most of our patients had quitted smoking in response to medical advice. The latter is supported by the findings that smoking is a risk factor for the disease and it correlates with disease severity (17,18).

The finding of current study that there was no association between diabetes mellitus and RA \( (P=0.833) \) was in agreement with that reported in a previous meta-analysis (19). However, current study showed that there was positive association between arterial hypertension and incidence of RA which agreed with previous studies (20). Moreover, the probable mechanism(s) behind this association could be the chronic inflammatory processes encountered in RA and its association with arterial rigidity, reduced arterial flexibility and subsequent increase in blood pressure.

Assessment of disease activity

In present study, the median SDAI scores were 22.25 and 10.30 in patients with moderate-high disease activity and those with low disease activity, respectively, (Table 1). These data were comparable to those reported by (21), but lower than those reported by (11). It is quite possible that use of analgesics had reduced the median score at baseline in current study.

Current study reported that treatment of RA with etanercept, with/ without methotrexate, (with regard to disease activity) did not produce significant differences regarding clinical variables (Table 2). The latter maybe because that the 12-week treatment was not enough to induce clinical improvement (22). Also, a recently-published study (23) revealed that Iraqi patients with RA who received early treatment with etanercept showed improved clinical outcomes.

Moreover, these data indicated that treatment with etanercept monotherapy was as effective as its combination with methotrexate as the latter did not produce superior effects to those of the former. Moreover, previous studies revealed that the synergistic combination of etanercept with sulfasalazine or methotrexate resulted in better outcomes than using either of the latter drugs as a monotherapy (24).

Taken together, early administration of etanercept as a monotherapy or in combination with other DMARDs is significant in treatment of RA.

Immunological markers

The reported higher serum levels of Hs-CRP, IL-1 alpha and IL-6 in RA patients enrolled in current study compared to controls might indicate that the inflammatory process underlying RA is still active in those patients despite the 12-week course of treatment. This finding is supported by previous data that reported a correlation between serum levels of these biomarkers and disease activity in RA (25). It seemed as if the 12-week course of treatment received by RA patients in current study was not enough to control disease activity and a longer course is necessary (22). Also, it is quite probable that increasing the sample size might make the results more understandable than they are.

Conclusion

SDAI formula can be used to measure RA disease activity in clinical practice. In addition, for effective control of RA disease activity, treatment, with etanercept, with/ without methotrexate, needs to be continued for more 12 weeks.

Abstract

Introduction: Burdens and types of occupation will cause psychological stress during Covid-19 pandemic, especially jobs in the medical field. The rapid transmission of the disease and the increasing number of people infected by Covid-19 bring anxiety and worry and decrease the level of happiness that will obstruct the secretion of oxytocin hormone that brings problems to breast milk production and breastfeeding process. This study was aimed at analyzing the correlation between occupation, stress level and breast milk production during Covid-19 pandemic in Indonesia.

Method: This correlational study was conducted by using cross sectional design. The technique used to collect the samples totaling 110 breastfeeding mothers was simple random sampling technique. The independent variables were occupation and stress level, whereas the dependent variable was breast milk production. This study used Perceived Stress Scale (PSS) questionnaire to measure the stress level and another questionnaire to measure the smoothness of breast milk production. Furthermore, data analysis was done by using Chi-square statistic test with the significance level of p < 0.05.

Result: The result of this study showed that of 110 respondents, most of them (67%) worked in the medical field; nearly all (70.9%) experienced severe stress; and nearly all (80%) had unsmooth production of breast milk. Whilst, the result of Chi-square test showed that the value of p =0.000 showing that there was a correlation between occupation, stress level and breast milk production during Covid-19 pandemic in Indonesia.

Conclusion: Occupation, stress level and breast milk production are correlated during Covid-19 pandemic in Indonesia. Therefore, the medical workers, especially nurses are expected to play their active roles to educate and teach the breastfeeding mothers how to manage stress correctly to maintain the production of breast milk in any conditions.

Key words: occupation, stress level, breast milk production, breastfeeding mothers, Covid-19

Introduction

Breastfeeding is a developmental task for postpartum mothers by way of giving breast milk (ASI). Breastfeeding is given at least 6 months (exclusive breastfeeding) after the baby is born.\textsuperscript{1}Breast milk has advantages as a nutrient compared to other nutritional sources. The macro and micro components contained in breast milk are needed at each stage of the baby’s growth. Macro components consist of carbohydrates,
proteins, and fats. Meanwhile, the micro components are vitamins and minerals. Breast milk also contains an antibody substance called IgA which acts as a defense system for the walls of the digestive tract against infection.

The World Health Organization (WHO) recommends that mothers breastfeed their babies within the first hour of delivery and continue until the first 6 months of their baby’s life for optimal growth and fulfillment of the baby’s developing nutrition. Breastfeeding mothers have concerns regarding the COVID 19 pandemic so that in Indonesia the data on breastfeeding has decreased. WHO data in 2018 globally exclusive breastfeeding is quite low, only 41%, while the RISKESDAS data for 2018 in Indonesia the number of exclusive breastfeeding only reaches 37%. The Indonesian government provides support for working mothers to continue to provide breast milk to their babies, this is supported by the enactment of government regulation Number 33 of 2012 concerning exclusive breastfeeding which requires every company or workplace to provide a space for breastfeeding mothers.

Breast milk production is greatly influenced by psychological factors. Stress due to the COVID-19 pandemic and maternal work, especially in the health sector, raises concerns for mothers to provide breast milk for babies. Breastfeeding mothers and their babies are a vulnerable group for exposure to COVID 19. Indonesia the number of positive cases of Covid-19 continues to increase. Based on data on May 5, 2020, announced by the Task Force for the Acceleration of Handling Covid-19 in Indonesia, there were 12,071. The United Nations International Children’s Emergency Fund (UNICEF) confirms that exclusive breastfeeding is safe to give to babies and still be given even though the mother is positive for COVID 19. COVID 19 is not detected in positive mother’s milk, but there is a concern of transmission through droplets while breastfeeding. Nursing mothers must apply the COVID 19 protocol, namely using a mask and washing their hands before and after touching the baby.

The psychological and emotional condition of the mother greatly affects milk production. If the mother experiences stress and an increase in workload, there will be a blockade from the oxytocin hormone release reflex/let down reflex. If the letdown reflex is not perfect, then a thirsty baby is dissatisfied. This dissatisfaction is an additional stressor for the mother. In addition, the increased workload during the COVID 19 pandemic made mothers unable to provide optimal breast milk for babies, especially mothers who work in the health sector, it is very difficult to find free time to pump breast milk. So that the result is a decrease in milk production. This study aims to analyze the relationship between work and stress levels on breastfeeding production of breastfeeding mothers during the COVID 19 pandemic in Indonesia.

Methods

The research design used was analytic with a cross-sectional approach, because there was a relationship between the independent variable and the dependent variable. The independent variable of this research is work and stress level and the dependent variable is breast milk production which is observed at the same time. The place where the research was conducted in Indonesia. The research was conducted in May. The population of this study was all breastfeeding mothers in Indonesia. The research sample was 110 respondents who were taken using probability sampling with a random sampling technique. The research instrument was a questionnaire Perceived Stress Scale (PSS) and the Smoothness of Breast Milk Production, the independent and dependent variables were nominal.

Test the validity and reliability of the questionnaire using 15 respondents. The results of the validity test of the Perceived Stress Scale questionnaire obtained the results of r count for each question between 0.580-0.922 while the questionnaire for the smoothness of breast milk production obtained the results of r count 0.615-0.901 for each question was greater than r table 0.550 so it could be stated that both questionnaires were valid to be used as questions. The results of the reliability test of the Perceived Stress Scale questionnaire showed
that the Cronbach’s Alpha value was 0.821, while the smoothness of milk production resulted in a Cronbach’s Alpha value of 0.938, which means it is very reliable or reliable so that the questionnaire is suitable for use in data collection. Data analysis was performed using the Chi-Square statistical test with a significant p <0.05.

P value 0.000
Table 3 shows that of the 67 respondents who work in the health sector, almost all (92.5%) of the quality of breast milk production is not smooth. Meanwhile, of the 78 respondents with very heavy stress levels, almost all of them (91%) the quality of breastmilk production was not smooth. The results of cross-tabulation of the relationship between work and stress levels with the quality of breastmilk production were analyzed using the Chi-Square test, the result was $p = 0.000$ which means that there is a relationship. work and stress levels with the quality of breastfeeding production of breastfeeding mothers during the COVID 19 pandemic in Indonesia.

**Discussion**

The results showed that there was a relationship between work and the stress level of breast milk production during the COVID 19 pandemic with a value of $p = 0.000$. The age of the respondents based on table 1 is mostly (73.6%) in early adulthood, this shows that the respondents are mostly in their productive period. In general, mothers of productive age have a better ability to lactate than mothers who are more than 35 years old. In this age group, it is a good age for mothers to get pregnant and give birth because the reproductive organs are in good condition. Whereas at the age of fewer than 20 years the reproductive organs have not grown optimally and at the age of more than 35 years after experiencing a decline in the reproductive organs. In line with research conducted by Fortner (2019), healthy reproductive age is 20-35 years. Apart from the productive age, they often experience shocks which result in a lack of attention to meeting nutritional needs.

Most of the respondents in this study (56.4%) were primiparous. Parity is related to maternal knowledge and experience so that psychologically primiparous mothers are less experienced than multiparous mothers. Multiparous mothers have previous experience with children, so they are more active and diligent in breastfeeding their babies. The autocrine control system begins when milk production stabilizes. Breastfeeding is very beneficial for babies, one of which is as a source of ideal nutrition with a balanced composition and by the growing needs of a perfect baby both in quality and quantity. Sherwood stated that mothers who provide exclusive breastfeeding can stimulate the prolactin hormone to increase breast milk, the more milk that comes out, the more breast milk is produced. This is in line with a 2016 Hackman study which stated that multiparous mothers had breastfeeding resistance for 6 months compared to primiparous mothers.

Mothers who have good knowledge or a high level of education will have more positive attitudes or behaviors, but this is the opposite of the research. The results showed that almost all of them (78.2%) were highly educated and almost half (48.2%) of respondents gave breast milk and formula milk to their babies. Mothers choose to provide additional formula milk to their babies in addition to fulfilling the baby’s nutrients. Mothers are attracted to advertisements for formula milk which is attractively packaged, so there is a concern that it will damage the mother’s perspective on exclusive breastfeeding. This can affect the understanding of mothers where formula milk can meet all the nutritional needs of the baby compared to exclusive breastfeeding. Apart from the addition of formula milk in this study, a small proportion (6.4%) of mothers gave additional food for their babies. The provision of additional food is due to the community’s habit of thinking that babies will be fussy if they are only given breast milk for the first 6 months. Feeding other than breast milk at an early age can increase morbidity. These babies will be prone to gastrointestinal and respiratory infections. The infant mortality rate in Indonesia is quite high due to the high rate of gastrointestinal and respiratory infections.

Almost all of the working mothers (76.4%) of the respondents worked and most (60.9%) worked in the health sector. Working mothers devote half of their time to work so that the time with their children will be reduced. Working hours can influence exclusive breastfeeding due to differences in working hours between mothers who have shift working hours, namely in the health sector and mothers who work not on shifts. This is in line with research by Murtagh (2011) which states that mothers who work shifts tend not to
Mothers who work in the health sector have excessive stressors because they have to treat patients with positive confirmation of COVID 19, and are worried about contracting the COVID 19 virus. This condition will put pressure both physically and mentally on medical personnel. Medical personnel must wear personal protective equipment by covering all parts of their body using masks, google glasses, black clothes, and booth shoes to protect them from contracting COVID 19. Mothers who work in the health sector spend their time caring for and interacting with COVID 19 patients throughout their shifts. Most of them say that they just take a break to eat and pray, they don’t have time, let alone pumping breast milk. The activity of pumping breast milk is carried out when conditions are free and the patient is reached in the field a little so that the mother can take the time to pump breast milk. These conditions can affect the psychological condition of the mother and have an impact on decreasing milk production. This study showed that most (70.9%) experienced very heavy stress levels and almost all of their milk production (80%) was not smooth. According to Krol, if the mother is tired or stressed, the production of the hormone oxytocin will be hampered which results in the quality of breast milk production decreasing.

Stress during the pandemic was mostly experienced by breastfeeding mothers in urban areas because the urban environment was a zone for the spread of the COVID 19 virus. This is the cause of excessive stressors in breastfeeding mothers, the volume of milk produced is influenced by the psychological condition of the mother, breastfeeding mothers are not subject to stress and anxiety excessively. Stress has a close relationship with the body’s biological function. Primiparous mothers who experience stress will experience several changes in their biological functions which have an impact on milk production. During the COVID 19 pandemic, mothers experienced stress because of limited space for mothers who worked in the health sector. When working mothers other than health work at home, working mothers in the health sector must always be on standby at the hospital to care for patients. Stress activates the hypothalamus to control two neuroendocrine systems, namely the sympathetic system and the adrenal cortical system. The sympathetic nervous system responds to hypothalamic nerve impulses by activating various organs and smooth muscles. Then the adrenal cortex system stimulates the release of hormones including sex hormones, namely oxytocin, endorphins, adrenal hormones and testosterone which are carried through the bloodstream followed by the neural activity of the sympathetic branch of the autonomic nervous system such that they play a role in the fight or flight response. The release of oxytocin is followed by a let-down reflex that the mother can feel as tingling or other breast droplets that the baby is sucking in. This reflex is influenced by the psychological condition of the mother. The skin attachment between the mother and her baby is a stimulus that will be transmitted to the brain. This stimulus will trigger the release of oxytocin which will have a positive impact on milk production.

**Conclusion**

The results showed that there was a relationship between work and stress levels of breastfeeding in breastfeeding mothers during the COVID 19 pandemic. Where almost all respondents who worked their milk production were not smooth, while for mothers with high stress their milk production was not smooth. Likewise, on the other hand, the mother does not work and experiences mild stress, her milk production runs smoothly.

Porotic Hyperostosis and Cribra Orbitalia as Indicators of Nutritional Problems in Ancient Population

Rachmadita Yoga Pratiwi
Postgraduate Student of Master Program in Forensic Science, Universitas Airlangga, Surabaya, Indonesia

Abstract

Background One of the most studied pathological conditions in human bone remains is porotic hyperostosis and cribra orbitalia, where the condition of porosity or bone tissue is porous and looks like a coral, sieve or sponge-like formation, and is often associated with a history of anemia, nutritional deficiencies, certain diseases and so on. This is often seen in the skull because the bone tries to increase the marrow space available for increased red blood cell formation. Porotic hyperostosis and cribra orbitalia (some paleopathologists put into the same category as porotic hyperostosis) occur due to conditions caused by the body’s attempts to produce more red blood cells in the marrow to compensate for iron deficiency. The longer this iron deficiency continues, the more clearly these lesions will form. Objective This study was conducted to see the picture of the lesion porotic hyperostosis and cribra orbitalia associated with anemia and nutritional deficiencies. Methods This study is a case study by observing an intact skull without a mandible, by inspecting the regions of the skull and the roof of the orbit. Results Found coral, sieve or spongy formations on the roof of the skull and the roof of the orbit. The presence of a skull lesion can be an indicator of the fragility of an individual’s bones. Conclusion Anemia and deficiency conditions can result in the formation of lesions in the skull.

Keywords: porotic hyperostosis, cribra orbitalia, iron deficiency anemia

Background

The study of human physiology that comparing of human health status in the past, aims to understand the pattern of human life so that can be evaluated in the present. A health condition of an individual or population can become a reference in physical anthropology as a new way to interpret human behavior and biocultural adaptations in the past and the present. One of the markers of human health status can appear in individual organs due to stress over a long period of time and a poor health status can affect the human condition, such as skeletal parts. So by analyzing the condition of human skeleton from the remains can be used to observe, predict, and explain the interactions between the human condition and the environment in the past.

Paleopathology is a study to understand the causes, frequency, characteristics, signs, and degrees of disease severity that existed in past populations in the prehistoric era. The study of paleopathology is often used as a measure of the health quality of a population in prehistoric era. Paleopathology can directly study a disease that has emerged and experienced by populations in the past through the discovery of prehistoric human skeletal remains, artifacts, and surviving medical records. Pathological findings of human skeletal remains are usually found in skull bones and teeth. Pathological conditions found in the skull include porotic hyperostosis and cribra orbitalia, while pathological conditions commonly found in dental findings include caries, tooth attrition, periodontitis, antemortem toothloss, and
enamel hypoplasia.  

Stress and health status that considered in human interaction with the environment can be a guide for interpreting the situation in the past, can be an anticipation for human health and condition for the present and future. The remains of human skeletons can provide very important and in-depth information about activity patterns, diet, demographics, stress and diseases that have been suffered. The human skeletons can provide information about the health status and lifestyle of humans in the past. Health status is most commonly understood as something that can be affected by the history of disease, infection, nutritional status, and psychological factors. Other factors that may affect include an individual or group’s access to good sanitation, proper nutrition, malnutrition, and resistance and resistance to stress and disease both genomically and epigenically.  

Some studies explained that the etiology of porotic hyperostosis and cribra orbitalia are the presence of pathogenic microorganisms that depend on the source of supply and the content of host’s iron. This can be exacerbated by the presence of iron deficiency conditions which are a physiological response that evolves to an increased pathogen load. Therefore iron deficiency is one of the clinical symptoms of anemia caused by nutritional deficiencies. 

The cribra orbitalia has a similar clinical characteristics of porotic hyperostosis, but the difference is that the orbital cribra is present only in the orbital roof. Many researchers treat cribra orbitalia as a symptom resulting from the same etiological and pathological processes as porotic hyperostosis. Iron deficiency anemia does not always result from malnutrition, but can also be caused by conditions of large amounts of blood loss in a short time, pregnancy, growth, menstrual conditions, chronic systemic diseases, poor personal hygiene, vitamin C deficiency, gastrointestinal ulcers, and parasites infection. This study aims to support previous theories about dietary patterns and poor environmental conditions in ancient populations that could lead to anemia and nutritional deficiencies, and to support evidence that severe anemia can result of lesions in the cranium, namely porotic hyperostosis and cribra orbitalia.

**Literature Review**

Sieve-like porous lesions, identified as porotic hyperostosis in the skull dome and cribra orbitalia on the orbital roof, are generally known having the same haematological process. The process indicates an abnormal demand for a hematopoietic marrow increases, that cause marrow hyperplasia or hypertrophy and the production of red blood cells increases. This overproduction results in an increase in the physical size of the red blood cell production centers. As the marrow space develops, the outer layer of bone becomes very thin, often exposing diploe trabecular bone. Expansion in the trabecular bone (the marrow containing space) exerts pressure on the outer table and eventually expands through it. The resulting exposure of trabecular bone on the outer surface gives a characteristic porous appearance known as porotic hyperostosis and cribra orbitalia lesions.

Porotic hyperostosis and cribra orbitalia are among the pathological lesions most frequently found in ancient human skeletal collections. Since the 1950’s, chronic iron deficiency anemia has been widely accepted as a possible cause of both conditions. Based on this proposed etiology, bioarchaeologists use the prevalence of this condition to infer the condition of individuals during their lifetime with iron deficiency, iron malabsorption, and iron loss resulting from diarrheal disease and intestinal parasitic infections in previous human populations. Some evidence suggests that the loss of acceleration and red cell overcompensation seen in hemolytic anemia and megaloblastic anemia are the most likely causes of the discovery of porotic hyperostosis.

Porotic hyperostosis lesions appear as macroscopic porosity on flat bones, especially in the frontal, parietal and occipital bones, where they produce a “coral-like” or “filter-like” shape in the solid bone of cranium. The appearance of the orbital cribra lesion is similar to that of
porotic hyperostosis, but only found on the orbital roof. Many researchers find that cribra orbitalia as a symptom resulting from the aetiology and pathological processes are the same as hyperostosis. Some etiology for both conditions are iron deficiency anemia disease, pathogen resistance, hemolytic anemia, megaloblastic anemia, or other infections.

Anemia is a pathological symptom, not a specific disease, that has literal meaning of “bloodless”. Anemia is defined as a pathological deficiency in either the red blood cells or the hemoglobin content. In a healthy homeostatic state, there is a balance between production and lysis of red blood cells in the spinal cord. There are three main causes of anemia, including massive blood loss, erythropoiesis disorders, and increased hemolysis. From an etiological perspective, anemia is divided into genetic and acquired (caused by infectious conditions, malignancy, or deficiency). The prevalence of anemia that is genetically acquired (eg, thalassemia and sickleemia) is less common than the prevalence of acquired anemia caused by excessive blood loss and nutritional deficiencies. The nutrients needed to maintain red blood cell homeostasis include essential amino acids, iron, and vitamins such as A, B12, B6, and folic acid. Iron is a key constituent of hemoglobin and thus iron deficiency is the most common cause of anemia. Although iron deficiency is frequently caused by blood loss, it can be caused by diet with iron deficiency, gastrointestinal iron malabsorption, or any combination of these factors. When the intake or absorption of iron or other essential nutrients is insufficient, red blood cell production is inhibited and can lead to anemia. The body increases its hierarchical response to anemia, shifting to cranial spinal cord expansion and remodeling only after easier measures fail to maintain homeostasis. Red blood cells usually mature over a seven day period and have a life span of about 120 days. The emergence of anemic conditions can cause hemoglobin levels to decrease and the body becomes deprived of oxygen. This hypoxic state triggers the release of erythropoietin, a hormone produced by the kidneys that accelerates the production and maturation of red blood cells.7

In chronic anemia, the cytokine response to the underlying condition (eg infection, inflammation or malignancy) occurs, via the anti-erythropoietin effect of tissue necrosis factor α (TFN-α), in suppressed mitotic activity in marrow erythroblasts. The supply of iron to the marrow for hemoglobin synthesis become impaired, resulting in the production of red blood cells with a reduced hemoglobin content (hypochromia). This is not due to iron deficiency stores, but indeed iron stores usually increase in these conditions. Thus, when iron deposits are reduced, iron supply is limited and hypochromic red blood cells are also produced. This is iron deficiency and a result of blood loss and / or a low iron diet. The functional difference between chronic anemia and iron deficiency anemia is that the erythropoietic activity is previously suppressed, whereas in iron deficiency anemia it is increased. However, since the rate of iron supply to stimulated red marrow is limited to iron deficiency, there are too many erythroblasts chasing too little iron. The result of this is that an increasing proportion will fail to make sufficient hemoglobin counts in the time available to become ready-to-function red blood cells; this is crushed in the marrow. In iron deficiency anemia there is a massive increase in intra-medullary ineffective erythropoiesis.8

The association between the incidence of porotic hyperostosis and cribra orbitalia with the incidence of iron deficiency is assumed to be the presence of known markers of skeletal conditions with clinically identified cases of hemolytic anemia, particularly sickle cell anemia and thalassemia. The premature destruction of defective red blood cells produced by this genetic condition is a contributing factor to marrow hyperplasia.5 Anemic conditions can cause disruption of hematopoiesis (production of blood cells) in the trabecular bone marrow of the skull. Porotic hyperostosis was caused by the expansion of the diploë, cranial spongy bone, either due to bone marrow hypertrophy (increased cell size) or hyperplasia (increased cell count). This process is also followed by the formation of an irregular outer cranial table, which is reabsorbed over time, making it thinner and with a visible porous lesion. In the most
severe case ever found, diploë spongy bones can also be seen. Within the cranial dome, diploe expansion occurs by gradually absorbing the outer dome of the skull. This resorption creates a porous formation which gives the hyperostotic porotic lesion that is characteristic of the “sponge” image. In extreme cases of anemia, as seen in the case of thalassemia major, diploe hypertrophy is found to be well beyond the sincipital ectocranial surface to create a palpable upper and distinct “hair-on-end” effect easily observable on radiographs.

Another explanation of iron loss that related to the body’s defense process against invading pathogens in the form of cutting iron. When faced with chronic infection and inflammatory conditions, the body’s natural response is to place iron-binding proteins at the site of entry of pathogens, reduce the absorption of iron from the gut from food, prevent the release of iron into the blood from storage sites, and bind that which is available. All of these mechanisms serve to inhibit the growth and reproduction of microorganisms, which do not store their own iron stores, and therefore require and obtain it from their hosts. This pathogen has several methods of obtaining iron from the host. They usually produce siderophores, which are iron-binding proteins that extract iron from transferrin in the blood supply, or bind directly with transferrin and other iron-carrying molecules. Some pathogens also break down red blood cells directly. In addition to inflammatory porous skeletal lesions, the porosity observed in the skeletal tissue is due to the formation of new blood vessels to remove blood accumulated along the bone surface. Because these blood vessels penetrate the surface of the cortex of the bone, they can easily be confused with the porotic lesions that are usually associated with anemia.

The general diagnosis of porotic hyperostosis is usually applied to cases of enlarged bone tissue that are porous, which can be caused by several types of systemic disease or lesions. Some diseases modify the cranial periosteum but do not affect the underlying tissue. A common type of pathology of the porotic state in the cranial, is the occurrence of hematopoietic marrow enlargement as a result of anemia, resulting in a visually porous-looking bone condition. This type of porotic hyperostosis usually results from a condition of thinning of the bone in the external lamina of the trabeculae. Enlargement of the cancellous bone can eventually create bone thickening in the form of atrophy of the hair-at-ends or comb-like structures.

In addition, pathological conditions caused by inflammatory conditions, such as periostitis, osteitis, and osteomyelitis, exhibit a different microscopic porosity structure than that observed in the appearance of hyperostotic porotic lesions. Because the disease-induced inflammatory response usually results in a combination of bone damage and reactive bone formation in areas of necrotic tissue. The resulting bone pathological condition appears as a rough surface with pitting space and new bone plaque. This is in contrast to porotic hyperostosis, where the remodeling of new bone only occurs with healed pathologies. In this early phase, porotic hyperostosis is triggered by anemia, thus showing a decrease in the structure of the bone marrow module, with the trabeculae occurring tangentially to the outside. After the outer table portion has been eroded, a thin flat squamous plate (osteophyte), in the form of an atrophic trabeculae, can be observed in its initial horizontal alignment. Since this is an early diagnosis of porotic hyperostosis (occurring before extreme hypertrophy) when the new cancellous bone appears as a radially patterned trabeculae - it cannot be mistaken for a pathological state caused by an inflammatory condition. The condition of the trabecular bone in the early stages of this pathological change has not yet formed hypertrophic bone beyond the area previously covered by the outer table, but at a more advanced stage the trabecula experiences a hypertrophic state that is expressed as generalized swelling of the cancellous bone. In addition, the marrow module exhibits a characteristic state, associated with anemia causing porotic hyperostosis, but not usually with pathologies caused by diseases related to the inflammatory response.

Inherited hemoglobinopathy conditions, such as sickle cell anemia and thalassemia, are associated with
the wide range of skeletal anatomical changes found in children. One of the changes observed, which is relevant here, is the expansion of the diploic bone and the thinning of the outer table in the frontal and parietal parts in particular; the occipital are generally spared because of their relatively lower bone marrow content. Such skeletal anatomical changes have also been observed in the previous literature with respect to the condition of iron deficiency anemia and at face value appear to support an association between iron deficiency anemia and subadult bone to skull changes. However, more research needs to be done to refute or support this theory of apparent relationships. In adult humans, at least, there is almost always room for the erythropoietic marrow to accommodate increased erythropoietic activity without disturbing the surrounding bone. Indeed, there is some evidence showing in adults that increased erythropoiesis can be accommodated without the need for physical expansion or changes in the ratio of fat cells. The wider distribution of erythropoietic marrow in children would be more likely to be, as mentioned, less accommodating, although again, more research is needed with respect to deficiency diseases in childhood (eg iron and B12 deficiency) and associated bone changes.

The apocryphal diagnosis that results from postmortem lesions, hypervascularization and osteitis is also influenced by other factors. Likewise, etiologies other than anemia, scurvy, rickets, hemangiomas and traumatic lesions can produce subperiosteal inflammation or hematoma. During the healing process, these blood clots turn into new, highly vascular, superiosteal bone plaques that on rough examination can appear identical to those of an orbital cribra lesion. Many factors aggravate chronic iron deficiency anemia and megaloblastic anemia, such as prolonged breastfeeding, weaning periods with low-iron cereals, and diarrheal diseases that have a different effect on childhood.

Methods

This research is a qualitative study with a case study approach, by observing the presence of porotic hyperostosis and cribal orbital in an intact cranium without mandible of an adult human as the study sample (Figure 1). This research was conducted in April 2019 and was carried out at the Ethnography and Anthropology Museum, Master Program of Forensic Sciences, Faculty of Social and Political Sciences, Universitas Airlangga, Surabaya, Indonesia.

Results

In the observed cranium, there were found lessions that look alike porosity, sponge, coral-like or filter-like formation in the region of the cranial dome (Figure 2) and in the orbital roof (Figure 3).
Porotic Hyperostosis and Cribra Orbitalia are the pathological conditions that most frequently found and reported in archaeological collections. This finding is important to assess the general condition or disease of human population in the past.\textsuperscript{11} The lesions are the result of pathological conditions, such as anemia, chronic metabolic disease, malignancy, chronic scalp infections, other chronic diseases, infection, or malnutrition.\textsuperscript{7} However, the only condition that is found or not present should not be considered as an indication of the health and / or nutritional status of the individual at the age of their death, because healed lesions can occur due to the condition or situation of the individual years before, and the individual can be in good shape for a long time before dying. As suggested by the paradox theory of osteology, Wood in 1992\textsuperscript{12}, investigators should be careful when interpreting the indicators of the physiological stress framework, as some may actually indicate a disease,
Hemolytic anemia conditions such as thalassemia or sickle cell anemia (which occurs when red blood cells lysis prematurely) or megaloblastic anemia (resulting from dietary deficiency and malabsorption of folic acid and vitamin B12) are etiologies of porotic hyperostosis which refers to the presence of hemolytic anemia. Chronic hypoferremic (or iron deficiency) is a physiological response to an increased pathogen load, coupled with symptoms of iron deficiency anemia caused by nutritional deficiencies. Several studies have noted that the cases observed by archaeologists of porotic hyperostosis are of increasing frequency, especially in equatorial populations, which may reflect microorganisms that thrive in hot and humid climates. When the body becomes hypoxic, it releases the hormone erythropoietin, which stimulates the acceleration and maturation of red blood cell production. Only if this initial hormonal response fails will the bone marrow go into action to produce more red blood cells. Because the erythropoiesis process is responsible for bone marrow hypertrophy which then manifests as porotic hyperostosis, and because erythropoiesis requires an adequate supply of iron, iron deficiency anemia is effectively associated with reducing the production of mature red blood cells, thereby expanding the hemopoietic marrow that paleopathologists recognize as porotic hyperostosis. and cribra orbitalia. Similar features found in the postmortem skeleton, hypervascularization and osteitis are also influenced by other factors. Likewise, etiologies apart from anemia, other factors such as scurvy, rickets, hemangiomas and traumatic lesions can also cause subperiosteal inflammation or hematoma. Study by Walker et al in 2009 reported that during the healing process, this blood clot transformed into a new, highly vascular, superiosteal bone plaque which on rough examination may appear identical to the orbital cribra. Many factors aggravate chronic iron deficiency anemia and megaloblastic anemia, such as long breastfeeding periods, weaning periods on cereals with low iron content, and diarrheal diseases that will have different effects on childhood health, especially those related to the condition.

Porotic hyperostosis in adults is most likely a lesion that heals from marrow hyperplasia that previously occurred during childhood, this is because children have bone plasticity and iron requirements are greater than adults. However, apart from that, anemia persisted in some adults, because the lesions in this case remained active and occurred until the death of the individual.

**Conclusion**

Porotic hyperostosis and cribra orbitalia are the common lesions that are identified on human bones and are result from thickening of the skull diplo in response to spinal hypertrophy, resulting in thinning and porosity of the outer part of the bone. These lesions were commonly used as indicators of the health, nutritional status, and anemia evidence of the ancient human population. Knowing the condition of an individual or a group through findings on the remains of a human skeleton can improve our understanding of the etiological, pathophysiological and physical manifestations of the skeleton with the living conditions of the past individual or group health. The result study can be a guide to overcoming the health problems for human life in the present and in the future.

**Ethical Clearance:** The academic institute declared there is no need an ethical clearance for studies that including media collections in laboratory and the action during research was a low risk/no cause a harm to the sample. The sample had been already got a prior approval by the academic institute.

The Effect of COVID-19 on Blood Pressure Control in Hypertension Patients– A Literature Review

Raditya Manusakti1, Judya Sukmana2, Wachjudi Kurnia3, Liliawanti3

1Student at Faculty of Medicine, 2Lecturers and Master of Patobiologi at Faculty of Medicine, 3Lecturers at Faculty of Medicine, Hang Tuah University, Surabaya, Indonesia

Abstract

COVID-19 is caused by Severe Acute Respiratory Syndrome Corona Virus 2 (SARS-CoV-2). First identified in Wuhan, China, in December 2019, and declared an International Public Health Emergency in January 2020, the WHO declared a pandemic in March 2020. Hypertension, a disease that has long been a problem for most people in Indonesia and around the world. COVID-19 can affect blood pressure control for people with hypertension due to obstruction of the RAAS system. This research was conducted to find out what effect COVID-19 has on blood pressure control in people with hypertension. In the condition of COVID-19 patients with comorbid hypertension, SARS-CoV-2 which attacks ACE2 can eliminate the role of ACE2 in the RAAS system. Inhibition of ACE2 can also cause buildup of angiotensin II which has a vasoconstrictive effect. This results in the absence of homeostasis in the blood pressure control system and makes blood pressure conditions that continue to be at high pressure.

Keywords: ACE2, Blood Pressure Control, Comorbidity, COVID-19, Hypertension, RAAS.

Introduction

Hypertension is a condition of systolic blood pressure ≥ 140 mmHg or diastolic ≥ 90 mmHg on three tests within 5 minutes between the three examinations. Hypertension is caused by a combination of genetic and environmental factors. Genetic factors in the pathogenesis of hypertension are played by at least 35 genetic locus, 12 of which are newly identified locus. Environmental factors that have the biggest role include hyperuricemia. Smoking, alcohol, unhealthy diet, lack of physical activity, and central obesity. This disease will arise when there is an imbalance between stroke volume and peripheral resistance due to functional / structural abnormalities of various organs that affect both chronically. Hypertension itself does not cause death directly, but can lead to various complications with high morbidity and mortality, including kidney disease, stroke, and heart disease. This condition is exacerbated by the emergence of a new disease in 2019 which is pandemic, namely Corona Virus Disease 2019 (Covid-19).

COVID-19 is a respiratory disease caused by infection with the Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) virus and was identified in December 2019 in Wuhan, China. Research conducted by Fang 2020 states that 23.7% of COVID-19 patients suffer from hypertension. Another study conducted by Zheng 2020 shows that the complication with the highest prevalence in COVID-19 patients is hypertension with a proportion of 30%.

It is well known that the main transmission of SARS-CoV-2 is via droplets. However, there is a possibility of fecal-oral transmission The virus can pass through mucous membranes, especially the nasal mucosa and...
larynx, then enter the lungs through the respiratory tract. Furthermore, the virus will attack target organs that express Angiotensin Converting Enzyme 2 (ACE2), such as the heart, lungs, renal system and gastrointestinal tract\textsuperscript{10,11}. The S protein in SARS-CoV-2 facilitates the entry of the corona virus into target cells. Viral entry depends on the ability of the virus to bind to ACE2, the extracellular membrane receptor expressed on epithelial cells, and depends on the priming of protein S to the cellular protease, namely TMPRSS2\textsuperscript{12}.

S-protein SARS-CoV-2 which binds to the ACE2 receptor causes a decrease in ACE2 regulatory activity, which in turn occurs overproduction of angiotensin by the ACE enzyme due to the small amount of ACE2 capable of becoming angiotensin (1-7). SARS-CoV-2 binds to ACE2 to stimulate peptidase incorporation and the virus can apply ACE2 from the RAAS system pathway\textsuperscript{13}.

RAAS has the same endogenous counterregulation system as any other homeostatic system. The RAAS counter-regulation system has an important component, namely ACE2. ACE2 will be widely expressed in the kidney and heart, as well as in target cells especially SARS-CoV-2, pulmonary epithelial cells. ACE2 is an enzyme that determines the main regulatory activity resulting in decreased levels of angiotensin II to angiotensin (1-7). Angiotensin (1-7) has a role in the process of decreasing vasoconstrictive action and proliferation caused by angiotensin II and mediated by Angiotensin II Receptor type 1 (AT1R). An imbalance between ACE1 and ACE2 can contribute to the deregulation of the blood pressure system\textsuperscript{14}. This research was conducted to determine the effect of COVID-19 on blood pressure control in hypertension patients.

**Methodology**

Articles were collected using Pubmed and Science Direct database. The search words include ACE2, Blood Pressure Control, Comorbidity, COVID-19, Hypertension, RAAS. Articles were collected from the year 2015-2020 and indexed in Scimago and Scopus.

**The incidence of hypertension is one of the comorbidities in COVID-19**

Hypertension is a disease that causes the highest death rate in the world. Hypertension can also kill silently and can lead to various complications affecting various organs, including cardiovascular disease, hypertensive encephalopathy, cerebrovascular hypertension, and hypertensive retinopathy\textsuperscript{15}. Hypertension is one of the common comorbidities found in sufferers of COVID-19, about 15\% of cases of hypertension are found in COVID-19 patients\textsuperscript{16}.

Based on the data that has been obtained, the most common comorbidities found in COVID-19 patients are hypertension, diabetes and cardiovascular disease. Several studies have stated that hypertension is the most common comorbidity, followed by diabetes mellitus and cardiovascular disease. Several studies show the incidence of hypertension is one of the comorbidities in COVID-19 in table 1.
In a study conducted by Ye et al., 2020 on 1099 patients in China, the incidence of comorbidity for hypertension, diabetes, and CVD was 164 patients, 81 patients, and 42 patients. Likewise with the study conducted by Chen T et al., 2020 this study involved 274 patients infected with COVID-19, stating that the incidence of hypertension, diabetes and CVD was 39 patients, 23 patients, and 7 patients. With similar results, Zhang, G et al 2020 in a study involving 221 patients stated that the incidence of hypertension, diabetes and CVD was 54 patients, 22 patients, and 14 patients. Liu et al., 2020 in their study involving 137 patients stated that the incidence of hypertension, diabetes and CVD was 13 patients, 14 patients, and 10 patients. Wang D, et al., 2020 in their study also showed that hypertension was the most comorbid among the 138 patients involved, with the incidence of comorbidity for hypertension, diabetes and CVD being 43 patients, 14 patients, and 17 patients. Chen Q et al., 2020 in their study involving 145 patients stated that the incidence of hypertension, diabetes and CVD was 21 patients, 14 patients, and 1 patient. In a study conducted by Chen R et al., 2020 on 507 patients, the comorbidity for hypertension, diabetes and CVD was 28 patients, 13 patients, and 14 patients. Cao et al., 2020 in their study involving 102 patients stated that the incidence of comorbid hypertension, diabetes, and CVD was 17 patients, 5 patients, and 5 patients. Zhou et al., 2020 in his study involving 191 patients showed that the incidence of comorbidity for hypertension, diabetes and CVD was 58 patients, 36 patients, and 15 patients. Mo P, et al., 2020 in a study involving 155 patients stated that the incidence of hypertension, diabetes and CVD was 21 patients, 14 patients, and 1 patient. In a study conducted by Richardson et al., 2020 on 920 patients, the comorbidity for hypertension, diabetes and CVD was 22 patients, 15 patients, and 22 patients. Wang, Z, et al., 2020 in their study also showed that hypertension was the most comorbid among the 69 patients involved, with the incidence of comorbidity for hypertension, diabetes, and CVD being 9 patients, 7 patients and 8 patients.

Notes: N: Number of patients in the study, HT: Hypertension, DM: Diabetes Mellitus, CVD: Cardiovascular Disorder, COPD: Chronic Obstructive Pulmonary Disease, CKD: Chronic Kidney Disease
There is research in other countries, namely in Italy, this study was conducted by Grasselli et al., 2020 with 1,591 patients showing the incidence of comorbidities for hypertension, diabetes, and CVD was 509 patients, 180 patients, and 223 patients. With similar results from Benelli et al., 2020 in their study involving 411 patients, the incidence of hypertension, diabetes and CVD was 193 patients, 67 patients, and 93 patients.

In addition, there is a study in America, this study was conducted by McMichael, et al., 2020 where 167 patients stated that the incidence of comorbid hypertension, diabetes and CVD was 67 patients, 38 patients, and 68 patients. Richardson et al., 2020 in a study involving 5,700 patients in America, showed that the incidence of comorbidity for hypertension, diabetes and CVD was 3026 patients, 1,808 patients, and 966 patients.

Notes : n : Number of patients in the study, SBP: systolic blood pressure, DBP : diastolic blood pressure, MAP : mean arterial pressure, SD : standard deviation, RR :Respiratory rate
Zhuang, Z et al. in his study of 803 patients in the above study, 609 had control of blood pressure at admission, and 295 (48.4%) had normal blood pressure at admission (SBP / DBP <140/90 mmHg). The mean systolic blood pressure and diastolic blood pressure at admission were 137.0 mmHg (± 19.7) and 84.2 mmHg (± 12.8), respectively. 82.4% (662/803) of COVID-19 patients had good blood pressure control, and 17.6% (141/803) had poor blood pressure control during hospitalization. Compared to those with good blood pressure control, patients with poor blood pressure control had higher mean systolic and diastolic blood pressure, higher SD SBP and DBP, and higher MAP and PP during this period. Patients with poor blood pressure control are more likely to have COPD and chronic kidney disease. Zhuang Z, et al. in his research also stated that the severity status of COVID-19 was also an influence on good and bad blood pressure control. Zhuang Z, et al in their study also stated that age ≥65 years had more poor blood pressure control results than those aged <65 years. Zhuang Z, et al. in his research also stated that the incidence of COVID-19 with comorbid hypertension in men was more than in women. In a retrospective study of 803 coexisting COVID-19 patients with hypertension, it was found that a high mean SBP and high SBP / DBP variability during hospitalization were independently associated with death in hospital, ICU admission, and heart failure. The findings suggest that low and stable blood pressure control is optimal to achieve a favorable prognosis for coexisting hypertensive COVID-19 patients.

Gao X, et al. in his study of 2828 patients in the above study, 2828 patients had blood pressure control and 1437 (50.4%) had normal blood pressure at admission (SBP / DBP <140/90 mmHg). As many as 50.4% (1497/2828) COVID-19 patients had good blood pressure control and 49.6% (1391/2828) had poor blood pressure control.

**Discussion**

Hypertension is a disease that causes the highest death rate in the world. Hypertension can also kill silently and can lead to various complications affecting various organs, including cardiovascular disease, hypertensive encephalopathy, cerebrovascular hypertension, and hypertensive retinopathy. Hypertension is one of the common comorbidities found in sufferers of COVID-19, about 15% of cases of hypertension are found in COVID-19 patients. Based on the data that has been obtained, the most common comorbidities found in COVID-19 patients are hypertension, diabetes and cardiovascular disorders, with an incidence of 5.6% to 53%. In the study of Richardson et al, the co-morbid incidence rates of hypertension, diabetes and cardiovascular disorders were 56%, 31.8%, and 17%.

SARS-CoV-2 is the newest β-coronavirus type. There are seven species of β-coronavirus that have been identified to cause infection in humans, with four species causing the flu effect, and three of them (SARS, MERS and COVID-19) causing illness that results in death. SARS-CoV-2 contains S-protein which has the ability to push viruses into host cells. The SARS-CoV-2 virus envelope consists of glycoproteins that bind to ACE2 receptors. SARS-CoV-2 enters cells through the process of fusion of the viral membrane with the plasma membrane. After the virus enters the cell, the RNA genome from the virus will be released into the cytoplasm and the genome will be translated into two polyproteins and structural proteins. Then the viral genome that has been translated will begin to replicate. The newly formed glycoprotein envelope will enter the membrane of the endoplasmic reticulum or golgi body, and the combination of genomic RNA and nucleocapsid proteins will form the nucleocapsid. Then there is the growth of viral particles in the endoplasmic reticulum-golgi compartment (ERGIC). Finally, the virus particles contained in the vesicles will combine with the plasma membrane to release the virus.
binds to ACE2 to stimulate peptidase incorporation and the virus can remove ACE2 from the RAAS system pathway\textsuperscript{13}.

Renin-Angiotensin-Aldosterone System (RAAS) is an important regulator that regulates blood volume and systemic vascular resistance. Meanwhile, when the baroreceptor reflex reacts to a short-term drop in arterial pressure, this RAAS has a role in systemic adjustment. There are three essential compounds in the RAAS system consisting of renin, angiotensin II and aldosterone. Of the three essential compounds, they function to increase the pressure of arterial blood flow to the distal tubule and increase beta-agonism as a reaction to increased renal blood flow. From this mechanism, the body can increase blood pressure for a long time. The binding of Angiotensin II which is the main active substrate of RAAS with Angiotensin II Receptor Type 1 (AT1R) causes vasoconstriction, salt retention and fibrosis\textsuperscript{14}.

RAAS has the same endogenous counterregulation system as any other homeostatic system. The RAAS counter-regulation system has an important component, namely ACE2. ACE2 will be expressed extensively in the kidney and heart, as well as in target cells especially SARSCoV-2, pulmonary epithelial cells. ACE2 is an enzyme that determines the main regulatory activity resulting in decreased levels of angiotensin II to angiotensin (1-7). Angiotensin (1-7) has a role in the process of decreasing vasoconstrictive action and proliferation caused by angiotensin II and mediated by Angiotensin II Receptor type 1 (AT1R). An imbalance between ACE1 and ACE2 can contribute to the deregulation of the blood pressure system\textsuperscript{18}.

Increased activity or expression of these compounds can occur in ACE2. In elderly people and male sex has the potential to have a higher ACE2 expression. Research conducted on mice shows that administration of ACE inhibitors and Angiotensin II Receptor blockers (ARBs) can increase mRNA expression for ACE2 in the heart, kidneys, aorta and various organs and tissues of the body. In a study conducted on ACEi-treated healthy humans and controls, the results showed that the duodenal ACE2 mRNA expression level increased by an average of 1.9 times compared to the untreated controls. Apart from gender and age, arterial hypertension and diabetes mellitus can be a factor in increasing ACE2. On the other hand, ACE2 levels decrease when there is inflammation and acute respiratory distress syndrome\textsuperscript{19}.

Consumption of ACEi or ARB class drugs causes an increase in ACE2 activity and expression in the heart of patients with COVID-19 with hypertensive comorbidities, so that they can play a protective role in the cardiovascular system. It is currently unknown whether ACE inhibitors or ARBs present in ACE2 in other organs can affect the level of ACE2 expression and activity in the lungs or not. If ACEi and ARB have a role in increasing the activity and expression of ACE2 in the lungs, then these two components play a dual role in handling COVID-19. On the other hand, if there is a higher level of ACE2 it can increase the susceptibility of cells to SARS-CoV-2 and activation of ACE2 can repair acute lung injury caused by SARS-CoV-2\textsuperscript{20}.

Therefore, ACE2 expression in patients infected with SARS-CoV-2 who are accompanied by comorbidities such as chronic hypertension who are treated with ARB-class drugs may protect against acute lung injury rather than put them at a higher risk of developing SARS. This can occur because of two complementary mechanisms, namely: preventing the activation of AT1R which is mediated by excessive angiotensin due to viral infection and increasing ACE2 so that angiotensin production by ACE decreases and increases the production of angiotensin vasodilators (1-7)\textsuperscript{21}.

ACE 2 receptors attacked by SARS-CoV-2 can decrease the activity of ACE2 in the RAAS system. ACE2 which has decreased its effectiveness can inhibit the process of angiotensin formation (1-7). In the RAAS feedback system, Angiotensin (1-7) is one of the compounds that plays a role. Inhibited ACE2 can also be a contributing factor to the buildup of angiotensin II which has a vasoconstrictive effect. This causes no homeostasis or imbalance in the blood pressure control system and results in blood pressure that continues
to be in a high pressure state. So that SARS-CoV-2 infection indirectly worsens the condition of patients with hypertension. Compared to those with good blood pressure control, patients with poor blood pressure control had higher mean systolic and diastolic blood pressure, higher SD SBP and DBP, and higher MAP and PP during this period. Patients with poor blood pressure control are more likely to experience COPD and chronic kidney disease. In this study coexisting co-morbid co-patients with co-morbid hypertension, it was found that a high mean SBP and high SBP / DBP variability during hospitalization were independently associated with heart failure. Findings suggest that low and stable blood pressure is optimal for achieving a favorable prognosis for coexisting hypertensive COVID-19 patients.

**Conclusion**

Based on the data that has been obtained, the most common comorbidities found in COVID-19 patients are hypertension, diabetes and cardiovascular disorders, with an incidence of 5.6% to 53%. In the study of Richardson et al, the co-morbid incidence rates of hypertension, diabetes and cardiovascular disorders were 56%, 31.8%, and 17%.

SARS-CoV-2 infection that attacks ACE2 can eliminate the role of ACE2 in the RAAS system. Inhibition of ACE2 can also cause buildup of angiotensin II, which has a vasoconstrictive effect. This results in the absence of homeostasis in the blood pressure control system and makes blood pressure conditions that continue to be at high pressure.

Facebook Ads for Health Promotion Against Covid-19: An Environmental Medicine Perspective

Rahmad Agus Dwianto¹, Nur Wening², Elita Dwi Hapsari³

¹Doctoral Student, ²Associate Professor, Post Graduate Program of Management, University of Technology Yogyakarta, ³Doctor, Dlingo II Community Health Center, Ministry of Health of the Republic of Indonesia

Abstract

This research aims to provide innovative ideas to disseminate information on environmental medicine during the Covid-19 pandemic via Facebook. The socialization of the environmental medicine information to the public was hampered during the Covid-19 pandemic. This study provides innovative information dissemination strategies and to increase public awareness and knowledge about environmental medicine. The research method uses literature reviews from various recent studies on the use of social media Facebook for the dissemination of information. The study found that Facebook advertising as a digital platform for the dissemination of environmental medicine during a pandemic to the public is more efficient in terms of time, energy, costs, and a wider target market. This study found innovations, namely the use of Facebook ads as a digital marketing platform for the disseminating of environmental medicine programs to the public during a pandemic. Further studies could combine Facebook Ads with other platforms such as Google Ads, SEO, and TikTok.

Keywords: Dissemination Strategy, Environmental Medicine, Facebook Ads

Introduction

Environmental degradation can cause several problems, such as natural disasters, drastic climate change, the emergence of disease, and environmental pollution (1). The causes of disease can be in the form of unhealthy environmental factors and the entry of pollutants into the human body. Pollutants are substances that are harmful to the environment and when they enter the human body they will accumulate in the body and cause short and long-term effects depending on the type of substance. Diseases that arise are not instantaneous but can occur over a long period.

During a pandemic like this, disease cases due to the influence of environmental conditions also have a great potential to occur. The quality of the environment (water, air, and land) is decreasing, the management of B3 waste and waste that is carried out improperly is outside of potentially bad procedures such as health problems for the people who live in the environment. The situation is getting worse with the current COVID-19 pandemic because medical waste is increasing. The Indonesian Institute of Sciences (LIPI) (2) noted that in the range of March 2020 to September 2020, it was recorded that the number of piles of medical waste including masks and Personal Protection Equipment (PPE) was estimated to be 1,662.75 tonnes.

Although the problem of environmental hazard is a serious threat and challenge in the health sector, public attention and awareness of environmental health are still low. From the results of research data from the Ministry of Health, it is known that only 20% of the total Indonesian people care about hygiene and health. This means that of the 262 million people in Indonesia, only around 52 million people have a concern for the cleanliness of the surrounding environment and its impact on health (3).

Various socialization programs to increase environmental and health awareness have not run optimally. Previously, socialization was carried out directly through meetings, appeals, as well as regular community habituation movements to care for the environment. However, socialization activities during the Covid-19 period were hampered due to the number of government policies stipulating to minimize activities outside the home to prevent the spread of the virus.

To increase public awareness of the importance of environmental and health, as well as to socialize environmental hazards and environmental medicine, other, more effective ways are needed. One way that can be used is through a strategy through advertising or promotion with the social media Facebook. The tendency of people today like to access information through social media and follow trending habits. Therefore, Facebook can be a good alternative for the promotion of this field with a broad target because Facebook itself has users from various groups ranging from adolescents to adults, besides that the costs incurred are low, the reach is wide and the results can be monitored and evaluated periodically.

Facebook Ads has many advantages that can be obtained in this study, including the main attraction of Facebook as an advertiser is that they collect information about interests, clear and manageable demographic characteristics including age, gender, reach of location, sociography, networking, social, and online behavior that can be used in developing the right profile for targeting (4). The low cost offered to create and distribute advertisements online and the ability to target advertisements online more precisely can broaden the range of candidates advertising and allow candidates to create messages to a narrower audience than on television (5). Facebook provides as an advertising interface has enabled a wide range of individuals to commission advertising, ranging from high-budget advertising, national advertising, with small budgets, as well as local initiatives (6). Facebook data also has the advantage of being up to date and available in real-time (7).

Materials and Methods

The research method used in this research itself is using qualitative research methods. Qualitative method is research that uses a scientific background, meaning that it interprets a phenomenon that occurs and is carried out by implementing existing methods. Qualitative research is usually used in “exploration” and generally qualitative research is used in “measuring” (8). In using qualitative research methods, these methods are usually used for interviews, observation or observation, and documentation (9).

Results and Discussion

The World Health Organization defines health as a state of complete physical, mental and social well-being and not simply the absence of illness or weakness. The living environment where all the inhabitants of the earth have a very big influence on the health and disease burden of the existing inhabitants. All diseases that exist theoretically can be caused by two factors, namely in the form of genetic factors or environmental factors. The causes of the disease depend on two things, firstly on inheritance and secondly on environmental pollution.

The reciprocity between humans and the environment raises several negative things that are accepted by the environment and have a direct impact on humans, namely in the form of water pollution, food poisoning, occupational hazards, and surrounding air pollution. While the effects of negative things that arise for humans themselves are in the form of high doses, namely acute health effects, and low doses, namely chronic health effects. High doses are acute health effects in the form of accidents, systemic poisoning, and respiratory diseases. While low doses are chronic health effects in the form of respiratory diseases, cancer (carcinogens), genetic diseases (mutagens), cardiovascular disease, neurological diseases.

An environmental problem can be assessed as a whole, with at least four steps involved namely determining the source and nature of any environmental contaminant or stress, assessing how and in what form
it relates to people, measuring effects, and applying controls when and where appropriate. Environmental health contains two important things, namely the danger to the environment, the effect on health, and the development of effective ways to protect from hazards in the environment. The goal of environmental health is to improve health by identifying, preventing, and reducing hazards in the environment and by assessing and managing the risks involved.

Environmental medicine is part of the broadest discipline - environmental health - a subfield of public health that is concerned with assessing and controlling the impact of people on their environment and the impact on them of the environment. All of these are interactions between risk genes and human health, including various risk factors, various diseases, and various genetic predispositions to disease. The goal of environmental medicine is to prevent disease. Environmental medicine focuses only on explaining how disease causes in an environmental context focusing on the effects that occur on the general population in the outdoor and indoor environment through air, water, food, consumer products, or soil. Besides, occupational medicine is a part of environmental medicine that deals with understanding the hazards of the work environment and their impact on the health of workers.

**Environmental Medicine Ads Targeting**

Facebook ads targeting is an advertising service by adjusting the audience according to the target Facebook has. Indonesia has a number of Facebook users around 130 million per month. With Facebook ads targeting, you can choose the types of audience according to the criteria that match the ad\(^{(10)}\).

**Audience Demographic Characteristic**

**Gender.** Based on ads targeting result, the target audience for the “Environmental Medicine” ads is 759,153,510 Facebook users. From the data, the proportion of gender in the audience, both male and female, is the same.

**Age.** The target audience for these ads is 18-65 years of age and over (Figure 1). With a percentage of 19% of the audience is 18-24 years old, 34% of the audience is 25-34 years old, 20% of the audience is 35-44 years old, 13% of the audience is 45-54 years old, and 7% of the audience is over 65 years old. From the data above, it can be seen that most Facebook users are with a percentage of 34% of the audience aged 25-34 years. Meanwhile, the smallest percentage was 7% of the audience aged 65 years and over.

![Figure 1. Age of Target Audience Environmental Medicine](image-url)
Marriage Status. Not only based on gender and age which are used for the advertising target of “Environmental Medicine” but also based on marital status. In the data above (Figure 2), marital status can be divided into 4 statuses such as single status which has a percentage of 34.5% of the audience, relationship status with a percentage of 14% of the audience, engaged status has 3.7% of the audience, and married with a percentage of 47.8% of the audience. With this data, it can be seen that the most marital status is married with a percentage of 47.8% of the audience.

Figure 2. Marital Status of Target Audience Environmental Medicine

Education Level. Quite some audiences who are the target of the “Environmental Medicine” advertisement include the world of education starting from high school, college, to graduate school. The highest percentage of the audience is at the tertiary level. As many as 23.6% of the audience is from high school education, 68.8% of the audience is from tertiary education and the lowest percentage of the audience is 7.5% of the audience is from postgraduate education (Figure 3).

Figure 3. Education Level of Target Audience Environmental Medicine
Job. It is not only the audience from the world of education that is the target of advertisements but also from the world of work. There are 10 occupations included in the ad target, namely Administrative Service with a percentage of 25.2% of the audience, Sales with 20.1% of the audience, Management with 17% of the audience, Healthcare and Medical Service with 16.7% of the audience, Production of 14.9% of the audience, Education and Libraries 13.6% audience, Art, Entertainment, Sport and Media 12% audience, Business and Finance 10.7% audience, Community and Social Service 9.6% audience, and the last one is Installation and Repair Service work as much as 8.2% of the audience (Figure 4).

![Figure 4. Job of Target Audience Environmental Medicine](image)

In the field of work, the Administrative Service is the target of “Environmental Medicine” advertisements because it can retrieve information from advertisements that are seen for additional knowledge purposes and as material in making decisions or policies related to administrative or public policy fields. Then in the field of work Sales can sell health products so that the information available in advertisements can be useful in attracting consumers and can increase the number of requests for a product being offered. Besides, management work in the environmental or even health sector can be useful as an ingredient in managing and taking actions that will have a major effect on decisions taken. This kind of advertisement is certainly very relevant and can be very enthusiastic for the field of work of Healthcare and Medical Service because it can be used as a medium in educating the general public regarding health. Not to forget, in the field of work, medical device production can consider what health products have a high chance of being produced and sold, especially during the current COVID-19 pandemic.

If the ad is targeted to a potential audience and has a work field that is relevant to the information displayed, then the ad has the opportunity to get high engagement, the information is conveyed right on target, and the purpose of the ad will be achieved.

### Devices Used to Access Facebook

Device. The highest number of devices used to access Facebook in the “Environment Medicine” advertisement were Android devices, followed by iPhone / iPod, Mobile web, Computer and finally iPad. The use of Android devices in accessing these ads reached 75.9%. The use of iPhone / iPod devices is ranked second in accessing Facebook ads, reaching 20.4%. 2.1% of mobile web
devices are used to access Facebook ads. Furthermore, 1.2% of computer devices are used to access Facebook ads. Finally, 0.5% of the devices used to access Facebook ads are held by the iPad (Figure 5).

![Figure 5. Device Use by Target Audience Environmental Medicine](image1)

![Figure 6. Desktop and Mobile Use of Target Audience Environmental Medicine](image2)

The number of percentages of the devices described on the ads targeting results (Figure 6). Where the result of the conclusion is that Desktop & Mobile are the most frequently used devices in accessing Facebook ads, then the next device for accessing Facebook ads is Mobile Only and the last device that is rarely used to access ads is Desktop Only. This data is also supported by a report from We Are School, where mobile phones now account for 53% of the time spent online, but the data clearly show that other devices still play an important role in life (11).
Countries. The country that most frequently accessed Facebook ads in terms of “Environment Medicine” was occupied by the US (United States) at 22.7%, followed by India which reached 19.9%, the Philippines at 8%, Pakistan at 3.8%, Bangladesh at 3.6%, UK (United Kingdom) 3.4%, Malaysia 2.8%, Nigeria at 2% and the last at 1.8%, namely Australia and Canada. This data is taken from all human populations in the world who are over 13 years of age. The data above is also supported by a report from We Are School, wherefrom the previous year to the present year there is an increase in the audience with ages between 13 years and 17 years all over the world who access Facebook ads (11).

Keywords Suggestion

Keyword Suggestion is a keyword that appears or is most often suggested automatically to internet users when typing a keyword in the search field (Table 1). This keyword suggestion is especially useful for website optimizers. The main benefit of keyword suggestion is getting the most searched keywords in the search field. Many applications provide services for keyword suggestions. The image below is an example of a keywords suggestion.

<table>
<thead>

Conclusion and Acknowledgement

Facebook Ads as a platform for advertising the dissemination of environmental medicine information in by optimizing various superior features of Facebook. Optimization of environmental medicine dissemination by targeting advertising audiences with the right demographic, psychographic and geographic characteristics. Facebook ads enhance public brand awareness about environmental hazard with a wide advertising reach, high engagement, and low advertising costs.

Ethical Clearance - We have no ethical clearance to disclose. We have coordinated with the ethical clearance committee of the Research and Development Institute, Ministry of Health of the Republic of Indonesia. This research paper does not require ethical clearance. This research does not use human subjects or other living things. The data presented in this study is not in the form of data on living things, but in the form of modeling to develop science and promote environmental medicine.

Source of Funding - The source of funding comes from the researchers’ self-funding. Researchers do not receive funding sources from any institution or institution.

Conflict of Interest - We have no conflicts of interest to disclose.

Study of Causes of Death, Histopathological and Microbiological Changes in Cases of Burns Brought for Autopsy at Gandhi Medical College, Bhopal

Rajendra Kumar Mourya¹, Priyamvada Kurveti Verma², Garima³, Pawan Rathor⁴, Dheeraj Singh Verma⁵

¹Assistant Professor, Department of Forensic Medicine and Toxicology, Government Medical College, Shivpuri, Madhya Pradesh, ²Ex-Resident, ³Associate Professor, ⁴Demonstrator; Department of Forensic Medicine and Toxicology, Gandhi Medical College, Bhopal, ⁵Associate Professor, Department of Microbiology, Gandhi Medical College, Bhopal, Presently ⁴Medical Officer, District Hospital, Shivpuri, Madhya Pradesh

Abstract

Death may occur immediately after burns or may get delayed for days & weeks, where burns may not be the actual cause of death; but its sequels & its complications leads to death. In such cases, determination of exact cause of death may be difficult. Hence, this study was aimed to find out the causes of death in burn cases during autopsy utilizing histopathology and microbiology & its comparison with clinical causes of death. All cases of burns autopsied at Gandhi Medical College & associated Hamidia Hospital Bhopal, for a period of 1.6 years were included in the study.

Out of 100 cases included, 45 (45.00%) showed the cause of death as septicemia, followed by hypovolemic shock in 30 (30.00%) cases, hypovolemic shock with acute renal failure seen in 4% cases. Bronchopneumonia was seen in 29% cases, out of which 12% cases were associated with septicemia. Multiple Organ Failure with septicemia was seen in 11% cases and in 2 (2.00%) cases of spot death; cause was neurogenic shock with asphyxia.

On histopathological examination, lungs revealed congestion and alveolar edema in 48% cases; Liver showed sinusoidal congestion in (39 %) cases; Kidneys showed hydropic degeneration of tubules in 62 % cases; being the most common findings. Pseudomonas aeruginosa was the commonest isolate, 61% in blood and 47% in pus culture. So, there is need of strict and 100% implementation of aseptic measures in burn wards, along with adequate supply of appropriate drugs specially antibiotics to the all hospitals.

Keywords: burns, cause of death, septicemia, histopathology, culture.

Introduction

A severe burn injury is the most devastating injury a person can sustain and yet hope to survive. Burns are the fourth most common type of trauma worldwide, following traffic accidents, falls and interpersonal violence.

Death may occur immediately after burns or may get delayed for days & weeks, where burns may not be the actual cause of death; but its sequels & its complications may result in death. The patient may survive in the initial post burn period, progressing satisfactorily and may even apparently become normal; even then sometimes death may occur suddenly as a result of sequel, complication
or some remote intervening cause.

Determination of exact cause of death may be difficult as external appearance may show the effect of burn as a cause, but internal findings may point to some other causes of death; for example, shock, electrolyte imbalance, septicemia, renal failure, hepatic failure, lung dysfunction and so many other causes.

So, to ascertain the exact cause, it needs meticulous autopsy to be done by autopsy surgeon along with gross and microscopic examination of relevant organs by pathologist, blood and pus culture by microbiologist & toxicological analysis in forensic science lab.

Hence, this study was designed to find out the causes of death in burn cases during autopsy; utilizing histopathology and microbiology & its comparison with clinical causes of death.

**Material and Methods**

Present study was carried out in the Department of Forensic Medicine and Toxicology in collaboration with Department of Pathology and Department of Microbiology at Gandhi Medical College & associated Hamidia Hospital Bhopal, for a period of 1.6 years.

All the burn cases either admitted or directly brought dead to the Hamidia Hospital Bhopal, cases with proper hospital records and the cases of spot death were included. Out of those, 100 cases were selected for the study by simple random sampling. Burn cases without proper hospital records, unknown, mutilated, decomposed bodies were excluded.

The relevant data was collected using a questionnaire that included demographic profile of deceased, history taken from the relatives and police, inquest papers, hospital records and autopsy findings. After gross examination, sections were taken from lungs, liver and kidneys (with due consent obtained from relatives). Histopathological examination of the sections was performed at department of Pathology; and blood and pus culture was done at department of Microbiology, Gandhi Medical College, Bhopal.

**Results and Discussion**

On analyzing the data, following results were obtained:

<table>
<thead>
<tr>
<th>Table-1: Causes of Death in Burn cases revealed after autopsy</th>

</tr>
<tr>
<td>Multi Organ Failure with Septicaemia</td>
</tr>
<tr>
<td>Total</td>
</tr>
</tbody>
</table>
In majority of cases i.e. 45 (45.00%) the cause of death was septicemia, followed by hypovolemic shock in 30 (30.00%) cases and hypovolemic shock with acute renal failure in 4% cases. Bronchopneumonia was seen in 29% cases in which 12% cases were associated with septicemia. Multiple Organ Failure with septicemia was seen in 11% cases and in 2 (2.00%) cases of spot death; the cause was neurogenic shock with asphyxia.

Burn shock is rapidly developing hypovolemic circulatory failure seen in the first 72 hours after burn injury. Infectious Complications are currently the principal cause of in-hospital death in burn victims. The infection usually is airborne and less often hematogenous from wound infection. Septicemia is another common cause of death and has a high mortality in burns patients. It usually is secondary to infection of the burn site.

Septicemia was common in victims who survived for more than 3 days. Similar observation were made by Harish D et al (2013) in their study on 381 burn cases, where cause of death was given as Burns shock in 31 (08%) cases, Toxemia & shock in 67 (18%) cases and Septicemia in 269 (71%) cases. Chawla R et al (2011) and Ande JD et al (2013) also observed the major cause of death as septicemic shock in 56% cases and septicaemia as the leading cause of death in 52.38% cases; respectively.

Khandare SV and Pawale DA (2014) also observed cause of death as septicaemia in 76.7% cases and shock due to burns in 20% cases. Pawar V et al (2014) studied 348 admitted burn cases out of which 196 patients died during treatment. Commonest cause of death was septicemia alone or in combination with other causes constituting (84.69%) cases.

On the contrary, Mazumdar A and Patowary A (2013) observed shock as the most common cause of death (122 cases), followed by exhaustion (62 cases) and septicemia (58 cases). Mangal HM et al (2007) observed maximum percentage of victims died within first 24 hours due to hypovolemic shock (burns- shock). Only 16 victims (5.33 %) were found dead on spot due to neurogenic shock, while 19 victims (6.33%) died within a duration of 24-36 hours, followed by 46 victims (15.33%) in 36-72 hours, 31 (10.33%) in 3-7 days and only 22 victims (7.33%) could survive more than a week.

In this study, Bronchopneumonia was seen in 29% cases; which is similar to the study of Mostafa M. Afifya et al (2006-2010) who observed that the majority of deaths occurred within a week (82%) and most of the victims died from neurogenic shock (54.7%) followed by Septicemia and pneumonia (23.5%). Kumar and Tripathi (2004) in their study reported Bronchopneumonia in 22 (20%) cases.

</tbody>
</table>
On studying the case files of admitted deceased, clinical causes of death mentioned were multiple organs failure in 61% cases and burn shock (neurogenic/hypovolemic shock) in 24% cases and multiple organ failure with septicemia in 15% cases. This was also seen in the study of Kallinen O, Maisniemi K et al (2012) who reported that, out of 71 burn deaths, 40% were caused by multiple organ failure (MOF). All 28 patients with multiple organs failure had acute renal failure, followed by liver damage, of which four patients had acute or chronic liver failure.

Table-3: Soot particles in Trachea

Soot particles were found in trachea in only 7 (7.00%) cases, out of 100, the rest 93% cases were devoid of the soot particles in the trachea. This observation was different from the findings of Mazumdar A and Patowary A (2013) who found soot particles in trachea in 19% of cases, Das. K.C.(1998) who observed soot particles in trachea in 18.05% cases, Nath D (2007) who reported soot particles in trachea in 34.07% cases and Kumar and Tripathi (2004) who noted soot particles in 26% of cases studied.

Most of the victims in the present study died in the hospital after receiving treatment, which included intravenous fluid and some oral medication. Many of the cases might have occurred in some open spaces. These two may be the reason for absence of soot particles in the trachea in most of the victims.

<td>-</td>
<td>27%</td>
</tr>
</tbody>
</table>
Lungs revealed congestion and in alveolar edema in 48% cases, inflammatory cell infiltrate in 43% and necrotic zone in 21%, macrophages in 16% cases. In most cases, these changes were observed more frequently after 72 hours of survival, alveolar edema had been increasing with increasing duration of survival whereas macrophages were more frequent after 7 days of survival.

Liver showed sinusoidal congestion in 39% cases, inflammatory cell infiltrate in 21%, necrotic changes in 15% and fatty change in 8% cases. Sinusoidal congestion was prevalent throughout, irrespective of the duration of survival. In Kidneys, hydropic degeneration of tubules was seen in 62% cases, tubular necrosis in 48%, tubular casts seen in 27% cases.

Similarly, Shinde AB and Keoliya AN (2013) studied 110 burn cases and observed similar findings in major vital organs. In lungs, bronchopneumonia was seen in 22 (20%) cases, pulmonary oedema in 61 (55.45%) cases, atelectasis in 16 (14.54%), emphysema in 19 (17.27%), interstitial haemorrhage in 42 (38.18%), intra alveolar hemorrhage in 39 (35.45%), interstitial pneumonitis in 30 (27.27%), macrophages in 51 (46.36%), congestion in 81 (73.63%), hemorrhagic necrosis in 5 (4.54%). These changes more frequently after 72 hours of survival.

In liver, they found congestion in 64 (58.18%) cases, fatty change in 17 (15.45%), centrlobular necrosis in 39 (35.45%), dilated and congested sinusoids in 42 (38.18%), infarction in 16 (14.54%), degenerative changes in 21 (19.09%) focal necrosis in 21 (19.09%), focal hemorrhage in 21 (19.09%), portal inflammation in 11 (10%), fibrin deposition in 2 (1.81%) and periportal necrosis in 6 (5.45%) cases.

In kidneys, they reported acute tubular necrosis in 18 cases and in 12 cases it was observed in death within first 5 days. Tubular casts in 35 and in 21 cases it was observed in death within first 5 days. Cloudy degeneration was present in 17 of 110 cases and in 12 cases it was observed in death within first 5 days.

<table>
<thead>
<tr>
<th>Findings</th>
<th>Blood culture</th>
<th>Pus culture</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pseudomonas aeruginosa</td>
<td>61%</td>
<td>47%</td>

</tr>
<tr>
<td>Proteus sp.</td>
<td>04%</td>
<td>1%</td>
</tr>
<tr>
<td>Staphylococcus aureus</td>
<td>-</td>
<td>12%</td>
</tr>
</tbody>
</table>

Psedomonas aeruginosa was the commonest isolate 61% in blood and 47% in pus culture, followed by Klebsiella pneumoniae 30% in blood and 8% in pus; Staphylococcus aureus seen in 12% cases. Similarly, Rajbahak S et al (2014) identified total of 215 bacterial isolates from 168 pus swabs. P. aeruginosa accounted for the highest percentage 98 (45.6%) from the burn wounds followed by S. aureus 41 (19.1%) and Acinetobacter spp. 38 (17.7%).

Skin burning causes general immunosuppression. The denatured protein in burn injured tissue provides a good substrate for microbial growth. The relative avascularity as a consequence of thermal thrombosis further promotes infection. Not surprisingly, the risk of burn infection is proportional to the area burned. Full-thickness skin burns usually are colonized by bacteria within a few days, with sparse Gram-positive organisms in the first week and dense Gram-negative organisms
thereafter.\textsuperscript{11}

Most episodes of septicemia occur between 6 and 10 days after the burn. Wound infection by specific organisms such as Streptococcus pyogenes or Pseudomonas aeruginosa or heavy colonization of a burn wound predispose to invasive sepsis with organisms invading living tissue adjacent to the wound.\textsuperscript{18}

**Conclusion**

The commonest cause of death revealed at autopsy was septicemia (45.00%), followed by hypovolemic shock (30.00%); while most frequent clinical cause of death was multiple organ failure in 61% and burn shock (neurogenic/hypovolemic shock) in 24% cases. Lungs revealed congestion and alveolar edema in 48% cases, liver showed sinusoidal congestion in 39 % cases, kidneys showed hydropic degeneration of tubules in 62 % cases; which were the most common histopathological changes observed. Pseudomonas aeruginosa was the commonest isolate 61% in blood and 47% in pus culture.

Similar findings have been observed by Harish D et al (2013)\textsuperscript{5} and Khandare SV and Pawale DA (2014)\textsuperscript{7} who reported septicemia as cause of death at autopsy in majority of cases; while Kallinen O, Maisniemi K. et al (2012)\textsuperscript{6} found Multiple organ failure as commonest clinical cause of death.

Shinde AB and Keoliya AN (2013)\textsuperscript{17} reported pulmonary edema, observed sinusoidal congestion in liver, found acute tubular necrosis and cloudy degeneration in kidneys; as commonest histopathological changes, which supports the findings of present study. Similarly, Rajbahak S et al (2014) found Pseudomonas aeruginosa accounting for the highest percentage (45.6%) of the burn wound flora.

Major causes of death found were septicemia, bronchopneumonia and hypovolemic shock. So, there is need of strict and 100% implementation of aseptic measures in burn wards following the guidelines given by WHO. Government should ascertain the supply of sufficient and appropriate drugs specially antibiotics to the all hospitals without interruption.

Study of gross and histopathological findings in visceral organs in autopsy of burn cases, as well as microbiological analysis of blood and pus in cases of spot death/brought dead and other burn cases, may help in planning an efficient treatment protocol for burn cases in future.

Determination of Capoten by Analytical Methods

Rana.S.A.L-Shemary

Lecture, Babylon University, College of Pharma, Science Dept., Hilla, Iraq

Abstract

The present analysis article points out numerous analytical methods for the quantitative identification of ACE inhibitor (ACE Inhibitor) by one in all the spectroscopical techniques (UV-spectrophotometry) and separation techniques, like superior liquid natural action (HPLC). Additionally, we tend to examine the contribution of optical biosensors to the clinical and pharmaceutical study of ACE inhibitor, which has applicable analytical procedures for internal control, pharmaceutical drug formulations and human.

In this report, a comprehensive sample of scientific papers published in different journals relating to medicinal, clinical and analytical chemistry was collected. Captopril was chosen because it is a popular medication in the pharmacy, a first-line antihypertensive agent, with a fast release, limited course of operation

Key words :- Captopril, ACE inhibitor, HPLC, UV, biosensor

Introduction

Captopril is the first oral angiotensin converting enzyme inhibitor to become available. It was used mainly for hypertension. In mild to severe hypertension, captopril is nearly as effective as normal doses of hydrochlorothiazide or propranolol, nearly one-half of these patients need the use of a diuretic to gain satisfactory regulation of blood pressure. (1)

In extreme hypertension captopril plus a diuretic (and in some cases a beta-blocker) blood pressure has typically lowered considerably better than could be done with ‘normal combination treatment’ in cases whom have not responded sufficiently to this protocol, and this also resulted in an increased sense of well-being in highly hypertensive patients that have previously undergone comprehensive multiple drug therapy. Indeed, at the present stage of drug production, patients who do not respond to or accommodate ‘ordinary’ antihypertensive treatment are the most effective candidates for captopril therapy (2).

Ultimately, the final role of captopril in the treatment of hypertension may depend on further confirmation of its profile of adverse effects. Captopril has shown promising changes in a limited number of patients with serious congestive heart failure resistant to traditional treatment, in addition to research on hypertension (3).

Captopril must be considered an interesting addition to the clinical armamentarium; it will continue to create a lot of excitement as its final role in therapy is best described by additional well-designed experiments to evaluate captopril, such as HPLC, UV-visible spectroscopy, GLC, optical biosensor, etc (4). Captopril tablets are shown in Fig.1.

Figure 1: A picture of captopril tablets.

Discovery and synthesis of captopril
One of the primary medications marketed for lowering blood pressure. Three researchers at the U.S. drug maker Squibb (now Bristol-Myers Squibb) made-up angiotensin converting enzyme inhibitor in 1975: Miguel Ondetti, Claude Bernard Rubin, and David Cushman. In February 1976, Squibb applied for U.S. patent rights for the drug and the U.S. In September 1977, a patent was issued. Captopril’s development was one of the early achievements of the groundbreaking idea of ligand-based drug design.

In the mid-20th century, the renin-angiotensin-aldosterone pathway was thoroughly researched and this mechanism provided many important goals in the production of new therapies for hypertension. The first 2 goals that were tried were proteinase associate degree an angiotensin converting enzyme inhibitor. ACE inhibitor was the results of attempts by Squibb’s labs to supply an angiotensin converting enzyme inhibitor. Ondetti, Cushman, and colleagues distended on work undertaken among the 19 Sixties by a team of researchers semiconductor unit by John Vane at the Royal college of Surgeons of European nation. Kevin K.F. created the first breakthrough. In 1967, the transfer of angiotensin I to angiotonin was blocked throughout its passage through the pulmonary circulation mistreatment bradykinin potentiating factor (BPF) equipped by Sergio Ferreira metric Ng and Vane. Later, BPF was found to be a peptide in the lancehead viper venom (Bothrops jararaca), which was the transforming enzyme’s “collected-product inhibitor.” A sting from this snake triggers an immediate decrease in its prey’s blood pressure, rendering it difficult to run. After it absolutely was found by QSAR-based modification that the terminal sulfhydryl moiety of the amide created a high efficiency of ACE inhibition, Captopril was formed from this peptide.

A non-peptide with a proline residue at the C-terminal is found in the venom. A effective regulator of the so-called angiotensin-converting enzyme (ACE) was found to be this non-peptide. It is a zinc-containing enzyme that catalyzes the synthesis of the angiotensin I peptide into the hormone angiotensin II active peptide that raises blood pressure. While the venom peptide’s very quick action can be useful for a starving snake, it is not helpful for humans.

Medicinal chemists have produced a sequence of proline-containing zinc-binding compounds using the catalytic mechanism of similar zinc-containing enzymes as the starting point. Succinyl-(S)-proline was the first ACE inhibitor to be synthesized. Medicinal chemists were able to improve the production of the ACE inhibitor more than 1000-fold by replacing the succinyl group with a structurally similar sulfhydryl group. In 1980, Captopril entered the market as the first inhibitor of ACE, as seen in Fig.2.
It was proprietary in 1976 and approved in 1980 for medicative use. attributable to its mechanism of action and conjointly attributable to the event method, it absolutely was the primary angiotensin converting enzyme inhibitor developed and was thought-about a breakthrough. At E, Captopril was found and grown. Centered on ideas pioneered by Nobel laureate Sir John Vane, R. Squibb & Sons Pharmaceuticals is now sold by Bristol-Myers Squibb.

On April 6, 1981, Captopril received FDA approval. In Feb 1996, once the business exclusivity maintained by Bristol-Myers Squibb for Capoten all over, the medication became a generic medication within the U.S. The production of Capoten was claimed as an indication of ‘biopiracy’ (marketing standard medicines), as no benefits flowed back to the associate estral Brazilian community WHO 1st used viper venom as an point poison (10).

Indication

1. Hypertension

Adult /Initially twelve.5-25 mg doubly daily, then augmented to a hundred and fifty mg daily in a pair of separated doses if necessary, doses to be augmented at periods of a minimum of a pair of weeks, once daily dose are often decent if any concomitant medicine medications square measure taken.

Initially 6.25 mg doubly daily, then augmented to a hundred and fifty mg daily if needed in a pair of split doses, doses to be augmented at intervals of a minimum of a pair of weeks, once daily dose are often decent if any concomitant medicine medicines square measure taken.

2- Prophylaxis of symptomatic internal organ failure in clinically healthy patients with symptomless left chamber malfunction (beginning 3-16 days when infarction) following infarction (under close to surgical supervision)

Adult / at first 6.25 mg daily, then hyperbolic to twelve.5 mg three times daily for two days, then hyperbolic to twenty five mg three times daily if tolerated, then hyperbolic to 75-150 mg daily if tolerated in 2-3 separated doses, rising steady to doses larger than seventy five mg daily.

3-Diabetic nephropathy in type 1 DM

Adult/75-100 mg in split doses daily.
4-Heart failure

Adult/(under shut medical supervision) at first 6.25-12.5 mg 2-3 times every day, then hyperbolic more and more at periods of a minimum of a pair of weeks, if tolerated up to a hundred and fifty mg daily in divided doses.

5-Short-term treatment of clinically competent patients with myocardial infarction within 24 hours of onset.

Captopril analytical measurement

Several assay strategies, like coulometric (13), conductometric, and colorimetric, are developed for the quantitative determination of Capoten (14). Infrared spectroscopy (15), mass spectroscopy and nuclear magnetic resonance spectroscopy (16) are used to determine Captopril. Captopril’s UV spectrum with one band at two hundred nm was obtained, whereas the CD spectrum consists of one peak at 210 nm (17).

Captopril by spectrophotometric method was calculated by Alberto (18) and iron and copper complexation with ACE inhibitor was additionally assayed (19) by ultraviolet illumination photometer. the amount of chromatographical strategies for the determination of ACE inhibitor has been defined as gas chromatography-mass spectrometry (20) Ahmed et al. (21) also published HPLC stability-indicating methods for its determination.

This approach is employed for the assessment of angiotensin converting enzyme inhibitor in pure type within the presence of the disulphide chemical compound and in pharmaceutical preparations, an answer containing 0.025 C and w / w Pd(II) chloride was used as a mobile step in a very mixture of acetonitrile-methanol-water comprising ten millimetre Britton-Robinson [BRb] pH scale 4.00 and 0.25 M KCl solution [1:4:5 v / v / v].

Another HPLC methodology determined by Stulzer et al. angiotensin converting enzyme inhibitor in controlled unleash tablets and analyzes were performed at temperature at the inverted part Phenomenex Luna column C18 (250 millimetre × 4.6 mm), mobile part water: methyl alcohol (45:55; v / v) and pH scale 2.5 at 1.0 mL.min⁻¹, and also the response was linear at zero.3–1.5 mg.mL⁻¹ (r² = 0.9983) (22).

Ivanovic et al. have revealed a valid RP-HPLC method for analyzing hydrochlorothiazide and Capoten in tablets. Jankowski et al., calculated by HPLC in blood with captopril (23). The captopril adduct recovery achieved 93.1% and the detection limit was 15 ng.mL⁻¹, while the conceptual limit was 30 ng.mL⁻¹. Inter and intra-assay RSD were below 9%, but precision was found to be below 8%. Captopril was calculated by Saleem et al. and Amini et al. (24) in plasma.

For the quantitative determination of angiotensin converting enzyme inhibitor by the quantity of scientists victimisation HPLC (25), variety of assay strategies are developed. a range of examinations are recorded victimisation HPLC for the determination of angiotensin converting enzyme inhibitor in bulk drug substances and their formulations (26). Direct determination of the four ACE-inhibitors Zestril, Enalapril, angiotensin converting enzyme inhibitor and Fosinopril in prescription drugs and blood serum by HPLC analyst separation was accomplished by RP-HPLC gradient with a mobile step consisting of acetonitrile: water (60:40 v / v) with ortho oxyacid changed to pH 3.0 (26), Fig.3 demonstrates captopril’s chemical composition.
Monitoring of in vitro trials of ACE inhibitor association with LC-UV symptom agents and parallel LC determination of rosvastatin, lisinopril, captopril, and angiotensin converting enzyme inhibitor in API, medicament formulations, and human blood serum (27).

Another Facile and Manifest Liquid chromatographical method for coinciding Determination of ACE inhibitor and NSAIDs in API and Pharmaceutical Formulations has been according and CAP has been isolated from NSAIDs by means that of a column of Purospher STAR C18 (250.4.6 mm, five μm) and a mobile section consisting of alcohol, water (80:20,v / v) (28).

Therefore, ACE inhibitor with water pill HydroDIURIL and diuretic in active pharmaceutical ingredients, medicative indefinite quantity formulations and human body fluid area unit used as combination indefinite quantity forms for alternative distinctive forms of drug substances like metal channel block medicinal drug, diuretics, etc. (29).

Other hypoglycaemic Capoten, medicinal drug and H2 receptor antagonist ways ar recorded in bulk, formulations, and human humor by RP-HPLC (30-32).

Biosensors have become important bioanalytical instruments in the last few years for environmental testing, biotechnology, pharmaceuticals, food safety and other consumer industries. Due to their high sensitivity, high precision, low expense, compact size and simple activity, the use of biosensors to test chemical species is an exciting opportunity.

High sensitivity and fast detection are key criteria for a sensor for detecting biomaterials. There has been a great deal of study over many decades to develop quick and responsive biosensors for various applications. In particular, owing to the probability of fast and direct (unlabelled) detection, optical methods have been reported to have a high potential.

A variety of biosensor instruments, including several interferometers, surface plasmon resonance sensors and micro ring resonator sensors, have been used to detect various biomaterials. While all these sensors offer sensitive and quick detection, they are only suitable for items up to 100 nm in size (33).

A light detector resistance (LDR) is AN optical device mounted in an exceedingly black PTFE cell and paired to a cheap multimeter (Ohmmeter). The chemical analysis is based on the reduction of ammonium ion molybdate by Capoten, producing a green-yellow compound in the presence of sulphuric acid (λmax 407 nm). By plotting the electrical resistance of the LDR against the CPT concentration, the standardization curves were obtained within the vary of 4.60 x 10^{-4} to 1.84 x 10^{-3} mol.L^{-1} with an affordable constant of determination (r^2 = 0.9962) (34).

Moreover, as a result of their uncommon optical properties and catalytic ability, Molybdenum compound nanomaterials have recently attracted widespread interest. There is, however, no literature up to now on the utilization of photoluminescent nanomaterials of Molybdenum compound in biological and pharmaceutical sensing.

Via Associate in Nursing easy method, photoluminescent Molybdenum oxide compound quantum dots (MoOx QDs) were synthesized and so the synthesized MoOx QDs were more additional as a
A replacement sort of photoluminescent probe to create a replacement off-on angiotensin converting enzyme inhibitor (Cap) detector supported the idea that the quenched photoluminescence of MoOx QDs by Cu$_2^+$ was fixed up to Cap by precise interaction between thiol cluster of Cap and Cu$_2^+$. The rebuilt photoluminescence strength showed a powerful linear relationship with the Cap material, variable from 1.0 to 150.0 μM, with a 0.51 μM (3σ / k) detection most, beneath ideal conditions. additionally, with the recently designed off-on device, the content of Cap was with success known in pharmaceutical samples, and therefore the recoveries were 99.4-101.7 percent, indicating that the newest off-on device includes a high accuracy.

Replicate (n = 10) measurements were created on an equivalent answer comprising the equivalent of 1.15 x 10$^{-3}$ mol.L$^{-1}$ of CPT to check the repeatability and preciseness of the measure methodology. Determinations (n = 10) were created with an equivalent answer containing CPT adequate to 1.15 x 10$^{-3}$ mol. L$^{-1}$.

This resolution was tested in conjunction with the prescribed approach for measurement the CPT content of pharmaceutical formulations. In terms of share relative variance (% RSD) (36), the accuracy was measured.

**The Biosensors Specifications**

The essential specifications for biosensors are the following:

Ø Ability to provide real-time data during a project at each development stage or at multiple time points. This would help in improved tracking and regulation of blood sugar levels, for example.

Ø It is feasible to customise several biosensor technologies to permit continuous flow analysis that’s terribly helpful in food process, observance of installation, and air quality.

Ø Through miniaturization, biosensors can reduce usage costs and can be incorporated into efficient, highly capable lab-on-a-chip tools.

Ø Biosensors is used for point-of - care or on-the-spot analysis wherever progressive molecular analysis is conducted while not the requirement for a progressive laboratory (37).

**Biosensor system**

In general, a biosensor uses a facet of biological recognition that detects the presence of an analyte (the species to be detected) and produces a physical or chemical change that’s remodeled into a symptom by an electrical device (detector). The general block diagram of the framework of biosensors is defined in Fig. 4. Specific system for biosensing. An analyte is inserted into the detector by the sampling machine. The identification issue attaches or responds to a specific analyte, giving a biodetection specificity. Enzymes, antibodies, proteins, DNA or additionally cells like yeast or bacterium are used as parts in biorecognition (38). In general, stimulus may be generated by optical, electrical, or other kinds of force fields that, as a result of biorecognition, extract a reaction. The transduction mechanism converts the physical or chemical process of biorecognition into an optical, electrical or another variety of signal within the presence of external stimuli that’s then detected by the detector device. For identification of the analyte, the detection device may provide pattern recognition.

A broad variety of real life applications are defined by biosensors (39). In essence, future uses are medicinal and nonclinical (40). The use of biosensors to track toxins (41), micro-organisms, microbes, viruses (42) and chemical and biological defense against terrorism is of more recent concern. In agricultural and environmental applications (43), it is also common. A few days now, applications based on nanotechnology (44) are also being created.
The Immobilization Techniques (Mechanism)

The biological part has to be correctly attached to the transducer to make a biosensor. Immobilization is called this method. On a solid support, the biorecognition components are typically immobilized. A membrane, rubber, copolymer, or semiconductor material are typically the solid supports. A biorecognition component, either by a physical methodology (such as adsorption) or by chemical association, is immobilized on the solid support. In sure ways, the issue of biorecognition is cursed with controlled porosity within the volume of the matrix (solid support), wherever solid support typically provides property against associate analyte of a precise size in step with its pore dimension (44).

Conclusion

A significant variety of drugs for effective treatment are administered to people diagnosed with hypertension, raising the risk of adverse effects and drug reactions. But Gupta et al. (37-44) have documented some electro analytical approaches.

UV and HPLC strategies and optical biosensors for the determination of ACE inhibitor in active ingredients, pharmaceutical formulations and biological specimens square measure investigated alone or in conjunction with different medication during this study.

In general, pricey instrumentation, provision for the utilization and disposal of solvents, labour-intensive sample preparation procedure and private skilled chromatographical techniques were needed for HPLC strategies.

Furthermore, several of the examined HPLC approaches have the ability to apply drug combination, multi-drug pharmacokinetics trials and association studies to clinical science.

Thus, optical biosensors are one of the most interesting alternatives in this situation, since they play an important role in drug quantification and are one of the most specific, sensitive, low-cost and easy-to-use options available at the moment. This has provided a niche for them as new clinical instruments that allow more precision medicine to be controlled therapeutically by minimizing symptoms or secondary effects as much as possible and contributing to safer patient treatment and prescription.

In addition, the use of biosensors offers doctors a benefit when making the most precise choices for
real-time dosing at the bedside of a patient, since biosensors are compact instruments that are easy to use and miniaturized. When formulating medicines, they have stricter and more effective regulation. There is an immediate need for more research based on the quantification of blood medications and including all pharmacological classes to ensure that a greater range of medications have personalized doses in accordance with the premise of usage.

Abstract

The choroid plexus (CP) is present in brain ventricles. It is responsible for cerebrospinal fluid (CSF) secretion and various vital functions. Special proteins present in choroidal epithelium play important roles in CSF production and energy metabolism.

This study aims to compare between the lateral and fourth ventricles CPs using hepatocyte nuclear factor 4 alpha (HNF4α), metabolism marker, to evaluate the functional activity of this tissue in the two regions.

Ten adult male albino rats were used to study the histological features of the CPs and to study the functional activity by quantitative immunohistochemical labeling with HNF4α marker.

The CP of the fourth ventricle had more functional activity than the CP of the lateral ventricle. A quantitative assessment of HNF4α using Aperio ImageScope Software Analysis showed that the lateral ventricle CP mean positivity 0.264 ± 0.083 pixel/micron² while the fourth ventricle CP have mean positivity 0.297 ± 0.043 pixel/micron². The immunohistochemical expression of marker in the fourth ventricle CP were significantly, P ≤ 0.05 higher than those in the lateral ventricle at P ≤ 0.05. Immunohistochemical detection of metabolism marker went along with findings of other histological and biochemical studies to define the CP as a highly dynamic structure with regional variations forming a continuum of one entity tissue capable of functional adaptation according to body needs.

Keywords: Choroid Plexus, Lateral Ventricles, Fourth Ventricle, HNF4α

Introduction

The choroid plexuses (CPs) are leaf-like highly vascular structures (1). Four CPs floating inside the ventricular cavities of the brain: one in each of the two lateral ventricles, one in the third, and one in the fourth ventricle (2).

Corresponding author:
Rasha A. Salman
Assistant lecturer at Madenat Alelem University College, Al-kadhmiya, Baghdad, Iraq
E-mail: Rashaabjad@gmail.com

The CPs are extensions of the ependymal lining of the ventricular walls and consist of a fenestrated vasculature core surrounded by a single layer of polarized cuboidal epithelium with an interstitial stromal layer of connective tissue rich in fibroblasts and cells of the immune system in between (3). Adjacent CP epithelial cells are joined together by tight junctions to form the blood-cerebrospinal fluid (CSF) barrier. Together with adherens junctions, the tight junctions also ensure the apico-basal polarity of membrane proteins (for example, transporters) that are critical for normal epithelial cell function (4).
The main known function of the CP epithelium is to produce CSF via passive filtration of peripheral blood across the choroidal capillary endothelium in the vasculature core followed by regulated active secretion across the single-layered epithelium (5).

Hepatocyte nuclear factor 4 alpha (HNF4α) may play a role in the transcriptional control of drug transporters. It is a member of the nuclear receptor superfamily that regulates a broad range of xenobiotic–metabolizing enzymes and thus regulating the metabolism in the CP (6). The HNF4α gene can also be found in the liver, pancreas, intestine, brain and recently in epithelial cell of CPs (7).

**Materials and Methods**

**Animals and tissue preparation:**

A sample of 10 adult male rats (*Rattus norvegicus albinus*). The animals aged 3-6 months, with 300 ± 50 g body weight, and were fed with standard pellet diet. Animals were euthanized with chloroform soaked cotton in an air tight chamber for 5 minutes, then the brains were removed from the skulls and fixed for 18 hours in 4% paraformaldehyde at room temperature (22°C).

The brains were cut in coronal planes rostral to the optic chiasma and caudal to the midbrain in order to obtain lateral and third ventricles specimens, while fourth ventricle samples were made by trimming the remaining caudal part of the brain (cerebellum and brainstem). The specimens were then left in the fixative for another 18 hours and finally transferred into commercial 70% methanol where they were kept until further processing. Paraffin blocks were made and 5 µm thickness sections were cut for immunohistochemical labelling (8).

**Immunohistochemistry Labeling:**

The Super Sensitive IHC for Detection Kit HNF4α antibody was found in CP by following all subsequent steps, which carried out at room temperature in a humidified chamber. Super Sensitive IHC Detection Kit was used. Sectioning at 5 µm were used and deparafinization, Incubate tissue in appropriate pretreatment or digestive enzyme for primary antibody and PBS/TBS wash 3 times for 2 minutes. Then incubate slide in Hydrogen Peroxide Blocking Reagent for 10 minutes, PBS/TBS wash 3 times for 2 minutes. Apply Blocking Reagent and incubate for 5 minutes, PBS/TBS wash 3 times for 2 minutes. Apply primary antibody and incubate according to manufacturer’s recommended protocol (overnight) incubation, PBS/TBS wash 3 times for 2 minutes. Apply HRP Polymer and incubate for 10 minutes, PBS/TBS wash 3 times for 2 minutes. Add 20µl of DAB Chromogen to 1 ml of DAB Substrate, mix by swirling and apply to tissue. Incubate for about 3-5 minutes, PBS/TBS wash 3 times for 2 minutes. Finally counter stain and cover slip using a permanent mounting media (9).

**Controls**

For positive controls, adult male rat kidney sections were labelled for HNF4α in the same procedure, while for negative controls adult male rat brain and kidney sections were labelled in the same procedure except that primary antibodies of HNF4α were replaced by PBS.

**Immunohistochemical Reaction Assessment**

For HNF4α marker, forty field images of immunohistochemically labelled slides were captured from the lateral ventricle CP, and a similar number of fields were captured from the 4th ventricle CP. A LEICA DM 750 light microscope equipped with Digital Microscopic Camera 5 Mega pixel digital camera were used to capture the fields. Images were processed with Aperio ImageScope v.11 program for total positivity. Microsoft office Excel® 2013 program was used to describe the collected data by calculating the Descriptive Statistics and t-Test were used to compare between means in this study.

**Results**

**Immunohistochemical Labeling of the Choroid Plexus**

**Hepatocyte Nuclear Factor 4 Alpha (HNF4α)**
Light microscopic examination of sections labeled with anti-HNF4α showed high reactivity in choroidal epithelium compared with other cells of brain tissue. There was no detectable difference between reactivity of lateral and fourth ventricles CPs. Ependyma showed weaker reactivity to HNF4α marker than the choroidal epithelium (Figures 1-2). Endothelium of choroidal vessels were highly reactive to HNF4α marker whereas blood cells inside these vessels were non-reactive with this marker (Figure 2).

Controls

External positive and negative controls, and internal negative controls are seen in (Figure 3).

Aperio ImageScope Software and Statistical Analyses

Assessment of Anti-HNF4α Reactivity

Statistical analysis of anti-HNF4α reactivity in the lateral and fourth ventricles CPs gave mean values of 0.264 ± 0.083 pixel/micron² and 0.297 ± 0.043 pixel/micron², respectively, with a wider range of reaction intensity in the lateral ventricle CP than that in the fourth ventricle CP (Figure 4). Two-sample assuming equal variances t-Test revealed a statistically significant difference between these values (p<0.05) (Tables 1-2).

Discussion

Previous studies on the CPs of the lateral, third and fourth ventricles considered them as one entity but some authors reported differences in activities of certain metabolic enzymes of the various CPs (10). The immunohistochemical reactivity of HNF4α in the CPs of both lateral and fourth ventricles were estimated with Aperio ImageScope software that could detect the cells labeled with the specified marker and categorized them into three groups: strongly positive, positive, and weakly positive, while negative areas were those without any reactivity. That was applicable for choroidal epithelium, ventricular ependyma, and endothelial cells of choroidal vessels, but not blood cells within (Figures 1(B)-3).

Positively labeled cells were marked up with Aperio ImageScope software as brown, light brown and yellow colored, indicating strongly positive, positive and weakly positive, respectively (Figure 4). In this study, it was not possible to localize, with precision, HNF4α receptors in cells which were previously localized in the basolateral side of choroidal epithelium plasma membrane, though it was clear to identify HNF4α labeling as a granular stain occur in the cytoplasm. This might be due to the presence of aggregations of transporter proteins across the B-CSF-B like ABCC, ABCB1, ABCB4 and transthyretin. In addition, HNF4α was observed in the endothelium preventing backflow of metabolites to the blood as ABCC proteins play a protective role in choroidal epithelium and mediate basolateral efflux of conjugates resulting from CSF drugs metabolism into the blood while ABCB1 proteins are distributed in the apical side of endothelium (11, 12).

Analysis of HNF4α reactivity in the CPs showed statistically significant higher readings in the fourth ventricle CP compared to that of the lateral ventricle (Tables 1-2), indicating higher activity in the choroidal epithelium of the fourth ventricle. However, cells of the CP of the lateral ventricle showed wider range of HNF4α expression, possibly reflecting a diverse state of activity in that CP since it is spread over wide regions in the brain’s ventricles when compared to the smaller size CP impacted in the fourth ventricle.

Expression of HNF4α regulates many proteins and metabolizing enzymes like the ATP binding cassette ABCC4 and ABCC1 in human and rat (12), and transthyretine which is one of the proteins present in the cytoplasm of CP cells (13) at the BCSFB. Demonstration of intracellular reaction of HNF4α by binding, for example, with transthyretin in choroidal cells cytoplasm reflects its role in regulation of this protein activity. The presence of well-developed endoplasmic reticulum and Golgi apparatus in CPs makes their ability to secret this protein high (14). Transthyretin is secreted specifically by the CP and not in other parts of brain and it binds with HNF4α to control drug transportation (15). All the above mentioned proteins can be labeled with anti- HNF4α to give a cytoplasmic reaction which may highlight an assumption of drugs metabolizing and transporting enzymes to be more concentrated in the fourth ventricle CP than that of the lateral ventricle, with clinical and pharmacological implications (16).

In this study, expression of HNF4α was significantly higher in the fourth ventricle CP compared to that of the lateral ventricle suggesting that protein regulation and metabolic activity are more in fourth ventricle CP, which is in contrast to that reported by Al-Kafagi et al. (16) who suggested the regulation of drug transporters is more in lateral ventricle CP. This disagreement might be due to the lack of use of controls in their work, or it might be caused by the different experimental setting when their conclusions were drawn on a different species. In addition, this study contradicts other findings on certain drugs metabolism where the CPs of lateral and fourth ventricles were found to be of similar activity (17), however, it is understood that the different methodology applied might explain this discrepancy.

Ependymal cells lining the lateral and fourth ventricles showed reactivity to HNF4α marker (Figures 1(B) and 2(B)), albeit at lesser extent on qualitative assessment. The mere observation of the ependymal cells expressing less HNF4α marker than the choroidal epithelium, but higher than the adjacent white matter of
the brain, needs to be analyzed quantitatively in a further extension from this study.

In addition to the ependymal lining, HNF4α labelling was also seen in endothelial lining of choroidal vessels (Figures 2(A)), however, assuming equal vascular density of both the lateral and fourth ventricles CPs, this labelling would not bias the results in this study, but further quantitative analysis of the vascular profile of the CPs is indicated.

In this study, the expression of HNF4α in choroidal cells of the fourth ventricle was higher than that of the lateral ventricle. Therefore, it might be expected to have abundant amounts of secreted proteins in the cytoplasm of choroidal cells, suggesting that the endoplasmic reticulum content of the fourth ventricle CP is higher compared with that of the lateral ventricle and consequently the metabolic rate is higher in the fourth ventricle CP, which agrees with previous studies (10).

Conclusion

While carrying the same name as a CP, that part in the fourth ventricle proved distinct functional characteristics from that in the lateral ventricle despite the structural similarities of their cells. In terms of transport system, this study showed preponderance in favour of the fourth ventricle CP, as well as in terms of metabolic activity no matter whether this is related to internal protein synthesis and fluid secretion, or is related to external substance metabolism.

These findings might add to previous works that showed higher functional activity in the CP of the fourth ventricle compared to that of the lateral ventricle, however short of addressing the two regions as distinct entities. Rather, they form a continuum of tissue capable of functional adaptation according to the body needs.

AgO Nanowires: Synthesis, Characterization and Bioactivity

Rawaa A. Faris¹, Layla M.H. Al-ameri¹
Lecturer, Institute of Laser for Postgraduate Studies, The University of Baghdad

Abstract

This study is focused on Nanostructured AgO due to its novel properties. Here AgO-NWs manufactured by low-cost, fast green synthesis using curcumin extract. AgO-NWs structures were characterized by FESEM field emission electron microscope scanning. Uniform distribution can be seen for the AgO -NWs. The AgO -NWs thin film exhibits a promising giant third-order nonlinearity and ultrafast character. It behaves as a tunable refraction and absorption character the exciting energy is varied in the range of 80–120 mJ. Silver is a wide-spectrum natural antimicrobial agent that applies to patented wound dressings with broad applications. Today, AgO -NWs have attracted attention in Biophotonic Sensor. Here, AgO-NWs used to as antimicrobial agent against common infecting pathogenic microbes E-coli. The results demonstrated that the AgO-NWs against pathogenic bacterial organisms, they have possible antimicrobial activity and could be regarded as an alternative antibacterial agent.

Keywords: green synthesis;FESEM; Z-scan; third-order, E-coli

Introduction

Nanowire research (NWs) is one of the nanomaterial studies that has drawn interest in recent years. NWs are one-dimensional (1D) nanostructures that range from a few hundred nanometers to micrometers with a diameter of less than 100 nm and a length [¹,²]. Silver Oxide nanowires (AgO-NWs) are one of the materials that have been developed as a result of a fascinating analysis of mechanical, magnetic, electrical, optical properties and their use as catalysts, scanners, nanoelectronics, and photonic devices [³-⁵]. Besides, extremely high electrical conductivity, silver nanowire (Ag NW) is a highly attractive metal [⁶,⁷]. Different Ag NW applications are available, like photocatalysis, biosensors, nanobiosensors, photonic crystals, and surface-enhanced Raman scattering [⁸-¹⁰]. Previous methods to prepare AgO- NWs have also attracted scientists. A variety of synthetic methods, including template free and template-directed, have been successfully demonstrated up to now. Specifically shaped nanomaterials such as carbon nanotubes, or micelles with rod shaped are prepared with controlled measurements through the use of templates [¹¹]. The manufacturing of these templates, however, is often complicated and expensive. Researchers synthesized very long AgO-NWs with polyol-process multi-step growth. Other scientists have investigated the effect of poly(vinyl pyrrolidone) (PVP) on the time of reaction, temperature and molecular weight on the morphology of silver nanowires [¹²,¹³]. The effects of using mediated agents on the morphology and growth of AgNWs have been considered by a few studies. Also, researchers used EG and glycerol as humorous agents and investigated the mechanisms of self-seeding and development of AgNWs. Here, a natural reducing agent, curcumin, a natural polyphenolic substance well established as a wound-healing agent, has been used in recent studies to achieve the green synthesis of silver oxide nanowires.

Materials and Procedures

AgO-NWs preparness

40ml solution of 1M AgNO₃ was prepared and stirred for 30 minutes. The freshly prepared Curcomin extract was added to the solution and heated to 25 Celsius with continuous stirring for 4 hours. It was noted that the colour of the solution changed to nearly
brown indicating the formation of Ag nanostructure. The solution was centrifuged for 30 minutes at 5000rpm to separate the obtained powder from the solution. The obtained powder was incubated at 50 degree Celsius overnight to remove the moisture from the samples.

**Characterization of the AgO-NWs mesurement**

**Fied emission scanning electronic microscopy**

The AgO nanowires casting on glass substrate surface was examined using MIRA3 (Czech Republic), a high-performance FE-SEM device with a high-brightness emitter from Schottky for high-resolution and low-noise imagery.

**Optical properties**

The surface plasmon resonance of the samples was reported in the wavelength range of 300-1000nm using a UV-VIS (SHIMADZU 1800) spectrophotometer in addition to the substance structure and chemical characterization.

The nonlinear optical features of the thin film of the as-prepared AgO nanowires have been studied. Using a Z-scan technique, this characterization was carried out. In Fig.1, the Z-scan configuration is shown. A ns-532nm Nd: YAG laser with an energy of 120 mJ, a beam diameter of <1.5 mm, and a beam divergence of 0.82 mrad is included in the system.

To focus the laser beam on the specimen, a lens with a 20 cm focal length was used.

To investigate the variance of the pulsed laser strength, AgO-NWs was placed on a linear translation step that can move around the focus. To test the difference in the signal, a photo-detector (RJ-7610) was used.

![Fig.1. Z-scan experimental setup.](image)

To calculate the nonlinear refractive index ($n_2$) and the nonlinear absorption coefficient ($\beta$), respectively, the open and closed aperture methods of the Z-scan technique have been used \[14-16\]. The normalized open-aperture signal is estimated as the following relationship.

$$ T(Z) = \sum_{m=1}^{\infty} \left( \frac{\beta \omega_0 L_{eff}}{l_0} \right)^m \left( \frac{1}{(m+1)^{2/2}} \right) $$

It refers to the intensity of the laser beam at the focusing point and describes the effective duration of propagation within the sample. Although the fitting equation was determined using\[17\]:

$$ n_2 = \frac{\Delta\phi_0}{kL_{eff}} $$

$k$ is wavenumber which equals to ($k=2\pi\lambda$) and, $\Delta\phi$ is the phase shift estimated by the equation:

$$ |\Delta\phi_0| = \frac{\Delta T_{p-v}}{0.406(1-S_p)^{0.25}} $$

The third-order nonlinear susceptibility $\chi^{(3)}$ can be calculated by below equation\[18-20]\:

$$ \chi^{(3)} = \sqrt{(\text{Re}\chi^{(3)})^2 + (\text{Im}\chi^{(3)})^2} $$

$$ \text{Re}\chi^{(3)} = 10^{-4} \frac{\varepsilon_0 c^2 n_2^2}{\pi} n_2 $$

$$ \text{Im}\chi^{(3)} = 10^{-2} \frac{\varepsilon_0 c^2 n_2^2 \lambda}{4\pi^2} \beta $$

**Bioactivity test**

Green synthesis antibacterials for AgO-NWs were tested using a well-diffusion system against E-coli. Microorganisms in the medium of Uti Chrom Agar (UCA) were grown at 37 °C. 18 to 24 hours of single colonies on agar plates were used for the preparation of bacterial suspension with a turbidity of 0.6 McFarland (equal to 1.6 X10^8) colony-forming units (CFU)/ml. With 90 µl impregnated with synthesized AgO-NWs, holes of 10 mm in diameter were filled and held at 37 °C. After the 24-hour incubation period, the diameter of growth inhibition zones was measured in millimeters.
Results and Discussion

FESEM results

FE-SEM images in Figure (2) showed a sparse and uneven distribution of AgO-nanowires in solution, and few clusters were observed or nanoclusters had a uniform distributional substratum surface with an average diameter of thirty nanometers.

Figure 2. FESEM images AgO nanowires (The magnification for images are 200,000 times and the bar of scale is 200 nm)

Optical properties results

Surface plasmon resonance property of our silver nanowires was characterized using UV-Vis spectroscopy. The spectrum (fig.3), shows two relatively sharp surface plasmon resonance peaks at 352 and 392 nm positions, which correspond to quadrupole resonance excitation and the transverse plasmon resonance of the nanowires, respectively. It is also observed that the plasmon resonance associated with the long and short axes are completely decoupled, confirming the high aspect ratio of our pentagonal nanowires.

Figure 3. Surface plasmon resonance spectrum

For both closed aperture and open aperture, the Z-scan profile of AgO-NWs at 120 mJ is shown in Fig. 4. AgO nanowires display a broad variety of nonlinear properties from this figure, such as self-defocusing, saturable absorption activity with massive absorption behavior where $\beta\beta = \frac{-0.06593 \ cm^2/GW}{-4834.28 \ cm/GW}$, and a strong $\chi^{(3)}$ of about $4.5*10^{-8}$ esu.

Figure 4. Normalized transmission of (a) closed aperture, and (b) open aperture.
Antibacterial activity of AgO-NWs against E-coli

The antibacterial activity of AgO-NWs showed positive results. The plant extract (curcumin) solution was no effect against E. coli, while AgNO₃ was showed little effect against E. coli with a zone of inhibition=11mm, but AgO-NWs showed a greater effect against E. coli with a zone of inhibition =18 mm compared to Trimethoprim-Sulfamethoxazole was effective against E. coli with a zone of inhibition=12mm as shown in figure (5).

Conclusions

Silver Oxide nanowires were successfully obtained from the green synthesis method thus paving the way for further investigation and synthesis of AgO-NWs structures using the green synthesis. The obtained AgO-NWs were characterized with FESEM. Synthesized AgO-NWs has shown the ability to serve as a great antioxidant agent and have anti-bacterial activity against E-coli.

Abstract

Cervical cancer is caused by infection with the human papilloma virus which can infect the genitals, anus, throat, mouth and cells on the surface of the skin. Cervical cancer is often late so that it can cause death, so efforts are needed to reduce the risk factors for cervical cancer, namely through primary prevention efforts. The purpose of this study was to determine the relationship between primary factors and cervical cancer prevention behavior in adolescent girls. The sample in this study were 77 young women who were taken by technique purposive sampling. The research design used was an observational analysis using a cross sectional approach and analyzed using chi-square. The results of this study illustrate that there is a relationship between knowledge, attitudes and social support with cervical cancer prevention behavior in adolescent girls. So we need efforts to reduce cervical cancer risk factors, namely through primary prevention efforts, by increasing outreach activities in the community to carry out a healthy lifestyle.

Keywords: knowledge, attitudes, social support, cervical cancer prevention behavior.

Introduction

Reproductive health is a health sector that is closely related to female reproduction, one of which is cervical cancer. Cervical cancer ranks second in prevalence after breast cancer. Cervical cancer is a disease that is difficult to detect, if it can be detected, it is often at an advanced stage so it is difficult to treat. Cervical cancer is also known as the ladies silent killer because it is the second killer after breast cancer (1,2).

Developing countries such as Indonesia, women who suffer from cervical cancer at this time still rank second after breast cancer, where the incidence of cervical cancer in Indonesia is estimated at 100 / 1000.000 thousand per year. Cervical cancer is a frightening disease, this is because cervical cancer is very malignant and can even cause death. There has been an increase in cervical cancer in Indonesia and one of the causes of death at productive age (3,4).

Cervical cancer can be cured if detected and treated early on, but due to the lack of symptoms, the treatment for cervical cancer is often too late so that it can cause death. The most important examination in early detection of cervical cancer is the Papanicolaou Smear (Pap Smear), especially for women who are already sexually active (5,6).

All women are at risk for cervical cancer, factors that have a high risk of cervical cancer such as use of oral contraceptives, smoking and casual sex. Adolescence is a period of transition from children to adulthood and at this time the teenager’s soul is still full of turmoil. Many of the teenagers behave deviantly such as smoking, free
sex. Adolescent smoking behavior is not only a gateway for all types of substance abuse but also causes various health problems \(^{(7,8)}\).

Cervical cancer is caused by infection with the human papilloma virus which can infect the genitals, anus, throat, mouth and cells on the surface of the skin. Women who do not use condoms during sex and frequently change sexual partners from adolescence have a higher risk of cervical cancer. Heredity is also a risk factor for cervical cancer because it has a tendency to be unable to fight infection with the human papilloma virus which can cause cervical cancer in women \(^{(9,10)}\).

So efforts are needed to reduce cervical cancer risk factors, namely through primary prevention efforts, by increasing outreach activities in the community to carry out a healthy lifestyle such as delaying sexual activity, using contraception and using vaccines \(^{(1,6)}\). This research is aimed at developing prevention efforts against cervical cancer problems in adolescent girls, planning strategies or activities health promotion programs in reducing the incidence of cervical cancer in Indonesia.

**Material and Method**

This study used an observational analysis design using a cross-sectional approach. The independent variables in this study were knowledge, attitudes, social support and the dependent variable was cervical cancer prevention behavior. The population used in this study were all students. Sampling using a technique purposive Sampling is a way of taking subjects not based on random, regional or strata-based, but based on the existence of certain goals. In this study, a sample of 77 respondents was obtained. The data analysis method used in this study is chi-square to see the relationship between the independent variable and the dependent variable.

**Findings**

Test Chi-square 0.001

Based on the results of table 3, it is stated that as many as 71.1% or 32 young women who get social support with good cervical cancer prevention behavior and as many as 20 young women or 62.5% who do not get social support with good preventive behavior. The results of the analysis said the p-value was 0.001, which means that there is a relationship between knowledge and cervical cancer prevention behavior in adolescent girls.

Discussion

Knowledge

Increased knowledge in society, especially young women can change negative behavior into positive behavior, knowledge can also form trust. Cervical cancer prevention behavior can prevent young women from risk factors that can trigger disease, namely cancer that can be caused by exposure to cigarette smoke, improve health, especially endurance by consuming a balanced nutritious diet and contain lots of vitamins such as folic acid, vitamin C and A. In implementing cervical cancer
prevention behavior, knowledge of risk factors that must be avoided and conducting early detection checks and increasing nutritional intake is needed. A person’s behavior which is based on knowledge will be more lasting than those that are not based on knowledge (5,11).

Information is one way to strengthen knowledge and change behavior. Knowledge is the impression in the minds of men as a result of the senses, which is quite different from the beliefs (beliefs), superstitions (superstitious), and caption information wrong (misinformations). This theory statement emphasizes that the meaning of correct information can be positive (12–14).

Knowledge is a person’s way of determining steps, choices, and attitudes in decision making, to determine steps for cervical cancer prevention behavior so that someone makes a behavior change, a fundamental stimulus through health education is needed so that information can reach the community, especially young girls to get their rights to it. reproductive health (15,16).

Attitude

A person’s attitude is influenced by several factors, namely culture, personal experience, mass media, emotional level, other people who are considered important, religion or educational institutions. Attitudes that shape cervical cancer prevention behavior support are influenced by the personal experiences of young women in the learning process at educational institutions, peers or family, the mass media as a media for scientific information about cervical cancer prevention and educational institutions that provide learning about reproductive health. These factors can provide a stimulus for young women in responding to cervical cancer prevention behavior (17–19).

From the description above it can be concluded that the attitudes of young women towards cervical cancer prevention behavior are formed through personal experiences, experiences of other people who are considered important such as parents, emotional level, educational institutions and thus stimulating the emergence of intentions to prevent cervical cancer behavior (20,21).

Social Support

Forms of social support such as reward support, emotional support, group support, instrumental support and information support. Support from other people such as family is a determining factor for this because support from family will provide reinforcement of motivation to carry out cervical cancer prevention behavior. families who have good knowledge can provide understanding and support for young women to carry out healthy behaviors (22,23).

The continuity and success of young women with healthy behavior really needs support from family members. Support from families, especially parents, is very important to improve the health status of young women. Family support can provide emotional benefits or can affect behavior in cervical cancer prevention behavior (22,23).

The culture of Indonesian society is still being carried out today where the family is the determinant of decisions that affect the behavior of young women in cervical cancer prevention behavior. This makes family support very meaningful in the continuation of preventive behavior considering that the family often acts as a decision maker for efforts to maintain the health of their family (22,24).

Conclusion

Analysis of this study illustrates that there is a relationship between independent variables such as knowledge, attitudes and social support with cervical cancer prevention behavior in adolescent girls.

Abstract

Background: Chronic Obstructive Pulmonary Disease (COPD) is one of World health cases that is commonly known, which is triggered by the combination of environmental factors especially cigarette smoking and genetic factors. The association between A disintegrin and metalloprotease 33 (ADAM33) polymorphisms and COPD has been investigated and reported by other researchers. Objective: The main aim of this study is to identify the association between single nucleotide polymorphisms (SNPs) in ADAM 33 gene with COPD in the Javanese population in Lampung, Indonesia. Methods: A randomized cross-sectional study was used in this research. PCR-Sequencing method was involved to analyze the polymorphic for three SNPs (T1, T2, and Q-1) of the ADAM33 gene. Statistical analysis data was performed in descriptive and comparative as well as it was measured by parametric/non-parametric tests. Results: The results showed that the T2 GG, and T1AG genotypes in COPD group were significantly more frequent rather than in control group (p < 0.05). In case of allele, it was found that the T1G and T2G was higher in COPD group rather than in the control group (p = 0.440 and 0.131, respectively). Conclusion: The results clearly conclude that there was significant association between T1 and T2 polymorphisms of ADAM33 gene and COPD in the Javanese population of Lampung, Indonesia.

Key Words: ADAM 33 gene polymorphism, COPD, smoking, Javanese, SNP

Introduction

A major disease which can cause morbidity and mortality in the world is chronic obstructive pulmonary disease (COPD). In addition, persistent airflow obstruction is identified as one of its characteristics. The COPD is correlated to an enhanced chronic inflammatory response in airways and lungs to noxious particles and gases, and it is also progressive(1). The global burden of COPD estimates that affects 300 million people worldwide resulting in approximately 3 million deaths annually (2). The prevalence of COPD kept increasing globally. In a recent survey the estimated prevalence of COPD was 4.5% in Indonesia(3). This is highly regarded in low tobacco control policies and large of smokers population(4). In a recent health cost study suggested estimation of the smoking treatment cost in Indonesia attained 2.5% of the gross domestic product.

Corresponding author:
Syazili Mustofa
syazilimustofa.dr@gmail.com
in 2015. Moreover, it became the biggest contributors of Indonesian state burden\(^5\).

There are great numbers of genes which have been associated to the pathogenesis of COPD. The protease–antiprotease pathways, inflammatory response to cigarette smoke pathways, and oxidant–antioxidant pathways have been explored by case–control genetic association\(^6\). Nevertheless, COPD genetic profiling use in the clinic is current limited to find out Alpha-1 antitrypsin deficiency\(^7, 8\). Furthermore, the relationship between A disintegrin and metalloprotease 33 (\textit{ADAM33}) polymorphisms and COPD has been reported by other researchers\(^9\)\(^-\)\(^11\).

\textit{ADAM} 33 is a complex molecule. It comes from a zinc-dependent metalloproteases \textit{ADAM} family and is produced by mesenchymal cells, involving smooth muscle and fibroblast. It is important for cell adhesion, fusion, signaling and proteolysis by releasing various of growth factors as activator and Th2 cytokines\(^12\). \textit{Its} gene, can be found in human chromosome 20\textit{p}13. It was investigated as COPD susceptibility gene\(^13\). The first genetic study reported on the association \textit{ADAM} 33 genetic polymorphisms and susceptibility done by Van-Dieman in a cohort of 1390 subjects in the general population. The research results highlighted that there was significant correlation between four SNPs (F+1, S1, S2, T2) and accelerated lung function decline\(^14\). Moreover, the reported research was strengthened by several similar studies in European and Asian regions such as India, China and Mongolia. Polymorphisms in \textit{ADAM33} to airway hyper-responsiveness have been correlated to airway inflammation in COPD, and accelerated lung function decline by other research\(^11\)\(^,\)\(^13\)\(^,\)\(^15\). As association between low lung function and high mortality risk, particularly on account of COPD, it is important to explore the genetic components that escalate susceptibility to lung function decrease and COPD. Later on, other researches, across different country studies were clearly explained the share of this gene in as COPD causation. COPD has become one of the common problems in Indonesia, especially for Javanese population. By considering smoking as their habit, they have high probability to get this disease\(^4\).

Therefore, the current study was conducted to explore \textit{ADAM 33} gene polymorphisms and COPD association in the Javanese population of Indonesia, which attained a high prevalence of this disease. This study might give an insight into the genetic basis of this disease and help in finding predictors for preventing COPD.

\textbf{Method and Material}

\textbf{Setting}

A randomized cross-sectional study was undertaken in this research. It included COPD male smoker patients who were randomly selected from Harum Melati Pulmonology Clinic and male healthy smokers who lived around Pringsewu District, Lampung Province, Indonesia. All researchers don’t have any conflict of interest. The research permission was acquired from Ethics Committee of Medical Faculty, University of Lampung. Participants who were involved attained at least 40 years old, they had smoked (The Brinkman Index, number of years of smoking multiplied by the number of cigarettes smoked per day, more than 0) and they also had no symptoms of lung cancer, infections, and other lung diseases. All of them fulfilled admission of spirometry and a baseline which were standardized questionnaire involving smoking history and social and demographic information. Thirty-two healthy age-matched male smokers (control group) who had no family history of COPD were already involved. In addition, The Institutional Ethics Committee of Medical Faculty, Universitas Lampung approved this research by number 1914/UN26.18/PP.05.02.00/2018. All the participants were taken part to make written informed consent.

Furthermore, Pulmonary Function Tests (PFT) were performed by using spirometer according to the Pneumobile Indonesian Lung Health Survey utilizing a flow spirometer which was made by CHEST MI, INC, in Tokyo, Japan its brand namely CHESTGRAPH HI 101\(^16\). All of measurement values, (forced vital capacity
(FVC) values and Forced expiratory volume in the first second (FEV1), were calculated and standardized in percent based on reference. The participants who had post bronchodilator FEV1/FVC attained airway obstruction if its ratio was less than 70%. Moreover, classification of airway limitation severity in COPD was categorized taken from the Global Initiative for Chronic Obstructive Lung Disease as source.

**Genetic analysis**

SNPS (T1, T2, and Q1) of the ADAM 33 gene were undertaken as genetic analysis (table 1). The genomic DNA extraction process was originated from 500 µL of blood using material from Promega’s DNA Wizard® made in Madison, USA following the manufacturer’s procedure. The results of DNA extraction were examined by using implant, a digital DNA nanophotometer, made in Germany. The DNA extracts were frozen at –20°C until they were analyzed.

Amplification of ADAM33 was performed using kit NEXpro™ e PCR 2x Master Mix solution (Nex diagnostics, South Korea). Two primer pairs were used thereby designed in nearly located on SNPs. The first pair amplified the SNP at the locus rs2280090 (T2) and rs2280091 (T1), it was caused by the distance between SNP rs2280090 and rs2280091 only 29 nitrogen bases. The second pair amplified rs612179 (Q-1). We had confirmed the results of PCR using QIAxcel DNA High Resolution Kit digital electrophoresis equipment (Singapore). Next, the amplicons were sent to Indonesian Bioneer Ltd for two directional sequencing. It was analyzed by BioEdit software developed by Tom Hall. Thereafter, the researchers constructed a phylogenetic tree using Mega X which was developed by Kumar et al\(^{(17)}\). It was involved from several representative samples using maximum likelihood, bootstrap method and 1000 times number of replications (Figure 1).

**Statistical Analysis**

The experimental data was analyzed by using parametric and non-parametric statistical tests. The data is showed as mean ± SD. The researchers performed data through SPSS type 11.0 which involved students't-test and chi square test. A significant different was indicated as p value of less than 0.05. Data analysis used IBM SPSS Statistics software version 23.0 (IBM Corp., Armonk, NY, USA).

**Result**

There were three position of SNPs ADAM 33 gene that researchers focused on. They were T1, T2, and Q-1. The amplifications of gene sequence that contained of them were attained by using the primers in table 1. Primers were designed by using Gene Bank code access DQ995342.1 from the website https://www.ncbi.nlm.nih.gov. The research involved 42 COPD subjects who were matched for age and sex with 32 healthy smoker controls. All participants were Javanese and they had smoking history. The COPD subjects were in clinically stable condition. On the other hand, the healthy smokers did not have lung disease. Their characteristics were listed in Table 2. Related to COPD patient included in this study were generally similar to the control but slightly older and had lower Brinkman Index. Interestingly, there were significant pulmonary functions identified in the male COPD patients compare to the male healthy smokers as a control. The result found that there was more significant frequency T2GG genotype and T1AG genotype in COPD group if the researchers compared them with in the control group \((p < 0.05)\). But, in the case of Q-1, there was no significant difference of genotype frequencies in the two groups (Table 3). Furthermore, there were no significant different allele frequencies in the two groups (Table 4). Based on phylogenetic tree the sequence of ADAM33 gene from Javanese ethnic in Lampung province was closely related to several populations especially Li and Han in China (Accession No: AF466288.1; DQ995342.1) with 99% and 86% respectively (Figure 1).

Figure 1. The phylogenetic tree of the ADAM33 gene sequence in Javanese smokers of Lampung. There are two big clades that are produced by phylogenetic analyzing ADAM33 gene. We can find ADAM33 gene sequence form Javanese which are located in same clade with ADAM33 gene sequence form Caucasian and China from them. It indicates that Javanese ADAM33 gene is similar with Caucasian and Chinese. ADAM33 Javanese sequence shown by the following arrow (by using code number start with 22).

Discussion

COPD is identified as a complex genetic disease. It also involves environmental risk factor such as tobacco smoking. COPD pathophysiology aspect is an imbalanced proteolysis theory. In line with this case, ADAMs is proteinases which strikingly associated with Matrix Metalloproteinases (MMPs). ADAMs proteins contain of metalloproteinase and disintegrin domains providing them with aspects of proteinases and adhesion
molecules. In addition, all kinds of physiological, pathological processes and display a wide spectrum of biological impacts comprising cell adhesion, cell fusion, cleavage of various substrates from the extracellular matrix, “shedding process”, cytokines or growth factors are correlated to proteinases of the ADAM family\(^{(18)}\).

*The structure of ADAM33* consists of a signal sequence, pre-domain, catalytic domain, disintegrin domain, cysteine-rich domain, EGF domain, transmembrane domain, and cytoplasmic domain with a long 3′-untranslated region (UTR). The structures of ADAM 33 that has been explained above indicate that it is involved in many cellular activities, including cell activation, adhesion, fusion, proteolysis and intracellular signaling. Angiogenesis is promoted by soluble ADAM33. It is explained that as a gene of remodeling tissue which has potential to influence lung functions single-handedly of inflammation and airflow obstruction\(^{(19)}\). It can stimulate the release of growth factors and cytokines. It can trigger inflammatory cells to infiltrate into the airway\(^{(18)}\). Furthermore, there is an implication of soluble ADAM33 in forming of new vessels and angiogenesis. It may stimulate cytokines and inflammatory cells or growth factors in the airway.

In the case of ADAM33, it has contribution in airway remodeling in consequence of its high expression in epithelium, fibroblasts, as well as the airway smooth muscle cells (ASMCs). Declining of proliferation and increasing the apoptosis of ASMCs in a rat model of allergic asthma can be caused by silencing of ADAM33\(^{(20)}\). The genetic susceptibility to patients who get chronic bronchitis caused by smoking or aerosols and industrial dust can be enhanced by ADAM33 gene polymorphisms\(^{(21)}\).

In addition, this current research demonstrated that there was an association between the polymorphisms of ADAM 33 and COPD in Javanese. To the best of our knowledge, it is the first research report which conducted in Indonesia context. In this association study, we genotyped 42 well-characterized COPD cases and 32 healthy smoker controls, who were long-term tobacco smokers for ADAM33 gene of three SNPs (T2, T1 and Q-1). The results revealed that SNPs T2 and T1 of this gene were significantly associated with COPD. Consistent with our result, Wang’s research indicated the T2 was significantly associated with total cells in COPD patient’s phlegm and SNP T1 was significantly associated with macrophage\(^{(9)}\). Our findings will give great contribution related to COPD genetic marker in Indonesia. It is caused by number of Javanese that attains 40% from of all Indonesian population and it is as the biggest tribe in Indonesia.

Furthermore, in East Asian population, the changes of pulmonary function and components of cells in sputum of COPD were obviously associated with T2, T1, and Q-1. Moreover, cytokines and mediators of inflammation in airway of COPD in recessive models were meaningfully associated with T1 and Q-1\(^{(9)}\). In the Kashmiri population of India, ADAM33 gene polymorphism in three SNPs (T1, T2, and Q-1) were obviously associated with COPD\(^{(11)}\). The results of present study showed that the similarities of findings in T1 and T2, but Q-1 was different. It was also supported from the study reported by Li et al found in a Chinese individual the polymorphism of T1 in ADAM33 would escalate patients COPD chance\(^{(10)}\).

In other studies, another ADAM33 SNPs was also associated with COPD. Vijaya Laxmi et al reported that the polymorphism of ADAM33 gene which had SNPs name S1 and S2 become the main genetic factors and risk for COPD\(^{(22)}\). Aierken et al also reported that the inclined risk of COPD in Chinese but not in Caucasians is correlated to S1 (rs3918396) polymorphism of ADAM33\(^{(13)}\). In addition, Tan et al, found COPD in the Mongolian of China was associated with Seven SNPs in ADAM33\(^{(15)}\). Study of Reijmerink et al, who investigated the polymorphism V4 of ADAM33 is associated with COPD in Venezuelan patients. Interaction of *in utero* cigarette smoke exposure with *ADAM33* results in reduced lung function\(^{(23)}\). It was also supported by meta-analysis study of Zhou et al which clearly revealed that the ADAM33 polymorphisms which had SNPs name F+1, T2, T1, S1, ST+5 and Q-1, correlation to the risk of COPD. Moreover, T2, T1, S1, ST+5 and Q-1 pointed
of the risk of COPD in the Asian populations. T2, ST+5
and Q-1showed the risk of COPD in the European populations(24).

In this present study, the results clearly showed that
when compared to the wild allele, heterozygous AG
genotypes of T1 SNP, and homozygous GG genotype
of T2 SNP were distributed significantly in higher (p
< 0.05) frequency among the populations; suggesting
that the increased susceptibility among carriers of these
genotypes to develop COPD.

Genetically, the Javanese is closer to the ethnic
groups in the Southeast Asia region, such as Thailand
and Vietnam while tribes in eastern Indonesia are
closer to people in the Pacific Ocean region. The Nias
and Mentawai tribes are closer to the native tribes of
Taiwan(25). The phylogenetic analysis of this study has
given the clear picture of the associations and the genetic
similarity of the 33 ADAM gene sequences in this study
with various populations in the world, thereby revealed
that the Javanese tribe ADAM33 gene sequence showed
similarities with Caucasian and Chinese populations.

Conclusions

The results demonstrated that T1 and T2
polymorphisms of ADAM33 gene have shown an
association of COPD. The results revealed that it might
be risk factors for COPD susceptibility. The contribution
of the disease-connected to SNPs must be clarified yet,
specifically in the COPD pathophysiology context. The
future studies are warranted to extend this preliminary
research to conduct with large number of sample sizes,
more SNP numbers to fully elucidate the potential
candidate genes implicated in the genesis of COPD
in Javanese population, and also further to develop
screening procedures to identify patients at risk of
developing COPD.

A 56 Year Old Man with Parkinson’s Disease and Depression: A Case Report on Treatment Management

Risza Subiantoro¹, Agustina Konginan², Erikavitri Yulianti²

¹Resident, ²Lecturer, Department of Psychiatry, Faculty of Medicine, Universitas Airlangga – Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Abstract

Background: Depression is the strongest predictor of quality of life for Parkinson’s disease (PD).

Presentation of Case: A 56 years old man came with the main complaint of difficulty sleeping due to thinking about tremors in his left hand since 6 months. Complaints are accompanied by feelings of sadness, lack of enthusiasm, and decreased appetite accompanied by weight loss. The patient had been diagnosed with PD 8 years previously and was on medication. One month before the visit, the patient underwent a thalamotomy operation. After surgery, the patient received therapy in the form of a combination tablet of levodopa/carbidopa/entacapone (100/25/200 mg) 4×1 tablet and 1×2 mg of ropirinole. On the Beck Depression Inventory (BDI) examination, a score of 23 was obtained and on the Montgomery Asberg Depression Rating Scale (MADRS) examination a score of 31 was obtained, both of which correspond to major depression. The patient was diagnosed with a major depressive episode without psychotic symptoms and was given escitalopram therapy 1×10 mg and lorazepam 1×2 mg. Patients also received biofeedback therapy with family psychoeducation and supportive psychotherapy. At the time of control, the patient admitted to feeling calmer and able to sleep after receiving therapy. Conclusion: Escitalopram has good efficacy for the management of depression in PD patients.

Keyword: Depression, antidepressants, parkinson’s disease

Introduction

Parkinson’s disease (PD) is the second most common neurodegenerative disease occurring in 0.5-5% of the population over 65 years of age. Depression is one of the most common psychiatric complications of PD with a prevalence of 20-35%. The prevalence of major depressive disorder was 17%, while the prevalence of dysthymia and mild depression were 13% and 22% respectively(1, 2). Depression is also the strongest predictor of quality of life in PD(3).

Depression is caused by changes in the dopaminergic, noradrenergic, and serotonergic systems. Depression is associated with reduced dopamine transporters in the striatum and limbic regions, reduced forebrain serotonin innervation, reduced dopaminergic and noradrenergic innervation at the locus ceruleus, thalamus, and limbic region, increased loss of neurons and gliosis at the locus ceruleus, and loss of cortical cholinergic neurons. Psychological reactions to a diagnosis of PD or a disability related to PD can also trigger depression(2). Depression in PD patients is quite difficult to diagnose because of the overlap between depressive symptoms and PD symptoms and the side effects of PD treatment(1). Based on the description above we are interested in reporting the management of PD patients with depression.

Case Presentation

A 56 years old man came to the hospital complaining of difficulty sleeping because of thinking about tremors in his left hand since 6 months. Complaints are accompanied by feelings of sadness, lack of enthusiasm, and decreased appetite accompanied by weight loss.

Tremors were first felt 8 years earlier on the right thumb. At that time, the patient was diagnosed with PD and received combination tablet therapy of entacapaone and levodopa. The patient is routinely treated, but after the tremor is reduced, the patient is no longer in control. At that time, there was no change in behavior. Two years later the tremors returned so that the patient returned to treatment and was given 2×1 tablets of a combination of levodopa and benzerazide HCl (100 mg/25 mg). Since 2 years ago, the patient began to experience walking problems so that the dose of the combination tablet of levodopa and benzerazide HCl was increased to 3×1 tablet and the patient was also given 2×2 mg of trihexyphenidil. One month before the visit, the patient was hospitalized because of complaints of severe tremor in the right hand, so the patient was decided to undergo thalamotomy surgery. After surgery, the patient received therapy in the form of a combination tablet of levodopa/carbidopa/entacapaone (100/25/200 mg) 4×1 tablet and 1×2 mg of ropirinole. The patient felt that the complaints of tremor in the right hand had decreased after surgery, but the tremors in the left hand were still felt. The patient had no previous medical history or history of smoking, coffee/alcohol consumption, and psychotropic use.

In the psychiatric examination, the patient’s awareness of comos mentis, sad mood, depressive effects, realistic thought processes, coherent flow, preoccupation thought content on complaints of tremor on the left, perceptions within normal limits, decreased willpower. Based on auto and heteroanamnesis, prior to experiencing PD, the patient had anancastic personality traits. The results of Mini Mental State Examination (MMSE)\(^4, \, 5\) obtained a score of 23 (normal). On the Beck Depression Inventory-II (BDI-II)\(^6\) examination, a score of 23 was obtained and the Montgomery Asberg Depression Rating Scale (MADRS)\(^7\) was obtained a score of 31, both of which correspond to major depression. The results of Hamilton Anxiety Rating Scale (HAM-A)\(^8, \, 9\) showed a score of 23 (moderate anxiety).

The patient was diagnosed with a major depressive episode without psychotic symptoms and was given escitalopram therapy 1x10 mg and lorazepam 1x2 mg. Patients also received biofeedback therapy with family psychoeducation and supportive psychotherapy. At the time of control, the patient admitted to feeling calmer and able to sleep after receiving therapy.

Discussion

Depression is one of the most common psychiatric complications of PD with a prevalence of 20-35%, where the prevalence of major depressive disorders is 17%. The risk factors for depression in this patient were the severity of motor symptoms (tremor) which was quite severe, the presence of anxiety which was confirmed by the HAM-A examination, and sleep disturbances\(^1, \, 2\). Apart from the pathophysiology associated with changes in the dopaminergic, noradrenergic, and serotonergic systems, in this patient depression was mainly due to a reaction to PD symptoms in the form of tremors\(^2\). Symptoms in these patients are consistent with depressive symptoms often found in PD patients with depression, namely loss of energy, anhedonia, changes in appetite and sleep, fatigue, and impaired concentration\(^3\).

In these patients, the management of depression was carried out with antidepressants as well as non-pharmacological therapy. The antidepressant used in this patient was escitalopram, a selective serotonin reuptake inhibitor (SSRI) class. A multicentre study in 2019 reported that SSRIs are the standard therapy often given to PD patients with depression. However, several previous studies reported that SSRIs were associated with higher apathy than other antidepressants. The study reported a side effect rate of 36% with SSRIs. Side effects found included nausea, vomiting, headache, somnolence, diarrhea, abdominal discomfort, and tremors. SSRIs have been shown to significantly reduce
depressive symptoms\(^{10}\). Apart from being able to improve symptoms of depression, SSRIs are also able to improve daily life and motor function\(^{2}\). Escitalopram, citalopram, or sertralin are also options in elderly patients in advanced PD. SSRIs are also an option in patients with comorbid anxiety disorders. This is consistent with this patient who has entered old age and has preoccupation/anxiety related to tremor symptoms. The ability of SSRIs to improve motor symptoms can also reduce tremor complaints that patients complain about. Another option that can be given to patients is antidepressants that have a sedative effect such as amitriptyline, mirtazapine, and trazodone given the difficulty of sleeping\(^{11}\). However, the patient has been given lorazepam which has a similar function and has succeeded in improving the symptoms experienced by the patient.

Patients also received biofeedback therapy with family psychoeducation and supportive psychotherapy. Previous case reports demonstrated the ability of psychotherapy to improve depression scores in PD patients. Studies comparing CBT with doxepine and placebo in PD patients have also shown that CBT is able to better improve the sleep quality index\(^{12}\). Other non-pharmacological therapies that can be applied to patients include physical activity\(^{13}\), acupuncture therapy\(^{14}\), or dancing\(^{15, 16}\), while the efficacy of repetitive transcranial magnetic stimulation and electroconvulsive therapy (ECT) is unclear\(^{2, 3}\). Deep brain stimulation (DS) also has inconsistent results in the management of depression in PD\(^{17}\).

**Conclusion**

Management of depression in PD patients includes non-pharmacological and pharmacological therapy. Escitalopram has good efficacy for the management of depression in PD patients.

**Conflict of Interest:** The authors declare that they have no conflict of interest.

**Funding:** None.

Legal Protection for Nurses in Pharmaceutical Services Where there are No Pharmaceutical Staffs at the Community Health Center

Rizka Dianita¹, Retno Ariani¹, Swabawa Wicaksana¹, Mokhamad Khoirul Huda²
¹Master of Law Student, Hang Tuah University, Surabaya, Indonesia, ²Professor, Faculty of Law, Hang Tuah University, Surabaya, Indonesia

Abstract

Puskesmas is a first-level healthcare service facility that organizes health efforts prioritized promotive and preventive actions. In executing its health efforts, puskesmas must take actions according to standards, including in pharmaceutical services. It will be different when the pharmacy service is provided by nurses instead of provided by pharmacy staffs. Following the prevailing law in Indonesia today, nurses’ authority in carrying out their pharmacy duties in practice is only limited. To provide assurance and legal protection for nurses in performing pharmaceutical services in health centres where there are no pharmacists/pharmaceutical technical staffs, laws and regulations related to nursing protection have an essential function. It also protects nurses to avoid criminalization of nurses by law enforcement officials.

Keywords: the community health center, Nurses, Pharmacy, Law, Protection

Introduction

In the National Health Insurance System era, healthcare services are no longer concentrated in hospitals or advanced healthcare facilities, but every healthcare facility level must provide it based on the patient’s medical needs. This condition aims to improve the community’s healthcare services, mainly focused on healthcare services at Authorized Primary Care Facilities. One of which is the community health center.¹

The community health center, as a healthcare service facility, organizes public health efforts and first-level individual health efforts by prioritizing promotive and preventive actions in its working area. The working area of the puskesmas covers based on the administrative working area; it is one sub-district or part of a sub-district. It has regional responsibility as one basic principle where Puskemas must empower and be responsible for health development in its working area.

One of the efforts to strengthen primary healthcare facilities requires health staff, including pharmacists and the person in charge of pharmacy at puskesmas, to provide standardized healthcare services. It needs sufficient human resources as the critical factor and also standardized facilities and infrastructures. Pharmacists as the person in charge of pharmaceutical services at the puskesmas are expected to be able to carry out standardized pharmaceutical services to improve service quality and patient safety.¹

A situation becomes different when there are no pharmaceutical staffs at the puskesmas. Other health staffs will take this duty so that pharmaceutical services can continue to run, and health staffs who usually replace pharmaceutical services at puskesmas are nurses. As stated in Decree of the Minister of Health
No. 74 of 2016 on Standard Pharmaceutical Services in Community Health Centers, Article 12 (paragraph 1), “At the time this Ministerial Regulation came into force, for Puskesmas with no pharmacists as the person in charge, the implementation of limited pharmaceutical services was carried out by pharmaceutical technical staffs or other health staffs assigned by the head of the district/city health office.”

According to the Law No. 38 of 2014 on Nursing (from now on referred to as Law of Nursing) article 29 paragraph (1).

In organizing nursing practices, nurses serve as:

a. nursing care provider;
b. counsellors for patients;
c. manager of the nursing service;
d. nursing researchers;
e. executing tasks based on the delegation of authority; and
f. task holder under certain limitations.

Article 33 paragraph (1): Implementation of duties in certain circumstances of limitations as referred to in Article 29 paragraph (1) letter f is an assignment of government carried out in the absence of medical staff and pharmacy staff in an area where nurses work.

Article 34 paragraph (3): In implementing the duties in certain circumstances of limitations as referred to in paragraph (1), the Nurse is authorized to:

a. giving treatment for common diseases in the absence of medical staffs;
b. refer patients according to the provisions of the referral system; and

c. perform limited pharmaceutical services in the absence of pharmaceutical staffs.

Based on the articles above, the nurse can carry out limited pharmaceutical services, include a. management of pharmaceutical preparations and medical consumables; and b. prescription services in the form of drug compounding, drug delivery, and drug information provision.

In line with science and technology development, pharmacy has shifted pharmaceutical services from managing medicines as a commodity to comprehensive services (pharmaceutical care). This orientation means that they are not only managing drugs but, in a broader sense, including the implementation of providing information to support the correct and rational use of drugs, monitoring of drug use to determine the ultimate goal, and the possibility of medication errors.

Pharmaceutical services are also required to directly interact with patients, such as providing drug information and counselling to patients in need. Pharmacists must understand and be aware of the possibility of medication errors in the service process and identify, prevent, and overcome drug-related problems, pharmaco-economic problems, and social pharmacy (socio-pharmacoeconomic). In order to avoid errors, pharmaceutical services must be based on service standards.

According to the enactment of Law no. 8 of 1999 on Consumer Protection provide opportunities for users of service or goods to file lawsuits against the business actors if there is a conflict between the customers and the business actors deemed to have violated their rights, being late in doing/not doing/being late in making something that causes losses to the users of service/goods, property loss or injury, or it could be death. In this case, the patients as consumers of healthcare services can sue hospitals, doctors or other health staffs if there is a conflict.

The current positive law applied in Indonesia only gives nurses authority in the pharmacy practice to have a limited pharmaceutical service. To guarantee legal certainty and protection for nurses who carry out pharmaceutical services at health centers where there are no pharmacists/pharmaceutical technical staff, laws and regulations related to nursing protection have an
essential function and effect to avoid criminalization of nurses by law enforcement officials (police). 8

Discussion

Standard Operational Procedure for Medical Services at The Community Health Center with the shortage of pharmaceutical staffs

Pharmaceutical services in puskesmas are an integral part of implementing health efforts, which play an essential role in improving the community’s healthcare services quality. It aims to identify, prevent and resolve drug problems and health-related problems. Patients and the community’s demands for a better quality of pharmaceutical services require a transformation to the new paradigm from the product-oriented (drug-oriented) into the patient-oriented paradigm. 9

The regulations on pharmaceutical practices are listed in Law No.36 of 2009 on Health and Government Regulation No.51 of 2009 on Pharmaceutical Works. As listed as follows:

1. Law No.36 of 2009 concerning Health - Article 108: Pharmaceutical practice covers manufacturing, including quality control of pharmaceutical preparations, security, procurement, storage and distribution of drugs, drug services for doctor’s prescription, drug information services and development of drugs, medicinal ingredients and traditional medicines carried out by authorized health staffs following statutory provisions.10

2. PP No.51 of 2009 on Pharmaceutical Works as follows:11

Article 2 paragraph 1: The Government Regulation regulates pharmaceutical works that include the procurement, production, distribution, distribution, and pharmaceutical preparations services.

Article 2 paragraph 2: Pharmaceutical works as intended in paragraph (1) must be carried out by a pharmaceutical staff with expertise and authority. The expertise and authority of the pharmaceutical staffs are proven by a license to practice. The pharmaceutical staffs referred to in this article are pharmacists and pharmaceutical technical personnel. A pharmacist is a bachelor of pharmacy who has graduated as a pharmacist and has taken the oath of office of a pharmacist. Meanwhile, what is meant by pharmaceutical technical staffs are personnel who assist pharmacists in carrying out their pharmaceutical work, consisting of bachelor of pharmacy, pharmacy intermediates, pharmaceutical analysts, and pharmacy intermediate staff/pharmacist assistants.

Article 21 article 3: In remote areas where there are no pharmacists, the Minister can place pharmaceutical technical staff whose Registration Certificate for Pharmaceutical Technical Officers at basic healthcare service facilities is given the authority to mix and deliver medicines to patients. The Registration Certificate for Pharmaceutical Technical Officers is written evidence provided by the Minister to registered pharmaceutical technical staffs.

Article 22: In remote areas where there are no pharmacy, doctor or dentist who already has a Registration Certificate has the authority to mix and deliver medicines to patients, which is carried out following the provisions of laws and regulations. The above laws and regulations are made as a legal basis for the public to obtain professional pharmaceutical care and protect the pharmacist profession in carrying out their pharmaceutical practices.

Legal protection for nurses in pharmaceutical services at the Puskesmas where there are no pharmaceutical staffs

Enforcement of regulations in the pharmaceutical sector creates contradictions when applied in areas with a shortage of health staff. Nurses as unauthorized health staffs to practice pharmacy are confused by the conditions in which both pharmacist and doctors are difficult to reach in the area. It causes a dilemma and is vulnerable to be blamed by law enforcement officials. On one side, there are limitations to the authority granted by law, and on the other hand, there is a shortage of authorized and having-expertise health staffs.12
Pharmaceutical practice by nurses where pharmaceutical practice regulation is enforced amid limited pharmacy in various places, nurses who practice pharmacy should not be legally blamed. It is usual for nurses, as health staffs have a bigger number than doctors and pharmacy staffs. They commonly play a double role in carrying out medical procedures and treatment in areas with no other authorized health staff.\textsuperscript{13}

As stated in article 108, paragraph (2) of Law No. 36 of 2009 on Health, pharmaceutical practices can only be carried out by health staffs who have the authority and expertise following statutory provisions; it called pharmaceutical staffs. In the absence of pharmaceutical staffs, sure health staffs can carry out limited pharmaceutical practices; it is the provision of free drugs and limited over-the-counter drugs, while hard drugs such as antibiotics and analgesics are prohibited from giving by nurses.\textsuperscript{14}

Ethical considerations are the justification basis of pharmaceutical practice by nursing staffs.

Based on the ethical decision-making framework above, the violations of pharmaceutical practices committed by nursing staffs where there are no other authorized and having-expertise health staffs in pharmacy can be described as follows:\textsuperscript{15}

\textbf{Value of Personal Belief}

The value of personal belief is influenced by religious principles and primary education (science). Religious teachings can provide a foundation of belief for humans in determining their attitudes and behaviour. Although it is rather challenging to be used as a guide in solving concrete problems, the principles in religious teachings can become the basis for a person to understand what is good and evil, the obligation to help others, and the threat of sanctions for violations. Primary education can influence a person’s perspective too. The fewer references to someone’s knowledge, the less their ability to study a problem based on scientific thinking.

\textbf{Code of Ethics.}

A code of ethics is a statement of professional standards used as a code of conduct and provides a framework for making decisions. In carrying out the duties and functions, a nurse in Indonesia is bound by the Indonesian national nurse code of ethics rules to avoid ethical violations. In article 9 of the nurse code of ethics, it is stated that “Nurses always prioritize the protection and safety of patients in performing nursing duties and are mature in considering abilities if they accept or transfer responsibilities related to nursing.”\textsuperscript{16} Likewise, in the Indonesian medical code of ethics, Article 10 states, “Every doctor must always remember his obligation to protect human life”. The health professional oath always prioritizes humanity and high respect for life. It is one aspect of health science, called a nurturer, where all aspects of life are respected and strived to be maintained and a balancing aspect that views disease and death as a cycle that is also respected naturally.

\textbf{Law}

Referring to Article 108 of Law No.36 of 2009 on Health and Article 2 and Article 22 of Government Regulation No.51 of 2009 on Pharmaceutical Works, the actions of nurses who give hard drugs to their patients are indeed against the law. However, as a guideline, the rule of law, in general, is applied to anyone, anywhere. Indonesia has a geographical condition consisting of thousands of islands and heterogeneous communities. Based on this background, law enforcement should adapt to the local wisdom conditions to achieve the values of justice and order in society. If it is applied without paying attention to society’s condition, the law loses its sociological effect. On the other hand, health science also has its legal principles. Although the law principle is not a concrete legal rule, it can be used as a general basis or a guide for applicable law. The principle in health science is Agroti Salus Lex Suprema (patient safety is the highest law) and Sa science et sa conscience (both knowledge and conscience are good). The point is that the intelligence of a health professional should not conflict with his conscience and humanity. Deminis
noncurat lex (the law does not interfere in trivial matters). Meaning is negligence committed by health staff; as long as it does not adversely affect the patient, the law will not prosecute.16

The moral concept determines whether a behaviour is good or bad from an ethical point of view. Therefore, the moral principle is the highest and cannot be conquered by other rules. This principle is formulated in positive and negative forms into a concept of action (moral concept). According to this view, every health profession in directing action is not based on choice but on what should be done for patients’ safety.

**Ethical principles and theories**

In classical ethical theory, there is something called teleology which means goal. This theory provides the basis that whether an action is correct or not depends on the results. It means if the action has a good result, it is permissible to do so. On the other hand, if the action has a bad result, it is prohibited. Second, still in classical theory, there is also a view of utilitarianism, which views an action as considered good if it benefits many people. One of the approaches is the intuitionism approach, which is the human view of knowing right and wrong regardless of the rational or irrational thinking of a situation. For example, a nurse in a remote area treats a patient, where no doctor can treat the patient immediately because of the long-distance and challenging terrain. Although professionally nurses are incompetent in providing diagnosis and treatment, their actions can be justified in the absence of a doctor. These actions result in more benefits for many people.

From the various considerations in ethical decision-making, giving hard drugs to patients by nurses is acceptable as long as they aim to save the patient and emergency. The emergency itself is defined as there is no pharmaceutical staffs or doctors in the area. This justification also applies legally because the nurses are put in a condition to escape from punishment even though they act against the law. The justification used includes the first because the nurses are in an emergency where there is no authorized health personnel, but the patient needs help. Second, orders and oaths as a nurse can be subject to criminal sanctions if they do not intentionally assist patients in an emergency. It is precisely the act of leaving patients in need of help that should not be justified because the community’s right to get healthcare services is not fulfilled.

Nurses who practise pharmacy where there are no authorized health staffs assigned to the area concerned is not an act of violation of the law. Such action is justified based on various considerations in making ethical decisions in health. However, this condition cannot be allowed to continue. Pharmaceutical practice is an essential element in the health sector, so that its implementation must be provided by authorized staffs and have expertise. Besides, nurses assigned to remote areas need legal certainty to improve their community’s health level but are confused about legal violations if they act outside their authority. Therefore, the distribution of health staffs, especially pharmacy staffs and doctors, must be considered evenly. The realization of Article 21 Government Regulation No.51 of 2009 on Pharmaceutical Works, which contains provisions for the placement of authorized pharmaceutical technical staffs at basic healthcare service facilities in remote areas, needs to be carried out immediately. Furthermore, the preparation of legal products, especially those concerning fundamental rights and the community’s welfare, must pay more attention to various realities in society so that the legal products produced are not viewed solely based on urban conditions. Regulations on authorized health staffs in pharmaceutical practices, which is contained in the Health Law and Government Regulations on Pharmaceutical Works, need to reconsider their application in emergencies involving the patient’s life.

**Conclusions**

One of the efforts to strengthen primary healthcare facilities requires health staff, including pharmacists and the person in charge of pharmacy at the community health center, to provide standardized healthcare services. It will be different when there are no pharmaceutical
staffs at the puskesmas. Pharmaceutical services at puskesmas will be carried out by other health staffs so that pharmaceutical services can continue to run. The current positive law applied in Indonesia only gives authority to nurses to practice limited pharmaceutical services. Nurses who practice pharmacy where there are no authorized health staff assigned to the area concerned are not acting against the law. Such action is justified based on various considerations in making ethical decisions in health. However, this condition cannot be allowed to continue. Pharmaceutical practice is an essential element in the health sector, so that its implementation must be provided by authorized staffs and have expertise.

Health Risk Behavior Related to Stroke in Indonesia

Rizmi Novishia Wijaya1, Djazuly Chalidyanto2, Agung Dwi Laksono3
1Magister Student, Faculty of Public Health, 2Lecturer, Faculty of Public Health, Airlangga University, Surabaya, Indonesia, 3Researcher, National Institute of Health Research and Development, the Ministry of Health of the Republic of Indonesia, Jakarta, Indonesia

Abstract
Stroke is a condition with clinical signs that develop rapidly in focal and global neurologic deficits, which can be severe and lasts ≥24 hours and cause death, without other apparent causes besides vascular. The study aims to analyze ecologically the health risk behavior related to the prevalence of stroke in Indonesia. The research conducted an analysis using secondary data from the 2018 Indonesia Basic Health Survey. The study takes all provinces as samples. Apart from the prevalence of stroke, four other variables analyzed as independent variables were the prevalence of obesity, the percentage of the population with less physical activity, the percentage of the people with fatty/cholesterol/ fried food consumption habits ≥1 per day, and the percentage of daily smokers. Data were analyzed using a scatter plot. The study results found that the higher the prevalence of obesity in a province, the higher the prevalence of stroke. The higher the percentage of the population with less physical activity in an area, the higher the stroke prevalence. The higher the rate of people with fatty/cholesterol/ fried food consumption habits ≥1 per day, the higher the prevalence of stroke in that province. The higher the percentage of daily smokers in a region, the higher the prevalence of stroke. The study concluded that the four health risk behavior analyzed ecologically were positively related to most stroke in Indonesia.

Keywords: stroke, ecological analysis, physical activity, healthy behavior

Background
Stroke is a non-communicable disease. Globally, stroke is the second leading cause of death globally after heart disease and the third leading cause of disability. World Stroke Organization data shows 13.7 million new stroke cases each year, and around 5.5 million die from stroke1. According to data from the South East Asian Medical Information Center (SEAMIC), Indonesia is a country in Southeast Asia with the largest stroke mortality rate2.

According to the World Health Organization (WHO), stroke is a condition that has clinical symptoms that develop rapidly in the form of focal and global neurological deficits. It can be severe and last ≥24 hours and can cause death, with no other apparent cause other than vascular. A stroke occurs when the brain’s blood vessels become blocked or burst, which will result in part of the brain not getting the blood supply that carries the necessary oxygen, resulting in cell/tissue death1.

The WHO states that Indonesia is ranked 97th globally for the highest number of stroke sufferers, with the death rate reaching 138,268 people or 9.7% of the total deaths in 20113. According to the 2018 Indonesia Basic Health Survey results, the prevalence of stroke based on doctor’s diagnosis in the population aged ≥15 years increased compared to 2013, namely from 7‰ to 10.9‰ or an estimated 2,120,362 people. The highest prevalence was in East Kalimantan province, namely 14.7‰ and DI Yogyakarta 14.6 ‰. The lowest prevalence was in Papua (4.1‰) and North Maluku provinces (4.6‰)4.

In terms of financing, *BPJS Kesehatan* noted that the cost of health services for stroke has increased from 2016 to 2018. If in 2016 it reached 1.43 trillion IDR, the figure would raise the following year to 2.18 trillion IDR and get 2.56 trillion IDR in 2018. The best prevention of stroke is to know the risk factors for stroke. It can control the risk factors more quickly, and it shows to be effective at reducing mortality from stroke even in some low-income people. For this reason, it is necessary to have an adequate understanding of what factors are related to stroke in Indonesia. Based on this background, this study aims to analyze ecologically health risk behavior related to the prevalence of stroke in Indonesia.

**Materials and Methods**

**Study Design**

The author designed the study using an ecological analysis approach. Ecological studies focus on comparisons between groups, not individuals. The data analyzed is aggregate data at a particular group or level, which in this study is the provincial level. Variables in ecological analysis can be in the form of aggregate measurement, environmental measurement, or global measurement.

**Data Source**

The study conducted the analysis using secondary data from the 2018 Indonesia Basic Health Survey report. The 2018 Indonesia Basic Health Survey reports is an official publication from the Ministry of Health of the Republic of Indonesia. The unit of analysis in this study is the province. The study analyzed all regions in Indonesia as a sample (34 provinces).

**Data Analysis**

The dependent variable in this study was the prevalence of stroke. Stroke was recorded based on the doctor’s diagnosis history. There were four independent variables analyzed in this study: prevalence of obesity, percentage of the population with less physical activity, percentage of the population with fatty/cholesterol/fried food consumption habits ≥1 per day, and percentage of daily smokers.

Data were analyzed bivariately using a scatter plot. The study used the linear fit line to determine the tendency of the relationship between the prevalence of stroke and the independent variable. The entire analysis process utilizes SPSS 26 software.

**Results and Discussion**

Table 1 shows the descriptive statistics of the prevalence of stroke and other variables analyzed in this study. The information presented informs that the lowest prevalence is 4.1%, while the highest prevalence is 14.7%. The range of prevalence of stroke among provinces in Indonesia is quite wide. Meanwhile, the prevalence range or the percentage of other variables also appears to be relatively high. For example, in the variable percentage of the population with fatty/cholesterol/fried food consumption habits 1 per day, the range is between 10.3%-58.4%.

Figure 1 shows a map of the prevalence of stroke by the province in Indonesia. Based on this spatial information, the figure indicates that most stroke tends to be lower in Eastern Indonesia. The result shows Papua, North Maluku, and East Nusa Tenggara have a lower stroke prevalence.

Figure 1. Map of the Prevalence of Stroke by Province in Indonesia, 2018

Source: The 2018 Indonesia Basic Health Survey
Figure 2 is a scatter plot of the prevalence of obesity and the prevalence of stroke by Indonesia’s province. The study result indicates that the relationship between the two variables shows a positive trend. The work means that the higher the prevalence of obesity in a province, the higher the prevalence of stroke.

The analysis results shown in Figure 2 are in line with previous research, which found that 56.5% of respondents who had a stroke had risk factors for obesity. In another meta-analysis study, the result found that being overweight and obese in young adulthood was associated with increased stroke risk. The risk effect will gradually increase as you gain weight. Being overweight and obese is associated with an increased risk of high blood pressure, diabetes, heart disease, and stroke.

Figure 3 shows the Scatter plot of the population's percentage with less physical activity and stroke prevalence by the province in Indonesia. The results of the scatter plot indicate that two variables tend to have a positive relationship. The condition means that the higher the population with less physical activity in a province, the higher the stroke prevalence.

Lack of physical activity causes blood circulation to become less smooth. Blood functions to carry oxygen and nutrients to body cells. Besides, lack of activity can lead to obesity, which is a risk factor for stroke. Exercise and activity can reduce the risk of stroke. Increased activity can reduce 80% of non-communicable diseases such as stroke, which is the largest contributor to death globally.

Figure 4. Scatter Plot of Percentage of Population with Fatty/Cholesterol/Fried Food Consumption Habits ≥1 per day and Prevalence of Stroke by Province in Indonesia, 2018

Source: The 2018 Indonesia Basic Health Survey
Moreover, Figure 4 shows the relationship between the percentage of the population with fatty/cholesterol/fried food consumption habits ≥1 per day and the prevalence of stroke by Indonesia’s province. The result indicates that the two variables' relationship shows a positive trend based on the scatter plot. The situation means that the higher the percentage of the population with fatty/cholesterol/fried food consumption habits ≥1 per day in a province, the higher the prevalence of stroke in that province will be.

The research results from Alchuriah, most respondents experienced an increase in cholesterol levels in the high and high category borderline due to a diet and lifestyle that consumed a lot of foods with high cholesterol and saturated fat. If the intake of cholesterol in food that enters the body is too high, the blood amount will increase. Cholesterol build-up in the blood can accumulate to form plaque and cause blood clots to form (atherosclerosis), leading to stroke.

Respondents with high cholesterol levels were 2.4 times more likely to have a stroke than respondents with low cholesterol levels. The situation may be because cholesterol directly impacts obstruction of blood circulation and can lead to stroke. In contrast, in the Japanese Adult Health Study, higher cholesterol intake was associated with a lower risk of ischemic stroke.

Respondents with high cholesterol levels were 2.4 times more likely to have a stroke than respondents with low cholesterol levels. Figure 5. Scatter Plot of Percentage of Population of Daily Smokers and Prevalence of Stroke by Province in Indonesia, 2018

Source: The 2018 Indonesia Basic Health Survey

Meanwhile, Figure 5 is the scatter plot of daily smokers' percentage and stroke prevalence by the province in Indonesia. The figure shows that the two variables' relationship shows a positive trend based on the scatter plot. The result means that the higher the percentage of daily smokers in a province, the higher the prevalence of hypertension.

Nicotine and carbon monoxide in cigarette smoke damage the cardiovascular system. Free radicals produced by smoking can increase the risk
of atherosclerosis. Smoking doubles the risk of stroke associated with a dose-response relationship between pack-years\textsuperscript{11,22}. If the initial age of tobacco before or when the age of 20 years increases the risk of atherosclerotic disease, it will also increase the risk of stroke\textsuperscript{21}. Smoking contributes to 15\% of all stroke deaths per year. A previous study said stroke risk would decrease if it is 2 to 4 years after quitting smoking\textsuperscript{11}.

**Conclusions**

Based on the results, the study concluded that there is a positive relationship between obesity, population with less physical activity, population with fatty/cholesterol/fried food consumption habits ≥1 per day, and daily smoker with the prevalence of stroke in Indonesia.

The Diagnostic Dilemma of a Large Infected Cyst in Anterior Maxilla- A Case Report

Roopika Handa¹, Arpan Manna², Tanha Khan², Monika Singh², Aiman Mahfooz², Dhruv Garg²
¹Professor, ²PG Student, Department of Oral Medicine and Radiology, Teerthanker Mahaveer Dental College and Research Centre, Moradabad

Abstract
Among all the odontogenic origin cyst, radicular cyst is the commonest. It is generally associated with nonvital tooth which have necrotizing pulp as it is an inflammatory cyst. Radicular cyst usually occurs in the periapical region of tooth. As a true cyst it consists of pathologic cavity which is lined by epithelium and commonly filled with fluid. Treatment option for the radicular cyst depends on the size, location and duration of the lesion which includes endodontic treatment, enucleation of the lesion, extraction of the offending tooth and marsupialization. In this case report, we are describing a case of infected radicular cyst in anterior maxillary region.

Keywords: Radicular cyst, Odontogenic Cyst, Cell rest of Malassez, Fine needle aspiration cytology (FNAC), Enucleation, Marsupialization, Occlusal radiograph

Introduction
Radicular cyst is also referred as periapical cyst, dental cyst, apical periodontal cyst or root end cyst. As a sequel of pulpal necrosis or trauma, the epithelial cell rests of malassez in the periodontal ligament proliferates and give rise to the radicular cyst.¹ Most often the radicular cyst involves the apices of the infected tooth but it can also occur along the accessory or lateral root canal of the infected tooth.² It accounts for 52% to 68% of all other cyst found in the jaw.³ There is male predilection in third to fifth decades of life. Maxillary anterior region is the commonest involved site.² Shear et al describe it as usually asymptomatic and there may be no visible extraoral swellings.⁴

Radicular cysts are generally ranging from 0.5 to 1.5 cm in size,² although, larger radicular cyst have been reported in literature.⁵ Treatment of the radicular cyst depends on the size and extension of the lesion. Although, endodontic therapy alone can heal the smaller lesions. For the larger or multiple lesion, enucleation, marsupialization or decompression along with endodontic intervention is the treatment of choice.⁶

Case Report
A 22 years old male patient reported to the department of oral medicine and radiology with the chief complaint of pus discharge from upper front tooth region for 15 days. Patient gave similar history of pus discharge 2 years back and subsequently undergone root canal treatment in upper front tooth region.

There was no related swelling and tenderness on extraoral examination.

On intraoral examination 11 was discoloured with pus discharge from the anterior labial sulcus. The previous dental treatment had resulted in reduced crown length and an edge to edge bite of 11 with 41. The margins of the gingiva were rolled out and inflammed (Fig 1). On palpation, there was no associated tenderness.
and fluctuancy with respect to related palatal and labial vestibular region. Based on the chronicity and recurrence of the lesion provisional diagnosis of radicular cyst in the affected region was given.

Radicular cyst, nasopalatine duct cyst, odontogenic keratocyst, pindborg tumor and central giant cell granuloma were evaluated as differential diagnosis.

The radiographic investigation with anterior cross-sectional occlusal radiograph revealed a mixed radiopaque-radiolucent lesion extending from the apices of 11 and 21 to the palatal aspect of 16 region crossing the midline measuring approximately 3x4 cm in size. The lesion had an ill-defined corticated margin and lateral root displacement of 11, 12, 21, 22 was seen (Fig 2).

Patient was then subjected to fine needle aspiration cytology (FNAC) as a part of chair-side investigation, which did not yield any aspiration. The vitality test of 12, 11, 21, 22 showed no response with respect to 12, 11, 21 and 21.

After correlating all the clinical and radiological findings, it was concluded to be an infected radicular cyst as final diagnosis.

![Fig 1](image1.png)  ![Fig 2](image2.png)

**Fig 1** Discoloured 11 with pus discharge from the anterior labial sulcus.

**Fig 2** Occlusal radiograph revealing a mixed radiopaque-radiolucent lesion extending from the apices of 11 and 21 to the palatal aspect of 16 region crossing the midline measuring approximately 3x4 cm in size.

**Discussion**

The radicular cysts are generally asymptomatic and not commonly noticed until they are secondarily infected and become symptomatic or as an accidental finding on routine radiographic investigation. Sometimes long standing lesions become symptomatic due to acute exacerbation. Cortical expansion is a common clinical feature of radicular cyst in maxilla, as compared to mandible. Consistency of the cystic swelling changes depending on the thinning of the bony covering from hard to springy to fluctuant. Resorption of the affected root, cortical expansion, adjacent teeth displacement are the common radiological features of radicular cyst. In our case no such features were appreciable. According to the available literature, the lesion adjacent to the teeth to the lesion frequently become nonvital as the lesion enlarges, and our present case also gave similar features. The epicentre of the lesion in non-vital tooth, usually located at the root apex where as in case of accessory canals it is usually located on the mesial or distal aspect of
However in our case the epicentre was located on the medial aspect of the offending tooth root and the associated teeth were non-vital. Usually radicular cyst have a well-defined cortical border until and unless it is secondarily infected in which case the cortical border becomes sclerotic. The outline of the cyst is curved or circular unless it is influenced by surrounding structures and sometimes dystrophic calcifications may develop in long standing conditions which appears as radiopacity sparsely distributed in the lesion.

The pathogenesis of radicular cysts includes three phases- i) phase of initiation ii) phase of cyst formation iii) phase of enlargement. Pathogenesis of the radicular cyst was described by Torabinejad (1983) according to the “breakdown/nutritional deficiency theory” and “abscess cavity theory.” The “breakdown” theory suggests that of pulpal necrosis the noxious stimuli continue to provoke the epithelial cells which are derived from epithelial cell rests of Malassez. These epithelial cells continue to proliferate and the lesion become larger and the central cells become deprived of nutrition from the connective tissue and as a result central cells undergo liquefactive necrosis, leading to the development of microscopic cyst. According to the “abscess cavity theory”, the epithelial cell tends to line the exposed connective tissue and these cells proliferate and lined the cavity.

Cystic fluid plays an important role for diagnosis in case of the odontogenic cysts as it can vary from lesion to lesion such as clear fluid, yellow coloured fluid which mainly contains protein. Generally, in radicular cyst, cystic fluid contains 5-11g protein per 100 ml of fluid which is quite higher as compared to other cysts of odontogenic origin such as odontogenic keratocyst, dentigerous cyst. Concentration of globulin (both α1 and β) in radicular cyst is higher than other odontogenic cysts.

In most studies it is seen that the healing process of this lesion is dependent on the lesion size. In most of the studies it is stated that treatment protocol depends on the size and extent of the lesion. If the lesion is small conservative treatment is sufficient and however in larger lesions which include decompression, marsupialization or enucleation of the cysts as the treatment choice.

**Conclusion**

Radicular cyst is one of the most common odontogenic cyst which can be encountered during dental practice though usually it is asymptomatic. Malignant transformation of radicular cyst is very rare. Non-surgical, conservative approach is the treatment of choice for smaller lesions nowadays. However surgical intervention might be necessary sometimes.

Detection of Enterotoxigenic \textit{Staphylococcus aureus} in Patients with Gastroenteritis in Erbil/Iraq

Rozhalat Khudhur Jarjees
Lecturer, Department of Pharmacy, Erbil Medical Technical Institute, Erbil Polytechnic University, Erbil, Iraq

Abstract

Gastroenteritis is one of the words serious public health problem, and enterotoxigenic \textit{Staphylococcus aureus} is one of the causes of gastroenteritis. The aim of this study was the molecular detection of enterotoxigenic genes in \textit{Staphylococcus aureus}, then detection the association of resistance patterns with the toxigenicity of strains. Microbiological analysis of fecal samples from patients with gastroenteritis was performed for detection of \textit{S. aureus}. The samples were cultured and identified by routine bacteriological methods and VITEK 2 system. Subsequently PCR amplification of enterotoxin genes (\textit{sea} and \textit{seb}) was carried out on all \textit{S. aureus} strains. The results indicated that in total of 417 fecal samples taken from patients with acute gastroenteritis, 30 grew \textit{S. aureus} (7.19%), and of 417 fecal samples 96 yielded bacterial pathogens (23.02%), \textit{S. aureus} was the most common bacterial pathogen found in 30/96 cases (31.25%). In 30 isolated of \textit{S. aureus}, penicillin sensitive \textit{S. aureus} were 2 (6.67%), methicillin sensitive \textit{S. aureus} were 19 (63.33%), multidrug resistant \textit{S. aureus} were 12 (40%), methicillin resistant \textit{S. aureus} were 11 (36.67%), Extensive drug resistance were 3 (10%), and none of them was pan drug resistant, and all isolates were sensitive to vancomycin. The PCR results showed that 7/30 (23.33%) of the \textit{S. aureus} isolates possessed the \textit{sea} gene, and 3/30 (10%) had the \textit{seb} gene. In total of 30 isolates Staphylococcal enterotoxin genes \textit{sea} and \textit{seb} were more prevalent among methicillin resistant \textit{S. aureus} were 6/11 (54.54%), 3/11 (27.27%) respectively, then in multidrug resistant \textit{S. aureus} which were 6/12 (50%), and 3/12 (25%) respectively, and in Extensively drug resistance \textit{S. aureus} \textit{sea} was 1/3 (33.33%) and there is no \textit{seb} genes, while in methicillin sensitive \textit{S. aureus} \textit{sea} was 1/19 (5.26%), and there is no \textit{seb} genes, and there was no Staphylococcal enterotoxin genes \textit{sea} and \textit{seb} in penicillin sensitive \textit{S. aureus}. The result confirmed the involvement of enterotoxigenic \textit{S. aureus} in the occurrence of gastroenteritis, and isolates with enterotoxin genes have a higher drug resistance rate.

\textbf{Keywords:} Gastroenteritis, \textit{Staphylococcus aureus}, \textit{sea} and \textit{seb} Enterotoxin genes.

Introduction

Gastroenteritis is a common clinical syndrome. It poses one of the words major clinical and public health problems. The principal clinical manifestation of gastroenteritis is diarrhea. The Word Health Organization Syndromic definition of gastroenteritis is “three or more abnormally loose or fluid stools over 24 hours”\(^1\). Diarrhea is the second disease that causes death in children in the world. Every year, around there are 1.7 million cases of diarrhea and cause around 525,000 deaths in children under the age of five in the world\(^2,3\). Overall, 1.7 billion global cases of diarrheal disease are reported annually and are associated with an estimated 2.2 million deaths. The burden of diarrheal disease is most critical in developing countries, facilitated by unsafe water supplies, poor sanitation, and nutritional deficiencies. While less common in high-income countries, diarrheal diseases remain a significant health concern. There are an estimated 211 to 375 million episodes of diarrheal illnesses each year in the United States, with 1.8 million

hospitalizations and 3,100 deaths\textsuperscript{4,5}.

A wide variety of viruses, bacteria, and protozoa may cause gastroenteritis\textsuperscript{1}. Acute bacterial gastroenteritis (ABG) can cause more severe symptoms than acute viral gastroenteritis in children\textsuperscript{6}, and the list of bacteria that cause gastroenteritis is continuously growing, include \textit{Campylobacter jejuni}, \textit{Staphylococcus aureus}, \textit{Bacillus cereus}, \textit{Escherichia coli}, \textit{Vibrio cholera}, \textit{Shigella dysenteries}, \textit{Salmonella enteriditis}, \textit{Yersinia enterocolitica}, \textit{Clostridium perfringens}, and \textit{Clostridium difficile}. Micro-organisms cause gastroenteritis by a number of mechanisms. They may release performed toxins prior to ingestion, multiply and produce toxins within the gastrointestinal lumen, directly invade the bowel wall, or use a combination of toxins and invasion\textsuperscript{1}.

On 21 September 2006, the Austrian media reported the occurrence of a cluster of gastroenteritis cases in a boarding school in Eisenstadt, capital of the province Burgenland in eastern Austria. \textit{S. aureus} was identified as the causative agent. From 45 stool samples, none of them contained \textit{Salmonella}, \textit{Campylobacter}, enterohaemorrhagic \textit{Escherichia coli} and \textit{Yersinia}. Of those 45 stool samples, 44 were positive for \textit{S. aureus}\textsuperscript{7}. \textit{S. aureus} may cause diarrhea, gastrointestinal carriage of MRSA has been associated with antibiotic associated diarrhea\textsuperscript{8,9}.

The existence of several virulence factors such as staphylococcal exotoxins have an important role in \textit{S. aureus} pathogenicity. One of these factors is enterotoxins which proved to be more tolerance to high temperature\textsuperscript{10}. Staphylococcal enterotoxins are low molecular weight proteins (MW 26.900–29.600D)\textsuperscript{11}. All enterotoxins are superantigens which are encoded by mobile genetic elements including phages, plasmids and pathogenicity islands\textsuperscript{12,13}. Also \textit{S. aureus} is one of the most important causes of food poisoning due to its ability to produce more than 22 different enterotoxins\textsuperscript{14,15}.

The \textit{S. aureus} enterotoxins (SEs) can be separated into two groups; the 5 serological classical types (SEA–SEE)), and the newer (SEG–SE/Y and counting) enterotoxin groups. Many members from both these groups contribute to the pathogenesis of several serious human diseases. Only enterotoxins with demonstrated emetic potential in monkeys were designated “SE,” whereas enterotoxins that failed to do so or have not been evaluated in non-human primate models of emesis are designated enterotoxin like (SEL-) toxins\textsuperscript{14,16}. Among these Staphylococcus enterotoxins, five of them (A, B, C, D and E) are known to be responsible for 95% of Staphylococcal food poisoning cases\textsuperscript{17,15}. \textit{S. aureus} strains can produce one or several of the five major SEs (SEA, SEB, SEC, SED, and SEE)\textsuperscript{18}. Staphylococcal enterotoxin SEA and SEB are two of the most important gastroenteritis causing agents. SEA and SEB are the most food poisoning agents (> 60\%) in USA and England. For the above-mentioned reason, these toxins can cause epidemic gastroenteritis\textsuperscript{19,11}. While the majority of MRSA isolated from food products in Denmark was negative for major virulence factors such as enterotoxins\textsuperscript{20}.

Staphylococcal enterotoxins (SE) A and B are two of the most important gastroenteritis causing agents in USA and England. There are several methods for detection of enterotoxigenic bacteria. The phenotypical methods are not reliable in specificity, because staphylococcal enterotoxins serotypes are antigenically similar. Therefore, molecular techniques such as PCR are recommended for detection of \textit{S. aureus} enterotoxins genes\textsuperscript{13}. Despite the potential role of \textit{S. aureus} enterotoxins in causing diarrhea a limited number of studies have focused on multidrug resistant \textit{S. aureus} colonized diarrhea. Herein we explored the prevalence of \textit{S. aureus} in the fecal of patients with gastroenteritis.

**Materials and Methods**

The study was carried out for six months from June to November 2020. Fecal samples were taken from patients admitted to Erbil Hospitals suffering from acute diarrhea and gastroenteritis infection.

**Bacterial Identification:**

Fecal samples under aseptic conditions were inoculated into a tube containing 10ml Tryptic soy broth.
The broth was incubated at 37°C for 24h then streaked from the enriched broth onto a selective mannitol salt agar medium, and incubated at 37°C for 24h. Suspected *S. aureus* colonies from each sample were evaluated based on morphology. All isolates were further identified for their species assignment by the automated VITEK2 compact system (bioMérieux, France). After the screening, the presumptive *S. aureus* isolates were stored at -20°C in Tryptic soy broth (TSB) plus 20% v/v glycerol.

**Criteria for finding multidrug resistance, methicillin - resistant *S. aureus*, extensively drug resistance, and pan drug resistance in *S. aureus***

Colonies of *S. aureus* were inoculated in 5ml of 0.85% saline, and the turbidity was adjusted to match 0.5McFarland standard. Then sterile cotton swabs were dipped into the inoculums and spread evenly on to Mueller Hinton agar, MHA. The following antimicrobial discs were applied aseptically to the MHA plates and incubated overnight at 37°C: penicillin(P,10U), amoxicillin (AX,25μg), gentamycin (CN, 10μg) ,vancomycin (VA,30μg), erythromycin (E, 15μg), tetracycline (TE,30μg), methicillin (MET,10μg ), cefoxitin (30μg), ciprofloxacin (CIP,5μg), amoxicillin-clavulanic acid (AMC,20μg/10μg), oxacillin (OXA, 1μg), fusidic acid (FA, 10μg), rifampicin (RA, 5μg), clindamycin, (DA, 2μg), and trimethoprim-sulfamethoxazole (SXT,1.25μg/23.75μg).

We categorized a specimen as penicillin-sensitive *S. aureus* (PSSA) if it was susceptible to penicillin and methicillin, methicillin - sensitive *S. aureus* (MSSA) if it was resistant to penicillin and susceptible to methicillin, and methicillin - resistant *S. aureus* (MRSA) if it was resistant to both penicillin and methicillin. Resistance to methicillin was inferred by testing for oxacillin and cefoxitin resistance. Multidrug resistance (MDR) one or more of these have to apply: (i) an MRSA is always considered MDR by virtue of being an MRSA (ii) non susceptible to at least one agent in three or more antimicrobial categories. Extensively drug resistance (XDR): non-susceptible to at least one agent in all but two or fewer antimicrobial categories. Thus, bacteria isolate that is characterized as XDR will also be characterized as MDR. Pan drug resistance (PDR) non-susceptible to all antimicrobial agents in all antimicrobial categories.

**DNA extraction**

Bacterial DNA was extracted from *S. aureus* using a DNA extraction kit (geneaid/Korea), according to the manufacture’s instruction. Nanodrop was used for measuring the concentration and the purity of nucleic acid. The DNA extracted samples were stored at -20°C for further use as template for PCR.

**Detection of Staphylococcal enterotoxin**

Amplification of Staphylococcal enterotoxin genes was done by specific primers and polymerase chain reaction method. Two PCR primers sets were used to detect the staphylococcal enterotoxin *sea* and *seb* encode SEA and SEB respectively, as described in Table 1.

The total of 25µl PCR master mix reaction volume was performed containing 1µl of genomic DNA, 12.5µl of 2x Go Tag green master mix (Promega, USA), and 1µl was added from each of the forward and reverse primer and completed with nuclease free water to 25 µl.

The PCR condition were as follows: a total of 32 cycles was performed with the first denaturation at 94°C for 5min, then consisted of 30 cycles, for denaturation at 94°C for one-minute, specific annealing temperature 55°C for one minute, extension at 72°C for one-minute, and the final extension at 72°C for 5min. The PCR products were separated in a 1% agarose gel and stained with Safe dye (GenetBio, Korea). The gel was visualized under UV trans-illuminator (Synegene, UK).

Results

In total of 417 fecal samples taken from patients with acute gastroenteritis, 30 grew *S. aureus* (7.19%), and of 417 fecal samples 96 yielded bacterial pathogens (23.02%), *S. aureus* was the most common bacterial pathogen found in 30/96 (31.25%) cases.

![Figure (1): *Staphylococcus aureus* on selective mannitol salt agar medium](image1)

These isolates showed different susceptibility towards antibiotics. All isolates of *S. aureus* were sensitive to vancomycin. However, the effect of other antibiotics was variable among the isolates, the heigh effective antibiotics were clindamycin, fusidic acid, ciprofloxacin, gentamycin, and trimethoprim-sulfamethoxazole. Adversely, the less effective antibiotics were penicillin, and amoxicillin, as depicted in Figure 2.

![Figure (2): Antibiotic susceptibility test](image2)
Of 30 isolated *S. aureus*, penicillin sensitive *S. aureus* were 2 (6.67%), methicillin sensitive *S. aureus* were 19 (63.33%), multidrug resistant *S. aureus* were 12 (40%), methicillin resistant *S. aureus* were 11 (36.67%), extensive drug resistance (XDR) *S. aureus* were 3 (10%), Bacteria isolates that is characterized as MRSA and XDR will also be characterized as MDR, and none of them was pan drug resistant *S. aureus* because all isolates of *S. aureus* were sensitive to vancomycin, as depicted in Table 2.

**Table 2**: Percentage of penicillin-sensitive *S. aureus* (PSSA), methicillin- sensitive *S. aureus* (MSSA), multidrug-resistance (MDR), methicillin resistance *S. aureus* (MRSA), extensive drug-resistance (XDR), and Pan drug-resistance *S. aureus* (PDR). Bacteria isolates that is characterized as MRSA and XDR will also be characterized as MDR.

Discussion

*S. aureus* is one of the major pathogens able to infect every organ, damaging tissues and causing severe, chronic, and/or recurrent infections, which require prolonged antimicrobial treatment, with a dramatic impact on the patient’s quality of life\(^{30,31}\). The result revealed that in total of 417 fecal samples, 30 grew *S. aureus* (7.19%), and of 417 fecal samples 96 yielded bacterial pathogens (23.02%), *S. aureus* was the most common bacterial pathogen found in 30/96 cases (31.25%).

The PCR results showed that 7/30 (23.33%) of the *S. aureus* isolates possessed the sea gene, and 3/30 (10 %) had the seb gene. In total of 30 isolates Staphylococcal enterotoxin genes sea and seb were more prevalent among methicillin resistant *S. aureus* (MRSA) were 6/11 (54.54%), 3/11 (27.27%) respectively, then in multidrug resistant *S. aureus* (MDR) which were 6/12 (50%), and 3/12 (25%) respectively, and in Extensively drug resistance (XDR) *S. aureus* sea was1/3 (33.33%) and there is no seb genes, while in methicillin sensitive *S. aureus* (MSSA) sea was 1/19 (5.26%), and there is no seb genes, and there was no Staphylococcal enterotoxin genes sea and seb in penicillin sensitive *S. aureus* (PSSA). *S. aureus* resistance against a wide range of antimicrobials is another important factor in spread of infections by this bacterium that is increasing worldwide.

Different results have been reported in other countries for the prevalence of sea and seb genes in *S. aureus*. isolated from fecal samples.

Our results consistent with the findings of other studies, in Seoul, Korea; Kim et al., 2017, they reported that out of 664 stool samples taken from children with acute gastroenteritis from age (1-18), 183 (27.6%) yielded bacterial pathogens, and *S. aureus* was the most common bacterial pathogen, found in 72 cases (39.3%)\(^6\). In a similar study in China hospitals the overall colonization prevalence of *S. aureus* and MRSA were 20.0% and 4.5% respectively, in fecal samples from patients with age 1day to 17 years old\(^{22}\).

Other studies reported different prevalence of *S. aureus*, in 2007, Flemming and Ackermann, reported that in German out of 2,727 stools investigated, 198 grew *S. aureus* (7.265%). A total of 114 *S. aureus* strains (57.58%), produced the following enterotoxins in vitro: A, 36 (31.58%); B, 20 (17.54%). Twenty-nine (14.6%) *S. aureus* strains were identified as methicillin-resistant\(^{32}\).

In 2014, Kadhim in Iraq detected *S. aureus* in (6.7 %) diarrhea samples, and (66.7%) were found to be positive for production of enterotoxin B\(^{21}\). In United States of America out of 625 human stool samples, 58 were positive for *S. aureus* (9.3%). A high number of isolates were resistant to multiple antibiotics including oxacillin (43.1%), and erythromycin (51.7%), all isolates were susceptible to vancomycin\(^{33}\). In developed countries, Salmonella was the most frequently detected bacteria found in German patients with acute gastroenteritis AGE, followed by enterotoxin gene-carrying *S. aureus* and *Campylobacter spp.* Enterotoxin-encoding *S. aureus* was 1.7% \(^{34}\).

Infection with *S. aureus* was detected in 64/345 fecal samples (18.6%), taken from Iranian patients with gastroenteritis. In total, 50% of the strains (32/64) carried the enterotoxin genes; the most common was sea (56.1%). These genes were more prevalent among MDR-MRSA (58.8%) compared with methicillin-sensitive *S. aureus* (15.4%) strains. *Staphylococcus aureus* should be considered an etiological agent of gastroenteritis. Infection with MRSA resistant to multiple antimicrobial classes (MDR-MRSA) is common among gastroenteritis patients\(^{35}\). In Iranian outpatients with underlying inflammatory bowel disease *S. aureus* were detected in 15.8%. In *S. aureus* isolates, only positivity for the presence of sea enterotoxin was detected\(^{36}\).

The prevalence of *S. aureus* and genes encoding enterotoxins in diarrhea samples in other studies were higher or lower than our results, these variation between our results and other studies, can be attributed to several factors, including the size of the samples tested, the season in which the sampling was done, and geographical
difference. Our result revealed that vancomycin is still the main antibiotic of choice for treatment of infection caused by methicillin resistant S. aureus (MRSA) and extensively drug resistance (XDR) S. aureus. Also, some strains of S. aureus remain susceptible to penicillin. Thus, this antimicrobial agent remains the treatment of choice for patients infected with penicillin sensitive S. aureus (PSSA).

In China, Liang and his colleague did research in 2018, in their result the highest rate of resistance was detected for penicillin (PEN) (93.9%), followed by erythromycin (ERY) (58.8%), clindamycin (CLI) (55.7%), tetracycline (TCY) (31.3%), sulfamethoxazole-trimethoprim (SXT) (7.6%), ciprofloxacin (2.3%), rifampicin (1.5%), nitrofurantoin (2.3%), and gentamicin (0.8%). All of the isolates were susceptible to vancomycin. In Italy, Rifampicin is one of the major drugs used on its own and also in combination to treat numerous infections sustained by methicillin-resistant Staphylococcus aureus (MRSA), but rifampicin resistance (RIF-R) is increasing in multidrug-resistant-MRSA isolates (16.4%), with respect to Europe (5.7%). Some S. aureus strains remains susceptible to penicillin. Thus, this antimicrobial agent remains the treatment of choice for patients infected with penicillin susceptible isolated. In Guangzhou, China, Ai and his colleague did research in 2020, they found that all MRSA strains were resistant to cefoxitin screening, also all MRSA strains were resistant to penicillin. The S. aureus strains exhibited highest rate of resistance to penicillin (PEN, 84.2%), followed by erythromycin (ERY, 38.8%), the resistance rates of antibiotics were lower for gentamicin (GEN, 2.7%), ciprofloxacin (CIP, 1.9%), and rifampicin (RIF, 0.7%); however, all isolates were susceptible to vancomycin.

Patients with MRSA colonized diarrheal stool impact significantly on environmental contamination. The epidemiology of prevalent MRSA is changing dynamically and geographically. Furthermore, having a gastrointestinal condition would increase the risk of intestinal S. aureus carriage.

Conclusions

These results confirmed the involvement of S. aureus in the occurrence of gastroenteritis, and the enterotoxigenic genes sea and seb were more prevalent among methicillin resistant S. aureus (MRSA), then multidrug resistant S. aureus (MDR), and extensively drug resistance (XDR) S. aureus. Vancomycin is still the main antibiotic of choice for treatment of infection caused by methicillin resistant S. aureus (MRSA) and extensively drug resistance (XDR) S. aureus. Our findings suggest that PCR is a rapid, specific, and inexpensive method for detecting SE.

Conflict of Interests: None.

Lipoteichoic Acid as Antibiofilm against *Staphylococcus aureus*

Ruaa SH¹, Suhad M²

¹Doctor of Immunology, ²Doctor of medical microbiology. Kufa University, Collage of Science, Laboratory of Investigation, Kufa City, Iraq

**Abstract**

**Background:** It is a polysaccharide substance produced by a group of microorganisms that helps it adhere to living and non-living surfaces and it is responsible for many diseases, as it has a role in staphylococcal diseases such as pneumonia, urinary tract infection and endocarditis. Although lipoteichoic acid is a component of biofilm. However, it has a role in preventing biofilm formation

**Materials and Methods:** The methods of this study included isolated and identification of bacteria from UTI samples and identified by morphology characters and biochemical test to identify *S.aureus*. Then discover their ability to formbiofilm and Use lipoteichoic acid in different concentration as antibiofilm

**Results:** The results of identification of bacterial isolatesshowed the colonies grown on blood agar causing the typical B hemolytic state, these samples not grown on MacConkey agar and under the microscope showed gram positive cocci, a cluster like grape, these samples were identified as *Staphylococcus* when grown on mannitol medium converted it to yellowish color and appeared round, smooth, raised, mucous and gelatinous. The *staphylococcus aureus* formed biofilms with different concentrations, where the fourth isolate was the lowest percentage (0.065), while the second and fifth isolates were given (0.120 and 0.153) and the first isolation was given (0.220),however the highest percentage was given by the third isolation (0.357). So this study showed that the concentrations of LTA (200) µg/mlare MIC. The results of this work showed that after 24 hours of treatment with LTA it impeded the formation of biofilms of *Staphylococcus aureus* and the result after treatment was the concentration 50 and 100µg/ml gave less percentage of inhibition, while 500µg/ml appeared 100% of inhibition, so (200,300 and 400 gave 61%, 80% and 90% inhibition to biofilm respectively.

**Keyword:** Biofilm, MIC, gram positive and UTI

**Introduction**

*Staphylococcus aureus* is a gram-positive bacterium that has the ability to adapt to living in various non-living environments. This bacterium is characterized by being an important factor in causing a variedcollection of clinical infections bacteremia and infectious endocarditis, osteoarticular, skin and soft tissue, pleuropulmonary, and device-related infections¹. These bacteria are distinguished by their ability to attach to non-living materials by producing a polysaccharide matrix, which is a virulence factor that gives bacteria the ability to resist antibiotics and the immune systemin hospital; this leads to the emergence of antibiotic resistance². This leads to chronic and destructive infections, as these membranes allow them to adhere to tissues such as heart valves and bones, and cause infective endocarditis and osteomyelitis, or on implanted medical devices such as catheters, artificial joints, artificial heart valves, and bone implants in hospitalized patients in the healthcare environment³. The first step is to create a biofilm at the place where the cells adhere to surfaces and reinforce
several mechanisms of irreversible adhesion\textsuperscript{4}.  

Lipoteichoic acids (LTA), are connected with the membrane of the cell through a glycolipid anchor in a Gram-positive bacterium such as \textit{S. aureus}, \textit{enterococci}, \textit{Listeriamonocytogenes}, \textit{Streptococcus pneumoniae}, and \textit{Bacillus subtilis}. LTA is an anionic 1,3-glycerolphosphate holding polymer attached to the cell wall\textsuperscript{5}.  

It has an important role in bacterial growth, cell wall working, membrane stability, and virulence\textsuperscript{6}. Anti-biofilm causes were developed as replacements to antibiotics to protect against infection associated with biofilms to prevent these membranes from developing without bacterial resistance. Bacteria-derived amphiphilic have been largely studied for their anti-biofilm properties\textsuperscript{7}.  

\textbf{Materials and Methods}  
\textbf{Collecting and diagnosing specimens}  

50 specimens of bacteria were collected from women suffering from urinary tract infection and who did not take any antibiotics, in Al-Sadr Hospital in AL-Najaf Governorate. Samples were cultured in pre-prepared media including (MacConkey agar, blood agar, and mannitol salt agar) then incubated at 37 c° for 24 h. the bacterium was diagnosed based on the phenotypic properties using biochemical tests, where was staphylococcus aureus diagnosed by gram staining, catalase after growing on mannitol salt agar medium, coagulase test\textsuperscript{8}, in order to check the diagnosis.  

\textbf{Preparation of lipoteichoic acid}  

It was the ready prepared solution (according to Sigma Aldrich, Germany) and supplied in a glass vial (5 mg/ml) provided with water (1ml) as a stock solution. The stock solution was diluted by adding distilled water in proportion to 100 µl of lipoteichoic acid: 900 µl D.W.  

\textbf{Minimum inhibitory concentration (MIC) of lipoteichoic acid}  

The minimum inhibitory concentration (MIC) of lipoteichoic acid was defined as the microdilution broth method. Briefly, serial concentrations of lipoteichoic acid (50, 100, 200, 300, 400, and 500 µg/ml) were set with tryptic soy broth. The lowest concentration that inhibits the growth of bacteria is considered as the MIC\textsuperscript{9}.  

\textbf{Biofilm formation}  

The biofilm assay defined by\textsuperscript{10}, with some alterations: 10 ml of trypticase soy broth (TSB) with 1% glucose was inoculated with a loopful of test bacterium from an overnight culture on nutrient agar. The flat bottom tissue culture plates (96 wells) were filled with 200µl of diluted cultures separately. uninoculated sterile broth assisted as blank. The control bacteria were also diluted and incubated. The culture plates were incubated at 37˚C for 24 hours. After incubation, kind tapping of the plates was finished. The bores were washed with 200 µl of Normal saline four times to eliminate free-floating bacteria. Biofilms that remained adherent to the walls and the bottoms of the wells stained with 0.1% crystal violet for 10 min. another stain was washed with Normal saline and plates were dried properly then adding 200 µl of the destaining solution (95% ethanol) for 10 min. Lastly, 200µl from each well was moved to a new microtiter plate and measured at 570 nm by a microplate reader. The biofilm degree was calculated as follows: Biofilm degree=Mean OD570 of tested bacteria- Mean OD570 of control.  

\textbf{Effects of lipoteichoic acid on biofilm formation}  

The method described by\textsuperscript{11} was accepted to investigate the effect of LPT on biofilm formation. An overnight bacterial culture (in trypton soya broth) was attuned with McFarland standard No. 0.5. Tryptone soya broth containing MIC of LPT was inoculated with a before prepared bacterial suspension and incubated for 24 hours at 37°C. An amount of 200 µl of the culture was transferred in triplicate into the vertical rows of a polystyrene microtiter plate well for each isolate and served as control. A volume of 200 µl of culture containing the MIC concentration of the LPT was transferred into another three wells. All plates were incubated at a temperature of 37°C for 24 hours. Subsequently, the
biofilm formation protocol was followed as mentioned earlier. Percentage of biofilm inhibition was calculated following the equation: 
\[ \text{percentage of inhibition of biofilm formation} = 1 - \left( \frac{\text{O.D of treatment}}{\text{O.D of control}} \right) \times 100 \]

**Results and Discussion**

**Collecting and diagnosing specimens**

50 samples were collected from women suffering from urinary tract infection and the results of the bacterial culture showed 5 samples grown on blood agar causing the typical B hemolytic state, these samples not grown on MacConkey agar and under the microscope showed gram positive cocci, a cluster like grape, these samples were identified as Staphylococcus when grown on mannitol medium converted it to yellowish color and appeared round, smooth, raised, mucous and gelatinous. The results of the current study showed that all mannitol fermenters 5(10%) were coagulant and catalase test positive, and therefore they were considered *S. aureus*.

**Biofilm formation**

In this study, the result was that the five isolates of *Staphylococcus aureus* formed biofilms with different concentrations, where the fourth isolate was the lowest percentage (0.065), while the second and fifth isolates were given (0.120 and 0.153) and the first isolation was given (0.220), however, the highest percentage was given by the third isolation (0.357) which was used in the subsequent experiments (table -1).

**Table-1)** show the percentage of the biofilm formed by *S. aureus*

**3.3 minimum inhibitory concentration (mic) of lipoteichoic acid**

The result of this study showed that the concentrations (500) µg/ml were lethal to *Staph aureus*, while (200) µg/ml were inhibitor and the concentrations (50,100 µg/ml) gave were not effective, (table-2).

**(Table-2)** minimum inhibitory concentration (mic) of lipoteichoic acid

</table>
found that the total 355 urine samples of UTI suspected patients were screened 119 (33.52%) sample showed grow out of which *Staphylococcus aureus*, while 13 found the *Staph aureus*(1.9%) from UTI. found the effect of *Lactobacillus plantarum* lipoteichoic acid on developed biofilm, *E. faecalis* was grownup on glass-bottom plate’s treatment with Lp.LTA for 24 h. The 3-week-old *E. faecalis* biofilm was condensed by Lp.LTA in a dose-dependent manner. In addition, appeared that *Lactobacillus plantarum* LTA could inhibit *S. aureus* biofilm development.

*S. aureus* is a bacterium that causes many inflammatory infections and biofilm development is closely related to antibiotic resistance and adhesion to surfaces. The inhibitory influence on the development of *Staph aureus* biofilm is a communal characteristic of LTA of gram-positive bacteria including *S. aureus*, *S. pneumoniae*, *S. gordonii*, *E. faecalis*, and *B. subtilis*. D-Alanine moieties in the LTA play an important role in inhibiting biofilm development, and many explanations have been found for this inhibition. First, the presence of the positive charge resulting from the presence of de-alanine has an inhibitory role as the positive charge prevents biofilms from forming. For example, an increase in the degree of N-deacetylation causing an increased positive charge. Second, D-amino acids interfere with the formation of biofilms as they break down biofilms. For example, *S. aureus* biofilm development was inhibited by D-phenylalanine, D-proline, and D-tyrosine. The inhibitory influence of LTA on *S. aureus* biofilm development is not only due to competition with bacterial cell membrane-anchored LTA, but is also due to bacterial sensing and signaling in response to LTA because LTA could finish the pre-formed biofilm.

**Conclusion**

The aim of this study was to investigate antibacterial activities and disruption of biofilm structure by Lipoteichoic acid. *Staph aureus* was chosen because its ability to form biofilm on surfaces makes the cells impervious to therapeutic concentrations.

Survey of Puree Users without Smoking History of Households in Kosebo Village, Angata District, Konawe Selatan District

Ruslan Majid1, Elma Prasetyaningsih1, Fikki Prasetya1, Jumakil1, Fifi Nirmala1
1Faculty of Public Health, Halu Oleo University, Kendari Southeast Sulawesi, Indonesia

Abstract

“Puree” in the local language is a process of concocting or mixing tobacco and whiting, finally forming a black paste and then rubbing it on the lips, the user. “Me puree” in local language terms is using “Puree”. The purpose of this study was to determine the survey of Puree Users with no smoking history among housewives in Kosebo Village, Angata District, South Konawe Regency in 2019. This research method used a descriptive method, carried out in Kasebo Village, Angata District, South Konawe Regency. The population of all housewives was 203. The sampling technique used was proportional random sampling, and obtained a number of 54 respondents. The results of the research after analyzing the frequency distribution showed that the respondents’ knowledge was lacking, the history of using “puree” was sufficient, the tradition of “puree” users was good, the income of “Puree” users was less and the previous disease history of “puree” users was less. It is recommended that a primitive program to provide public health education by conducting outreach to identify risk factors that can increase the incidence of both smokeless and smoked tobacco use.

Keywords: Puree, Knowledge, User History, Tradition, Income

Introduction

“Puree” The term local language is a process of concocting or mixing tobacco and whiting, finally forming a kind of black paste which is smeared on the user’s lips. “Me puree” means using “Puree”. Tobacco is a type of plant that is well known among Indonesian people. In addition, people use tobacco as chewing, especially among mothers in rural areas. The dangers of tobacco use include diseases related to the heart and lungs such as heart attack, stroke, chronic obstructive pulmonary disease, emphysema and cancer. Reproductive disorders and pregnancy can also result from tobacco use.

Dependence on tobacco has become a global epidemic that can cause disability, disease, decreased productivity and death. This is because in the tobacco leaves there are several kinds of alkaloids that can give pleasure to the user, namely nicotine, nicotine and myosin. So that this alkaloid gives an addictive effect for those who use tobacco. Some of the negative effects caused by the habit of consuming chewing tobacco are cataracts, pneumonia, leukemia, stomach cancer, pancreatic cancer, cervical cancer, kidney and other diseases. These diseases add to a long list of diseases caused by consuming tobacco, such as cancer of the lungs, esophagus, larynx, mouth and throat. Lung disease, emphysema and bronchitis, stroke, heart attack and other cardiovascular diseases. Nearly 90% of lung cancers are caused by tobacco consumption. Tobacco can also damage the reproductive system, contributing to miscarriage, premature birth, low birth weight, and diseases in children such as hyperactivity.

Smokeless Tobacco or smokeless tobacco is the use of tobacco without having to be burned like cigarettes. Smokeless tobacco contains several carcinogenic compounds that have been linked to various diseases.
such as oral cancer, hypertension, heart disease and other diseases. Smokeless tobacco is also used in several countries and various uses for each country such as dipping tobacco. Smokeless tobacco products such as: snus, tobacco cream or toothpaste, chewing tobacco, dissolved tobacco, topical tobacco paste, water tobacco, smokeless tobacco herbs, and others.

The use of smokeless tobacco is more common in Asian, African and Middle Eastern countries than in Europe and America. The prevalence of smokeless tobacco uses in the United States according to the Surveillance System Study of use ranges from 1-9% in different countries and more in young men with low educational status, and in countries with a high smoking prevalence. The United States Population Survey reports a significant reduction in smokeless tobacco use from 1992 to 20023.

The US National Health Interview Survey (1991-2003) also reported a decrease in smokeless tobacco use. The prevalence of smokeless tobacco use has also been reported from European countries. This is almost similar to the United States with rates ranging from 1-9% in 3 different countries.

“Puree” is one of the products used by the residents of Angata for their smoking cessation efforts which contain tobacco or in the palace it is called Smokeless Tobacco. “Puree” as a substitute for cigarettes during smoking cessation. The fact shows the result that Puree’s herb is effective as a therapy to quit smoking. Puree is seen as local wisdom in Angata District for smokers who are motivated to quit. The residents of Angata support the use of Puree as a smoking replacement therapy for adult smokers, they engage with this product on a smoking cessation pattern without knowing the carcinogenic effects of Puree. The puree is made from tobacco water and whiting then becomes a kind of paste and rubbed on the user’s lips. The health hazards posed by Puree come from tobacco components that contain harmful substances to health such as nicotine1.

Puree is a smokeless tobacco product, apart from having a positive impact, puree also has a negative impact on health so that puree as one of the smokeless tobacco products certainly has a negative impact that needs to be researched. By knowing the survey of puree users without a smoking history among housewives, they can take the right steps in an effort to improve public health by changing wrong behavior habits.

Method

This research uses descriptive method so that the main objective is to make an objective analysis of the situation. Determination of respondents used Probability sampling technique to take the subject from each stratum or each area that is determined balanced with the number of subjects in each stratum or region. By using the proportional random sampling technique, the total sample size is 54 respondents.

Results

1. Knowledge

Based on respondents’ knowledge of using Pure without a history of smoking, the results show that from a total of 54 respondents, the majority of respondents said Yes as much as 58.95% and respondents who answered No were 41.05%.

2. Pure Usage History

Based on the history of the use of “Pure” without cigarette production, the respondents who answered “Pure” without the product of cigarettes, as for the results of a total of 54 respondents, the majority said Yes as much as 57.93% and respondents who answered No were 42.07%.

3. Tradition

In accordance with the traditional results of using “Pure” without a history of smoking, from a total of 54 respondents, the majority answered Yes as much as 58.95% and respondents who answered No were 41.05%

4. Income

Respondents’ income of “Pure” users without cigarette production, can be seen in the following table:
Based on the table, it shows that of the total 54 respondents, most of them had less income, namely 38 (70.4%) and the number of respondents who had sufficient income was 16 (29.6%).

5. Previous Disease History

The distribution of respondents based on previous history of using “Pure” without history. The history of the respondent’s illness in the last 6 months can be seen in table 2 as follows:

Table 2. Distribution of Respondents Based on Previous Disease History Using “Pure” Without Cigarettes.

<table>
<thead>
<tr>
<th>Number</th>
<th>Previous Disease</th>
<th>Total (n)</th>
<th>Percentage (%)</th>

<td>Stomach</td>
<td>13</td>
<td>59.09</td>
</tr>
<tr>
<td>Total</td>
<td></td>
<td>22</td>
<td>100</td>
</tr>
</tbody>
</table>

Based on the table, it shows that of a total of 22 respondents, most of them suffered from gastric disease as much as 13 (59.09%) and as many as 9 (40.91%) had diarrhea.

Discussion

1. Knowledge

Knowledge or cognitive is a very important domain in shaping one’s actions (overt behavior). From experience and research, it is proven that behavior which is conscious of knowledge will be more lasting than behavior which is not based on knowledge. In the person, a sequence of processes occurs, namely: Awareness, Interest, Evaluation, Trial, Adoption. Knowledge, namely 34 (63.0%). This is because respondents do not know the impact of pure. And not always someone’s knowledge can allow someone not to use puree.

As many as 20 respondents (37.0%) had less knowledge. This is because some respondents do not know about pure both in terms of benefits and in terms of its impact. This is in accordance with the research conducted by Rahayu regarding “The Relationship Between Knowledge of the Dangers of Smoking and Smoking Behavior in Students at the Muhammadiyah University of Surakarta” states that there is a significant
relationship between the level of knowledge and smoking behavior. This shows that there is a tendency that low knowledge will shape smoking behavior, whereas high knowledge is more likely to have non-smoking behavior. The behavior of students who often smoke in the Pakuan University campus environment is influenced by a lack of knowledge about the dangers of smoking.

2. Usage History pure

Tobacco is a plant that can cause addiction because it contains nicotine and also carcinogens and other toxic substances. After being processed into a product, whether it is cigarettes or other products, the added chemicals have the potential to cause tissue damage and cancer. The main toxins in tobacco are tar, nicotine and CO₂.

Pure is made from tobacco water and whiting then becomes a kind of paste and rubbed on the user’s lips. The health hazards posed by Pure come from tobacco components that contain harmful substances for health such as nicotine.

Based on the results of research on the history of the use of pure respondents, it is known that all respondents have a real history of using pure, namely as many as 54 respondents (100%), with an average weight of puree that they consume per day is 157.97 g / day. Researchers assume that respondents use puree because puree does not contain the ingredients used in the cigarette which they know are very harmful to the body. This is what becomes a benchmark for people in China that it is better to use puree than cigarettes besides that puree is easier to obtain and cheaper than cigarettes.

Smokeless tobacco is much lower in continuous risk than burnt products, but the risk varies within product classes for example: Snus, Swedish type nitrosamines are low compared to other smokeless tobacco with high nitrosamine levels. It is thought that the safety risks of smokeless tobacco are similar to those of e-cigarettes. There is no safe level of using smokeless tobacco. This disease is associated with a number of adverse effects such as dental disease, oral cancer, esophageal cancer and pancreatic cancer, as well as adverse reproductive effects including stillbirth, premature birth and low birth weight. Smokeless tobacco contains cancer-causing chemicals. About 28 chemical elements present in smokeless tobacco are carcinogenic, of which nitrosamines are the most prominent. The results of research conducted by Fikki P. in 2018 show that pure ingredients are effective as a therapy to quit smoking. It is something very different, but has a big impact, on the success of quitting smoking. Pure is seen as local wisdom in Angata for smokers who are motivated to quit. Angata residents support the use of pure as a smoking therapy for adult smokers. They are involved with this product in a smoking cessation pattern, without knowing the carcinogenic effects of the pesticide.

3. Tradition

Tradition has become part of the life of a group. The most important thing in a tradition is the existence of information from generation to generation, both oral and written. Community behavior is often influenced by the culture or customs that prevail in the community itself. One of the cultural factors found in society is the habit of chewing. Betel nut is the process of concocting a mixture of several ingredients such as betel, areca nut, lime and Gambier which are then chewed together. Betel behavior has generally been practiced since a long time ago in the South East Asia and Asia Pacific regions. The origin of this culture of betel nut is not known exactly when it started, but it is thought to have existed since approximately 2000 years ago.

Based on the results of research on the tradition of respondents, it is known that most of them have good traditions, namely as many as 51 respondents (94.4%) and the number who have less traditions is as many as 3 respondents (5.6%). This is because respondents still consider beetching or using puree to be good for their health because many of their parents who use puree are more likely to live a long life than parents who do not use puree.

The most commonly used ingredients of betel are betel, areca nut, lime and Gambier. Some regions
also add tobacco to the betel mixture. The betel nut seeds used for betel contain phenolic compounds. This phenolic content is relatively high. When the process of chewing betel nut seeds in the mouth, reactive oxygen or what is commonly known as free radicals will form phenolic compounds. The mixture of betel nut and whiting will produce alkaline pH conditions. This will more quickly stimulate the formation of recommended oxygen. This oxygen causes DNA or genetic damage to epithelial cells in the oral cavity.

Several countries in the world chewing by concocting a mixture of betel ingredients together with tobacco. In Indonesia, betel behavior follows local culture. Indonesian society has long recognized the behavior of beetling. They believe that chewing can strengthen teeth, heal small sores in the mouth, get rid of bad breath, stop bleeding gums, and as a mouthwash. Betel leaf is also used as an antimicrobial against Streptococcus mutants which is the bacteria that most often causes tooth decay.

This is in line with the research conducted by Kamisorei, entitled “An Overview of Beliefs About the Efficacy of Chewing in Papuan Communities in Adipura 1 Jaya Pure Selatan Village.” feels fresh, eliminates sleepiness and betel as a form of friendship.

4. Income

Income can be defined as revenue generated for a business or activity. According to Iskandar Putong, income is all types of income, including income obtained without providing any activity that is received by the population of a country.

Cigarette consumption in Indonesia continues to increase, increasing cigarette consumption worsens the economy of a family, especially for poor families. The income they earn is mostly used for consuming cigarettes and will reduce the consumption of other foods that will support health. The higher the consumption of cigarettes it will endanger health When sick, spending will increase and will worsen the economy and will result in a cycle of poverty.

Tax is used as an alternative to reduce cigarette consumption, the higher the tax, the higher the sales price, with the aim that the community can reduce cigarette consumption. In addition, on the one hand, cigarette tax revenues can be used as income to finance health losses caused by smoking or can be used as funds for the development of facilities and infrastructure such as the development of smoke-free areas.

In the poorest households in some low-income countries, more than 10% of total household expenditure is on tobacco (de Beyer, et al., 2001; Efroymson, et al., 2001; Mary Assunta, 2010; WHO, 2004b, 2004d). This means that families have less money to spend on basic items such as food, education and health care. It is even worse in Bangladesh, that the poorest households in Bangladesh spend nearly 10 times as much on tobacco than on education.

5. Previous Disease History

Smokeless Tobacco or smokeless tobacco is a tobacco product that is used for other than smoking. Uses include chewing, sniffing or placing this product between the gum and the cheek or lips. Smokeless tobacco products are produced in various forms such as: Chewing tobacco, Snus tobacco and soluble tobacco products. Smokeless tobacco products usually contain more than 3000 constituents. All smokeless tobacco products contain nicotine and are therefore very addictive. Quitting smokeless tobacco is just as difficult as quitting smoking.

Smokeless tobacco is much lower on the risk continuum than burnt products, but the risk varies within product classes for example: Snus, Swedish type nitrosamines are lower than other smokeless tobacco with high nitrosamines. It is thought that the safety risks of smokeless tobacco are similar to those of e-cigarettes. There is no safe level of using smokeless tobacco. This disease is associated with a number of adverse effects such as dental disease, oral cancer, esophageal cancer and pancreatic cancer, as well as adverse reproductive effects including stillbirth, premature birth and low birth weight. Smokeless tobacco contains cancer-
causing chemicals. About 28 chemical elements present in smokeless tobacco are carcinogenic, of which nitrosamines are the most prominent.

The negative impact caused by the habit of consuming smokeless tobacco is the emergence of gastric cancer, lung cancer, kidney cancer, stroke and heart attacks. Nearly 90% of lung cancers are caused by tobacco consumption.

Based on the results of research on the respondent’s previous medical history, it is known that most of the respondents did not have a previous history of disease, namely 46 respondents (85.2%) and the number of respondents who had previous disease histories was 8 respondents (14.8%). Researchers assume that pear user/pure user does not have the disease before using puree, which can make the disease worse if the respondent uses puree.

People are not fully aware of the risk of disease and premature death due to their decision to buy tobacco products, because several factors cause it, among others, it takes 20-25 years since people start smoking and symptoms of the disease appear. Most of the smokers or people who use puree are those who already know the health effects of tobacco and they are aware of the powerful addictive effects of nicotine which increases and makes it difficult for people to stop consuming it.

The study by Gupta, entitled “Smokeless tobacco and cardiovascular disease in low and middle income countries”. Smoking is an important cardiovascular risk factor, but smokeless tobacco use is also important but not well researched. smokeless tobacco use is high in South and Southeast Asian countries, Africa and Northern Europe. The use of smokeless tobacco accelerates Atheros thrombosis much like smoking cigarettes. The importance of this study for improving public health and clinical interventions to reduce smokeless tobacco smokeless tobacco addiction.

**Conclusion**

Based on the results of research conducted on “PURE” users without a history of smoking. So it can be concluded several things, namely

1. Knowledge “Pure” users without smoking history, have less knowledge
2. User History “Pure” No Smoking History, having a user history of “pure” is sufficient.
3. Tradition of “Pure” User with No Smoking History has a good tradition.
4. Income “Pure” User without Smoking History has less income.
5. Previous Disease History “Pure” user without smoking history, has no previous medical history.

**Suggestion**

Based on the results of research conducted on “PURE” users without a history of smoking. Then the following suggestions can be made: It is necessary to increase public awareness that using tobacco even though in the term pure packaging will not be free from disease, it can even get worse and it is recommended to relevant agencies to always provide education/counseling regarding the dangers of cursing pure to the community.

**Ethical Clearance:** The ethical clearance was taken from the Ethical Research Committee of the Ministry of Education and Culture, University of Halu Oleo and community agreement.

**Source of Funding:** The funding of this researches comes from all authors’ contribution.

**Conflict of Interest:** Author declares that there is no any conflict of interest within this research.

Evaluation of Incisor Index as a Forensic Tool in Gendural Dimorphism – A Study in South Indian Population

S.Prasanna¹, L.S.Makesh Raj², P.Sai Krishna³, V.Jai Santhosh Manikandan⁴, Srikant.N⁵
¹Senior Lecturer, ²Associate Professor, ³Professor & Head, ⁴Senior Lecturer, Department of Oral and Maxillofacial Pathology, Tagore Dental College & Hospital, Chennai, Tamil Nadu, India, ⁵Professor & Head, Dept. of Oral Pathology and Microbiology, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Introduction: Forensic odontology plays a vital role in investigation and presenting the dental evidences to the court of law. The challenges that are encountered by the forensic odontologist are identifying the individual which includes certain characteristic features to define an individual. Gendural dimorphism means systemic difference in form (shape or size) between individual of different genders in the same species. Teeth being considered as one of the stable part which can withstand any environmental changes even after death of an individual in situations where there are minimal supporting evidences. Odontometrics is the field involving measurements of a tooth.

Aim and Objective: This study aims in determining the sex of an individual using incisor index of maxillary and mandibular arches as a tool in forensic investigation with brief review on literature.

Material and Method: A total of 1200 permanent maxillary and mandibular teeth from 150 study models with an age range of 18 – 25 yrs were measured using manual divider and scale. The Incisor index (Ii) was analysed by using the formula as given by Aitchison (1964). The values were noted separately for maxillary and mandibular dental arches with regards to central and lateral incisor and these data were subjected for statistical analysis.

Result: Maximum mesio-distal dimension of the all the incisors (maxillary and mandibular) were higher in males than females. Incisor index of maxilla was higher in female when compared to male which was not statistically significant. The Incisor index of mandible was higher in male when compared to females which was also statistically non-significant.

Key words: Incisor index, forensic odontology, Gendural dimorphism, odontometrics

Introduction

Forensic odontology is that branch of dentistry which deals with application of dental findings in legal situations. Dental evidence can be preserved for indefinite period and can be presented before the justice. Tooth can be analysed and recorded during ante-mortem and post-mortem. Major problem in acquiring and interpreting the ante-mortem records are due to poor record maintenance and variation with time duration.

Dental remains will be the sole identification when there is no information about the deceased and remains one of the important and crucial evidence in the analysis. Teeth are the important component of the masticatory apparatus of skull which are considered as good source of aid for civil and medico legal identification. As they are resistant to bacterial decomposition, fire, to some
extent in acid attacks they serve a valuable source of information in forensic investigation.\textsuperscript{4}

Gender identification is one of the most crucial steps in the forensic investigation. Sex determination is the first and foremost challenge for a forensic expert in identifying the mutilated bodies beyond recognition in mass disasters, chemical and nuclear bomb explosions.\textsuperscript{2} The systemic difference which are seen with regards to shape or size between individuals of different genders within the same species are known as Genderual dimorphism. This dimorphism is greatly appreciated with regards to tooth.\textsuperscript{5}

Numerous articles were published in the literature regarding dimorphism with respect to tooth size. Among these, very few publications were related to incisors. Present study aimed in determining the gender of an individual employing incisal index as the forensic tool in a South Indian population and to determine the percentage of sexual dimorphism.

**Materials and Methods**

The study was carried out in Department of Oral and Maxillofacial Pathology, Tagore Dental College and Hospital, Vandalur, Chennai during the period between 2019 – 2020. A total of approximately 1200 permanent maxillary and mandibular teeth from 150 study models with an age range of 18 – 25 yrs were measured. Patient who have teeth that were periodontally weak, affected with dental caries, fracture, restored with crown, spacing, diastema and previous orthodontic treatment were excluded from the study. Maximum Mesio-distal diameter of the lateral incisor (MDI\(_2\)) and central incisor (MDI\(_1\)) was measured using divider and scale. The Incisor index (Ii) was analysed by using the formula as given by Aitchison (1964):\textit{Ii} = \left\{\frac{MDI_2}{MDI_1}\right\} \times 100

The values were noted separately for maxillary and mandibular dental arches with regards to central and lateral incisor and these data were subjected for statistical analysis.

**Results**

Maximum mesio-distal dimension of the all the incisors (maxillary and mandibular) were higher in males than females. Mesio-distal dimension of maxillary central incisor (male = 8.63±0.859, female =8.33±0.763) and mandibular lateral incisor incisor (male = 5.84±0.624, female =5.54±0.609) showed a statistically significant difference between males and females with a p value of 0.029 and 0.008 respectively. (Table 1)

Incisor index of maxilla was higher in female compared to male with a t value of 1.537 and is statistically non-significant. While Incisor index of mandible is higher in male when compared to females with a t value of -1.879 which is also statistically non-significant. (table 2)

(Graph 1: Independent T test for comparison of the gender for maxillary and mandibular incisors)

(Graph 2: Independent T test for comparison of the gender for Incisor index in maxilla and mandible)
Discussion

Tooth shows coronal completion at the early stages of tooth development and the dimensions are unaltered during further growth and development, except in situations like disorders in functionality, pathology and nutrition which can alter the dimensions of the crown. Hence odontometrics can be used in situations where osseous features are not yet defined.6

Sexual dimorphism in humans are a result of survival strategy which is a balancing action between high degree of biological variation within species and narrow range of variation in females whose physical structure focuses on supporting an infant prenatally and postnatally.7

So these variations are mirroring the on-going events happening in the evolution process and the genetic background has been explained which is put forth by the polygenic model of inheritance and there by this forms the reason behind the sexual dimorphism in the morphological and metric attributes of males and females.4

The results of our study regarding mesio-distal dimension of the maxillary central incisors higher in males than females which is statistically significant with p value 0.029. Our results were inaccordance with those of Mohammed Nahidh (2014)4, Khangura RK et al (2011)8, Bakkannavar SM et al (2012)9, Kalia S (2006)10, Al-RifaiyMQ(1997)11 in contrary SandipamuThabitha Rani (2017)12 showed a similar mean value as that of our study but with a statistically non-significant p-value (0.098).

The mesio –distal dimensions of the mandibular lateral incisors were higher in males than females which was statistically significant with a p value of 0.008. Our results were in accordance with that of Islam et al(2012)13 but SandipamuThabitha Rani (2017)12 showed a similar mean value with a statistically non-significant p-value (0.098).

Tooth proportions are considered for gender assessment, so Aitchison (1964)14 have given the Incisor index (Ii) which tends to be higher in males than females. With regards to our study, the incisor index in maxilla, females have a higher index value than males which was not in agreement with Aitchison (1964)14 and no supporting article was found on through literature search. The present study results can be because of lesser mesiodistal width of lateral incisors in males which is not inaccordance with SchrantzDT(1963)15 who reported that females have smaller lateral incisor than central incisor.

Our study results regarding incisor index in mandible, males had a higher incisor index value than females. Our study results were in accordance with ST Rani et al (2017)12, Cristiana Pereira (2010)16, Aitchison (1964)14.

Conclusion

Forensic odontology is important branch which will help in victim identification in a situation where it is difficult to identify. Out of various modalities in sex determination, incisor index is considered as a valuable tool. The present study shows that incisor index is high in females with regard to maxilla and higher in males with regard to mandible.

To further validate the accuracy of this forensic tool, future studies can be carried out with more study subjects, different geographic locations, population and other parameters for consideration of study samples.

Emotional Intelligence Training Program and its Effect on Nursing Students Problem Solving Skills

Sabah Mohamed Ragab1, Mona Mostafa Shazly2, Hemat Abdel-Azeem Mostafa3

1Master degree of Nursing Administration, 2Professor and head of Nursing Administration, 3Assistant Professor of Nursing Administration, Nursing Administration Department Faculty of Nursing Ain Shams University, Egypt.

Abstract

**Background:** Emotional intelligence is comprised of individual, emotional, and social abilities. It includes the competency of an individual to manage their relationships with others, and regulate emotions and efficiently solved their problem. **Aim:** this study aims to assess the effect of emotional intelligence training program on nursing students problem solving skills. **Design:** A pretest- posttest one group quasi-experimental study design was used. **Setting:** The study was conducted at the Technical Nursing Institute at El-Fayoum University. **Subjects:** included all the available nursing students at second year was 200 nursing students. **Tools of data collection:** Data were collected by using two tools emotional intelligence questionnaire and problem solving skills questionnaire. **Results:** 48.5% of the nursing students had high emotional intelligence before the intervention. This increased to 86.5% at the post intervention phase and the improvement continued through the follow up phases reaching to 89.5%. Half of nursing students in the study sample were high problem solving skills before the intervention. This rose to 87.5% at the post intervention phase and reached 90.5% at the follow-up phase. **Conclusion:** There were highly statistically significant correlations between emotional intelligence and problem solving skills. **Recommendations:** The Technical Institute of Nursing should adopt the emotional intelligence, educational approach in all its different grades and Enhance nursing problem solving skills through providing them with supportive and positive training environment.

**Key words:** Emotional intelligence - Nursing students- Problem solving skills

Introduction

Emotional intelligence is defined as a set of emotional and social competencies and knowledge regarding other mental skills. This concept was introduced by John Mayer, emphasizing on the ability of individuals to control their feelings and those of the others, accept the views of others, and control social relations and feedback. Emotional intelligence is the capability of individuals to explain and interpret their emotional status. In fact, emotional intelligence is a form of competence, which determines the processes through which skills could be utilized optimally13.

Goleman states that EI consists of four fundamental capabilities: “self-awareness, self-management, social awareness and social skills”. Self-awareness is understanding one’s own personal preferences, strengths and limitations. Self-management is the ability of one person to manage personal internal states and intuitions to assist in pursuing goals. On the other hand, social awareness is the ability of a person to sense and understand what other people are going through including their feelings and concerns. Social skill is the ability to encourage appropriate responses in other people15.

Emotional intelligence can assist student nurses in managing their own and their patients’ emotions,
showing genuine emotional responses, being empathetic and communicate emotions without introducing conflict. It also helps in dealing with instinctive feelings, such as anger and dissatisfaction, a nurse–patient relationship. By attempting to view the circumstance patients’ points of view and empathizing with their feelings, nursing students can manage many clinical situations. When patients are cared for by a nurse who demonstrates emotional intelligence skills, they feel that the nurse is actually concerned about their welfare and health, which is the essence of nursing and caring17.

Emotional intelligence is the ability to understand feelings and emotions, put them in a ways that make emotion and intelligent mature and healthy. Emotional intelligence is comprised of individual, emotional, and social abilities. It includes the competency of an individual to manage their relationships with others, and regulate emotions and efficiently solved their problem (Saleh, 2020).

Nursing students face unique problems which are specific to the clinical and therapeutic environment, causing a lot of stress during clinical education. This stress can affect their problem-solving skills. They need to promote their problem-solving to meet the complex needs of current health care settings and should be able to respond to changing circumstances and apply knowledge and skills in different clinical situations. Institutions should provide this important opportunity for them 3.

A problem is defined as the difference between the actual situations and desired situation. In other words, a problem is the gap between where one is and where one wants to be. A problem occurs when there is deviation from standards or routines which cause conflict and becomes a barrier to the achievement of organizational goals 20.

Problem-solving is defined as a cognitive and behavioral process that involves creating effective options, selecting and applying the most appropriate one to cope with a particular situation. Problem-solving skill means acquiring knowledge to reach a solution, and a person’s ability to use this knowledge to find a solution requires critical thinking. The promotion of these skills is considered a necessary condition for nursing students’ performance in the nursing profession3.

Problem-solving skills are essential in nursing education at undergraduate and graduate nursing schools are faced with the critical challenge of preparing students to safely and effectively perform nursing tasks in a complex, ever-changing healthcare environment. However, since these skills have not been systematically integrated in the nursing curriculum, nurses who are expected to offer the best and fastest solutions in response to patient needs and problems have been reported to lack sufficient problem-solving skills22.

To solve the problem at hand, nursing students will take steps related to the problem-solving process. The problem-solving process is explained as a complex process that requires a lot of skills in applying it. Steps that must be passed by nursing students in solving problems there are six steps are namely: 1) determines the existence of the problem, 2) identify and define the problem, 3) find solutions (generate alternative), 4) evaluate the solutions (prioritization), 5) implement the chosen solution and 6) evaluate the outcome5.

Emotional intelligence in the person health students is proven to have a big share in the ability solve the problem (Problem Solving Skill). This is because health students while studying and become a health worker later will be faced with a variety kinds of human emotions so health students must have abilities that are smart in terms of emotionality and fast and firm in solving problems. Ability in solving problems cannot be measured by only looking at cognitive abilities someone, but must be to see emotional intelligence abilities when something happens crisis or problem14.

**Significance of the Study:**

Nursing profession can be regarded as a difficult profession because of the fact that it requires making vital decisions and due to the negative feelings during this process. Nursing students need to have advanced
problem solving skills so as to be able to cope with these negative emotions. Improved decision making and problem solving performance of nursing students vary depending on their emotional intelligence. In addition to the development of nursing students professional knowledge and skills, it is suggested that attempts to increase and improve their emotional intelligence should be made.

The Aim of the Study

This study aims to assess the effect of emotional intelligence training program on nursing students problem solving skills.

Hypothesis:

Emotional intelligence training program will improve nursing students problem solving skills.

1) Research design

A pretest- posttest one group quasi-experimental study design was carried out in the study.

Subjects and Methods

Setting:

The study was conducted at Technical Nursing Institute at El- Fayoum University, where nursing students were having their training. Technical Nursing Institute at El- Fayoum University consists of two classrooms, Medical Surgical lab, Obstetric and Pediatric lab., Computer lab, and library in addition to two administration offices. The Period of study at the Technical Institute of Nursing is two years and six months internship.

Subjects of the study:

Study subjects included all 2nd year nursing students who were enrolled in the Technical Nursing Institute at El-Fayoum University at the time of study during the data collection period (academic year 2019-2020). The study sample was 200 nursing students

Tools for data collection

Data for this study was collected by using two tools, namely emotional intelligence questionnaire and problem solving skills.

Emotional intelligence Questionnaire (Appendix I): This tool consisted of three parts:

Part I: It was included data related to personal characteristics of nursing students such as; age, gender, marital status, residence, attended training about emotional intelligence and problem solving.

Part II: This part was developed by the researcher based on a literature review Motamedi & El Ghoul. It aimed to assess nursing student knowledge regarding emotional intelligence and problem solving skills. It included (2) basic dimensions contained 35 questions (15) multiple choice question, (10)Matching and (10) True and False questions covering different aspects of emotional intelligence and problem solving skills.

Part III: This tool was developed by Abo Hashem, 2008 based on Mayer &Salovey. It aimed to assess the emotional intelligence among nursing students. It was included (5) basic dimensions contained (61) items

2-Problem solving skills questionnaire

It was developed by Abuzaitoun & Banat. It aimed to assess perceived problem-solving skills among nursing students. It consists of 40 items grouped under five dimensions.

2) Operational Design:

The current study was carried out on three phases: preparation, pilot study and field work.

A- Preparatory phase

This stage lasted from May to the end of August. It extend for four months, before constructing the program. The researcher reviewed of related literatures and theoretical knowledge of various aspects of the study using books, articles, internet, periodicals and magazines on the review, the researcher prepared the
tools for data collection.

**B- Pilot Study**

A Pilot study was done on “20” nursing students selected randomly which represents approximately 10% of the main study subjects at the mid September. A pilot study was done for testing the clarity and applicability of tools and their relevance to study. It also helped to estimate the time needed to complete the data collection forms that approximately ranged from 25 – 30 minutes. Since there wasn’t any change done in the tools, the pilot study subjects were included in the main study sample.

**C- Field Work**

The fieldwork of the study was performed in the period from the beginning of October 2019, and was completed by the March 2020. The study involved four phases (assessment, planning, implementation and evaluation phases).

§ **assessment phase.**

Permission to conduct the study was obtained from the director of technical nursing institute El-Fayoum University. This questionnaire was distributed three times throughout the study pre, post program and after three months of the program implementation. In the beginning, the researcher met the nursing students to explain the purpose and the benefits of the study. This phase was conducted at the beginning of October 2019. The researcher explained to the participants the questionnaire sheets (Knowledge assessment, Emotional intelligence questionnaire and problem solving skills questionnaire). The researcher, distributed data collection tools to the respondents individually in the class, each respondent had adequate time to complete the questionnaire sheets. The time needed to complete the data collection forms that approximately ranged from 25 – 30 minutes. The researcher was present during this time to clarify any inquiries. Each participant filled the tools and back it to the researcher to check for completeness. These constituted The baseline pre-test data of the study intervention. After completing of the data collection during the Assessment pre test phase, analysis was done in order to identify all the nursing students needs

§ **Planning Phase.**

During this phase, the researcher developed the content of the training program. This was based on the pertinent literature from text books, articles, magazines, internet search and guided by the results of the assessment pre test phase. The suitable place and time for conducting the sessions determined after took the approval with the director and study subjects agreement, as well as the program schedule were prepared accordingly. This phase was conducted at the end of October 2019. The program consisted of two main parts. The first theoretical part (7) sessions covered knowledge regarding objectives and content of the program, as concept of emotional intelligence, importance of emotional intelligence, types of intelligence, characteristics of emotional intelligent personnel, components of emotional intelligence and problem solving skills knowledge as concept of problem solving, importance of problem solving skills, types of problem and characteristics of problem, process of problem solving. The second part was (8) practical sessions included small group activities to apply rules of emotional intelligence, role play to apply components of emotional intelligence and brainstorming for applying problem solving techniques.

§ **implementation phase.**

The program was implemented at Technical Nursing Institute at El- Fayoum University where nursing students were having their study.

The program was implemented throughout two months (November and December 2019). The time allowed for achieving the program was “30 hours for two groups”: (21 theoretical and 9 practical). Two days weekly, one session was offered daily, two hours for each session.

At the beginning of each session, the objective of the session was explained. Daily feedback was done about the previous session and at the end of each session. In
the first session the researcher explained the aim of the study, program objectives, plan and content.

The researcher used various teaching methods to attract students attention and motivate them to participate. The teaching methods used during the implementation of the program were lecture, brainstorming, discussion, role play, group activities, while the teaching media used were data show, white board and marker, video, poster and flip chart. The researcher distributed a handout about content of the program to all nursing students. At the end of last session; a post test was done to assess the effect of training program.

§ Evaluation phase

A post test was done at the end of the program implementation at the last week of december using the same tools used as in the pre-program assessment to evaluate the effect of emotional intelligence training program on nursing students problem solving skills.

§ Follow up phase

Was done after Three months after implementing of the program at the march 2020 using the same evaluation tools.

Ethical Considerations: Prior study conduction, an approval was obtained from the scientific research and “ethical committee of the faculty of nursing, Ain Shams University” The researcher clarifies the aim of the study to all nursing students who agree to participate in the study prior to data collection. Respondents were assured that anonymity and confidentiality would be guaranteed, and were informed about their right to refuse or withdraw from the study at any time. The study procedures do not entail any harmful effects on participants.

3) Statistical design

Data entry and statistical analysis were done by using (SPSS) Version 20 statistical software package. Data were presented using descriptive statistics in the form of frequencies and percentages for qualitative variables, and Means and standard deviation and range of quantitative variables. Student t-test (t) was used for comparisons between two-independent quantitative variables. Cronbach alpha coefficient was calculated to assess the reliability of the developed tool through its internal consistency. Spearman rank correlation was used for assessment of the interrelationships among quantitative variables and ranked once in order to identify the independent predictors of the scores of knowledge and multiple linear regression analysis was used and analysis of variance for the full regression models was done. Statistical significance was considered at p-value <0.05 and highly significant at p-value <0.001. Correlation Coefficient (r) test was used to test the closeness of association between two variables.

Results

Table 4 presents an correlation matrix between knowledge, emotional intelligence, and problem solving skills dimensions scores. It shows highly statistically significant correlation between Total knowledge and total emotional intelligence questionnaire\(r=0.482\). Meanwhile statistically significant strong positive correlation between total knowledge and total problem solving skills and between total emotional intelligence questionnaire and total problem solving skills.

Discussion

Emotional intelligence is a concept that fascinates academic scholars and health care professionals. Emotions affect thinking and are essential for people to make the right decisions, to best solve problems, to cope with change, and to succeed. Emotional intelligence is actually a mixture of abilities to identify emotions, integrate emotional information into problem solving processes, perceive and cope with the complexity of emotions and the regulation of emotions in oneself and one’s environment. Nursing is a stressful occupation. Therefore, nursing students need to develop the ability to control emotions and channel their moods in a beneficial way Ayala & Keren\(^7\).

According to the present study results, nursing students knowledge of emotional intelligence was deficient at the pre intervention phase. However, at post and follow-up program phase majority of nursing students had adequate knowledge. From the researcher point of view, this result may be due to most of nursing students were the first time they knowing and hearing about the emotional intelligence.

In this respect, Mousa \(^19\) in a study on Ain Shams University in Egypt who studied “The Effect of Emotional Intelligence training Program on stress among nursing students” and reported that less than one fifth of nursing students had adequate knowledge regarding emotional intelligence at preprogram. However, at post and follow-up program phase majority of nursing students had adequate knowledge.

In further confirmation of the positive effect of the current study intervention on nursing students total knowledge, the multivariate analysis identified it as the main significant positive predictor of knowledge score. This shows the independent influence of the intervention on the nursing students knowledge scores regardless other confounding factors. The positive effect of the intervention might explained by its focus on problem solving skills so that the attendance realize the importance of applied content to close the gap between theory and practice.

This study result is consistent with Ancel, et al.\(^4\) in a study in Turkey reported that most of the students had unsatisfactory knowledge level pre training program about concepts related problem solving because they had not received PS education before the training program.

The implementation of the present study intervention led to significant improvement in nursing students emotional intelligence. Such improvement could be attributed to the effect of the intervention as evidenced by multivariate analysis, which identified it as the main positive predictor of the study score. This success of the intervention is undoubtedly due to its content which was tailored to fit students’ needs and the process of intervention which entailed true hands-on training the emotional intelligence.

In agreement with the foregoing current study findings, Bikmoradi et al.\(^8\) in a study in Iran conducted a study to identify the correlation between emotional intelligence and leadership style of nursing managers. These study findings revealed that, nursing managers had high level of emotional intelligence. It also revealed that emotional intelligence of nursing managers was at good ability level.

The current study intervention has also led to a significant improvement on nursing students problem solving skills. This continued to increase reaching ninety and half percent at the follow-up phase. Such improvement
is attributed to the effect of intervention. problem solving skills help nursing students to be innovative, responsible, flexible, courageous, adventurous, different thinker, self-confident, logical, objective, comfortable, emotional, energetic, effective, creative and producer has a structure. These characteristics are important for the success of one’s life.

The finding of this study supported by Ebrahem who said that the studied participants who trained on problem-solving skills were able to mention the cause of the problem, define problem, discuss alternative solutions and make decision toward solution and evaluate the solution. This may be due to the efficacy of the program for improving the students’ ability to solve the problems and the effective role of the researchers in using real life situations and helped students express reactions to problems and develop alternative and more adaptive behaviors by using role-playing, video modeling, skill practice, and reinforcing desired behaviors.

as an evidence the present study demonstrated significant positive correlations between emotional intelligence dimensions and problem solving skills dimensions. This result may be due to the implementation of the intervention helped students to recognize own emotions and effects easily, always take responsibly of personal performance and aware of own strengths and limits, they learn how to judge self-worth and capabilities, exercise effective tactics for urging and work with others toward mutual goals and easily solve problems.

On the same line the study conducted by Arefnasab in a study in Iran found that People with high emotional intelligence significantly solve problems better than people with low emotional intelligence.

On the same line the study conducted Shahbazi who reported that training emotional intelligence and problem-solving skills can be successful in controlling the emotional reactions of individuals and can reduce adverse reactions to problem and reported that teaching emotional intelligence and problem-solving skills and can both play a significant role in reducing students’ aggression. Conversely, Ergin in a study in Turkey reported that there is a negative relationship between emotional intelligence and problem solving.

**Conclusion**

In the light of the study findings, it is concluded that, the majority of nursing students in the study setting lack knowledge of emotional intelligence and problem solving skills. Implementing emotional intelligence training program for these students is effective in improving their emotional intelligence as well as problem solving skills. A number of student characteristics as age, gender, marital status do influence their emotional intelligence and problem solving skills and the extent of their improvement after the intervention. There is statistically significant relation between emotional intelligence and age and gender of nursing students. There were highly statistically significant correlations between emotional intelligence and problem solving skills.

**Recommendations:**

- The Technical Institute of Nursing should adopt the emotional intelligence educational approach in all its different grades.
- Emotional intelligence should be applied in all nursing curricula to enhance life-long self-directed learning and improve professional performance of future nurses.
- Giving students the opportunity to express their feelings and discuss situations that may cause problems and effective communication between students and teachers.
- Enhance nursing problem solving skills through providing them with supportive and positive training environment.
- Continuing assessment of the application of the problem solving skills should be done regularly through soliciting the feedback from students.

Abstract

Background: Coronaviruses are a large family of viruses and a subset of Coronaviridae. The present study is the first report of voice sensitivity in patients with Covid-19.

Case Report: In this case report, the patient was a 35-year-old man who referred to a private clinic specializing in infectious and febrile diseases on October 26, 2020. According to the clinical symptoms and laboratory test, the coronary test of the patient SARS-COV-2 (RdRp gene) and (E gene) SARS-COV-2 was positive. The patient suffers from severe noise sensitivity from the first day of infection until 10 days after treatment.

Conclusions: The patient was so sensitive to sound that different sounds had painful and excruciating effects on the patient’s mind and psyche. Therefore, sensitivity to sound can be one of the symptoms of Covid-19.

Keywords: COVID-19, Noise Sensitivity, Case Reports, Clinical Symptoms

Introduction

Coronaviruses are a large family of viruses and a subset of Coronaviridae that range from the common cold virus to the cause of more severe illnesses such as SARS and Mercovid-19 [1]. In December 2019, in the Chinese city of Wuhan, people contracted pneumonia for no apparent reason, a new type of coronavirus was identified that could spread to humans. SARS-Cov-2 (Covid-19) is a new virus in the coronavirus category. The virus is an emerging natural and biological hazard that originated in Wuhan, China, and now pervades the entire planet [2]. Covid-19 disease is a highly contagious infectious disease caused by the new coronavirus and can be transmitted from person to person through close contact [3]. There is currently no drug or vaccine for this disease [4]. The most important clinical symptoms at the onset of patients with Covid-19 include fever, cough, sputum, headache, vomiting, diarrhea, fatigue, rhinorrhea and chest pain, the most important of which are fever and cough [2-4].

Case Report

The patient is a 35-year-old man who referred to a private clinic specializing in infectious and febrile diseases on September 26, 2020. The patient’s problem is with symptoms of fever, severe headache, cough, voice change, body aches, nausea, lethargy, sweating, difficulty breathing and sensitivity to sound. The patient’s body pain was so severe that he had severe insomnia for 10 days and nights, so much so that he slept...
for a maximum of about 1 hour a day. The patient has an underlying allergy (respiratory) disease and cough with a history of 16 years of allergies. Clinically, the patient had fever, cough, lethargy and difficulty breathing, and the patient’s blood oxygen was 93. Finally, according to the clinical symptoms and laboratory test, the patient’s coronary test SARS-COV-2 (RdRp gene) and SARS-COV-2(E gene) were positive. The patient suffers from severe noise sensitivity from the first day of infection until 10 days after treatment.

The patient was severely sensitive to sound. The sound of dripping water, the sound of television, etc. had affected the patient’s nervous system and had painful and excruciating effects on the patient’s mind and psyche.

**Discussion**

Although the virus is known as acute respiratory syndrome, it has recently been confirmed that in addition to systemic respiratory symptoms, it also causes symptoms in other parts of the body. For example, the results of a study showed that 36.4% of patients with Covid-19 show neurological symptoms such as headache, paresthesia and confusion in consciousness [5]. The results of autopsy studies in patients with coronavirus-induced death (Covid-19) indicate inflammation of brain tissue and partial nerve degeneration [6]. There has also been a case report of viral encephalitis due to Covid-19 [7]. In Covid-19 disease, fear of illness and fear of death, along with disruption of daily activities, cause anxiety [8]. Other symptoms that may occur due to nervous system involvement due to Covid-19 include a lack of sense of smell and taste [9]. It can probably be said that this virus, like pathogenic bacteria, destroys the blood-brain barrier and causes a secondary infection inside the skull, which are the symptoms of these injuries [10]. Finally, it can be concluded that sensitivity to sound is due to nervous system involvement as well as insomnia caused by Covid-19 pain. There have been many reports of epidemics and symptoms of Covid-19 disease. This speech was written in November 2016 and about 9 months after the onset of Covid-19 disease, the above report (severe sensitivity to sound) is reported for the first time.

With the high rate at which this disease is occurring and new symptoms are being reported every day, there is no doubt that our scientific knowledge contributes very little to our ignorance or ill-knowledge about this disease. However, there is no doubt that for the decisive fight against the epidemic of the present century (Covid-19), the publication and dissemination of all scientific knowledge is crucial.

Presentation and Sources of Pediatric Odontogenic Infection

Sahar Abdulkader Ismaeel¹, Saif Saadedeen Abdulrazaq², Reem Fadhil Abbas³

¹Lecturer, ²Assistant Professor, Department of Oral and Maxillofacial Surgery, College of Dentistry, University of Baghdad, Iraq, ³Specialist, Department of Periodontics, Al-Shaikh Omar Specialist Dental Center, Baghdad, Iraq

Abstract

Background and Objectives: The causes, clinical presentation and management of the odontogenic infection in children during the mixed and premixed dentition period should be thoroughly studied as it differs from that of adults. The study aimed to identify the common sources and presentation of dental infection in those children.

Methods: The selected cases were 122 (54 females and 68 males). All cases presented with odontogenic infection, examined meticulously to diagnose the source of infection.

Results: The mean age was 6.5 years old (The age range was 3-10 years). The most common source of infection in primary teeth was the second primary molars (38 cases; 31.1%). The most common source of infection in permanent teeth was the first permanent lower molars (30 cases; 24.6%). The most common presentation was vestibular swelling (56 cases; 45.9%).

Conclusion: Dental care should be provided early especially to the permanent first molars in children to avoid losing them. Teamwork between the oral surgeon and the general pediatrician is necessary for better management.

Keywords: Odontogenic infection; dental abscess; surgical drainage; fascial spaces.

Introduction

Dental caries is a chronic disease affecting especially children, with more aggressive behavior than in adults, causing tooth decay. The modern lifestyle fill of high-sugar content sweeties with the unwillingness of the children to brush their teeth makes tooth decay more destructive. Lack of parents monitoring of the dental health of their children makes the tooth decay having a poor prognosis.¹, ²

Untreated dental caries may end with an odontogenic infection presented clinically as an oral and/or facial swelling along with the tenderness of the accused tooth on eating, pus discharge from oral sinus or orocutaneous fistula. An oral and maxillofacial surgeon must manage the infection by providing antibiotic coverage either orally or intravenously in the hospital if the acute status of infection present, the surgical part include pus drainage by incision, tooth extraction or through the root canal. Despite appropriate antibiotic coverage, severe odontogenic infection or its complications such as Ludwig angina may occur.³, ⁴

The most common causative source of odontogenic infection is dental caries; other causes include periodontal abscess, pericoronitis, unsuccessful endodontic treatment or deep-seated tooth fillings. All these sources end with bacterial invasion of the root canal to form thereafter a periapical lesion that spread to the adjacent fascial spaces.⁵, ⁶
The aim of the study was to identify the sources and the clinical presentation of odontogenic infection in children during the age of 3-10 years old.

**Materials and Methods**

The study involved 122 patients received at the department of oral and maxillofacial surgery with the initial presentation of intra- or extra-oral swelling or draining sinuses; the diagnosis of all cases was an odontogenic infection. There were 54 females (44.3%) and 68 males (55.7%).

All the cases pass through the routine examination protocol; history, clinical and radiological examinations to locate the exact causative tooth and to define the appropriate treatment plan.

**Results**

The age range of the cases was (3-10 years); the mean age was 6.5 years old. The majority of cases (117 cases; 95.9%) were treated as outpatient, while five cases (4.1%) needed admission to the hospital for better management. The primary teeth were the source of the infection in 74 cases (60.67%), while the permanent teeth were the source of infection in 48 cases (39.3%).

The majority of cases (92 cases; 75.4%) were managed by tooth extraction, while the other cases (30 cases; 24.6%) were managed by root canal therapy.

The total number of the primary teeth involved was 74 (60.7%), while the permanent teeth were 48 (39.3%). The most common cause of infection was caries (109 cases; 89.3%) followed by traumatic pulp necrosis to upper incisors (13 cases; 10.7%).

As shown in table 1, the most common source of infection in primary teeth was the second primary molars (38 cases; 31.1%). The most common source of infection in permanent teeth during mixed dentition was the first permanent lower molars (30 cases; 24.6%).

The most common chief complaint was swelling (110 cases; 90.2%) (Table 2). During clinical examination, the most common presentation was vestibular swelling (56 cases; 45.9%) (Table 3) (Fig. 1).

**Discussion**

The first line of antibiotics for odontogenic infection is amoxicillin or clindamycin, erythromycin is less effective especially with severe odontogenic infection\(^7\). Good choice of antibiotics hasten the healing, shorten the hospital stay and delay dental or surgical procedures\(^5\). The study protocol was to use amoxicillin/clavulanic acid, if the child sensitive to penicillin, clindamycin is the drug of choice as a substitute. Antibiotic coverage is not enough if surgery does not treat the accused tooth or drain the pus.\(^8\)

If the treatment plan involves tooth extraction, the accused tooth (the source of infection) extracted as soon as possible after the acute phase of infection disappeared for better resolution of the infection and to decrease the hospital stay\(^5\). Management of the dental abscess or odontogenic infection is similar in both primary as well as permanent teeth except in the way of treatment of the accused tooth; we try to save the permanent tooth by root canal therapy rather than a tooth extraction.

Diagnosis of the mild to moderate orofacial infection is straightforward by history, clinical as well as radiological examinations (the study used orthopantomograph screening imaging technique), whereas in severe type of infection computed tomography with contrast is the ideal technique to focus on the most dependent area of the pus for easy surgical access.\(^9\)

Whether to treat the patient as an outpatient or plan for admission to the hospital, authors put criteria to select admission, include severe cellulitis, shortness of breath, difficulty in swallowing, involvement of deep spaces, high fever, severe limitation of mouth opening, uncooperative patients and immunodeficiency\(^{10, 11}\). We admitted five cases to the hospital, as they were uncooperative and with limited mouth opening, one case with multiple space involvement. Infection with multiple space involvement increase the severity of the infection and in most cases warrant the admission to the hospital\(^{12}\). Only one case (0.8%) of multiple space infection in our study was observed.

The family motivation to seek dental care was the appearance of swelling intra- or extraoral which indicates delay in providing proper early dental care. Differential diagnosis of orocutaneous fistula (Fig. 2) include many skin lesions, this is one of the main causes of treatment delay as the parents and the general pediatricians deal with it as a skin lesion\(^{13}\). To avoid misdiagnosis and mismanagement, teamwork between parents, general pediatricians and oral surgeons should be made whenever extraoral facial draining fistula present.

**Conclusion**

The study concluded the following: dental care should be provided to the primary and permanent carious lesion in children as early as possible to prevent
further spread of infection especially to the permanent first molars. Teamwork between the oral surgeon, the parents and the general pediatrician is necessary for better management of the facial draining fistula. It is better to do tooth extraction for the badly carious primary tooth rather than lengthy conservative treatment if the tooth is associated with a dental abscess, while the opposite is correct for the permanent teeth; it is better to do conservative treatment rather than extraction.

**Declarations**

Conflict of Interest the authors declare that there are no potential conflicts of interest related to the study.

**Source of Funding:** Nil

**Ethical Clearance:** This research has exemption as it a routine treatment (no new materials were used).

Improvement of Self-Efficacy of Mothers Inpostpartum Period Through Home Visit by Health Workers in Aceh

Said Usman¹, DewiMarianthi², Irwan Saputra¹, T.M. Rafsanjani³
¹Assistant Professor, Universityof Syiah Kuala, Magister Program of Public Health, Medical Faculty, Banda Aceh, Aceh, Indonesia,²Associate Professor, Department of Nursing, Health Polytechnic Faculty of Health Minister, Aceh Besar, Aceh, Indonesia, ³Instructor, University of SerambiMekkah, Public Health Faculty, Banda Aceh, Aceh, Indonesia

Abstract

World Health Organization recorded that about 44% of infant deaths in 2012 happened in the first 28 days after birth, and 78.5% of deaths happen in the first week after births. It was estimated that 80% of infant deaths happen at home (with little or no contact with health workers). Good quality care service for infants especially newborns at home is a serious challenge, thus an effort that could be performed is to optimize the role of health workers in the community by doing home visit. The goal of this research is to identify the self-efficacy of postpartum mothers before home visit and after home visit, to compare the self-efficacy of intervention group and control group on newborn care by means of health workers role during home visit. This research use quantitative research with quasi-experimental non-equivalent control group design method. The sample of the research was health workers; each with responsibility of one fostered family of a mother in postpartum period. The research site for the intervention group was the working area of UleeKareng Health Center, and for the control group was the working area of Baiturrahman Health Center. The result of the research revealed that there was a change in self-efficacy of postpartum mothers on newborn care after three home visits by the health workers. The difference of the average efficacy score was 12.5, with p value of 0.0001. When the efficacy of postpartum mothers from the intervention group (who received home visits) was compared to that of mothers from the control group, there was a significant difference found, with p value of 0.003. Home visit executed by the health workers can improve self-efficacy of the postpartum mothers on newborn care. This can be seen from the difference between self-efficacy of the postpartum mothers before and after home visit by the health workers.

Keywords: Health workers, home visit, newborn care, self-efficacy.

Introduction

World Health Organization (¹) recorded that about 44% of infant deaths in 2012 happened in the first 28 days after birth. The deaths of newborns, especially of age one day to two months, are relatively higher than older infants, both with or without complication, and 78.5% of deaths happen in the first week afterbirths (²).

Health profile of Aceh in year 2015 (³) documented that the NMR (Neonatal Mortality Rate) was 11 per 1.000 live births, IMR (Infant Mortality Rate) was 15 per 1.000 live births, and UFMR (Under-Five Mortality Rate) was 16 per 1.000 live births.

In National average, data obtained from Indonesia ministry of health 2017 revealed that IMR (Infant Mortality Rate) have started to decline from 2015 to the first semester of 2017. IMR decreased from 33.278 cases in 2015 to 32.005 in 2016. Meanwhile, in first semester of 2017 there were 10.295 cases of infant mortality. According to WHO, in year 2019, Indonesia recorded in the top 10 countries with the highest cases of neonatal mortality (NMR) with 60.000 cases.

Moreover, UFMR was recorded decrease in 2017 with 32 cases out of 1000 lives compared to UFMR in 2012 in which 36 cases out of 1.000. Meanwhile, the
MMR (Maternal Mortality Ratio) was 149 per 100,000 live births. While the coverage of neonatal visit (NV) in Aceh in 2015 the NV-1 obtained was 83.67%, with the complete NV coverage of 80.53%. This data shows a number slightly below the Indonesian standard, which is 83.74%. However, the coverage of neonatal complications treatment in Aceh is still very low, at 50.51%.

The profile of Banda Aceh City Health Office (2016)(4) stated that the cause of infant deaths in the city of Banda Aceh was asphyxia and low birthweight. There are also other causes that are not easily identifiable. Various factors allegedly contributed to this include the lack of skilled health workers and lack of appropriate equipment in the health facilities, the lack accessibility and the willingness of the community to change their traditional unhealthy life patterns to healthier lifestyles.

According to WHO and UNICEF (2), 80% of infant deaths happen at home (with little or no contact with health workers). Good quality care service for infants especially newborns at home is a serious challenge. An effort that can be made to optimize the role of health workers in a community is by visiting houses (homevisit) to give education, provide counseling and perform early detection of newborns at risk (5).

Home visit executed by the health workers is expected to be a solution to the problems stated above. In Aceh, there is a culture for the mothers named ‘madeung’, in which the mothers are prohibited to step out of home 44 days after the birth delivery. In mean time, health workers are expected to visit mothers at homes as a way to improve the healthcare access for the mothers and their babies. The purpose of home visit is to maintain the health status of and prevent disease among the infants through growth monitoring, breastfeeding monitoring and immunization. One of the indicators of a healthy infant is that the growth is in synchronization with the age. Additionally, home visit by the health workers also can improve mothers’ knowledge of postpartum, these visits are also to ensure that the postpartum mothers are capable of taking care of themselves and their babies (6).

The capability of postpartum mothers in taking care of themselves and their babies cannot be separated from the efficacy of the mothers themselves. Self-efficacy is the postpartum mothers’ belief of their own capability to perform the tasks or actions needed to achieve certain outcomes. Bandura (7) explained that self-efficacy is the result of cognitive process in the form of decisions, beliefs, or rewards on how far an individual estimate his or her own ability in performing a certain required task or action to achieve the desirable outcome.

People with high self-efficacy believe that they are able to do something in order to change their situations, while people with low self-efficacy regard themselves as incapable of doing anything (8). This is proven in a study by Rahayuningsih (9) on the relation between preparation training for postpartum period with self-efficacy of the postpartum mothers in the Regency of Sragen, Central Java. The result of the study revealed that the preparation training for postpartum period effectively improved the self-efficacy of postpartum mothers.

As stated above, self-efficacy of postpartum mothers linked with mothers’ abilities in taking care of their babies and themselves. One of the factors that can increase the postpartum mothers’ self-efficacy is by home visiting. However, the quantity of health workers is limited to cover all of the home visiting, hence, social workers are prepared to cover this shortage. This research was obtained to identify self-efficacy of postpartum mothers can be increased by social workers home visit.

**Method**

This is a quantitative research with quasi-experimental non-equivalent control group design (10) method. The sample of the research was 48 health workers in the working area of Ulee Kareng Health Centre, Banda Aceh. A self-administered questionnaire was used in this study to measure postpartum mothers’ Self-efficacy level. The measurement was consist of 22 items, adapted from Bandura’s General Self-Efficacy Scale and has been tested for reliability and validity. Further, the design of the research can be depicted as follows:
Pretest Home-visit posttest

Intervention Group $O_1 \longrightarrow X_{1,2,3} \longrightarrow O_2$ Control Group $O_3 \longrightarrow O_4$

from the scheme above, self-efficacy questionnaire was given two times (in the beginning and ending of the experiment) to the both intervention and control group of postpartum mothers. However, in the intervention group, three times of home visit was done by social workers before the second test of self-efficacy was administered.

This research assessed any change in efficacy of the postpartum mothers on newborn care before and after three home visits by the health workers. The health workers, accompanied by local midwives, visited the homes of the postpartum mothers in their own villages. The schedule of the visits was adjusted to the schedule of neonatal visits, where NV-1 is the first visit executed on the 3rd to the 7th day after childbirth. NV-2 is the second visit on the 8th to the 28th day. NV-3 is the last neonatal executed on the 29th day to the 44th day after childbirth (11).

On the home visits, the health workers accompanied by the midwives held a discussion on condition during postpartum period by using the mother and baby’s health book (pink book) (12). Meanwhile, for the control group, the postpartum mothers studied the materials in the mother and baby’s health book given by the health centre during their pregnancy on their own.

The research for the inter vention group was conducted for post partum mothers in the area of Ulee Kareng Health Centre, while for the control group was in the area of Baiturrahman Health Centre. The sampling was taken using samplesize meanin dependent (13) technique. 44 samples were required from the calculation. To anticipate drop out, 10% was added which resulted in 48 samples.

Results

In this research, there was a change in the number of the research subjects, due to dropouts in every stage of the execution. On the first visit, according to the sample calculation, the supposed number of the research subjects was 48 respondents, but only 45 respondents acquired fostered family. Meanwhile, out of 48 respondents for the control group, only 46 respondents agreed to join their research.

Furthermore, to learn the characteristics of the research subjects, the result of the demographic data of the research subjects is displayed in the table below.

In the table 1 above, the number of health workers for the intervention group was 45 respondents and 46 respondents for the control group. The education level of most of the respondents was middle school, which was up to 71.4%. As for the employment status, most of the respondents were not working, as 86.8% of them were housewives. The average age of the respondents was 40.1 years, with the youngest being 23 years old, and the oldest being 63 years old. The average length of time of being health workers were 7.7 years, with the shortest time of 1 year and the longest time of 40 years.

Next, the characteristics of the postpartum mothers as the research subjects in intervention group and control group during home visits by the health workers is shown in the table 2 below.

</tbody>
</table>

From the characteristics description it was revealed that before the home visit, the number of the postpartum mothers who were present on NV-1 from the intervention group were 42, while from the control group were 35 mothers. Most of their education level was middle to high level; with most of them not working, only staying at home as housewives. After home visit, the number of the postpartum mothers who were present on NV-3 from the intervention group were still 42 mothers, while from control group were 44 postpartum mothers. Their education level was middle to high level; with most of them not working.

To discover the change in self-efficacy of the mothers on newborn care during postpartum period, before and after three home visits by the health workers (NV-1, NV-2, and NV-3), paired t test (14) was conducted. Paired t test is a paired test on the same subject using the same measuring instruments.

In this research, the researcher only conducted test on the intervention group because no home visit was made by the health workers for the control group. The postpartum mothers from the control group were given the mother and baby’s health book (pink color) by health workers after their baby delivery. The researcher divided the control group following the same characteristics of
the intervention group, where the pretest group was postpartum mothers of day 3 to day 7 after childbirth (NV-1) and posttest group was postpartum mothers of day 29 to day 44 after childbirth (NV-)

The result of the home visits executed by the health workers was self-efficacy of the postpartum mothers on newborn care. Pretest measurement was conducted before NV-1, and posttest was conducted after NV-3. The test result of the influence of the home visit for the postpartum mothers is displayed in table 3 below:

![Table 3: The Score of Self-Efficacy of the Postpartum Mothers of Intervention Group Before and After Home Visit in UleeKareng Health Center Banda Aceh (n = 42)](image)

Based on the table 3 above, it was revealed that the self-efficacy of mothers on newborn care during postpartum period before and after the home visit has the p value of 0.000. Therefore, it can be concluded that there was a change in the mothers’ self-efficacy on newborn care after three home visits by the health workers.

Then, to find out the difference between the intervention group and the control group, independent t test was conducted. The data of self-efficacy of the mothers on newborn care for the independent t test from the intervention group was only taken after home visit. This is because the data of the mothers in the control group was only taken once, with the division of categories of postpartum mothers who were in NV-1 and NV-3.

The result of the independent t test of self-efficacy of the postpartum mothers on NV-1 and NV-3 is displayed in the table below:

![Table 4: The Score of Self-Efficacy of the Postpartum Mothers from Intervention Group and Control Group](image)
Analysis of the independent t test of self-efficacy of postpartum mothers from the intervention and the control group revealed that there was a significant change with the p value of 0.000 in NV-1 and 0.003 in NV-3. Hence, it can be concluded that there was score difference in self-efficacy of postpartum mothers from the intervention group and the control group on newborn care.

Discussion

From the test result, it was discovered that there was a change in attitude of the postpartum mothers on newborn care after three home visits executed by the health workers. The difference of the average score of the mothers’ self-efficacy was 12.5 with p value of 0.0001. Based on this result, it can be concluded that there was a change in self-efficacy of the postpartum mothers before and after home visit by the health workers.

When the scores of self-efficacies of the mothers from both groups were compared, a significant difference was found between mothers from the intervention group who received home visit and mothers from the control group, with p value of 0.003.

Self-efficacy is one’s self perception of whether or not he can function well in certain situation. Efficacy is also correlated with the self-belief that one has the ability to perform the expected actions (15). Parental efficacy is the belief of a mother of being capable of doing something according to her ability in certain conditions, as well as the ability of parents to plan and carry out specific actions that can produce results (16).

Self-efficacy of postpartum mothers on newborn care is a crucial aspect in facilitating a mother’s adaptation and experience. One of a mother’s characteristics that influences self-efficacy is maternal confidence (17). Self-efficacy is also obtained from self-confidence by influence of other people. Health workers as a part of the community and have experiences on childbirth and infant care are considered to have experienced similar condition that the postpartum mothers are experiencing. Thus, this condition can improve someone’s self-efficacy (18).

Home visit executed by health workers can improve self-efficacy of the postpartum mothers. Moreover, in correspondence with previous study by Salonen (19), it was discovered that there was a significant improvement of parenting self-efficacy of postpartum mothers who joined parenting program compared to mothers who did self- treatment at home. A visit by people who have capacity in health subject and to be given direct lesson on health care is one way to improve self-efficacy and strengthen the belief of the community that they have capacity to succeed Systematic literature conducted by Warren et al (20) on self-efficacy of mothers who have just given birth during postpartum period. The result of the study was that self-efficacy of a mother who has just given birth is the mother’s satisfaction in taking care of the baby. A good self-efficacy of a postpartum mother can also be associated as a mean to minimize depression of a postpartum mother.

The result of this research can be implied in Puskesmas Aceh/Health care system by regulating a new policy towards home visit to the postpartum mothers in each area covered by each Puskesmas, in which social workers are prepared as the home visitors for helping, monitoring, and educating postpartum mothers in the health care area.

Conclusion

Generally, it can be concluded that there is a correlation between home-visit executed by health workers with self-efficacy of postpartum mothers on newborn care. Specifically, the result of the research showed improvement of self-efficacy of the postpartum mothers after home visits by the health workers in the area of UleeKareng Health Center, Banda Aceh. There was a difference between self-efficacy improvement of mothers in the intervention group and of ones in the control group.

Suggestion

The health workers in the UleeKareng Health Centre Banda Aceh are expected to conduct home visit
as a way to improve self-efficacy of postpartum mothers in the community. The health workers could also build partnership with local health workers through referral program during home visit in the community.

**Data Availability**

The data used to support the findings of this study are available from the corresponding author upon request.

**Ethical Approval**

Ethical clearance for publishing the results of this study has been given by the Department of Ethic, Medical Faculty at Syiah Kuala University where the writer-researchers work.

**Conflicts of Interest:** The authors have all declared that no conflicts of interest exist.

**Acknowledgement:** The Head of Ulee Kareng Health Center and the Head of Baiturrahman Health Center who had permitted the researcher to utilize the working area of the health centers as the research sites. Also, to all the health workers and the postpartum mothers who agreed to participate in this research.

The authors thank the Aceh Health Polytechnic for funds provided to do this research amounting to Rp.30,900,000{about US$ 2,060}.

Abstract

Aim: To assess the prosthetic status and prosthetic needs of Head and Neck Cancer Irradiated Patients suffering from Xerostomia in Delhi India.

Materials and Method: A multi-centric, cross-sectional observational study was conducted among 120 head and neck cancer irradiated patients suffering from xerostomia in Delhi. The information related to socio-demographic data, the prosthetic status, and prosthetic need was obtained using a proforma based on WHO oral health assessment form 1997.

Results: Out of 120 participants, 103 were males and 17 were females. The mean age of the study participants was 47.68 ± 10.26 years. Stage 1 carcinoma was diagnosed in 69 (57.5%) of the participants while stage 2 carcinoma was diagnosed in 51 (42.5%). Out of 120 individuals, 7 (5.8%) needed single unit prosthesis, 33 (27.5%) needed multi-unit prosthesis, 48 (40%) needed a combination of a single and multi-unit prosthesis, and 18 (15%) needed a full prosthesis.

Conclusion: The need for prosthesis was high among Head and Neck Cancer Irradiated Patients. There is a need to emphasize dental service utilization among this group of people.

Keywords: Head and neck cancer, prosthetic status and needs, radiotherapy, xerostomia

Introduction

Each year, approximately 500,000 new cases of head and neck cancer (HNC) are diagnosed worldwide.¹ Oral cancers are the most common cancers among head and neck cancers that determine and modify the prosthetic needs of the patient.² Head and neck cancers are the eighth most prevalent form of cancer worldwide, usually destructive, and cause extensive tissue damage related to both hard and soft tissues.² Treatment modalities include surgery, radiation, and combined surgery and radiation.³,⁴

RT plays a pivotal role in the management of patients with HNC, but it is also associated with several side effects. Commonly, the salivary glands, oral mucosa, and jaws will inevitably be included in the RT field. Changes induced by exposure to radiation occur during and after completion of therapy, which include xerostomia, mucositis, candidiasis, osteoradionecrosis, and radiation caries.⁵,⁶

Xerostomia or dry mouth is a major side effect of radiotherapy. It is also the most common and permanent...
side effect. Radiation-Induced Xerostomia often occurs as a late effect, however, acute xerostomia after radiotherapy is also known.7,8 Xerostomia in head and neck cancer patients is associated with a reduced quality of life.9 This may be due to various complications which include difficulty in swallowing, eating and problems in speaking as well as tooth decay. These patients invariably need dental prosthesis for restoring the lost form and function and thereby enhance their life quality. Further, xerostomia also modifies the ease and compliance for wearing denture prosthesis. However, there is limited data available in the scientific literature on the prosthetic status and needs concerning to cancers of head and neck irradiated patients in India. Hence, this research was done to assess prosthetic status and needs in Head and neck irradiated patients suffering from xerostomia in Delhi.

Materials and Method

This cross-sectional observational study was carried out in the head and neck cancer irradiated patients suffering from xerostomia to understand the prosthetic status and prosthetic needs of such patients. This multi-centric study was conducted among three tertiary care cancer hospitals in Delhi, India. Ethical committee approval and protocol approval was obtained from the Institutional Ethics Committee (IEC) of Manav Rachna Dental College, Faridabad, vide letter number MRDC/IEC/2018/11.

Patients with the following characteristics were included in the study:

1) Head and neck cancer irradiated patients after 3 months of completion of radiotherapy.

2) Patients who provide informed consent for participation in the study.

3) Patient whose normal whole salivary flow rate < 0.7 ml/min.

Patients who had either learning, audio-visual, psychiatric/ intellectual disability or disorder were excluded from the study. A list of cancer hospitals in Delhi was made to choose the hospitals for study. Out of a total of 10 hospitals, 3 hospitals were chosen using the lottery method. After hospital selection, the permission for conducting the study was taken from these hospital authorities. The research was conducted for 12 months from April 2019 to February 2020 at (Rajiv Gandhi Cancer Hospital), (Balaji Action Cancer Institute) and (Max Hospital, Shalimar Bagh) in Delhi, India.

Sample size:

Sample size calculation was done using a formula for cross-sectional epidemiological studies.

\[ N = \frac{4 \times P \times (1-P)}{d^2} \]

\( N = \) Sample size

\( P = \) Prevalence of Prosthetic need among the head and neck cancer patients.

\( d= 10 \) (Relative Precision of 20%)

Level of Significance- 5%

An earlier study by Jham et al (2008), on the oral health status of 207 head and neck cancer patients before, during, and after radiotherapy found the prevalence of prosthetic needs among these patients as 50.2%.10 This prevalence rate was used to calculate the sample size for the present study. A non-response rate of 20% was considered and was added to the minimum sample size. A sample size of 120 patients was established for the present study.

Participants who were to be included in the research were briefed about the research by the researcher (SG) and provided with a patient information sheet containing the details of the study, confidentiality, benefits, and risks. The patients were encouraged to clarify any doubts about the research. Those who decided to participate in the study were provided with an informed consent document and asked to sign it in front of an independent witness to ensure that the informed consent process was free and non-coercive. The informed consent document and patient information sheet were made available both in Hindi as well as in English. For the patients who could
not read and write, a person who was independent of the study was made available to read out the patient information sheet and informed consent document. For such patients, a thumbprint was used instead of a signature.

Based on convenience non-probability sampling, all the eligible patients present on the day of the study and gave consent were included. A full medical history of the patient was taken at the outset. The details about the oral cancer staging and grading as well as the diagnosis were obtained from the patient records. The treatment provided including chemotherapy and radiotherapy was noted. The number of cycles of radiotherapy undergone till the date of examination was also noted from the patient records.

For assessment of xerostomia, the patients were instructed to brush their teeth using a soft toothbrush and toothpaste one hour before saliva collection. They were asked to refrain from eating after brushing their teeth. The collection was done in the morning time usually a few hours after breakfast time. Not more than 10-12 patients were examined in a day to avoid examiner fatigue.

The Swab method was used to measure xerostomia. Three pre-weighed cotton swabs were placed into the mouth of the patient. The swabs were placed at three locations on the floor of the mouth to facilitate maximum possible saliva absorption. The patient was asked not to swallow saliva for 5 minutes. The cotton swab was then retrieved and collected in a corked test tube and weighed. A digital scale (Kerro P5B,BL 3000) was used to weigh the cotton swab before and after the procedure. The difference of weight between dry and saliva-soaked pellet was recorded. The rate of salivary flow was expressed in the units of ml per minute. A weight of one gram was considered to be equal to one ml.

The enrolled patients were then interviewed to obtain data on socio-demographic variables ie education, occupation, annual income. Socio-economic status was calculated using the Kuppuswamy scale updated for 2019. This was followed by oral examination, which was performed by a single calibrated examiner who assessed the dental prosthetic status and treatment needs according to the criteria described in the WHO Oral health assessment form 1997.11

Intraoral examination of the patient was done in the type II setting. All the data were tabulated in Microsoft Excel. Data were analyzed through IBM SPSS™ Statistics for Windows, version 20.0 (IBM Inc., Armonk, NY, USA). Descriptive statistics and differences among prosthetic status and prosthetic needs, according to gender, age, grade, stage of cancer, and socio-economic status were calculated using Chi-square test. All the statistics were considered significant at a P-value of equal to or less than 0.05.

Results

The total number of participants included in this study was 120. The mean age of the study sample was 47.68 + 10.26 years. The largest number of individuals belonged to the age group of 51 to 60 years (n=43, 35.8%). The number of participants in the 18-30 years age group was 7 (5.8%), 31 to 40 years age group was 25 (20.8%), 41 to 50 year age group was 37 (30.8%) and 61 to 70 years was 8 (6.7%). The sample was predominantly men as 103 (85.8%) of the study participants were men. On the other hand, 17 participants (13.3%) were women. Most of the participants belonged to upper-middle and upper-lower socio-economic strata. The study sample comprised of 8 (6.7%) participants from lower SES, 23 (19.2%) from lower-middle SES, 42 (35.0%) from upper-lower, 45 (37.5%) from upper-middle, and 2 (1.7%) from upper SES.

Stage 1 carcinoma was diagnosed in 70 (57.5%) of the participants while stage 2 carcinoma was diagnosed in 50 (42.5%) population. While 44 (36.7%) participants received concomitant chemotherapy, 76 (63.3%) participants did not receive chemotherapy. The mean number of radiotherapy cycles obtained by the respondents was 18.4 (SD = 8.881) with a range from minimum of 2 cycles to a maximum of 35 cycles.
The majority of the people in the study sample brush once a day (n = 116, 96.7%) while 2 people each do not brush their teeth or brush twice a day. About 81% (n=126) patients had not visited the dentist in past 12 months while 18.2% (n = 28) participants had visited dentist in past 12 months.

According to table 1, the proportional difference in prosthetic status among genders was not found to be significant in the present study sample ($\chi^2 = 3.440$, p=0.969). The proportional difference in prosthetic status among different socioeconomic strata was not found to be significant in the present study sample ($\chi^2 = 21.768$, p=0.353). The proportional difference in prosthetic status among patients with stage 1 and stage 2 cancer was not found to be significant in the present study sample ($\chi^2 = 1.228$, p=0.746). The proportional difference in prosthetic status among patients who received and did not receive chemotherapy was found to be statistically significant in the present study sample ($\chi^2 = 13.568$, p=0.019). (Table 2)

The highest percentage of individuals (n=38, 31.7%) had 14 teeth in their upper dentition, while only 1 person (0.8%) had 4 teeth. Fourteen teeth were present in 36.7% of the population (n=44) which was the highest number, while 8 teeth were present only in 1 person (0.8%). The minimum number of teeth present was 5.

Table 3 shows the distribution of population according to the number of teeth requiring replacement. A total of 46 participants did not need any replacement of teeth. Of the other participants who needed replacement, the highest number (n=16),13.3% needed replacement of 4 teeth, followed by 14 participants needing replacement of 7 teeth and 12(10%) each needing replacement of 6 and 8 teeth. ( Table 3)

Of a total of 120, 75% (n=90) did not have any prosthesis, 10.8% (n=13) had one bridge while 3.3% (n=4) had more than one crown and bridge prosthesis in their mouth. Partial dentures were seen in n=10 (8.3%) participants, (n=2) (1.7%) had bridge and partial denture both while (0.8%) n=1, person had a complete denture prosthesis.( Table 4)

Only (11.7%) n=14of the total study sample had no prosthetic needs. Of the total of 120 individuals, n=7 (5.8%) needed a single unit prosthesis, n=33 (27.5%) needed multi-unit prosthesis, n=48 (40%) needed a combination of a single and multi-unit prosthesis, and n=18 (15%) needed a full prosthesis. **Discussion**

Prosthetic needs increase with age and the presence of health-related conditions. Head and neck cancers may be directly responsible for tooth loss due to the infiltration of cancer cells into the surrounding dental tissues including the support structures of teeth. Additionally, radiotherapy in head and neck cancers may be one of the major reasons for xerostomia or dry mouth and subsequently for dental caries leading to loss of a tooth. Thus, it is premised that prosthetic status and needs of head and neck cancer irradiated subjects may differ from those of individuals not under radiotherapy as well as healthy individuals.12–14

The present study showed that there was a statistically significant difference in the proportion of patients using prosthesis among those who had undergone radiotherapy and those who were not given radiotherapy. The proportion of people using prosthesis was lower in the irradiated patients as compared to radiated ones. On the other hand, the prosthetic needs of irradiated patients were higher than of the non-irradiated patients. Many of these patients needed multi-unit or a combination of a single and multi-unit prosthesis. It may be explained that since there are higher needs and lower use of prosthesis in irradiated patients, much of the need that has arisen might be a recent one. This may be due to the impact of radiotherapy on the health of oral tissues. The causes of this difference among irradiated and non-irradiated patients need to be affirmed through the establishment of sound evidence indicating the cause.

A significantly higher percentage of subjects in the upper SES categories had some kind of prosthesis as compared to subjects in the lower SES category. The social pressure of maintaining the esthetics and function could be the driving force that influences the subjects in the upper class to get their missing teeth replaced.15 In addition to this, the attitude and awareness toward dental care, and the cost of dental treatment might also be the significant factor that determines the prosthetic status of a person.

According to database data available online, the present study is the first one to assess the prosthetic status among head and neck cancer patients who underwent treatment during the time of the study. The study showed that about 25% of the sample used one or the other kind of prosthesis. Of those who needed prosthesis, about 67% of the individuals required a multi-unit or a combination prosthesis. Hence there was an extensive tooth loss in the population with a large number of those who needed prosthesis requiring
long span and complex prosthesis. This indicates the complex process of tooth loss among head and neck cancer patients. Many causative elements may work in tooth loss including the effect of pathology as well as the treatment including radiotherapy and chemotherapy on the teeth and their supporting structures. All these factors should be considered as a part of the multifaceted etiology leading to tooth loss in such patients.

Geographical as well as demographic features of the population under study have an important influence on the results. The present study was conducted in the capital of India. It is predominantly urban area with high availability of healthcare facilities and higher health literacy among the residents. However large variations are seen among the health parameters within this geographical region. These are mainly related to socio-economic status. These factors may result in different health-related status among different population groups. For a health-related condition such as head and neck cancer, these variations may be the primary reasons for the difference in dentition status among various groups. Since, upper-middle and upper-lower socio-economic strata formed the majority of the study sample, this may affect the overall prosthetic status of patients in the present study.

The results of this study show that almost 64% of individuals had at least one missing tooth except for third molars in the lower arch, while this percentage was close to 70% of individuals having at least one missing tooth in the upper arch. The percentage of patients with some kind of prosthesis was 25%. Prosthetic status was better than those of healthy elderly in Kerala as seen in a study conducted by Joseph et al (2016) where 18.2% had dentures. However, the prosthetic need in the present study was also higher at almost 88% of patients requiring prosthesis as compared to about 63% in Joseph et al study. According to the another study conducted by Yadav et al (2016) among institutionalized elderly in Delhi in which the prosthetic status and needs were determined, about 25% of participants required prosthesis as compared to 88% in the present study. This reflects the difference between prosthetic needs of healthy and head and neck cancer irradiated individuals. The higher prosthetic needs in cancer irradiated patients may be attributed to the pathologic process of cancer as well as conditions such as xerostomia that lead to enhanced tooth loss after cancer radiotherapy.

The present study could not compare the differences among males and females because only 17 (15%) of the study sample were females. However, various studies assessing prosthetic needs in India showed that females have higher prosthetic needs when compared to their male counterparts. There were also studies showing results in contrast.

A weakness of the study was that patients at various doses of radiation therapy were included in the study. There may be differences in the dentition status between various doses of radiotherapy concerning their oral health and oral healthcare needs.

**Conclusion**

The present study established a high oral health risk as well as a high oral disease burden in the head and neck irradiated population of Delhi. It also indicates towards the adoption of a robust framework integrated with a treatment plan for this population. A collaborative teamwork of oncologist and prosthodontist on a cohesive treatment plan for head and neck cancer will not only help in reducing the oral disease burden in this population but also help in improving oral health-related as well as general health-related quality of life among these patients.

Abstract

Biological control represents an important approach for controlling many dermatophyte fungi. Pleurotuseryngiiisa promising and effective bioagent against many pathogenic fungi. In this paper Pleurotuseryngiiwere screened for their efficacy against Trichophytonrubrum. The results had been revealed that the fruiting bodies extract of the bioagentPleurotuseryngiiaffected the radial growth of the dermatophyte fungus Trichophytonrubrum. The extract of test fungus at all test concentrations had inhibitory effect on the radial growth of Trichophytonrubrum. The results had been revealed also that ethanolic extract was more effective than the aqueous extract of Pleurotuseryngii but lower than the affectivity of the antifungal drug clotrimazole.

Keywords: BIOcontrol, Trichophytonrubrum, Pleurotuseryngii, antifungal activity.

Introduction

Dermatophytosis is caused by pathogenic, keratin-digesting fungi in the genera Microsporum, Trichophytonand Epidermophyton. The genus Trichophyton especially T. rubrum was the most frequently agent of dermatophytosis worldwide1.

About 76% of the dermatophyte species isolated from humans are Trichophytonrubrum, 27% are T. mentagrophytes, 7% are T. tonsurans, 3% are T.verrucosum and another dermatophyte fungi (less than 1%)2.

A great attention was made to use microorganism or their metabolities in treatment of various infection and diseases. Mushrooms contain some potential antibacterial and antifungal compounds such as peptide eryngin and polypeptide alveolarin originated from Pleurotuseryngiiand Polyporusalveolaris, respectively which have highly antifungal potential3.

Extract of Pleurotuseryngiǐhas great antifungal activity against fungi Candida albicans, Candidaglabrataand Trichophyton spp4.

The bioactive compounds of mushrooms are responsible for antiviral and antibacterial properties. Examples of such bioactive compounds are polysaccharides, dietary fiber, antioxidants (vitamins C, B12 and D; folate; tocoherols, ergothioneine, carotenoids and polyphenols), phenolics and polyphenolics5,6.

Eun-Ji, et al.7 found that the ethanol extract of Pleurotuseryngiihave antimicrobial activity and contain higher levels of polyphenols and flavonoid compounds than other solvents.

Ligninolytic enzymes that produced by Pleurotuseryngii such as laccase (Lac) and Mnperoxidase (MnP), are able to degrade aflatoxin B1 (AFB1), the most harmful among the known mycotoxins8.

Not much literature is available with regard to their antifungal activities of Pleurotuseryngii against dermatophyte fungi, so this study was
performed to determine the antifungal activity of *Pleurotus eryngii* against *Trichophyton rubrum* in laboratory.

**Materials and Methods**

**Source of *Trichophyton rubrum* isolate**

Specimens were collected from patients in hospital and medical clinic. Specimens then cultured on SDA medium and identified morphologically.

**Source of *Pleurotus eryngii* isolates**

*Pleurotus eryngii* isolates were obtained from Plant Protection Directorate, Ministry of Agriculture, Iraq.

**Source of antifungal drug**

The antifungal drug (Clotrimazole) obtain as a standard solution from nation pharmacy.

**Pleurotus extract preparation**

**Aqueous extract of *Pleurotus eryngii***

To obtain water extract of *Pleurotus eryngii*, 10 g of dry powdered of fruiting bodies was boiled with 100 mL distilled water for 30 min. and then cooled. The cooled solution was filtered through Whatman filter paper No. 1. To obtain dried extract, filtered solution evaporated in the oven (55 °C). The dried extracts kept at 4°C for further studies. To prepare different concentrations, extract was dissolved by distilled water, sterilized by filtration (using Millipore 0.45 filter paper), and the requisite dilutions were prepared.

**Ethanolic extract of pleurotus**

To obtain ethanolic extract of *Pleurotus eryngii*, 10 g of dry powdered of fruiting bodies were mixed with 100 ml of ethanol 70% , the container was shook 2 or 3 times per day and returned to warm dark place. The liquid was filtered through Whatman No. 1 filter paper and leave it to evaporate to obtain dry extract. To prepare different concentrations, dry extract was dissolved by dimethyl sulfoxide(DMSO), sterilized by filtration (using millipore0.45 filter paper), and the requisite dilutions were prepared.

**Effect of *Pleurotus eryngii* on *Trichophyton rubrum* in dual culture technique**

To evaluate the effect of *Pleurotus eryngii* on *T. rubrum* in dual culture technique, both tested fungi were grown on SDA for a week at 30 ± 2°C. 5mm disc of the target fungus cut from the periphery of culture and transferred to the Petri dish contain SDA. 5mm disc of *Pleurotus eryngii* was transferred in the same plate of opposite end of the plate at equal distance and was incubated at 30 ± 2°C for 7 days. In control plates, a sterile agar disc(without *Pleurotus eryngii*) was placed at opposite side of the *T. rubrum* agar disc. The experimental design used was a completely randomized design (CRD) with three replicates for each treatment. Radial colony growth of *T. rubrum* was measured after three and seven days. The percentage of inhibition of the mycelial growth of the test fungus was calculated using the formula of Philippe et al.,

\[
\text{Inhibition of mycelial growth (\%) = \left(\frac{dc - dt}{dc}\right) \times 100}
\]

where \( dc \) is mean diameter of colony in the control sample and \( dt \) is mean diameter of colony in the treated sample.

**Effect of *Pleurotus extract* on growth of *T. rubrum* by disc diffusion method**

To evaluate the effect of *Pleurotus* extract (aqueous and ethanolic) on growth of *T. rubrum* by disc diffusion method, different amount of dry extract of fruiting bodies mixed with distilled water to obtain the concentrations 25 (2gm/80ml), 12.5, and 6.25mg/ml in the case of aqueous extract and with Dimethyl Sulfoxide (DMSO) in the case of ethanolic extract and sterilized by filtration (using Millipore 0.45 filter paper). Paper discs (5 mm) were sterilized by autoclave and soaked in a pleurotus extracts (ethanolic and aquatic extract) solution and putted in a petri plate contain SDA previously inoculated with targeted fungus. The agar plates maintained at room temperature for 2 h allowing for diffusion of the solution. All plates were then incubated at 30 ± 2°C for the specified period of time. The zones of inhibition were subsequently measured in Millimeters.
Effect of clotrimazole on growth of \emph{T. rubrum}

To evaluate the effect of clotrimazole on growth of \emph{T. rubrum} by disc diffusion method, different concentrations of clotrimazole 10, 5 and 2.5 μg/ml were used. Paper discs (5 mm) were sterilized by autoclave and soaked in each concentration and putted in a petri plate contain SDA previously inoculated with targeted fungus. The agar plates maintained at room temperature for 2 h allowing for diffusion of the solution. All plates were then incubated at 30 ± 2°C for the specified period of time. The zones of inhibition were subsequently measured in Millimeters\textsuperscript{12}.

Results

Effect of \emph{Pleurotus} \emph{enyrgii} growth of \emph{T. rubrum}

The results of this study that presented in Table (1) and figure (1) showed that the \emph{Pleurotus} \emph{enyrgii} inhibited the radial mycelial growth of \emph{Trichophyton rubrum}. The Mean of radial growth of \emph{Trichophyton rubrum} after three days and seven days of treatment was 2.5 cm, 2.7 cm respectively as compared with control which were 3.1 cm and 7.8 cm respectively. The percentages of inhibition of radial growth (PIRG) values after three days and seven days were 19.35 % and 65.38 % respectively.

The fungus recorded high antagonistic activity and completely overgrew the test pathogen \emph{Trichophyton rubrum} and grows on the entire surface of petri-plate after 14 days of treatment.

**Effect of Pleurotus extract on *T. rubrum* by Disc diffusion method**

The results of the antifungal activity of culture filtrate of *Pleurotus eryngii* against *T. rubrum* by disc diffusion method are summarized in the figure (2) and figure (3).

All tested concentrations of ethanolic extract affected the growth of *T. rubrum* significantly as compared with the control, and the effect was increased with the increasing of concentration.

The highest zone of inhibition was recorded at the case of ethanolic extract at the concentration (25mg/ml) which was 18.66 mm followed by the concentrations 12.5 and 6.25mg/ml which were 11.83 mm and 7.16 mm respectively.

The result also showed that aqueous extract recorded no inhibition zone at the concentration 6.25mg/ml but recorded 9.33mm and 4.66mm at the concentration 25mg/ml and 12.5mg/ml respectively.

The statistical analysis refers to the significant differences between all treatments as compared with the control except aqueous extract at the concentration 6.25mg/ml.

Effect of clotrimazole drug on growth of *T. rubrum* by disc diffusion method

The results of this study that presented in table (4) and figure (5) had been revealed that the antifungal clotrimazole affected the growth of *T. rubrum* in all tested concentrations and the effect was increased with the increasing of concentration. Highest inhibition zone was recorded in the case of the concentration 10 mg/ml which was 29.33mm and the lowest was 12.33mm at the concentration 2.5 mg/ml.

Discussion

Oyster mushroom produce secondary metabolites which was important against pathogenic fungi. These metabolites include triterpenoids, polysaccharides, proteins and enzymes (Patel, et al. 2012). Also, the ability of oyster mushroom to produce metabolic materials such as enzymes give it inhibition force toward decay cellular walls of pathogenic fungi.

Mycelium of Pleurotus tuber-regium was able to completely overgrow the keratophilic fungus Chrysosporium keratinophilum.

Both fruiting body and mycelium of mushrooms contain compounds with wide ranging antimicrobial activity. They are rich sources of natural antibiotics, where the cell wall glucans are well known for their immunomodulatory properties, and many of the externalized secondary metabolites combat bacteria, fungi, and viruses.

Results of study revealed that the ethanolic extract was more effective than aqueous extract and this results in agreement with the results of Eun-Ji, et al., who found that the ethanolic extract of Pleurotus eryngii were the most effective against tested microbes and contain higher levels of polyphenols and flavonoid compounds. Thillaimaharani, et al., who investigate the antifungal activity of four different solvents extracts of Pleurotus florida against three dermatophyte fungi such as Trichophyton rubrum, Epidermopontflocossumand Microsporum gypseum and they observed that the ethanolic extract of P. florida exhibited highest activity and produced minimum inhibitory concentration.

Kalu and Kenneth, reported the presence of bioactive compounds, saponin, carbohydrates, tannins, flavonoids and proteins in both ethanolic and aqueous extract while glycoside and alkaloids, were found only in ethanolic extract.

The results also agree with Egra, et al., who found the antifungal activity of oyster mushroom against Candida albicans and found that ethanolic extract affect the growth of the fungus and the effect increased with the increasing of concentration and the inhibition zones ranged between 9.3 to 10.8mm.

Clotrimazole also is the most potent agent and oldest antifungal drugs. This antifungal agent showed excellent in-vitro potency against most dermatophyte fungi. Khalaf et al., investigated the antifungal activity of Nystatin, Fluconazole, Griesofulvin, Clotrimazole and Fluconysin against Trichophyton mentagrophytes and found that Clotrimazole and Fluconysin were more effective than the other.

Genotyping of Histological Cutaneous Leishmaniasis Isolated by Dental Broach Smear in Iraqi Patients

Salah Mahdi Hassan¹, Bushra Qasim Dhumad²

¹Assistance Professor, ²Assistant Lecturer, Department of Medical Laboratory Technology, College of Health and Medical Technology, Baghdad, Iraq

Abstract

Cutaneous leishmaniasis is a major public health problem as a disease endemic in Iraqi population. Many diagnostic tools are used to establish the diagnosis like smear, histopathology and culture. To find more rapid, sensitive and specific diagnostic method for the diagnosis of cutaneous leishmaniasis, and to detect the genotypes of *Leishmania tropica* and *Leishmania major* strains in Iraq. Sixty six patients (43 males and 23 females) with clinical diagnosis of cutaneous leishmaniasis were included in present work during the period between December / 2019 to May / 2020 in Al-Yarmook Teaching Hospital and Al-Karama Teaching Hospital. The age of patients ranged from 6 months to 55 years, with median age 24 years. The following diagnostic techniques were carried out for diagnosis of cutaneous leishmaniasis including dental broach smear, histopathology examination and culture on Roswell park medium institute (RPM I 1640) and on NNN media. In addition to polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP), genotype techniques were performed for all patients. Sixty patients with other skin lesions were processed for PCR as a control group.

Key words: Cutaneous leishmaniasis, genotypes, Al-Karama Hospital, PCR, histopathology.

Introduction

Cutaneous leishmaniasis is a clinical manifestation in which the parasite causes one or more slow-healing ulcer on the skin. The diagnostic methods available at present are mostly based on clinical and epidemiological evidence and parasite detection (¹). So far, no single laboratory method has been accepted as a gold standard for diagnosis CL. Parasitological tests of a skin biopsy specimen are not always conclusive in patients with a clinical diagnosis of CL (²). The different species of Leishmania present the same morphology when classical diagnostic methods, such as microscopic examination of Giemsa-stained smears or parasite culture, are used (³). This led to the development of molecular approaches combining high sensitivity for direct detection and identification in clinical specimen with species specificity by amplifying either species-specific DNA sequences or genus-specific sequences that allow for subsequent differentiation of Leishmania species (⁴). Polymerase chain reaction (PCR) is a technique that permits the exponential amplification of a known DNA sequence from minimal sample quantities, increasing the sensitivity of detection (⁵). Due to its high sensitivity and specificity afforded, the PCR has been widely used in the diagnosis and epidemiological studies (⁶). There are in numerous DNA sequences used as targets for the diagnosis and detection of Leishmania in PCR protocols. The principal sequences used are kinetoplast DNA (kDNA), mini-exon, ribosomal DNA, and glucose-6-phosphate dehydrogenase, among others (⁷). Only a few of the assays described in the literature permit identification of the etiological agent of American Cutaneous Leishmaniasis (ACL) at species level, the majority identifies genus and subgenus (⁸). The mini-exon gene of kinetoplastid protozoa, which is involved in the transsplicing process of nuclear mRNA, is present as 100 to 200 tandemly repeated copies per nuclear genome. Each repeat consists of three major parts: a transcribed
region comprising a highly conserved 39-nucleotide exon; a moderately conserved intron, approximately 55 to 101 bp; and a nontranscribed, intergenic spacer of variable length (51 to 1,350 bp) depending on the genus and species (9).

**Material and Methods**

Cutaneous leishmaniasis is a major public health problem as a disease endemic in Iraqi population. Many diagnostic tools are used to establish the diagnosis like smear, histopathology and culture. To find more rapid, sensitive and specific diagnostic method for the diagnosis of cutaneous leishmaniasis, and to detect the genotypes of *leishmania tropica* and *leishmania major* strains in Iraq. Sixty six patients (43 males and 23 females) with clinical diagnosis of cutaneous leishmaniasis were included in present work during the period between December / 2019 to May / 2020 in Al-Yarmook Teaching Hospital and Al-Karama Teaching Hospital. The age of patients ranged from 6 months to 55 years, with median age 24 years. The following diagnostic techniques were carried out for diagnosis of cutaneous leishmaniasis including dental broach smear, histopathology examination and culture on Roswell park medium institute (RPM I 1640) and on NNN media. In addition to polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP), genotype techniques were performed for all patients. Sixty six patients with other skin lesions were processed for PCR as a control group. Gene sequences the results were compared with basic local alignment reference sequences.

**Statistical Analysis**

The data were analyzed by using Microsoft Excel 2007 and SPSS version 18. The Chi-square test was used to compare of differences between study groups.

**Results**

In all age groups, males 43(65%) were more frequently infected with CL than females 21 (35%) as shown in table (1). The differences between genders were statistically highly significant (p. value < 0.05). The highest age group infected with CL was (30-44) years. The differences between age groups were statistically significant (p. value < 0.05).

Discussion

Cutaneous leishmaniasis, also known in Iraq as aghdad boil, is the most common form of leishmaniasis. It is a skin infection caused by a unicellular parasite that is transmitted by sand fly bites. There are about 20 species of Leishmania that may cause cutaneous leishmaniasis. The total incidence of cutaneous leishmaniasis in Iraq varies from 2.3 to 45.5 / 100000 (10). According to age and gender in patients group, the present study showed significant differences between males and females infected with CL in all age groups. In the present study, males were the predominant (65%) than females (35%) were in agreement with previous Iraqi study (11) where males were (57%) and females were (31.7%). But our results were disagree with the other study done by (Saki et al. 2010) in Iran which has found that females were more predominant (54.68%) than males (45.31%). These results are somewhat difficult to explain and may be due to the fact that males are working out-door and also due to men are less covering than women and expose to the insect biting more than females. The more frequency of CL in this study was in age group 0-14 years showing agreement with the other studies done in Iraq (11). This difference in age group playing outdoors for long time and more exposure to the infected sand flies. The most of Cutaneous leishmaniasis lesions were present on the exposed parts of the body; the highest frequency was (38.5%) at upper limbs and hands followed at face (25%) and then lower limbs and feet (21.5%) while the lowest frequency was in other parts of the body (15%). These results were in agreement (12), in which was (57%) in upper limbs followed by face (25%) then lower limbs (15%) and also agreement with other studies done in Sri Lanka (13), which had found that CL lesions occurred mainly on the upper limbs and the lower limbs, and less frequently on the face. When the number of lesions from 1-9, males were suffering more than females, but when the number of lesions 10 or more, females were much more suffering than males and showed the significant difference between male and female with number of lesions.

The present study showed two type of Leishmania Spp. In Iraq, by used mini-exon PCR assay, showed L. major (60%) while L. tropica (40%) and this agreement with other Iraqi studies (14), and other study in nearby countries such as Iran (15) hence the high frequency of L. major may be due to the presence of reservoir animals in large numbers, especially rodents and dogs (reservoir of L. major). Obviously, dense populations of natural hosts of L. major, together with abundant vector sand flies, are the key elements responsible for the high rate of human infection. (16). This study used a new genotype assay for molecular diagnosis of the different Leishmania species and strains in Iraq, it is based on amplification of the mini-exon gene and combined it with restriction digests of PCR product (RFLP technique), a method which is routinely used for genotyping tasks (17). The resulting patterns of restriction fragments were characteristic for each species and achieved a high resolution and high discrimination power. The exon is highly conserved, whereas the intron and non-transcribed spacer region vary in size and sequence among different species. Species identification was performed by digesting mini-exon PCR products with one or two different restriction enzymes (15) Restriction fragment length polymorphism (RFLP) generated species-specific patterns of bands visualized in agarose gels, which allowed differentiating each species and strain unequivocally. This study was in agreement with Saki et al 2010 these all Leishmania species of subgenus Leishmania can be distinguished by mini-exon PCR-RFLP, with Eae I being the most informative restriction enzyme. However, in two L. tropica samples used in our study, Eae I failed to cut the mini-exon PCR products of these samples and we used another restriction enzyme Hae III to digest the products of PCR. The mutation that occurrence in the numbers of positions in substantiation nucleotides in comparison of reference isolates KY612611.1. Leishmania Major: G＞A, A＞G, C＞A, T＞C, T＞G, G＞C, G＞A, A＞G, and C＞A, while Leishmania Tropica: T＞C, G＞A, A＞G and C＞A.

Conclusions

Sampling using dental appeared to be more active
than other sampling techniques used in this study. Histopathological sections have identified the focal presence of the parasites. Polymerase chain reaction (PCR) and restriction fragment length polymorphism (RFLP) was more specific than other methods.

Correlation of High sensitivity C-reactive Protein Levels with Body Mass Index in a Group of Adults in Erbil City

Salam Naser Zangana¹, Namir G Al-Tawil², Suhad Ali Khazaal³

Abstract

Background and Objectives: The prevalence of overweight and obesity is increasing worldwide. Obesity is related to morbidity and mortality. High sensitivity C-reactive protein (hs-CRP) is an important inflammatory marker to predict cardiovascular diseases. This study aims to correlate between hs-CRP levels and BMI among healthy adults.

Materials and Methods: A cross-sectional study was conducted on 200 healthy adults from May 2019 to October 2019. The study population was divided into four groups based on BMI; normal, overweight, obese I, and obese II. Hs-CRP level was measured in all groups. Multiple linear regression analysis was done to find out the independent factors affecting hs-CRP.

Results: Out of 200 participants, 56 (28%) had normal BMI, 43(21.5%) were overweight, 57(28.5%) were obese group I and 44 (22%) were obese group II. The mean hs-CRP of the normal weight and overweight participants was 1.03 mg/dl and 1.37 mg/dl respectively (p= 0.725), then there was a marked increase to 3.75 mg/dl and 7.69 mg/dl among the obese I and obese II participants respectively (p < 0.001). A positive significant correlation was found between the hs-CRP levels and the BMI (r = 0.436, p < 0.001). The only factor that was independently associated with the high hs-CRP was the BMI (B = 0.357, p < 0.001).

Conclusion: Rising BMI was significantly correlated with hs-CRP. The higher the BMI, the higher will be plasma hs-CRP levels, suggesting the presence of chronic systemic inflammation which might lead to cardiovascular events in the future.

Keywords: High sensitivity C-reactive protein, Body mass index, Obesity.

Introduction

Being overweight or obese means that you have more body fat accumulated to an extent to cause negative health effects.¹ Fat accumulation is multifactorial. It may be due to more calorie intake, lack of exercise and daily activities, hormonal imbalance, genetic factors, or the combination of all.²⁻³ BMI is an accurate measure of body fat content than simply measuring a person’s weight. The BMI is defined as the body mass (weight in kilograms) divided by the square of the body height (in meters) and is expressed in units of kg/m². Overweight and obesity is a presentation of rising BMI.⁴ A BMI equal or more than 25 is considered overweight, while a BMI of 30 and above is considered obese. The prevalence of overweight and obesity is increasing worldwide.¹,⁵
2013, the increase in weight reached epidemic levels globally, with more than two billion adults being either overweight or obese, and many medical societies including the American Medical Association and the American Heart Association view obesity as one of the most serious public health problems of the 21st century and classify it as a disease. The prevalence of overweight and obesity in Iraq is different from one city to another. According to the 2006 World Health Organization survey, 26% of Iraqi men and 38% of Iraqi women aged 25-65 years were obese. A study was done in 2018 at Kufa city among employees women, showed that the prevalence of overweight and obesity was 27.5% and 43.1%, respectively. In Basrah city, the prevalence of overweight was 31.3% and obesity was 23.8% according to Mansour et al study. The prevalence of overweight and obesity in Erbil city was 33.4% and 40.9%, respectively.

Obesity increases the likelihood of many diseases such as cardiovascular diseases, obstructive sleep apnea, certain types of cancer, and metabolic syndrome. Adipose tissue produces many proinflammatory cytokines such as Tumor Necrosis Factor (TNF), interleukins-1, and 6 (IL-1 and IL-6) which can regulate the synthesis of CRP in the liver. CRP is an acute-phase protein whose circulating levels increase in response to inflammation. There is growing evidence to link inflammation and many chronic health conditions including diabetes, metabolic syndrome, and cardiovascular disease. As a result, and to enhance the clinician’s ability to predict these diseases, many studies have demonstrated that biomarkers of inflammation, such as CRP, can improve risk prediction. A hs-CRP test measures low levels of CRP using laser nephelometry. The test gives results in 25 minutes with sensitivity down to 0.04 mg/L. The American Heart Association and U.S. Centers for Disease Control and Prevention have defined risk groups as follows: low: hs-CRP level under 1.0 mg/L, average: between 1.0 and 3.0 mg/L, and high: above 3.0 mg/L. It was mentioned that healthy individuals with elevated hs-CRP values were up to 4 times as likely to have coronary heart disease.

Although the association between high BMI and rising levels of hs-CRP were mentioned in previous studies (correlating this rise with aging and concomitant diseases like rheumatoid arthritis, diabetes, and other cardiovascular diseases), recent studies reported that an increase in hs-CRP levels was related to weight gain without the presence of other diseases. There is still a disagreement regarding this subject.

To the best of our knowledge, there was no previous study done in Erbil city regarding the same subject. Accordingly, this study aimed to correlate between hs-CRP levels and body mass index among apparently healthy adults.

**Materials and Methods**

This cross-sectional study was conducted in Nawroz primary health center and Rizgary Teaching Hospital in Erbil city, Iraq, from May 2019 to October 2019. A convenience sample of 200 healthy adults, aged ≥ 18, with variant BMI, who came for routine health check-up, was selected to participate in this study. The exclusion criteria for this study considered having any of the followings: hypertension, diabetes mellitus, kidney or liver disease, an endocrine disorder, Rheumatoid arthritis, Inflammatory bowel diseases, a history of recent infection or inflammation (for the last two weeks), pregnancy, using weight-loss drugs, vitamins, taking contraceptive pills, statins, or Non-Steroidal Anti Inflammatory Drugs (NSAIDs). The weight of the participants was measured in kilograms using a calibrated digital scale. The height was measured in centimeters using a portable tape measure which was fixed on the wall. Calculation of BMI was done using the formula: Weight (kg)/ Height (m)². The participants were classified into four groups based on BMI as Normal (BMI 18.5-24.9 kg/m²), Overweight (BMI 25-29.9 kg/m²), Obese I (BMI 30-34.9 kg/m²), and Obese II (BMI 35-39.9 kg/m²), according to WHO standards. Under aseptic precautions, a blood sample was drawn from all participants to estimate serum hs-CRP levels using
COBAS INTEGRA cardiac C - Reactive Protein High Sensitive (CRPHS) test, and to be analyzed using fully automated Cobas E601 clinical chemistry analyzer. The American Heart Association (AHA) recommends that for most women/men, an optimal level of hs-CRP is less than 0.5 mg/l.\textsuperscript{24} Hs-CRP is the analyte of choice for cardiovascular risk assessment, due to superior assay precision, accuracy, availability, and the existence of standards for proper calibration when compared to other acute-phase reactants.\textsuperscript{15} According to the Centers for Disease Control (CDC) and AHA, low risk for cardiovascular disease is defined as hs-CRP <1 mg/L, average risk as 1 to 3 mg/L, and high risk as >3 mg/L.\textsuperscript{15}

**Questionnaire and data collection:**

An interview was made to collect the data using a questionnaire that was designed by the researchers. The questionnaire consisted of many sections regarding sociodemographic data (like age, gender, occupation, marital status, parity, and educational status), risk factors’ data (like smoking and alcohol consumption), body fat anthropometric index like BMI, and finally the laboratory investigations (like serum hs-CRP level).

**Ethical considerations:**

Ethical approval was obtained from the Ethics Committee of the College of Medicine at Hawler Medical University, and a facilitation letter was obtained from Erbil Directorate of Health (DOH). This study was conducted by using informed verbal consent that was obtained from all patients before participation in the study. The purpose of the study was carefully explained to each patient, and none of them refused to participate.

**Statistical Analysis**

Data were analyzed using the Statistical Package for Social Sciences (SPSS, version 25). The Chi-square test of association was used to compare proportions. Fisher’s exact test was used when the expected count of more than 20\% of the cells of the table was less than 5. A scatter plot was made between the hs-CRP and BMI using the Microsoft Excel (2013) computer program. The correlation coefficient (r) was calculated to assess the strength of the correlation between hs-CRP and BMI. One way analysis of variance (ANOVA) was used to compare three means. A post hoc test (LSD) was used to compare the means of each two groups (after doing the ANOVA test). Multiple regression model was made where the dependent variable was the hs-CRP. A p-value of ≤ 0.05 was considered statistically significant.

**Results**

Two hundred persons participated in the study. Their mean age ± SD was 33.01 ± 9.91 years. The age range was 18 to 60 years, and the median was 31 years. Table 1 shows that the highest proportion of the sample (38\%) was aged 20-29 years, and the majority (73\%) were females.

| Table 1. Basic characteristics of the study population. |
|----------------|----------------|---|
| **Age**       | **No.**        | **(\%)** |
| < 20          | 11             | (5.5) |
| 20-29         | 76             | (38.0) |
| 30-39         | 59             | (29.5) |
| 40-49         | 39             | (19.5) |
| ≥ 50          | 15             | (7.5)  |
| Mean (±SD)    | 33.01          | (±9.91)|
| Gender        |                |       |
It is evident in Table 2 that the mean hs-CRP of the normal weight and overweight participants was 1.03 mg/dl and 1.37 mg/dl respectively (p = 0.725), then there were a marked increase to 3.75 mg/dl and 7.69 mg/dl among the obese I and obese II participants respectively (p < 0.001).

Figure 1. Correlation between Hs-CRP and BMI.

It is clear in Table 4 that the only factors that are associated significantly with the high hs-CRP were age (≥ 30 years) (p < 0.001), and not practicing regular exercise (p = 0.017). No significant association was detected between hs-CRP and the following variables: gender (p = 0.089), socio-economic status (p = 0.583), smoking (p = 0.902), and alcohol (p = 0.471).

**Discussion**

The present study found a strong positive correlation between BMI and hs-CRP. The mean hs-CRP level was increasing with weight gain. This result is in correspondence with many previous studies done by Klisic et al., Aronson et al., and Kao et al.

In the Kurdistan region, as in Iraq, the prevalence of overweight and obesity is increasing and becomes a major health problem. Obesity is considered an important risk factor for many chronic diseases like hypertension, stroke, diabetes mellitus, and other cardiovascular problems. Multiple pathophysiological mechanisms had been presumed to bind obesity to cardiovascular diseases. One of these mechanisms is inflammation, which recently has been postulated to be the cornerstone process in the initiation of CVDs. Overweight and obesity were found to be associated with the presence of low-grade systemic inflammation indicated by higher levels of acute-phase reactants like CRP, and this result is in agreement with our study which revealed a significant rise in the hs-CRP level with the increasing BMI from normal weight to obese participants. The association between obesity and increasing hs-CRP levels can be elucidated by the potential role of adipose tissue in the body, which produces many proinflammatory cytokines such as Tumor Necrosis Factor (TNF), interleukins-1 and 6 (IL-1 and IL-6) that can regulate the synthesis of C-reactive protein (CRP) in the liver, as mentioned above. Adipose tissue can approximately produce 25% of IL-6 in vivo. The release of IL-6 from adipose tissue may produce low-grade systemic inflammation in individuals with increase body fat. TNF α can also play a role in raising hs-CRP levels with increasing BMI by potentiating the effect of IL-6 in CRP production. Another finding in the present study is that the proportion of patients with elevated hs-CRP levels (a CRP concentration of more than 1 mg/dl) among the normal weight participants was nearly 30% which is considered high when compared to previous studies like the Third National Health and Nutrition Examination Survey (NHANES III). In this study, which included 16 616 adult US population from 1988-1994, clinically raised CRP levels (a CRP
concentration of more than 1 mg/dl) were present in 4.4% of men and 8.9% of women. In the same study, and with increasing BMI, the prevalence of clinically raised CRP levels increased to 7.7% in over-weight women, and 20.2% in obese women. These results are in agreement with our study, but the prevalences were much higher in our study. Accordingly, this will put our over-weight and obese participants at an increased risk for cardiovascular disease.

In the current study, we included healthy participants with no previous history of diseases or conditions that might affect the accuracy of the results and also reduce any chances or possible reasons for raising hs-CRP levels. However, in this study, two factors emerged to affect hs-CRP levels in addition to BMI and they were significantly associated with the high hs-CRP, and those were age of 30 years or higher, and not practicing regular exercise. But after performing the multiple regression analysis [including hs-CRP as a dependent variable and the above mentioned parameters (age, exercise, and BMI) as independent variables], BMI was found to be the only factor that was significantly correlated with hs-CRP. Similar results were observed by other studies. On this base, and taking into account the results of this study, we recommend that all necessary and required measures should be taken to produce changes in the diet, physical activity, and lifestyle so that the BMI will be maintained within the normal range and as a result, the incidence of cardiovascular and other chronic diseases will be reduced.

Conclusion

BMI was found to be the only factor that is significantly and positively correlated with hs-CRP. So irrespective of the other factors, we can predict the presence of high hs-CRP by knowing the BMI of the individual; hence we can prevent the incidence of CVDs.

Effect of 410 nm Diode Laser Irradiation on Human Sperm Motility in Vitro

Sama E. Mohammed, Layla M.H. Al-ameri

1Researcher, 2Lecturer, Institute of Laser for Postgraduates Studies, University of Baghdad, Iraq

Abstract

Background: Infertility can be defined as an absence of pregnancy after 12 months of regular unprotected sexual intercourse, the most important of the sperm function disorders are reduced sperm motility (asthenospermia). Photobiomodulation have an effect on the decrease of the sperm disorder.

Materials and Methods: Diode laser with wavelength of 410nm was used to induce the sperm motility in an asthenozoospermia human seminal fluid in vitro, 20 fresh seminal fluids samples were used in this study and each sample was divided into two parts, one of them non-irradiated by laser light (control) and the other was exposed to laser irradiation with exposure time of 30 seconds of 410nm diode laser with 0.67 W/cm², power density.

Results: Progressive motility was significantly increased while non-progressive motility was non significantly increased and the immotile sperms were significantly decreased at 5 min following irradiation compared to non-irradiated samples, while at 15, 30, 45 min following irradiation begin to decreased. We found that low power laser could induce a short term bio stimulation effect on sperm motility.

Key words: asthenozoospermia, bio-stimulation, laser.

Introduction

Infertility can be defined as an absence of pregnancy after 12 months of regular unprotected sexual intercourse (1). Male infertility factor is a term that involves a variety of different sperm function disorders that can make fertilizing an egg under normal conditions difficult for sperm, problems with male fertility factor due to changes in the quality of the semen as evaluated by the semen analysis, the most important of these are reduced sperm motility (asthenospermia), defective sperm morphology (teratospermia), and low concentration of sperm (oligospermia), semen volume and other seminal markers of prostatic, epididymal and seminal vesicle function are less well associated with infertility (2). The sperm motility is one of the most essential parameters required to determine the reproductive capability of the semen sample because of male with complete lack of motile sperm is sterile since that immotile sperm either it dead or alive cannot penetrate the cervical mucus as well as the fertilizing potential can also be affected by the form of the movement therefore sperm swimming in closed circle cannot easily pass through the uterotubal junction and only sperm with straight motion can fertilize the ova (3), also, that in order to accomplish its biological function of delivering the male haploid DNA complement to the oocyte, the sperm cell must reach the fertilization site in the oviduct, therefore the sperm cell must be able to develop a motility pattern during maturation in the testes to reach the oviduct and retain this motility pattern throughout its migration via the reproductive tract of the female, and The ability of the sperm cell to exhibit motion in vivo as well as in vitro is greatly dependent on its capability to produce ATP that in turn is used by the contractile proteins of the flagellum as the dynein ATPase substrate to transform chemical energy into the mechanical function (4). Low sperm motility can be caused by genital infection, anti-sperm

antibodies, inflammation of the accessory sex gland and sperm structural defect, Ultrastructural defects in the sperm midpiece or tail, a condition called immotile cilia syndrome or Kartagener’s syndrome can lead to a complete absence of motility (5). Photobiomodulation or low-level laser therapy is the application of light (usually LED or low power laser in the range of 1 mW to 500 mW) to pathology to facilitate tissue repair, decrease inflammation and reduce pain (6). And in the field of reproductive research, photobiomodulation can be used to improve viability, metabolism, and motility of the sperm cells because of its positive effect on mitochondria due to the activation of the mitochondrial respiratory chain, and the production of ATP, this therapy can certainly be helpful for preventing the use of certain chemicals in the culture medium of spermatozoa and also in promoting the survival and the motility of the sperm cells particularly the following thawing or in largely immotile sperm samples (7). Several studies used the laser to enhance the sperm motility, (8) found that 830 nm diode laser improve progressive motility depending on both post-exposure time and laser density. (9) study the diode laser effect on human sperm motility by comparing two different wavelengths red (635 nm) and infrared (830 nm) with each other and with no laser control group, all sperm motility parameters are significantly increased in both infrared and red with no statically significant difference between two laser group and slightly better results in the infrared group. (10) study the effect of He-Ne laser 632.8nm on the motility of sperm in asthenozoospermia samples in vitro, the results show that progressive motility in treated samples increased significantly while non-progressive motility is not significantly increased also the percentage of non-motile sperms are significantly decreased.

Aim of the Study

The main purpose of this study is to evaluate how exposure to continuous wave 410 nm diode laser effect the motility of sperm.

Materials and Method

This study was conducted at the laboratory in the institute of laser for postgraduate study at university of Baghdad during period from February to September 2020, the semen sample of twenty males with decreased sperm motility (Asthenozoospermia), and age between (20-43 years old) was selected then used after routine semen analysis. After a sexual abstinence time of (48-72) hours, all samples were obtained by masturbation of males into a wide-mouthed sterile specimen container. Samples were then incubated to be liquefied at 37°C for 30 min. After liquefaction, each sample was divided into two parts: one was called control and the second was exposed to the laser beam.

A Continuous-wave 410 nm diode laser with 100 mW output power and laser diameter of 0.15 cm² was used in this experiment. Each sample was divided into two portions one called control (non-irradiated) and the second was exposed to the laser beam for 30 seconds. 1 ml of each liquefied sample was put in the Eppendorf tube and the laser probe was positioned at 30 cm distance above the Eppendorf tube. Irradiation was performed from above that mean whole sample was evenly irradiated (the common method for irradiating liquid samples).

Computer Assisted Semen Analysis (Mira-9000 CASA) was used to evaluate the motility of the sperm, this system follows WHO (2010) strict criteria for motility patterns and morphometric assessment of human semen. The motility of the sperm was assessed after 5, 15, 30, 45 min after irradiation, after every measurement the sample was put in the incubator at 37°C to overcome the influence of temperature on the motility of the spermatozoa.

The statistical analysis was carried out by SPSS (v 20). ANOVA test was used to analyze repeated measure between irradiated sample and control. Data expressed as mean±SE. Values of p>0.05 were considered statically non-significant while p≤0.05 and <0.01,0.001 were considered significantly different, highly significantly different respectively. Estimate of correlation coefficient between different parameters in this study.

Results and Discussion

Diode laser with wavelength 410 nm was used to enhance the motility of the sperm. As shown in the table 1 the progressive motility was significantly increased after laser irradiation, the maximum influence of laser on the progressive motility was at 5 min following irradiation and the progressive motility of control samples was decreased by passing of time while non-progressive motility non-significantly increased after laser irradiation as shown in results in table 2, also the number of immotile sperm of irradiated samples was significantly decreased and total motility was significantly increased.

We supposed that the low power laser can enhance the mitochondrial respiratory chain components and increased the energy supply to spermatozoa and this study is the first study that use laser with wavelength of 410 nm to enhance the human sperm motility in vitro. One of the most important causes of reduced sperm motility is characterized by impaired integrity of the mitochondrial membrane and impaired function of its sheath because mitochondria provide apart of energy necessary for the motility of the sperm as light is applied to cells, the first sites of light absorption are mitochondria and the photoreceptors are assumed to be cytochromes, consequently photon absorption induces a sequence of reactions known as cellular signaling pathways which result in ATP synthesis as well as the production of ROS, mitochondria house the electron transfer chain which includes complex I, II, III, and IV and photon absorption by these complexes induce electrical excited states which can speed up electron transfer reactions and this result in increased ATP synthesis because of more electron transport necessitate for increased ATP production. Flavins and flavoproteins such as Flavin mononucleotide and Flavin dinucleotide are believed to be excited by blue light (400-500 nm), complex II, is a Flavin containing cytochrome (contain FADH2) that absorb blue light, as a result, it’s possible that blue light may influence mitochondrial function like red and NIR light.

Conclusion

We found that low power laser could induce a short term bio stimulation effect on the motility of the sperm.

Indonesian National Social Security Management Law Problematics with the Enabling of Law Number 40 of 2004 Concerning a National Social Security System

Nurrochmah Ihayani 1, Nurul Istiqomah S H 1, Sitti Nursanti 1, Budi Pramono 2
1 Master of Law Students at Hang Tuah University, Surabaya, Indonesia, 2 Lecturer, Faculty of Law, Hang Tuah University, Surabaya Indonesia

Abstract
This study discusses legal problems that occur in the management of Indonesia’s national social security with the enactment of Law number 40 of 2004. This research is a normative legal research with a conceptual and statutory approach. This study uses the theory of Laurence M. Friedman as a knife of analysis that the problem of managing national social security includes institutional structures, substance, the Healthcare and Social Security Agency and The National Social Security regulation and legal culture. It is hoped that the management of national social security will accelerate the transfer of management of the Savings Fund and Civil Servant Insurance Company and the Social Insurance of the Armed Forces of the Republic of Indonesia Company, so that they do not have to wait up to 25 years.

Keyword: Law Problematics, National Social Security System, Healthcare and Social Security Agency

Introduction
The right to obtain the fulfillment of social security for all Indonesian people is stipulated in Article 28 H paragraph (3) of the 1945 Constitution of the Republic of Indonesia, which states that “Everyone has the right to social security which enables his or her complete development as a dignified human.” This norm is then reinforced in Article 34 paragraph (2) of the 1945 Constitution of the Republic of Indonesia, which explains that “The state develops a social security system for all people and empowers people who are weak and underprivileged according to human dignity.” These articles constitute a material constitutional reason in the field of social security, which confirms that social security is a right not a privilege.

Email – budi.pramono@hangtuah.ac.id

The concept of social security for all Indonesian people is then accommodated in state life with the passing of Law Number 40 of 2004 concerning the National Social Security System, Law Number 11 of 2009 concerning Social Welfare, Law Number 24 of 2011 concerning Healthcare and Social Security Agency (BPJS), and Presidential Regulation Number 64 of 2020 concerning Second Amendment to Presidential Decree Number 82 of 2018 concerning Health Insurance.

With the enactment of this National Social Security System Regulation, there has been a change in legal norms, from which the government’s obligation to fulfill the right to health of the people becomes the obligation of the people to pay dues in order to fulfill their rights. Subsequent developments, in 2011 the Healthcare and Social Security Agency Regulation, was enacted which appointed a government-owned implementing agency that had the role of an insurance company.

This fact shows that the legal politics of the formation of National Social Security System Regulation...
and Healthcare and Social Security Agency Regulation have not shown a responsive-populist character that prioritizes the interests of the people. These two legal products have not fulfilled the rights to social welfare and health of the Indonesian people, which should be the responsibility of the government (state). Therefore, the President and the DPR together need to make changes to the two legal products so that they are in accordance with the mandate of the 1945 Constitution of the Republic of Indonesia. The purpose of this research is to knowing law problematics with the enabling of law number 40 of 2004 concerning a national social security system.

Methods

To answer the problems that have been formulated in this study, a normative legal research type is used with a statutory and conceptual approach.

Result and Analysis

Social security is part of the concept of social protection, where social protection is broader in nature. The difference between the two is that social security provides social protection for individuals with funds obtained from periodic contributions, whereas social protection usually involves many parties in providing protection either to individuals, families or communities from various unpredictable life risks such as economic crises, or natural disasters. Health issues are valuable things that the people yearn for, so that the fulfillment of the right to health is one of the basic needs of the people. Health is the basis of recognition of human dignity, an unhealthy individual will automatically reduce his right to life, he cannot exercise his right to work properly, he cannot use his right to congregate and express thoughts, he cannot use his right to education for his future, and so.

The following will explain the problems in the management of national social security which include aspects of its structure, substance and culture or legal culture.

1. Problems in the Institutional Structure of The National Social Security

The National Social Security institution is one of the elements of the National Social Security System with the function of carrying out the realization of social security objectives which have been formulated in accordance with the underlying principles. The National Social Security System administration is formed by two organs, namely the National Social Security Council (DJSN) and the Healthcare and Social Security Agency (BPJS).

The Healthcare and Social Security Agency (BPJS) is a legal entity established under The Healthcare and Social Security Agency Regulation to administer social security programs. Law Number 24 Year 2011 established two Healthcare and Social Security Agency, namely Healthcare and Social Security Agency that focused on healthcare (BPJS Kesehatan) which functions to organize health insurance programs and Healthcare and Social Security Agency that focused on Labor (BPJS Ketenagakerjaan) which functions to organize work accident insurance, death benefits, old age savings and pension benefits.

Since the enactment of the Healthcare and Social Security Agency regulation, the existing social security administering body is declared the Healthcare and Social Security Agency according to this law. This is in accordance with the norms of Article 5 of the National Social Security System regulation, the formulation is as follows:

(1) Healthcare and Social Security Agency (BPJS) must be established by law.

(2) Since the enactment of this Law, the existing Healthcare and Social Security Agency (BPJS) is declared a Healthcare and Social Security Agency according to this Law.

(3) The Healthcare and Social Security Agency as referred to in paragraph (1) are:

   a. Labor Social Security Company (Jamsostek);

   b. Savings Fund and Civil Servant Insurance Company (Taspen);
c. Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri); and

d. The Company (Persero) Indonesian Health Insurance (Askes).

(4) In the event that a Healthcare and Social Security Agency other than those referred to in paragraph (3) is required, a new one can be formed by law.

Article 52 National Social Security System Regulation have functions to fill the legal vacuum so that Social Security, Savings Fund and Civil Servant Insurance Company (Taspen), Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri), and The Company (Persero) Indonesian Health Insurance (Askes) are still valid as long as they have not been adjusted to this law. Based on the provisions of Article 52 paragraph (2), it is given 5 (five) years from the time of promulgation to comply with this law. The transfer mechanism of Social Security, Savings Fund and Civil Servant Insurance Company (Taspen), Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri), and The Company (Persero) Indonesian Health Insurance (Askes) from the Ministry of Indonesian State-Owned Enterprises (BUMN) to become under The Healthcare and Social Security Agency through a transformation program.

The following will explain the development and transformation process of Social Security, Savings Fund and Civil Servant Insurance Company (Taspen), Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri), and The Company (Persero) Indonesian Health Insurance (Askes) which were previously under the Ministry of the Indonesia State-Owned Enterprises to become under the authority of The Healthcare and Social Security Agency.

The preparation period for the transformation of The Company Indonesian Health Insurance (Askes) into the Healthcare and Social Security Agency (BPJS Kesehatan) for two years starting November 25, 2011 to December 31, 2013. During the preparation period, the Board of Commissioners and Directors of The Company Indonesian Health Insurance (Askes) were given the task of preparing the Healthcare and Social Security Agency (BPJS Kesehatan) operations, as well as preparing for asset transfers, and The Company Indonesian Health Insurance (Askes) liabilities, employees and rights and obligations to Healthcare and Social Security Agency (BPJS Kesehatan).

Preparation for the transfer of assets and liabilities, employees and rights and obligations of The Indonesian Health Insurance Company (Askes) to the Healthcare and Social Security Agency (BPJS Kesehatan) , including the appointment of a public accounting firm to audit: (1) the closing financial statements of The Indonesian Health Insurance Company (Askes); a report on the financial position of the opening Healthcare and Social Security Agency (BPJS Kesehatan); report on the financial position of the opening of the health insurance fund. When the Healthcare and Social Security Agency (BPJS Kesehatan) started operating on January 1, 2014, The Indonesian Health Insurance Company (Askes) was declared disbanded without liquidation. All assets and liabilities as well as legal rights and obligations of PT Askes (Persero) become assets and liabilities as well as legal rights and obligations of Healthcare and Social Security Agency (BPJS Kesehatan), and all employees of The Indonesian Health Insurance Company (Askes) become employees of Healthcare and Social Security Agency (BPJS Kesehatan).

At the same time, the Minister of Indonesian State-Owned Enterprises (BUMN) As General Meeting Of Shareholders ratified the closing financial position report of The Indonesian Health Insurance Company (Askes) after an audit of the public accounting firm. The Minister of Finance ratifies the opening financial position report for the Healthcare and Social Security Agency (BPJS Kesehatan) and the opening financial report for the health insurance fund. For the first time, the Board of Commissioners and Directors of The Indonesian Health Insurance Company (Askes) were
appointed as the Supervisory Board and the Board of Directors of the Healthcare and Social Security Agency (BPJS Kesehatan) for a maximum period of 2 (two) years since the Healthcare and Social Security Agency (BPJS Kesehatan) began operating. Starting January 1, 2014, the social health insurance program that has been implemented by the government has been transferred to the Healthcare and Social Security Agency (BPJS Kesehatan). The Ministry of Health no longer operates the Public Health Security (Jamkesmas) program. The Ministry of Defense, The Armed Forces and Police no longer carry out health service programs for their participants, except for certain health services related to their operational activities as determined by Government Regulations. The Labor Social Security Company (Jamsostek) no longer maintains an employee health insurance program.1

b. Transformation of The Labor Social Security Company (Jamsostek)

The transformation of the Labor Social Security Company (Jamsostek) is carried out in two stages, namely the first stage is the transition period of Labor Social Security Company (Jamsostek) to the Healthcare and Social Security Agency Employment (BPJS Tenaker) which lasts for 2 (two) years, from 25 November 2011 to 31 December 2013. The first stage ends with the establishment of the Healthcare and Social Security Agency Employment (BPJS Tenaker) on January 1 2014. the Healthcare and Social Security Agency Employment (BPJS Tenaker) will continue the implementation of three the Labor Social Security (Jamsostek) programs, namely the work accident program, the old age security program, and the death security program no later than 18 (eighteen) months later (1 January 2014–3 June 2015). Provisions for the implementation of these three programs are still based on Law Number 3 of 1992 concerning Social Security.1

The second stage is the preparation stage for the operationalization of the Healthcare and Social Security Agency Employment (BPJS Tenaker) for the implementation of work accident insurance, old-age savings, pension and death security programs. The second stage of preparation takes place no later than 30 June 2015 and ends with the operation of the Healthcare and Social Security Agency Employment (BPJS Tenaker) for the implementation of the four programs in accordance with the provisions of the National Social Security System regulation by 1 July 2015.

Preparation for the transfer of assets and liabilities, employees and the rights and obligations of the Labor Social Security Company (Jamsostek) to the Healthcare and Social Security Agency Employment (BPJS Tenaker) includes the appointment of a public accounting firm to audit the closing financial statements of the Labor Social Security Company (Jamsostek), report on the financial position of the opening of the Healthcare and Social Security Agency Employment (BPJS Tenaker), and reports on the financial position of opening funds. employment guarantee. As with the dissolution of Health Insurance Company (Askes) on January 1, 2014 the Labor Social Security Company (Jamsostek) was declared dissolved without liquidation and the Labor Social Security Company (Jamsostek) changed to the Healthcare and Social Security Agency Employment (BPJS Tenaker). Government Regulation Number 36 of 1995 concerning the Determination of the Manpower the Healthcare and Social Security Agency is revoked and declared no longer valid.

All assets and liabilities as well as legal rights and obligations of the Labor Social Security Company (Jamsostek) become assets and liabilities as well as legal rights and obligations of the Healthcare and Social Security Agency Employment (BPJS Tenaker). All employees of the Labor Social Security Company (Jamsostek) are employees of the Healthcare and Social Security Agency Employment (BPJS Tenaker). At the time of dissolution, the Minister of Indonesian State Owned Enterprises (BUMN) As General Meeting of Shareholders ratified the closing financial position report of the Labor Social Security Company (Jamsostek) after an audit was carried out by a public accounting firm. The Minister of Finance ratifies the position of the financial statement for the opening of the the Healthcare and
Social Security Agency Employment (BPJS Tenaker) and the financial position report for the opening of the employment guarantee fund. Since January 1, 2014 until no later than June 30, 2015. The Healthcare and Social Security Agency Employment (BPJS Tenaker) will continue the implementation of the three programs that have been organized by the Labor Social Security Company (Jamsostek), namely the work accident insurance, old age insurance and death insurance programs, including accepting new participants.

c. Transformation of the Savings Fund and Civil Servant Insurance Company (Taspen) and the Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri)

The Healthcare and Social Security Agency Regulation did not dissolve the Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri) and the Savings Fund and Civil Servant Insurance Company (Taspen), nor did they transfer the two Persero to become The Healthcare and Social Security Agency. The Healthcare and Social Security Agency Regulation does not regulate the dissolution of the agency, transfer of assets and liabilities, transfer of employees and the rights and obligations of the Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri) and the Savings Fund and Civil Servant Insurance Company (Taspen). The Healthcare and Social Security Agency Regulation only transfers the second function of the Company, namely the implementation of the old age protection program and pension payments organized by both of them to the Healthcare and Social Security Agency Employment (BPJS Tenaker) by 2029. The Healthcare and Social Security Agency Regulation delegates the arrangements for program transfer procedures that are carried out by the two of them to a Government Regulation. Article 65 paragraph (1) and paragraph (2) of Law no. 24 of 2011 concerning the Healthcare and Social Security Agency requires The Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri) and the Savings Fund and Civil Servant Insurance Company (Taspen), to compile a transformation roadmap no later than 2014. The transfer of the Savings Fund and Civil Servant Insurance Company (Taspen), and The Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri) from the Ministry of Indonesian State-Owned Enterprises (BUMN) to the Healthcare and Social Security Agency no later than 2029, which requires a period of 25 years is very unrealistic. The government, in this case the Indonesian State-Owned Enterprises (BUMN) Ministry, seems to be delaying in transferring its management to the Healthcare and Social Security Agency. The Litigation Director of the Ministry of Law and Human Rights explained that, regarding this transfer, the government represented by the Ministry of Law and Human Rights and the Ministry of Manpower have a different view. Director of Litigation for Laws and Regulations of the Ministry of Law and Defense, Ardiansyah, revealed that the transfer of the program from the Savings Fund and Civil Servant Insurance Company (Taspen) and The Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri) to Healthcare and Social Security Agency (BP Jamsostek) is an order of the National Social Security System-related laws that the government must realize, but it must be understood that the matter of transfer is actually the program, not the institution within the National Social Security System. He said, programs other than those implemented by Healthcare and Social Security Agency (BP Jamsostek) could still be held by the Savings Fund and Civil Servant Insurance Company (Taspen) in the National Social Security System regulations and institutions, while the Old Age Security (JHT) and Pension Security (JP) benefits programs were still held by Healthcare and Social Security Agency (BP Jamsostek).
The regulations are clear. Law Number 24 of 2011 concerning The Healthcare and Social Security Agency, Law Number 40 of 2004 concerning Social National Security System. The implementation is how program transfer will be derived through a Government Regulation (PP). Regarding the transfer of the program from the Savings Fund and Civil Servant Insurance Company (Taspen) and The Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri) to Healthcare and Social Security Agency (BP Jamsostek), he emphasized, it would not cause overlapping regulations. Because, Ardiansyah continued, from the start there had been cross-ministerial coordination and harmonization facilitated by the State Secretariat (Setneg). There was even an assignment for Ministry of State Apparatus Utilization and Bureaucratic Reform to follow up the Minister Regulation program transfer. Including the roadmap like what because it involves civil servants, said Ardiansyah.2

The Indonesian State-Owned Enterprises (BUMN) Ministry’s move is understandable because indeed one of the duties of the Indonesian State-Owned Enterprises (BUMN) ministry is to carry out a business that functions to increase non-tax state revenue. According to the author’s analysis, it is not very suitable if the Savings Fund and Civil Servant Insurance Company (Taspen), and The Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri) have social functions, but in their organizational structure under the Ministry of Indonesian State-Owned Enterprises (BUMN), whose main task is to carry out business (business) to increase non-tax state revenue, so it is more appropriate to accelerate the transfer. The Savings Fund and Civil Servant Insurance Company (Taspen), and The Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri) from the Ministry of Indonesian State-Owned Enterprises (BUMN) to The Healthcare and Social Security Agency.

2. The National Social Security System Substance Problems.

Problems related to the substance of the National Social Security System Regulation that can interfere with the implementation of the national social security system, the problem is that National Social Security System Regulation combines social security with social insurance. The formation of National Social Security System Regulation and the Healthcare and Social Security Agency Regulation which combine social security with social insurance has dragged legislators into the neo-liberalism scenario. Neo-liberal theory has its roots in classical political work by Thomas Hobbes, John Lock and John Stuart Mill which essentially argued that an essential component of a society is individual freedom. Broadly speaking, neo-liberal proponents argue that social security should be provided by self-help groups, religious institutions or by families. The role of the state is only as a residual agent or night guard who can only interfere when the above institutions are no longer able to carry out their duties.3

Social security is a system of giving money and or social services to protect a person from the risk of not having or losing income due to accident, disability, illness, unemployment, pregnancy, old age, and death. Paul Spicker (1995), provides limits and explanations for social security as follows:

The term social security is mainly now related to financial assistance, but the general sense of the term is much wider, and it is still used in many countries to refer to provisions for health care as well as income. Although the benefits of security are not themselves material, they do have monetary value; people in Britain, where there is a National Health Service, are receiving support which people in the US have to pay for through private insurance or a Health Maintenance Organisation.4

Social security can be provided through the social insurance system which is funded by insurance premiums or through social assistance whose funds are obtained from tax revenues. Social insurance is determined based on insurance expertise, the provision of insurance benefits is calculated based on insurance premiums, the government together with other public
Institutions are the providers of social insurance. Social insurance membership is compulsory (obligatory), the medical insurance system and pension insurance are two types of social insurance that are very widely known.

The definition of insurance in general is a system for a group of people to protect the risks that may occur to them. A number of people who are deemed to have a similar risk form a group, and each member of the group pays a premium as a precondition for obtaining benefits when facing an accident or risk in the future. Meanwhile, the definition of social insurance is social security provided to insurance participants based on the premiums they pay. The formation of the National Social Security System Regulation and the Healthcare and Social Security Agency Regulation has not been in accordance with the mandate of Article 28H paragraph (3) of the 1945 NRI Constitution, the formulation of which is as follows:

(1) Every person has the right to social security which enables his complete development as a dignified human being.

The formation of the National Social Security System Regulation and the Healthcare and Social Security Agency Regulation has changed the government’s obligation to fulfill the right to people’s health to become an obligation for the people to pay dues in order to fulfill their right to health. The right to health is a fundamental right and must be realized in accordance with the aspirations of the people as stated in Pancasila and the 1945 Constitution of the Republic of Indonesia, so that legal support is needed to realize the health status of all Indonesian people. Legal support aims to ensure that the government can fulfill the right to health of the Indonesian people. Legal support aims to ensure that the government can fulfill the right to health of the Indonesian people. Legal support aims to ensure that the government can fulfill the right to health of the Indonesian people. Legal support aims to ensure that the government can fulfill the right to health of the Indonesian people.

Health issues are valuable things that the Indonesian people crave, so that the national social security system must be able to protect the people in a certain way. Therefore, the fulfillment of the right to health is one of the basic needs of the people.

The establishment of the the Healthcare and Social Security Agency Regulation appointed a government-owned implementing agency to act like an insurance company, which could collect fees, manage funds, impose sanctions for those who do not pay premiums, and make investments. The role of the implementing agency like this has the potential to shift the role of the government-owned administering body to the role of the private-owned administering body. This concern began to appear when the Coordinating Minister for Maritime Affairs LB. Pandjaitan plans to invite China’s Ping An Insurance company to help the Social Security Administration Agency, which is currently in financial deficit. Concerns grew when the Coordinating Minister for Human Development and Culture confirmed the increase in dues starting January 1, 2020. The people had high hopes for the government to safeguard national sovereignty and interests. The government must be responsible for fulfilling the right to health of the Indonesian people, lest the fulfillment of the right to health of the Indonesian people be delegated to private-owned administering bodies. This consideration is based on the idea that the formation of laws relating to the fulfillment of the right to health of the people must prioritize national sovereignty and interests. The Indonesian government needs to take lessons from the Australian Government which is strong in its stance to protect and safeguard national sovereignty and interests.

In fact, the issuance of the National Social Security System Regulation and the Healthcare and Social Security Agency Regulation is not a complete and perfect legal product, so that some legal experts have criticized it. Jimly Ashhiddiqie suggested that the the Healthcare and Social Security Agency Regulation be revised immediately because many problems arise in the governance run by the the Healthcare and Social Security Agency. Jimly Ashhiddiqie’s suggestion needs to be responded to by the government and the member of Indonesia parliament, with the consideration that the fulfillment of the right to health is a form of basic rights as stipulated in the 1945 Constitution of the Republic of Indonesia. The President and the the member of Indonesia parliament need to make changes to the two legal products so that they are in accordance with the orders of the 1945 Constitution of the Republic.
of Indonesia.

3. Problems in the field of Legal Culture

According to Hilman Hadikusuma, legal culture is the same general response from certain societies to legal phenomena, this assumption is a unified view of legal values and behavior. So the legal culture shows a pattern of individual behavior as members of society that describes the same response (orientation) to the legal life lived by the community concerned. Legal culture is closely related to legal awareness and is manifested in the form of behavior as a reflection of legal compliance in society. In the legal culture, it can be seen that a tradition of daily community behavior is in line with and reflects the will of the law or legal signs that have been established which apply to all legal subjects in the life of the nation and state. In the legal culture of society, it can also be seen whether the community in its legal awareness has really upheld the law as a rule of the game in living together and as a basis for solving any problems that arise from the risk of living together.

The potential for fraud in health services is increasingly visible, emerges and widens due to pressure from the new financing system, opportunities due to lack of supervision, and there is justification for taking action. Shariari (2010) explains that the potential for fraud from clinical groups may arise due to several things, which are as follows:

1. low paid medical personnel,
2. there is an imbalance between the health service system and the burden of health services,
3. service providers do not provide adequate incentives,
4. a shortage of medical equipment supply,
5. inefficiencies in the system,
6. lack of transparency in health facilities, and
7. cultural factors.

From the questionnaire distributed to the blended learning participants with the topic of prevention, detection, and enforcement of hospital group health services fraud in 2015, the INA CBG’s rates which are considered low by clinicians and the high workload make them think of unreasonable efforts to defend themselves so as not to until you lose. The worse thing is that these clinicians sometimes share experiences in this self-rescue effort. They then apply these experiences in providing health services so that it becomes a culture. The basis for setting price list is also mysterious for most groups, causing dissatisfaction with the system.

This dissatisfaction also encourages doctors and hospitals to implement coping strategies as a step to cover up their shortcomings or at least to seek profit even from something illegal. This coping mechanism is present when the surveillance system is weak and is unable to cover opportunities for individuals to commit fraud. Certainly people will continue to commit this fraud as long as they can still enjoy the benefits with the opportunity that is always open to commit fraud. A systematic and ongoing effort is needed to control health service fraud. Activities in the anti-fraud system must be in the form of a cycle starting from awareness building, reporting, detection, investigation, imposing sanctions, and returning to awareness building. Awareness building is the key to preventing or spreading fraud in health services. Awareness building can be done in the form of socialization and education.

In the regulatory group, prior to the issuance of Minister of health regulations Number 36 of 2015, regulators such as district / city health offices assumed that the responsibility for eradicating fraud lies with the Indonesian Ministry of Health or only reaches the provincial level health office. Whereas at the regional level, the authority to build an anti-fraud system lies with the district / city health offices. They also thought that their authority was only to control fraud at the Primary Level Health Facility (FKTP) level and not to the Advanced Level Referral Health Facility (FKRTL). However, after being given socialization and education, the awareness of this regulatory group increased. Education and advocacy for regulatory groups (district
process of detecting potential fraud. Other challenges faced in the detection process include the limited human resources to process the available data. The Healthcare and Social Security Agency has a lot of claim data that can be used as a source of potential fraud detection. However, limited technology and human resources hinder this process. Furthermore, this large amount of data has not been optimally utilized to develop potential fraud detection technology. Investigations are carried out to confirm the alleged national health insurance (JKN) fraud, an explanation of what happened, and the background / reasons thereof. The challenge faced in Indonesia is that currently there are no special investigators for health service fraud. In contrast to the United States, which already has a special investigator profession for fraud cases in the health sector, which is a member of the Association of Healthcare Fraud Investigators (AHFI). After the investigation process, the investigator will provide recommendations for sanctions for the perpetrators who are proven to have committed fraud. Firm sanctions for perpetrators of fraud will have a deterrent effect. In Minister of health regulations Number 36 of 2015, administrative sanctions can be given to perpetrators of fraud. However, currently these sanctions have not yet been firmly applied.

There are legal problems related to the management of the National Social Security (JSN), which includes the structure, substance and culture of law. In the National Social Security (JSN) structure, the transfer of the Savings Fund and Civil Servant Insurance Company (Taspen) and the Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri) from the Ministry of the Indonesia State-Owned Enterprises to Healthcare and Social Security Agency in 2029 requires a period of 25 years, although juridically in accordance with statutory regulations, it is unrealistic. The formation of the National Social Security System Regulation and the Healthcare and Social Security Agency Regulation has changed the government’s obligation to fulfill the right to people’s health into an obligation of the people to pay contributions so that the right to health is fulfilled, which is not in accordance with the norms of Article 28.
Paragraph (3) of the 1945 Constitution. The problem with the legal culture that was found was that there was fraud that occurred in various fields, from the basic to the high ranking officials. The management of national social security is carried out by accelerating the transfer of management of the Savings Fund and Civil Servant Insurance Company (Taspen) and the Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri) from the Ministry of the Indonesia State-Owned Enterprises to Healthcare and Social Security Agency, then synchronizing several laws and regulations in the field of social security systems.

Conclusion

There are legal problems related to the management of the National Social Security (JSN), which includes the structure, substance and culture of law. In the National Social Security (JSN) structure, the transfer of the Savings Fund and Civil Servant Insurance Company (Taspen) and the Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri) from the Ministry of the Indonesia State-Owned Enterprises to Healthcare and Social Security Agency in 2029 requires a period of 25 years, although juridically in accordance with statutory regulations, it is unrealistic. The formation of the National Social Security System Regulation and the Healthcare and Social Security Agency Regulation has changed the government’s obligation to fulfill the right to people’s health into an obligation of the people to pay contributions so that the right to health is fulfilled, which is not in accordance with the norms of Article 28 H Paragraph (3) of the 1945 Constitution. The problem with the legal culture that was found was that there was fraud that occurred in various fields, from the basic to the high ranking officials. The management of national social security is carried out by accelerating the transfer of management of the Savings Fund and Civil Servant Insurance Company (Taspen) and the Social Insurance of the Armed Forces of the Republic of Indonesia Company (Asabri) from the Ministry of the Indonesia State-Owned Enterprises to Healthcare and Social Security Agency, then synchronizing several laws and regulations in the field of social security systems.

Effect of Using Smart Mobile Device on Child Prosocial and Difficult Behaviors in School Age; Parents’ Perception

Samar Salah Eldin Mohamed Diab
Assistant Professor of Pediatric Nursing Faculty of Nursing, Menoufia University, Egypt

Abstract

Background: The time that children spend using digital devices is increasing rapidly with the development of new portable and instantly accessible technology. Mobile devices are embedded in and dominate the daily lives of young children. Research Aims: assess the effect of using smart mobile device on child Prosocial and difficult behaviors in school age. Methodology: A cross sectional research design was utilized at August 2019 - January 2020. Convenience sample include the 400 school children. An online survey by using Google form, which contains three parts (characteristics of parents, children and Strengths and Difficulties Questionnaire). Results: revealed that 47.2% and 47.7% of studied children had abnormal emotional symptoms and conduct problems. In addition (34.5%) of studied children was normal related peer problems domain. Also, (51.2%) of them was abnormal related hyperactivity. While, (30%) of studied children had normal Prosocial behavior. Conclusions: the current study concluded that about half of studied children had abnormal Prosocial and difficult behaviors and less than one quarter of them had borderline Prosocial and difficult behaviors. While, less than one third of them had normal Prosocial and difficult behaviors.

Keywords: Smart mobile, Prosocial, difficult behaviors, parent perception

Introduction

Mobile devices (mobile phones, + iPads /tablets, iPods, computers, etc.) play an increasingly important role in today’s rapidly changing and developing the information technology sector. They are becoming the preferred media choice for children because of their mobility, broad content, and interactivity. Mobile devices are embedded in and dominate the daily lives of young children.

Smartphone are becoming an important part of life for people of all ages worldwide, and Smartphone use has begun to change daily activities, family relations, and social interactions. Because smart phones can be carried easily and accessed anywhere and at any time and allow use of a variety of applications, overuse of Smartphone by children and adolescents has emerged as a significant social issue.

The time that children spend using digital devices is increasing rapidly with the development of new portable and instantly accessible technology, such as Smartphone and digital tablets. Furthermore, with the dramatically rapid development of media games, learning packages, and educational applications for young children, opportunities for using mobile devices have been growing, children’s usage time has become increasingly longer, and child target users of mobile devices are becoming younger.

Research suggested that cell phone exposure could affect children’s behavior. The children in the study who were hyperactive or had emotional or behavioral problems, including trouble getting along with other kids, were much more likely to have mothers who used...
cell phones during pregnancy. Excessive screen time is associated with poor sleep and risk factors for metabolic and cardiovascular diseases such as high blood pressure, obesity, low HDL cholesterol, insulin resistance, and reduced bone density.

The current generation is the first generation of children growing up with mobile devices from birth; hence, no empirical longitudinal data exist on the long term effects of mobile device usage on children’s development. A review of the literature on both mobile devices and social interaction practices indicated that, although mobile communication is becoming more prominent, what is not known is the extent to which social competency is affected by the way mobile devices are being used.

Aims
The current study aimed to assess the effect of using smart mobile device on child Prosocial and difficult behaviors in school age.

Research questions:
- What is the effect of using smart mobile device on child Prosocial and difficult behaviors?
- What are factors affect child’s Prosocial and difficult behaviors?

Methods
Research design: A cross sectional research design was utilized at August 2019 - January 2020

Research Setting: The study was carried out at primary schools in Menoufia Governorate. This study was conducted at Al-Nasr Primary School (governmental school) Serce Ellian city, Menoufia governorate. The number of classes in the school was 12 semesters, two classes for each grade, the average number of students per class was 51 children.

Subjects: Convenience sample include the school children were available and enthusiastic to participate at the study regardless gender and graduate year, with inclusion criteria age of children 6 -12 year and their parents had computer skills to full online questionnaire. At our study 422 children’ parents participate at the study and excluding 22 subjects due to incomplete the questionnaires, so total subjects were 400.

The estimated sample size was 422 school children, at confidence level 95%, and the precision rate at 0.05 by using the equation devised by Thompson (2012) as the total number of available of school children was 35200.

P= 0.5, N= Total population, Z= Z value “1.96”, D= Standard Error, n= sample size

Related to the principles and rules of social distancing and limit the spread of COVID-19, we used an online survey and using email, Facebook, Whatsapp and telegram services to collect the data from the parents of children. Google form permits questionnaire design, collection of data, descriptive analysis of results, and download data through excel spreadsheet for extra analysis.

The instruments:
Study instrument was designed by the researchers based on literature review related effect of using mobile on children behavior and included three parts:

Part I: Characteristics of the parents such as age, educational level, average spending time of talking or playing with children, monthly income and number of children.

Part II: Characteristics of the children such as age, gender, academic year, mobile devices child used, purpose of mobile device use and period mobile device used / day.

Part III: The Strengths and Difficulties Questionnaire (SDQ) is a 25-item measure of parents’ perceptions of their children’s Prosocial and difficult behaviors. The measure is categorized into five subscales: conduct problems (five items), hyperactivity/inattention (five items), emotional symptoms (five items), peer problems (five items), and Prosocial behavior (five items). In the
present study, the conduct problems, hyperactivity/inattention, emotional symptoms, and peer problems subscales were used to assess children’s emotional and behavioral problems. Items were rated on a 3-point Likert scale ranging from 0 (Not true), 1 (somewhat true) and 2 (Certainly true). Normal if score from (0 – 18), Borderline if score (19 – 21) and Abnormal if score (22 – 50).

**Pilot Study:**

The pilot study was conducted with 42 students who represent 10% of total sample at the previously mentioned settings in order to test the applicability of the constructed tools and the clarity of the included tools. Also, to assess the reliability and validity of developing tool before using at the study. The pilot also served to estimate the time needed for each subject to fill in the questionnaire.

A group of experts in the pediatric and community nursing ascertained the content’s validity; their opinions were elicited regarding the format, layout, consistency, accuracy, and relevancy of the tools. Reliability testing was carried out to test the reliability in terms of Cranach’s Alpha for instrument was 0.886, after deleted five items to improve reliability of the scale.

Data collected from the studied sample was revised, coded, and entered using Personal Computer (PC). Computerized data entry and statistical analysis were fulfilled using the Statistical Package for Social Sciences (SPSS) version 24. Data were presented using descriptive statistics in the form of number and percent. Pearson correlation coefficient was used to measure of linear correlation between two sets of data. A linear regression model is a linear approach to modeling the relationship between a scalar response and one or more explanatory variables.

**Ethical Consideration:**

The research ethics committee revised and approved the study. The submission of the online answer to the questionnaire was considered as consent to take part in the study. Confidentiality of the study subjects’ data was sustained throughout the study by making the students’ data nameless.

**Results**

Table (1) showed that (39%) of the studied parents their age was 28 - <38 year with mean 40.38±6.75 year and (54%) of maternal educational level was bachelor. Regarding to parent educational level, (39.7%) of them had secondary level. Also, (77.3%) of them spending time of talking or playing with children <60 minutes. Moreover, (56%) of them had insufficient monthly income and (41%) of them had one child.

Table (2) revealed that (40%) of the studied children had age ranged from 8 < 10 year with mean 8.95±2.46 year and (56.2%) of them were female. Regarding to academic year, (25.8%) of them was at third level. Also, (53%) of them used own mobile. Moreover, (50.7%) of them used mobile 60 m or more per day and (78.7%) of them used mobile device for learning/using applications related to education.

Table (3) demonstrated that, 47.2% and 47.7% of studied children had abnormal emotional symptoms and conduct problems. In addition (34.5%) of studied children was normal related peer problems domain. Also, (51.2%) of them was abnormal related hyperactivity. While, (30%) of studied children had normal Prosocial behavior.

Figure (1) illustrated that, (49%) of studied children were abnormal related their total strengths and difficulties questionnaire scale. While, (30%) of them were normal and (21%) of them were borderline related their total strengths and difficulties questionnaire scale.

Table (4) showed that, there were highly statistically positive correlation between emotional symptoms domain and their conduct problems domain, hyperactivity domain and Prosocial behavior domain at (P= 0.01). While there were slight positive correlation between peer problems domain and their emotional symptoms domain, conduct problems domain and hyperactivity domain at (P= 0.05).
Table (5) stated that high significant model detected through F test value was 12.210 with p value .000. This model explain 46% of the variation in children’s strengths and difficulties questionnaire detected through R2 value 0.46. Also, explained that, academic year, mobile device child used “own mobile”, period mobile device used per day had high frequency positive effect on children’ strengths and difficulties questionnaire at p value <0.01**. While, male gender and increasing age of children had slight positive effect on children’ strengths and difficulties questionnaire with p value <0.05.

a. Dependent Variable: Strengths and Difficulties Questionnaire

b. Predictors: (constant): Academic year, Gender “Male, Mobile devices child used Own mobile”, Period Mobile device used / day and Age

Discussion

According to parents’ characteristics, the current study demonstrated that mean age was 40.38±6.75 year and more than half of maternal educational level was bachelor. Regarding to parent educational level, more than one third of them had secondary level. Also, more than three quarters of them spending time of talking or playing with children <60 minutes. Moreover, more than half of parents had insufficient monthly income and more than one third of them had one child. These results inconsistent with the study conducted by Chang et al.3, who revealed that about three quarters had high income and mean of their age was 35.41±4.2. Also, disagree with the study performed by Kiliç et al.9 who detected that the minority of studied mothers and fathers had university education; more than one third of maternal education was primary.

Related children characteristics, the present results mentioned that revealed that mean age of studied children was 8.95±2.46 year and more than half of them were female. Regarding to academic year, about one quarter of them was at third level. Also, more than half of them used own mobile. Moreover, about half of them used mobile 60 m or more per day and more than three quarters of them used mobile device for learning/using applications related to education. These results explained as related COVID-19 pandemic and to achieve social distancing, electronic education has been relied upon, so the child’s interaction with mobile phones has increased during that period. These results in cohort with the study by Domoff et al.5 who reported that more than half of studied children were male and less than two thirds of
them had age less than 6 year. While, supported with the study conducted by Lee & Kim\textsuperscript{13} who stated that half of them were female and more than half of them used Smartphone more than one hour.

According domains of strengths and difficulties questionnaire scale, the current study demonstrated that less than half of studied children had abnormal emotional symptoms and conduct problems. In addition about one third of studied children were normal related peer problems domain. Also, more than half of them were abnormal related hyperactivity. While, only more than one quarter of studied children had normal Prosocial behavior. Also, about half of studied children were abnormal related their total strengths and difficulties questionnaire scale. These results attributed to more than half of studied children used mobile device more than 60 minutes per day and more than half of them had own mobile. These results similar with the study performed by Hosokawa & Katsura\textsuperscript{8} who detected that regular use of mobile devices was significantly linked to conduct problems (IPTW-OR: 1.77, 95% CI: [1.03–3.04], \( p < .05 \)) and hyperactivity/inattention (IPTW-OR: 1.82, 95% CI: [1.15–2.87], \( p < .01 \)). Also, regular with the study by Bozzola et al.\textsuperscript{2} who stated that using mobile device had negative effect on children behavior. In addition, similar with the study done by Kwon et al.\textsuperscript{11} who revealed that attention-deficit hyperactivity disorder symptoms were positively correlated with Smartphone addiction (\( r = .424, p < .01 \)) and poor sleep quality (\( r = .313, p < .01 \)). Also, supported with the study by Topan & Kuzlu Ayyildiz\textsuperscript{22} who reported that technological device use negatively impact on children physical and emotional health with \( p \) value <0.05\textsuperscript{*}. In addition, agreement with Liu et al.\textsuperscript{15} who demonstrated that violence/pornography on mobile devices were more likely to have emotional and behavioral problems.

Regarding to correlation between domains of strengths and difficulties questionnaire scale, there were highly statistically positive correlation between emotional symptoms domain and their conduct problems domain, hyperactivity domain and Prosocial behavior domain at (\( P= < 0.01 \)). While there were slight positive correlation between peer problems domain and their emotional symptoms domain, conduct problems domain and hyperactivity domain at (\( P= < 0.05 \)). These results cohort with the study performed by Panagiotidi & Overton\textsuperscript{18} who stated that there was highly significant correlation between Hyperactivity domain, inattention domain and withdrawal domain with \( p \) value <0.01\textsuperscript{**}.

According to Multiple Linear regression model, the current study explained that, academic year, mobile device child used “own mobile”, increase period mobile device used per day had high frequency positive effect on children’ strengths and difficulties questionnaire at \( p \) value <0.01\textsuperscript{**}. While, male gender and increasing age of children had slight positive effect on children’ strengths and difficulties questionnaire with \( p \) value <0.05. These results similar with the study conducted by Xie et al.\textsuperscript{23} who detected that gender was found to moderate the indirect effect of on mobile phone addiction. These results consistent with the study by Srisinghasongkram et al.\textsuperscript{21} who stated that had high significant correlation between gender and conduct, hyperactive behavior of child. Also, cohort with the study performed by Domoff et al.\textsuperscript{5} who detected that there was association between excessive mobile device use and children’s physical health outcomes.

**Conclusion**

To conclude our study, about half of studied children had abnormal Prosocial and difficult behaviors and less than one quarter of them had borderline Prosocial and difficult behaviors. While, less than one third of them had normal Prosocial and difficult behaviors. Also, academic year, mobile device child used “own mobile”, period mobile device used per day had high frequency positive effect on children’ Prosocial and difficult behaviors at \( p \) value <0.01\textsuperscript{**}. While, male gender and increasing age of children had slight positive effect on children’ strengths and difficulties questionnaire with \( p \) value <0.05.

**Conflict of Interest:** Not present any conflict

**Funding:** Self-funding, without any external source.

Nursing Intervention to Improve the Caregivers’ Practices toward Elderly Care at Geriatric Homes

Sanya Zakarya Mohammed1, Magda Abdelsattar Ahmad2, Nadia Hamed Farahat2
1Assistant Lecturer of Community Health Nursing, Faculty of Nursing, October 6 University, Cairo, Egypt; Studied at Faculty of Nursing, Ain Shams University, 2Professor of Community Health Nursing, Faculty of Nursing, Ain Shams University, Cairo, Egypt

Abstract

Population ageing is a global phenomenon with the number of persons 60 years and over estimated to reach two billion by the year 2050; living longer is joined to challenges of disability and being dependent on caregivers who should have the chance to perform their practices by professional way as an integral part of elderly care. Aim: To evaluate the nursing intervention program to improve the caregivers’ practices of elderly care at geriatric homes. Design: Quasi-experimental research design. Setting: In geriatric homes at Cairo governorate. Sample: A convenient sample of all elderly caregivers working in the previous mentioned settings. Tool: Was used an interviewing questionnaire to assess socio-demographic characteristics of elderly caregivers, their knowledge, their practices & factors causing stress to them & their coping with stress. Conclusion: The nursing intervention program implementation had statistically significant positive effect on elderly caregivers at geriatric homes regarding to their knowledge, practices & coping with stress.

Keywords: Elderly, Elderly Caregivers, Practice, Nursing intervention & Geriatric homes

Introduction

The trends of ageing in the Arab countries and the increase of life expectation at 60, is accompanied by an increase in disability rates for old age. In Egypt, in 2018, the number of elderly persons reached 6.410 million (3.418 million men, 2.992 million women) by the ratio of elderly, 6.7% (6.9% men, 6.4% women) of the total population, this number increased in 2031 to 11.5%. The total number of geriatric homes are 54 one, where there are 1774 elderly person & 639 caregiver.

As the numbers of elderly people requiring nursing or residential care increase, the professionalism of the elderly caregivers employed in this setting grows in importance. Caregiving is inevitably a demanding and stressful job in a complex organizational setting and it has been widely regarded as one of the most stressful occupations, associated with high levels of lacking of knowledge, skills & coping with work stress.

The role of the caregiver includes actions that are intended to assist the elderly people prevented physically or mentally from performing the practical tasks of activities of daily living and self-care. A caregiver is defined as being the person that is responsible for caring for a sick or dependent person, facilitating the performance of their daily activities, such as feeding, personal hygiene, providing routine medication and accompanying them to the health services, or carrying out other things required in their daily lives.

Geriatric homes provide a broad range of health-related services for people aged ≥ 60 years. The services provided include skilled nursing care, rehabilitation services, and dietary services. Disabling or burdensome disorders, most commonly dementia, incontinence, and immobility may
trigger consideration of geriatric home placement.\(^5\)

Nursing intervention through the community health nurse (CHN) is involved in primary, secondary, and tertiary prevention efforts for elderly and caregivers. The major areas in which CHN plays a vital role toward elderly are decrease of risk and maintenance of independence; supervision and encouragement of caregivers. CHN should become involved in exploring service options for elderly individuals and in educating the general public in the problems and needs of elderly individuals and their caregivers. These goals can be accomplished by designing and carrying an intervention that educate elderly caregivers and organizations or by advocating for legislation to assist elderly independence and elderly caregivers when possible.\(^6\)

### Aim of the Study

The aim of this study is to evaluate the nursing intervention program to improve the caregivers practices of elderly care at geriatric homes through:

1. Assessing caregivers’ knowledge about elderly care.
2. Assessing caregivers’ practices toward elderly care.
3. Assessing factors leading to stress to caregivers and influence the pattern of care provided to the elderly.
5. Designing and implementing a nursing intervention program to improve the caregivers’ practices toward elderly care at geriatric homes.
6. Evaluating the effectiveness of nursing intervention program to improve the caregivers’ practices of elderly at geriatric homes.

### Subjects and Methods

#### Research hypotheses:

The educational program will improve quality of life for adult client with a permanent pacemaker at home pre/post program.

#### Subject and methodology:

I- Technical design

II- Administrative and ethical design

III- Operational design

IV- Statistical design

#### I-Technical Design:

The technical design includes; the setting, sample & tools were used in the study.

#### B- Setting:

This study will be conducted to half number of districts in Cairo governorate, and select two geriatric homes of each district that more density in the following geriatric homes which located at Cairo governorate and these settings were chosen because they serve the community around Ain Shams University. Where those are; facility of mosenensamanelsheikh (Rod el farag), daranwaralmostafa & Dar mosenenalrahman (Almataria), botrosghaly for elderly (Alwaily), darmosenen and mosenat el hadialeslamy (Alsharabia), darMosenenalkhairiaaleslamia (alsaidazainab).

#### C- Sampling:

A convenient sample was used in this study. The total numbers of elderly caregivers who work in the previous mentioned setting were 73 person and pilot study it was chosen and carried out on 13 person whom & excluded later the study sample. The sample became 60 person for both genders (male & female), 10 persons from each geriatric home, elderly caregiver from 20 to 60 years old. Work at geriatric homes and accepting to participate in the study program.

#### C. Tools of data collection:

Four tools were used for data collection.

1. **Interview questionnaire form (Appendix I):**
   
The questionnaire sheet was designed by the investigator and written in simple Arabic language based on scientific
literature review, experts’ opinion and personal experience and filled. It is comprised of two parts:

**Part I:** It was used to assess demographic characteristics of elderly caregivers include age, gender, education, marital status, No of elderly people who are caring for and No of caregivers care for (preprogram)

**Part II:** It was used to assess knowledge about elderly care such as concept of aging, factors of elderly wellbeing, health problems related aging, human rights related elderly at geriatric home, normal changes related aging (physical, mental, social and psychological), daily care for elderly (physical exercises, healthy & balanced nutrition, sleeping disturbance, personal hygiene, bed sores, elderly falls) and first aids for common cases (bruises, fracture, fainting, diabetic coma, diarrhea and burn) (pre/ post program).

Scoring system for knowledge questions:

The questionnaire of the elderly’ caregivers related to knowledge (pre & post program application) was constructed in the form of Multiple Choice Questions. The right answers were scored one and those wrong were scored zero. These scores were summed-up and converted into a percent score and categorized into three levels as:

§ Poor: if the percent score was 70-100%
§ Fair: if the percent score was 50-69%
§ Good: if the percent score was 0-49%

**II. Reported practice through self-assessment tool (Appendix II):**

It was designed to assess the elderly’ caregivers practices and filled by investigator to meet their needs through asking questions regarding role of elderly caregiver to keep legal issues related elderly at geriatric home, meet elderly needs related aging (physically, mentally, socially and psychologically), perform daily care for elderly (physical activity, preparing healthy & balanced nutrition, provide safety during nutrition the elderly, defecating, sleeping & rest pattern), assist elderly according to his ability to do personal hygiene (mouth & teeth, hair, nail, foot care and bathing), provide safe environment for elderly, take care of unable elderly (mobilization in bed, ambulation (helps the elderly to get up and sit, helps the elderly to stand and walk), lifting from bed to chair & inverse, proper precautions to avoid bed sores, right steps for elderly bed lying bathing and first aids for common cases (nasal bleeding, bruises, fracture, fainting, diabetic coma, diarrhea and burn) (pre & post program application).

Scoring system for practices questions:

§ Score from 0 < 60 referred to not competent practices.
§ Score from 60 ≤ 100 referred to competent practices.

**III. Factors leading to stress to care givers (Appendix III):** The tool was adopted from Leonard & Shirley (1990) and adapted as translated; modified and filled by investigator to assess the factors causing stress to care givers (preprogram application) as follows:

A-Primary stressors of caregivers (that are based on the health, behavior and functional capabilities of the elderly):

1- Dependency in Activity of Daily Living.

It is used to detect dependency in performing activities of daily living (ADLs) and to plan care accordingly. In ADLs each function is scored at two-point scale (independent = 1 and dependent = zero). Summation of items scores yields a total score ranging from “zero to 6”. Where score 0 = low (very dependent elderly) and 6 = high (independent elderly).

2- Cognitive status of elderly: to measure the range and difficulty of caregiving activities and the ability of caregivers to manage their relationships with their impaired elderly grow out of the elderly’s memory loss, communication deficits, and recognition failures. The evaluation of cognitive status, although made by the caregiver, is based on standard tests typically used in the clinic. The questions asking about elderly’s cognitive status are 8 questions, presented in five scales placed in: can’t do at all = (4), very tough = (3), fairly tough = (2), just a little tough = (1) and not at all tough = (0). A score of 0 to 4
was given to each response, whereby higher scores indicated a stronger intention. The reliability (alpha) of this scale was 0.86.

3-Problematic Behavior: to measure the level of elderly’s awareness that must be maintained and the “damage control” that must be exercised to ensure that the elderly harms neither himself nor others constitute. It consists of 16 questions, presented in four scales placed in: 5/more days = (4), 3/4 days = (3), 1-2 days = (2) and no days = (1). A score of 1 to 4 was given to each response, whereby higher scores indicated a stronger intention. The reliability (alpha) of this scale was 79.

4-Overload (burnout felt by caregiver): the items constituting the measure reveal not only the level of fatigue felt by caregivers but also the relentlessness and rigid nature of its source. It was composed of 4 items and answers were coded according to the following: wholly = (4) score, quite a bit = (3), fairly = (2) and not at all = (1). By means of higher scores indicated a high stress because of overload.

B- Secondary stressors: Role strains and intrapsychic strains

5-Work colleagues conflict: to assess the elderly’ caregivers stress because of conflict with work colleague. Three dimensions of conflict was identified in issues of seriousness/safety of elderly, attitudes & actions toward elderly and attitudes and actions toward caregiver and composed of 9 questions. Where issues of seriousness/safety of elderly was included in 3 items (Q1-Q3), attitudes and actions toward elderly included was involved in 4 items (Q4-Q7), and attitudes and actions toward caregiver was comprised in 2 items (Q8-Q9). Answers were coded as the following: a lot of conflict = (4), some conflict = (3), just a little conflict = (2) and no conflict = (1). Through the higher scores indicated that care givers under high stress because of work colleagues’ conflict.

6- Personal Gain: the measure of personal gain or enrichment is proof to the fact that many people manage to findsome inner growth as they face the severe challenges of caregiving. Competence & gain were included partly out of interest in whether the enhancement of self is negatively related to stress outcomes, the deterioration of self to be positively related to stress. They were also included to determine if the enhancement of some elements of self-counter balanced or compensated for the deterioration of others. It was composed of 4 items and answers were coded according to response categories as follow: very much = (4), somewhat = (3), just a little = (2) and not at all = (1). By means of lower scores indicated a high stress.

7-Caregiving Competence: to measure the adequacy of performance as caregivers, (alpha = 0.74). Competence is measured by a four-item scale that essentially asks caregivers to rate the adequacy of their performance as caregivers and answers were coded as next: very much = (4), somewhat= (3), just a little = (2) and not at all = (1). By means of lower scores indicated a high stress as inability to be adequate at perform caregiving.

IV: Caregivers Coping with stress (Appendix IV): the tool was adopted from 7,8&9 and adapted as translated, modified and filled by investigator to assess caregivers coping with stress(pre & post program application) as follows; caregivers coping in response to elderly caregiving problems as having three possible functions: management of the situation giving rise to stress; management of the meaning of the situation such that its threat is reduced; and management of the stress symptoms that result from the situation. Where function of management of the situation was included in 6 items (Q1-Q6), management of the meaning of the situation was involved in 8 items (Q1-Q8), where this item involves three parts, one involves the reduction of expectations (Q1-Q3), a second the use of positive comparisons (Q4-Q5), and the third a search for a larger sense of the illness (Q6-Q8),and management of the stress symptoms was comprised in 6 items (Q1-Q6). Answers were coded according to the following: very often = (4), fairly often = (3), once = (2) and never = (1). Through the higher scores indicated that care givers can represent coping behaviors and practices to manage stressors that lead to from caregiving to the elderly at geriatric homes.

The Validity: it was tested through 5 experts, from community health nursing department, faculty of nursing, Ain Shames University.
The reliability was done by Cronbach’s Alpha coefficient test which revealed that each of the three tools consisted of relatively homogenous items as indicated by the moderate to high reliability of each tool, where the reliability of them was 0.831

III. Operation design:

The operational design for this study consisted of three phases, namely preparatory phase, pilot study, and fieldwork.

A. Preparatory Phase

This phase included reviewing of literature related to caregivers’ knowledge about elderly care at geriatric homes by using books, articles, journals, and internet, in order to get a clear picture of the research problem, as well as, to develop the study tools for data collection. During this phase, the investigator also visited the selected places to be familiar with the personnel and the study settings. Development of the tools was under supervisors’ guidance and experts’ opinions were considered.

B. Pilot Study

A pilot study was conducted on ten of the elderly caregivers in the pre-mentioned settings, in order to test the eligibility, including the suitability and feasibility, availability of the study population. Also, to determine the time required to conduct the constructed research tools. Modification of the tools was done based on the findings of the pilot study, some questions and items were omitted, added, or rephrased, and then the final form was developed. The subjects included in the pilot study were excluded from the study sample.

C. Fieldwork

After obtaining a permit the investigator started to interview the caregivers. The investigator started with introducing herself and explaining the aim of the study for the subjects. The investigator assured that the data collected will be confidential and would be only used to achieve the purpose of the study. Caregivers were asked to answer the pretest questions to fill the interviewing questionnaire. The investigator asked the question and recorded the answers and each interview lasted for approximately 30 minutes to answer these questions. The investigator collected the sheets and checks any missed item.

All tools were used to get a baseline assessment for the elderly caregivers prior to the development of the program, and also used after the program implementation, in order to compare between the findings results (pre & post) to determine the level of improvement.

Data collection for this study was carried out within a period of six months, started from the beginning of December 2019 till the end of May 2020. The investigator visited the selected settings (six geriatric homes) as follow; 2 geriatric homes for 2 months, 4 days per week (Friday, Saturday, Sunday and Monday) 2 days for each geriatric home from 9 am to 1 pm.

The investigator had identified an appointment from the subjects for meeting them at the geriatric home which include an assessment for caregivers’ knowledge & practices. Also, the assessment was done after program implementation.

The intervention aimed to increase elderly caregivers’ knowledge and skills through 8 weeks (two-hour per week). 60 caregivers divided into 6 groups where each geriatric home represents one group, the number of caregivers attended in each session was 10 elderly caregivers. At the end session of program implementation, the investigator evaluates the caregivers’ knowledge & practices to ensure exposure of all elderly caregivers to the same learning experience, each of them received the same program content, using the same teaching strategies, discussion, and correction on the spot and real objects.

Program construction:

The educational program was constructed by the investigator and consists of the following stages:

• Preparatory stage, which included selection of the specific program, related topics outline, objectives, knowledge which based on the identified needs of caregivers through the data obtained from pre-assessment tools. The investigator conducted advanced
search for relevant studies on local and global levels. Search process included libraries of local universities, regional electronic web sites especially those of Egypt, and global electronic web sites including PubMed, Cochrane library, Medscape, and Medline, and the items needed to be included in the educational program were identified. The constructed program was disseminated to a panel of experts to be evaluated. The investigator took all comments of experts into consideration and modified.

- **Planning stage**, which plans for a series of sessions and preparing the suitable media.

- **Implementation stage**, where the program was implemented through application of Communication techniques and teaching-learning strategies. Lecture, discussions and demonstrations of the practical skills were approached as teaching methods. Audiovisual methods such as PPT, Videos, Handouts and Poster were used to facilitate the process of education. The investigator planned to meet the caregivers at the selected geriatric homes. The program was practical in nature, to improve elderly caregivers’ practices, based on one-to-one caregiver assessments. Knowledge and practices for each group by the end of the teaching experience were revised. Time was opened for attendance to ask questions and to receive the corresponding answers as well as to express their feedback toward the teaching session.

**Program sessions:**

Time allowed: 16 hours has been allocated for health education sessions. Involve theory and practices training. Teaching sessions were conducted at any available hall at each geriatric home were student being 6 grouped and every group included (10) caregiver.

At the beginning of the first session, an orientation about the program and its purposes was given. It was agreed at the time of the break with the elderly caregivers. From the second session and so on each session started by a summary about what was given through the previous sessions and objectives of the new one.

By the end of each session a summary was made and time allocated for questions and answers & plan for next session were made. Except for the last session a termination of sessions through feedback was done.

Educational media will use the poster, laptop, guidance handout which includes instruction and information for caregivers as a reference during and after program implementation. Teaching material will use Arabic Handout and audiovisual materials.

- **Evaluation of the program**, this stage aimed to evaluate the level of improvement in elderly caregivers’ knowledge, practices and their coping with caregiving stress through implementation of program. This was done through giving posttest similar to the pretest, evaluation administered to study subjects after completion of the program in order to estimate the effect of program on elderly caregivers’ knowledge and practices related to elderly care.

**Program Handout:**

The educational handed was designed by the investigator, including the all content of the program and given to as an educational reference during program implementation and as self-learning reference after program implementation. Its aim was providing accurate knowledge & practices related guideline instructions about obesity, risk factors and its consequences.

**Ethical consideration:**

Verbal approval was obtained from the caregivers before inclusion in the study; a clear and simple explanation was given according to their level of understanding, physical and mental readiness. They secured that all the gathered data was confidential and used for research purpose only.

**The ethical research considerations include the following:**

§ The research approval was obtained from the faculty ethical committee before starting the study.

§ The investigator clarified the objectives and aim of the study to caregivers before starting
§ The investigator was assuring anonymity and confidentiality of subjects’ data included in the study.

§ The subjects was informed that they are allowed to participate or not in the study and they have the right to withdraw from the study at any time.

**Limitation of the Study:**

1. Some geriatric homes {Dar mosenatalkarma&Agaezaramelahkarma (Shobra), Mosenena and mosenatalkelmaaltaeba&alqswahba (Alsahel)} refused the conduction of any kind of research for fear of transfer of infection of COVID-19.

2. The geriatric homes {Facility of mosenatsaneaelkhairat (Rod el farag), Evergreen (Alwaily), Dar Mosenenyomalmostashfiat (alsaidazainab)} were excluded from the sample because there was lack of flow of elderly caregivers, where they terminated from work.

**III- Administrative design:** To carry out this study, a letter was issued to pre-mentioned settings from the dean of Faculty of Nursing, Ain Shams University explaining the aim of the study to obtain permission and help. The necessary approval letter was obtained from the head of geriatric homes in pre-mentioned settings. The title, objectives, study technique and tools were explained to gain their approval in data collection.

**IV. Statistical design:** Data were revised, coded, analyzed and tabulated using the number and percentage distribution and correlations and carried out in the computer. The statistical analysis was performed using the statistical package for social science (SPSS) program, version 20 for Windows Data Editor.

**The following statistical techniques were used:**

Percentage, the arithmetic mean (X), the standard deviation (SD), the chi-square test (X2), and proportion probability (P-value).

**Results**

Table 1 displays that the caregivers’ age ranged between 20 to 60 years old. 40% of them were between age 41 and 50 years. As regard gender, it was found that the 71.7% of caregivers were females. Regarding educational level 58.3% has basic education. Concerning marital status, the table shows that 55% of the sample was married. Regarding the number of elderly people who are caring for, it was found that, 73.3% was caring for more than three elderlies. In relation to the health condition of the elderly person who cares for him the table shows that, 70% of caregivers were caring for both able and unable elderlies.

Figure (1): Distribution of total knowledge of the elderly caregivers about elderly care at geriatric homes (n= 60).

X268.217 at P <0.001***

*** Very highly statistically significant
Figure 1, indicated that, 3.3% of the elderly caregivers had good knowledge preprogram implementation regarding the total knowledge about elderly care at geriatric home, improved to 75% post program implementation with very highly statistically significant differences at P value < 0.001***

\[
\chi^2 = 34.17 \text{ at } P < 0.001^{***}
\]

*** Very highly statistically significant

For the total practices of the elderly caregivers toward elderly care at geriatric home, the above figure showed that 25% of the elderly caregivers were competent preprogram, while they improved to 78.3% post program implementation with very highly statistical significance at P value <0.001***

Figure (3): Distribution of the elderly caregivers according to total factors leading to stress to them (pre-program) (n= 60)
The above figure indicates that, total factors leading to stress to the elderly care givers were 76.7% of them felt stress in caring of their elderlies at geriatric home.

**Figure (4): Distribution of the elderly caregivers according to their total coping with stress (pre / post program) (n= 60).**

X234.17 at P<0.001***

*** Very highly statistically significant

The above figure, pronounced that total elderly caregivers’ coping with stress regarding being confronted were 25% preprogram changed to 78.3% post program application, there was a very highly significant difference between caregivers’ coping with stress regarding being confronted pre, post program application at P<0.001***

**Discussion**

Population ageing is a global phenomenon with the number of persons 60 years and over estimated to reach two billion by the year 2050; for some persons, living longer is accompanied by challenges of disability and being dependent on others to assist with everyday tasks. Already, 101 million people 60 years and over worldwide are estimated to be care-dependent.

Elderly caregivers should have the opportunity to perform their practices by professional way on a day-to-day basis as an integral part of elderly care. That is why the current study was carried out.

According to demographic characteristics of the elderly caregivers, the present study found that, elderly caregivers’ age ranged between 20 to 60 years old with two fifths of them age was ranged from 41 to less than 50 years old with the mean age was 38.53 ± 9.79. (Table 1). The findings of the present study are consistence with Van Houtven et al.10 who studied essential long-term care workers commonly hold second jobs and double or triple duty caregiving roles in northeastern United States who stated that, the mean age of long-term care workers was 41 years.

Bilal et al.11 disagree with the current results, where the previous study about elderly care in the time of coronavirus: perceptions and experiences of care home staff in Pakistan found that, the majority of elderly caregivers were less than 40 years. In this regards Shi et al.12 who studied Perceived stress and social
support influence anxiety symptoms of Chinese family caregivers of community dwelling older adults: a cross-sectional study illustrated that 39.83% of caregivers were less than 40 years.

Concerning gender, the current study demonstrated that, the dominance of females than males, who were in common married. this finding is in agreement with that of Moholt et al.13 who studied the factors affecting the use of home-based services and out-of-home respite care services: A survey of family caregivers for older persons with dementia in Northern Norway who reported that the more than three fifth of elderly caregivers were females. As well, Fagerström et al.14 who found in their study about the analyzing the situation of older family caregivers with a focus on health-related quality of life and pain: cross-sectional cohorts study in Sweden that, the great majority of their studied sample married.

This trend was opposite to what was found in a study in China by Shi et al.12 who found that, more than half of the studied sample were married men, in this regards James et al.3 revealed in their study about socio-demographic, health and functional status correlates of caregiver burden among care recipients age 60 Years and older in Jamaica that, more than half of the studied sample were single female. In Egypt, caregiving is a female occupation, and this give a reason why the majority of the study sample were more females than males.

In relation to the level of education, this study revealed that, more than half of them had basic education. This explains why they are not responding easy to the knowledge given to them so most of them feel stress in caring of their elderlies at geriatric home. This finding is in agreement with that of Ekström et al.15 who studied high burden among older family caregivers is associated with high prevalence of symptoms: data from the Swedish Study “Good Aging in Skane (GAS)”. Where they concluded that, more than one third of caregivers were with low educational level. Contradicting with the previous findings, Kehoe et al.16 found in their study about quality of life of caregivers of older patients with advanced cancer in United States that, more than half of the studied caregivers obtained some college or above.

As regard to total knowledge of the elderly caregivers about elderly care at geriatric homes pre/post program (Figure 1) the present study revealed that, only 3.3% of them had good knowledge preprogram implementation, while changed to three quarters of them post program implementation with very highly statistically significant differences pre/post program for elderly caregivers, this finding agree with a study about training of formal caregivers dealing with Alzheimer diseased patients at Helwan City Cairo Egypt by El-Kattan et al.17 who find that the pre/posttests among formal caregivers revealed that overall knowledge, attitude and practices improved with highly statistically significant differences at p < 0.001 that approved the hypothesis of implementing training program for formal caregivers.

Concerning total practice of the elderly caregivers about elderly care at geriatric homes pre/post program (Figure 4) the present study shown that, one quarter of them were competent preprogram implementation, while improved to more than three quarters of them post program implementation with very highly statistically significant differences pre/post program for elderly caregivers, this finding was in concordance with previous study about the effectiveness of a training program in developing professional performance of social workers with elderly groups in Egypt by 18 who indicated that the results of the research training program succeeded to develop this professional performance.

In relation to the total factors causing stress to caregivers preprogram (Figure 5). The current finding denoted that, more than three quarters of them felt stress in caring of their elderlies at geriatric home. These results agreed with those of Rachel and Francesco19 Who studied factors associated with and impact of burnout in nursing and residential home care workers for the elderly which conducted across a range of academic databases and suggested that nursing care aids working within nursing homes have high levels of job efficacy.
(a facet of burnout) but also hold a moderate risk for burnout domains of emotional exhaustion and cynicism. This would suggest that although care home workers place value and importance in the work they do, they also have a risk for developing a distrustful attitude and levels of emotional exhaustion. It is concerning to note that studies have reported how time worked at a nursing home negatively predicts personal accomplishment, a burnout factor. That is, the longer that staff worked at a nursing home, the lower their level of satisfaction and accomplishment around their work.

Considering total coping with stress pre/post program (Figure 6) from the data gathered, it appears that, one quarter of them was confronted pre-program implementation, while enhanced to more than three quarters of them post program implementation with very highly statistically significant differences pre/post program for elderly caregivers. This finding goes in the same line with the study about effect of counseling on burden and coping among caregivers of cancer patients with terminal illness in Kanyakumari District in Asia by Sam et al. who showed that, the pretest mean coping score was 27.46 ± 8.02 and the post test score was 92.66 ± 7.15 and statistically significant. And the counseling program is effective in reducing the level of burden and improving the coping among primary caregivers of terminally ill cancer patients.

**Conclusion**

The educational program implementation had statistically significant positive effect on elderly caregivers at geriatric home regarding their knowledge, practices & coping with work stress.

**Recommendation:** Continues of geriatric home program to all elderly caregivers to improve their knowledge and practices regarding elderly care. A further research on a large sample is recommended to achieve more generalization.

Assessment of Knowledge and Awareness about Medico Legal Issues among Interns and Post Graduate Students in Rajahmundry, Andhra Pradesh

Saptarishi Bose\(^1\), Naresh Jyothula\(^1\), U. Vinod Venkata Kumar Andey\(^1\), Ganapathi Swamy Chintada\(^2\), Paromita Roy\(^3\)

\(^1\)Assistant Professor, \(^2\)Associate Professor, Dept. of Community Medicine, \(^3\)Senior Lecturer in Dept. of Oral Medicine & Radiology at GSL Dental College, Rajahmundry, Andhra Pradesh

Abstract

In recent times there has been increased number of complaints and lawsuits against doctors. Therefore having knowledge about Medico Legal issues is as important to the practice of medicine as clinical skills. The present study was conducted to evaluate Awareness and Knowledge about Medico Legal issues among Interns and Post Graduate Students. Total 140 interns and 110 Post Graduate students participated in the study. Post graduate students had more knowledge about Medico Legal issues and consent than interns but there was deficit of knowledge about Injury and Death certificates. About Consumers protection act (COPRA) there is little awareness but regarding Human organ transplantation Act (HOTA) and Hospital indemnity Insurance awareness should be increased. Our study conveys that action should be taken to cover the lack of awareness and knowledge for doctors as well as patient safety.

Key Words: Medico Legal issues, Consent, Consumers protection act, Interns, Post Graduate students Rajahmundry, Andhra Pradesh

Introduction

It is important to have a good knowledge of all the branches of medical and ancillary science taught to a medical student during the course of studies for an expert medical witness\(^1\). The trainee period is a critical time for foresting ethical reasoning\(^2,3\). Good medical practice requires that medical graduates can demonstrate in practice knowledge and understanding of the law\(^4\).

Universal trends of medico legal issues are slowly gaining the attention of the public and complaints against physicians looks to be going up in developing countries. This has brought to the fore need for a high sense of professionalism among health care practitioners. This professionalism depends on knowledge and application of medical ethics in daily practice of the practitioners\(^5\). The knowledge of Medico Legal issues are essential for maintaining the patient doctor relationship and prevent the commercialization of the profession\(^6,7\). Lack of understanding of legal aspects of medicine practice is important matter that needs to be dealt promptly\(^8\).

However, it is not possible for medical schools to give ample time to teaching of ethics, confidentiality and medico legal issues. The curriculum on medico legal issues may be inadequate or impractical enough to permit the medical students to address all ethical difficulties likely to be faced in practice\(^8\). Widespread deficiencies in knowledge and understanding of legal rules has been reported by students and practicing doctors.

Training period is the crucial time for developing the ethical views and awareness in young doctors\(^2,7\). Doctors get acquainted with the regulations and laws that deal with in their practice. Doctors deal with many ethical moral and legal obligations in their duties.
It is therefore very important that every doctor understands the nature of these obligations and then fulfils these obligations to the best of their ability\textsuperscript{9,10}. They should improve the quality of patient care by identifying, analyzing and attempting to resolve the ethical problems that arise in practice\textsuperscript{2}.

Medical practitioners must be aware of legal and ethical implications of clinical practice\textsuperscript{11}. Law and Medicine go hand in hand. The recent trends towards codifying the individual rights and freedom has filtered down to the relationship between physicians and patients\textsuperscript{12}. Future doctors must have a good grasp of the law and the confidence to apply the understanding if they are to uphold and advocate effectively for the legal rights of patients\textsuperscript{4}.

By keeping these things in mind we carried out our present study to assess Knowledge and Awareness about Medico Legal issues among Interns and Post Graduate Students (PG Students).

Objective:

To assess knowledge and knowledge about Medico Legal Issues among Interns and Post Graduate Students.

Material and Methods

A questionnaire based cross sectional study was conducted in GSL Medical College and General Hospital, Rajahmundry, Andhra Pradesh, India, in month of October to November 2020. The study was carried out in and 140 Interns and 110 Post graduate Students. Aim of the study was explained to the participants and written informed consent was obtained from them. Confidentiality about the result was ensured to participants so as to get reliable answers. Those who not willing to participate were excluded from the study. A structured self administered questionnaire related to medico legal cases(MLCs), Consent taking, Consumers protection act(COPRA), Human organ transplantation Act(HOTA), Hospital indemnity Insurance containing 14 questions were designed. The data was collected, tabulated and analysed statistically for numbers and percentage.

**Questionnaire :**

1. Do you know what is the Medico Legal case(MLC)?
2. Do you know your responsibilities while handling Medico Legal case?
3. Which is the best type of consent in MLC?
4. For how many years Hospital is legally bound to maintain the Medical records?
5. Do you know steps in management of poisoning case?
6. Do you know which preservatives are used for gastric lavage in poisoning cases?
7. Do you know Rule of nine?
8. What evidence should be collected in case of Sexual Assault cases?
9. Do you know how to give Injury certificate?
10. Do you know how to give WHO Death certificate?
11. Which cases require Medico legal Autopsy?
12. Do you know what is COPRA(Consumers Protection Act)?
13. Do you know what is HOTA(Human organ transplantation Act)?
14. Do you know about Hospital indemnity Insurance?

**Results:**

Total 140 interns and 110 PG students were included in our study, out of which it was observed that 53 interns and 71 PG students can identify the MLC and know about their medico legal responsibilities while handling the case.

<td>47(43%)</td>
</tr>
</tbody>
</table>

62% interns and 93% of PG students were aware that Written and Informed consent is the best type of consent in MLC. 46% interns and 80% PG students knew about Medical record keeping in Hospital.

24% interns and 63% PG students knew about the steps in management of poisoning cases and the preservatives used for analysis of gastric lavage. Rule of nine which is utilized to calculate and manage burn cases was known to 65% interns and 70% PG students, but very few i.e. 21% interns and 47% PG students knew about evidence to be collected in Sexual assault cases.

20% interns and 30% PG students were knew the proper way to write Injury certificate, but only 14% interns and 25% PG students were aware about Death certificate designed by WHO (World Health Organization). 48% interns and 76% PG students were aware of the cases which needed Medico legal Autopsy.

45% interns and 88% PG students know about Consumers protection act (COPRA) but only 12% interns and 40% PG students know about Human organ transplantation Act (HOTA). Hospital indemnity Insurance which holds big importance for Private Practitioners was known to 11% intern and 43% PG students.

Discussion

An MLC is defined as case of injury/illness where the attending doctor, after taking proper history and examination of patient, has the impression that some investigation by law enforcement agencies is essential to establish and fix responsibility for the case in accordance with the law of the land. Many doctors
are apprehensive in handling such cases may be because of fear, unwarranted laws and regulations, attending the court, harassment by the lawyers and questions by police personnel\(^{14}\).

With the increase in use of internet and social media, there is an increase in awareness among public on subject of ethical conduct of medical practitioners. Hence there are more cases against doctors. This issue is of immediate concern to medical fraternity. Hence all medical practitioners must be aware of legal and ethical implications of clinical practice.

We carried out a study to determine the knowledge and awareness in interns and PG students in our institution. In our study of 140 interns and 110 PG students we noticed that PG students were more aware about MLCs than that of interns may be because they are exposed to more MLCs during their post graduation. This is in accordance with the study by Dash S.K. in 2010\(^{9}\).

Most Interns and PG students had good knowledge about written informed and valid consent but less were aware about medico legal record keeping in hospital. There is no certain time limit after which Medico Legal reports can be destroyed; so they have to be preserved carefully. In view of the multitude of cases against the doctors under the Consumer Protection Act, it is advisable to preserve all the inpatient records for at least 5 years and outpatient department records for 3 years\(^{13}\). This was known to less participants. This finding is similar to study conducted by Rai JJ, et al among interns and postgraduates about medical law and negligence in Vadodara in 2016\(^{2}\).

PG students can manage the poisoning cases and know how to preserve the gastric lavage, but both interns and PG students don’t know exactly the matter and manner of injury certificate and WHO death certificate i.e. How to write immediate, antecedent and other cause of death in death certificate. Our findings are in agreement with study to assess the need of Medico legal Education in interns and residents by Pratibha Mardikar and Arti Kasulkar in 2015\(^{15}\). Medical council of India (MCI) has recommended that it is compulsory to know about injury report, collection of biological material and all aspects of medico legal cases for MBBS graduates\(^{13}\).

Interns and PG students are aware about COPRA but very less is known about HOTA and Hospital indemnity insurance. Awareness about human organ donation among people is more due to social media, doctors should also make themselves aware about laws related to the same. Due to increase in medical negligence cases by doctors should have their Hospital indemnity insurance. Workshops related to various medical acts should be conducted regularly so as to update the knowledge.

**Conclusion**

This study was an attempt to evaluate the Knowledge and Awareness of Medico Legal issues in Interns and Post Graduate Students. Majority of the interns have lack of knowledge about Medico Legal issues while average PG students are aware about ML cases and can handle them independently. But both have poor knowledge about certificates, laws and hospital indemnity insurance. One month compulsory posting in Forensic Medicine Department should be introduced in their training period to increase the knowledge and awareness about Medico Legal issues. Also Medical associations should try to organize seminars, case discussions and CME’s for interns and post graduates to increase awareness and to update them about Medico legal issues in medical practice.

Human Fatalities from Wild Elephant Attacks: A Fiveyear Autopsy-Based Study

Saptarshi Chatterjee¹, Ranjan Biswas², Tanmay Sardar¹, Shobhan Roy³

¹Associate Professor, Department of Forensic Medicine and Toxicology, ²Assistant Professor, Department of Psychiatry, Bankura Sammilani Medical College, Bankura, West Bengal, ³Assistant Professor, Department of Forensic Medicine and Toxicology, Deben Mahata Government Medical College, Purulia, West Bengal

Abstract

Background: Human-Elephant Conflict may take many forms, from crop raiding and infrastructural damage, to injury or death of humans or elephants. Conflicts or co-existence between human and wildlife is mostly attributed to the loss, degradation, and fragmentation of wildlife habitats through human activities like logging, animal husbandry, agricultural expansion, and development projects. The present study is conducted to study the prevalence of fatal wild elephant attacks, the socio-demographic profiles of the victims along with their nature of injuries and the risk factors associated with these conflicts.

Methods: This is a cross-sectional descriptive study, which was conducted by analysing 41 cases of fatal Human-Elephant Conflicts, which attended to B.S. Medical College Police Mortuary between 2015 to 2019.

Conclusion: Authors feel that the blockage of elephant migratory routes, coupled with cultivation of elephant preferred crops and scarcity of food in the forest in some season, inevitably attracts more human-elephant conflicts.

Keywords: Human-Elephant Conflict, Musth, Crop raiding

Introduction

Expansion of human settlements and agricultural fields across Asia and Africa has resulted in widespread loss of elephant habitat, degraded forage, reduced landscape connectivity and a significant decline in elephant populations relative to their historical size and overall range ⁴. As their habitats shrink, elephants are progressively forced into closer contact with people, resulting into more frequent and severe conflicts over space and resources with consequences ranging from crop raiding to reciprocal loss of life. Fatalities due to animal attack are rare in forensic medical work, but have been known to pose problems due to their potential to mimic homicide ².

Human-elephant conflicts (HEC) have been a common phenomenon, which accounts for 1,713 human and 373 elephant deaths by unnatural causes, including electrocution and poaching ³. The conflict occurs when the needs and behaviour of wildlife impact negatively on the goals of humans, or when the goals of humans negatively impact the needs of wildlife ⁴. Conflicts or co-existence between human and wildlife is mostly attributed to the loss, degradation, and fragmentation of wildlife habitats through human activities like logging, animal husbandry, agricultural expansion, and development projects ⁵.

Dr. Shobhan Roy
Assistant Professor, Department of Forensic Medicine and Toxicology, Deben Mahata Government Medical College, Purulia, West Bengal
Though human deaths from wild elephant attack is common in various parts of the country, including West Bengal, reports on autopsy-based studies are scarce in literature. The most recent assessment in West Bengal on the number of human injuries and fatalities from wild elephants was conducted about 10 years ago. In this backdrop, the present study is conducted to study the prevalence of fatal wild elephant attacks, the socio-demographic profiles of the victims along with their nature of injuries, who fell prey to these wild elephants. Our study also aims to assess the common risk factors contributing to these HEC, and hence to suggest preventive strategies to be taken to protect the vulnerable population from the wild elephant attack.

Aims and Objectives

1. To study the prevalence of deaths due to wild elephant attacks from 2015 to 2019.

2. To study the socio-demographic profiles of the victims of elephant attacks.

3. To analyse the nature of injuries on the victims.

4. To assess the risk factors of human-elephant conflicts.

Materials and Methods

a. Place of study: Bankura Sammilani Medical College Police Mortuary, Bankura, West Bengal, India.

b. Period of study: 1st January – 30th June, 2020

c. Study population: All the patients sent for autopsy examination at BS Medical College Police Mortuary between 2015 to 2019 (From the Post-Mortem register)

d. Sample size: All the victims of fatal elephant attacks, attended to BS Medical College Police Mortuary for autopsy examination between 2015 to 2019.

· Exclusion criteria:
  i. Victims of fatal animal attacks, other than elephants
  ii. Cases with incomplete or inadequate history

e. Study design: Cross-sectional descriptive study

f. Source of data:
  i. Post-Mortem register of Bankura Sammilani Medical College Police Mortuary

g. Statistical analysis: Details regarding the cases were obtained from the inquest report, interviewing the eyewitnesses and the family members of the deceased. All the data were manually checked and edited for completeness in a pre-determined format and were then coded for computer entry. Collected data was recorded in Microsoft Excel worksheet and SPSS IBM 19. The data was collected, tabulated and statistically analyzed by applying student’s t-test. The p <0.05 was considered as statistically significant.

Results

1. Prevalence of Fatal Human elephant conflicts

The number of victims due to HEC was maximum in 2015, with a gradual decline over years [Figure 1].

2. Distribution according to age

Majority of the victims of fatal HEC belong to the age group of 30 to 70 years [Figure 2].

3. Distribution according to gender

Of all the victims of fatal HEC, males constituted 63.4% and the rest 36.6% were females.

4. Distribution according to residence

In our study, 38 out of total 41 victims (92.68%), belonged from places situated within 6 kilometres from the jungle.

5. Place of occurrence
28 victims (60.9%) were attacked in the crop fields, 5 victims (12.2%) each in jungles and roads, and the remaining 3 victims (7.3%) in their respective houses.

6. Time of attack

46.3% of the victims were attacked in between 8.00 pm and 12.00 midnight, followed by 28.8% of the victims between 4.00 pm and 8.00 pm. The rest 26.83% of the victims fell prey in between 12.00 at midnight to 8.00 in the morning.

7. Situations leading to Human-Elephant conflicts

As stated by the eye witnesses during interaction and inquiry, 41% of the victims were drunk and were chasing elephants in the crop fields and near households, 27% were returning home after dark from work, 11% had gone collecting fuelwood from the forests and 10% were defecating in the open at night. 3 victims succumbed to the injuries in their sleep, when their mud house’s wall accidentally caved in to an elephant’s rampage. One woman was attacked by a tusker, as she tried to offer prayers to the elephant in the name of a Hindu god.

8. Distribution according to months

Maximum number of deaths due to HEC was recorded between February to May [Table 1].

9. Causes of death of the victims

In our study, 37 victims (90.2%) died due to trampling of vital organs and three persons died due to traumatic asphyxia as a result of house collapse in their sleep. The body of the woman, who went to offer prayers, exhibited one fatal perforated wound in the abdomen produced by the tusk.

10. Elephants attacking in herd or single

In all the cases, the aggressors were lone tuskers, except three cases where the offender was a female elephant in herd.

**Discussion**

Elephants are usually peaceful animals. Females may, however, become aggressive when they are excessively irritated by the villagers and when they apprehend dangers to their young. Bulls can be exceptionally aggressive during musth, when they usually venture away from their home range in search of mating opportunities. All elephants may become aggressive when sick, injured or harassed.

According to the Union Environment Ministry, 2,398 people have died since 2014 up to March 31, 2019 due to Human-Elephant conflicts, with West Bengal recording the maximum 403 deaths in last five years. However, in our study, a total of 41 people died due to HEC from 2015 to 2019, with a steady decline in the mortality rate from 2016 onwards. A combination of early warning to detect elephants before they enter the crop fields and the employment of elephant driving squads, coupled with a front line communal guarding strategy proved most successful. Consistent to another study from the same region, the majority of the victims were between 30 to 70 years, with males predominating in all the age groups. Farmers and labourers are mostly males and often go alone in the forest path or work in agricultural lands near forest, and thus, they are most vulnerable to these human-animal conflicts.

Previous studies concluded that elephants do not discontinue using the high-risk human settlements, which were once part of their original home range and instead modify their activities by travelling faster or being nocturnal within such areas. Human mortality and morbidity in population residing around forest areas are primarily due to continued harassment and taunting of elephants while being driven back to forests from crop fields or by getting too close or getting involved in provoking activities to already injured, traumatized, harassed mammals or males in musth or females with young calves. The same findings are being reflected in our study, where more than 90% of the victims recorded their residence within 6 kilometres from the jungle, making themselves more vulnerable to the fatal HEC.

Human-elephant conflicts can be largely attributed to colonialism, with the people taking over the elephants’
indigenous culture, as they are pushed into smaller places and killed outright. Elephants need a large space to roam, with lots of vegetation and abundant water supplies to help them digest all that roughage. When those areas are taken up with human crops, elephants are happy to adjust eating corn or other plants meant for people. This very fact is amplified in our study, where the majority of the deceased were attacked in their crop fields. Chattopadhyay and Das reported that most of the incidents were noted between 4.00 am to 6.00 am. Contrary to this finding, critical time of major HEC in our study was between 8.00 pm to 12.00 at midnight, where almost 3/4th of the victims got affected while chasing elephants under intoxication or during late homecomings from workplaces. The growth of industries in the last ten years with increased employment and increased cash flow, adding to a steep rise of substance abuse and other intoxications, coupled with poor transportation may explain this difference in findings. This tilt in time frame may also be due to increased habits of indoor latrines amongst people of this area, compared to the ones in 2007-2009, when people usually visited outdoors for defaecation.

In order to understand the seasonal patterns of damage by elephants, the attractiveness of crops in relation to wild forage in a particular season, the extent of availability of crops, and the presence of elephants near cultivated areas should be considered. When the attractiveness of crops in relation to wild forage crosses certain threshold, high encounters can be expected, like we observed in our study between the months of February to May. The abundance of rains from June to October determined local agricultural practices and by January-February most of the seasonal crops become ripe, attracting the elephants. Coupled to this, the dry months of March to May, with scarce water and food resources, compel these mammals to descend to low elevated lands from the Dalma Hills in Jharkhand for their steady supplies.

In an attempt to kill, elephants usually first grab the victim with their trunk and then crush them under their feet. Sometimes they throw them from high lifting position on the ground, followed by trampling. Females and older males are less likely to put up much resistance. In concordance to this, 90.2% of the victims of our study died due to trampling of vital organs. The death of the three persons due to traumatic asphyxia as a result of house collapse, can be attributed to accidental encounters with these mammals.

Elephant males tend to move alone or in small temporal groups, whereas females move in family based larger groups. Studies on behavioural strategies between adult males and female-led herds indicate that the solitary tuskers are more ready to assume the risks of crop raiding than females. It has been suggested that females might become obligate crop raiders when living in highly fragmented habitats, where resources are more limited and scattered in human dominated landscapes. Reports in various newspapers also suggest that high number of human deaths occurs in the months of March to May due to sudden unprovoked attacks by lone tuskers. This is also considered to be the mating season of elephants in this region, where many adult bulls are in their musth state. During this musth phase, tuskers become violent and aggressive toward all other animals, even to its own kind. The same results are reflected in our study, where 38 out of 41 victims succumbed to their injuries inflicted by lone tuskers.

Human-Elephant Conflict may take many forms, from crop raiding and infrastructural damage, through disturbances of normal activities such as travel to work or school, to injury or death of humans or elephants. HEC is a problem that poses serious challenges to wildlife managers, local communities and elephants alike.

In the present study, majority of the victims belonged to the age groups of 30 to 70 years, with male preponderance in all the ages. Most of the victims of HEC were affected between 8.00 pm to 12.00 at midnight, in their act of either chasing the mammals under intoxication or while returning home from workplaces in the late hours. Though crop fields were the usual places of encounters, majority of the incidences occurred between February to May. Trampling of vital organs by
lone tuskers remain the usual finding in victims of HEC. Blockage of elephant migratory routes due to various anthropogenic activities coupled with cultivation of elephant preferred crops in large extent along the forest ranges and lack of food in the forest in some season inevitably attracts more human-elephant conflicts. However, understandings of how people living in or near conflict prone areas use natural resources, and how they make decisions about current and future resource use, remains key to addressing the underlying drivers of Human-Elephant conflict and their spatial variation. Without this knowledge, the task of resolving Human-Elephant Conflict and finding a means for these species to coexist in the Anthropocene is Sisyphean.

Acknowledgements: The authors are grateful to authors, editors and publishers of all those articles, journals and books from where the literature of this article has been reviewed and discussed.

Conflict of Interest: No conflict of interest is associated with this work.

Other Interest: The same article was sent to another Journal for consideration. However, even after receiving the acceptance letter from the editor, the authors refrained themselves from paying the processing charges and publication in the said journal, after finding the Journal not indexed as per The Gazette of India (Board of Governors) dated the 12th of February, 2020.

The Unrevealed Truth about the Tongue in Forensic Identification

1MPH Candidate, Temple University College of Public Health, Department of Epidemiology and Biostatistics, Ritter Annex, 9th floor, 1301 Cecil B Moore Ave, Philadelphia, 2Professor; 3Professor & HOD; Department of Oral and Maxillofacial Pathology and Microbiology, D.Y. Patil University School of Dentistry, Sector 7, Nerul, Navi Mumbai, Maharashtra, India, 3Professor & HOD; Department of Oral Medicine and Radiology, 5Associate Professor; Department of Oral and Maxillofacial Pathology and Microbiology, 6Assistant Professor; Department of Oral and Maxillofacial Pathology and Microbiology, D.Y. Patil University School of Dentistry, Sector 7, Nerul, Navi Mumbai, Maharashtra, India, 7Analyst, Department of Population Health, New York University Grossman School of Medicine, New York, NY

Abstract

Background: Forensic odontology, a branch of dentistry includes identification of individuals in various crime scenes, natural calamities, and mass disasters. The identification is possible because every individual body is unique and so is our tongue due to its morphological variations. The primary objective of the study was to assess the morphological features of the tongue and its use in sex determination.

Methods: The study included a sample size of 100 individuals (50 males and 50 females) in the age range of 20-50 years old. Photographs were taken of front and side view of the tongue; visual inspection was done and lastly impressions of the tongue were made with help of alginate and then poured with the help of dental stone. IBM SPSS statistics 20.0 (IBM Corporation, Armonk, NY, USA) was used for the analyses of the data. Microsoft word and Excel were used to generate graphs, tables etc. Females presented with triangular shape, presence of shallow fissures more commonly and a sharp lingual apex of tongue. Males presented with rectangular shape, presence of deep fissure/absence of fissures more commonly and septate/sharp lingual apex of the tongue.

Conclusion: Tongue exhibits various unique characteristics and can be used in sex determination.

Keywords: forensic odontology, morphological characteristics, sex determination, tongue impressions

Introduction

Forensic odontology, a branch of dentistry comprises of various aspects dealing with diagnostic and therapeutic evaluation and examination of various parts of oral cavity, identification of individuals and evaluation of bite marks in criminal investigations, sexual assaults, child abuse cases, mass disasters and in personal defence circumstances\(^{(1)}\). Various components of the oral cavity like teeth, saliva, pulp, dentin, lips etc. can be used in forensic odontology for age estimation, sex determination, DNA analysis and identification of the criminal.

The human tongue is a muscular organ covered by a thin mucous membrane which lies partly in the oral cavity and partly in the oropharynx. The tongue is well protected from the external environment and has its own skeletal muscles, nerve supply and blood vessels\(^{(2)}\).
The human tongue serves many purposes like being the organ of taste, articulation of speech, mastication, and intimacy. It is an internal organ which can be used for inspection thereby offering proof of life.

According to the Traditional Chinese Medicine, the tongue is a unique vital organ, and its vitality is well scored as, ‘Tongue of Life’ in the same (3). This muscular organ plays a very significant role in forensic identification due to its unveiling portion encompassing information with diverse visible changes from one individual to the other called as lingual impression thereby making it unique (2).

It possesses numerous characteristics presenting both geometric shape and physiological texture information which indeed can be useful in identity verification applications (4). The shape of tongue of an individual is unswerving and the physiological texture of tongue is immutable (2). In respect of shape and surface textures, everyone has unique pattern of tongue (5). The lingual morphological aspects are scrutinized with the help of alginate moulding technique which is the most reliable method for recording minute details of tongue; this in turn helps the forensic investigator to identify the person (2).

**Materials and Methods**

The present study was conducted in DY Patil Dental College and Hospital, Oral Pathology and Microbiology Department on June 17 for over 2 months. The study was carried out on 100 individuals (50 males and 50 females) in the age range of 20-50 years of age exclusively of Navi Mumbai population.

The inclusion criterion for the study is:

1. Individuals who are clinically healthy.
2. Individuals with clinically healthy tongue.

The exclusion criterion for the study is:

1. Individuals possessing any medical illnesses like HIV, diabetes, thyroid problems, hypertension, Down syndrome etc.
2. Individuals possessing any developmental anomaly or pathology of the tongue.

Institutional Ethics Research committee approval for the study and a written consent from each study participant was obtained prior beginning the study.

![Fig-1 shows a disposal tongue cleaner.](image)

Before the examination of the tongue, the patient was requested to clean his tongue with a disposable tongue cleaner and rinse his oral cavity [Fig 1]. The examination process of the present study was divided into three categories: 1) Photographs, 2) Visual inspection and 3) Impressions. The study participants were requested to protract their tongue in a relaxed position to prevent any contraction of the striated lingual muscles which would thus alter various characteristic features.
Fig-2a fig-2b shows the front and the side view of the tongue.

Fig-3a fig-3b shows making of impression, the alginate impression, and the cast of the tongue.

Photographs of the front and side view of tongue were then taken in the same setting using DSLR camera [Fig-2a and fig-2b]. Later, visual inspection was done i.e., clinically all the characteristics of the tongue such as the shape, colour, surface texture, type of lingual apex etc. that were visible were noted down on the performa. Lastly impressions of the tongue were made with the help of chromatic alginate impression material (Tropicalgin) [Fig-3a]. Chromatic Alginate was chosen as the choice of impression material as it has got an excellent property of duplicating minute details and it can be easily removed. To prevent the regurgitation reflex, impression was made from the level of the oral commissures up to the lingual tip of tongue and was then poured with the help of dental stone [Fig-3b]. This helped us obtain a relevant positive image for identification.

At the end of the examination, all the characteristic features of the tongue that were obtained using the above three methods were cross checked and evaluated.

**Statistical Analysis**

Descriptive and inferential statistical analyses were carried out in the present study. Results on categorical measurement were presented in number (%). Level of significance was fixed at $p=0.05$ and any value less than or equal to 0.05 was statistically significant.

Chi square analysis was used to find the significance of study parameters on categorical scale. The Statistical software IBM SPSS statistics 20.0 (IBM Corporation, Armonk, NY, USA) was used for the analyses of the data and Microsoft word and Excel were used to generate graphs, tables etc.
**Results and Discussion:**

In the current study, various features of tongue like shape, fissures and type of lingual apex were included.

Based on the study participants, the shape of tongue was categorised into 1) Triangular, 2) Ovoid, 3) Rectangular and 4) Square. Fissures of tongue was categorised into 1) Absence of fissures, 2) Shallow fissures and 3) Deep fissures. Lastly, the lingual apex was categorised into 1) Septate and 2) Sharp.

Table 3 shows comparison of lingual apex among males and females. There was a significant difference seen in lingual apex among males and females. 100% of females presented with sharp lingual apex. In comparison, 86% males presented with sharp lingual apex and 14% of males presented with septate lingual apex. When these results were analysed statistically analysed using chi square test, significant results were obtained.

Forensic odontology is gaining great interest in today’s world due to presence of innovative and efficient identification systems. The purpose of introducing the use of tongue prints in forensic odontology is due to the uniqueness of the tongue. In the present study, females presented with triangular shape of tongue and presence of shallow fissures more commonly than deep or absence of fissures. While males presented with rectangular shape of the tongue and presence of deep fissures more commonly than absence of fissures. As far as lingual apex was considered, females presented with sharp lingual apex while men presented with sharp as well as septate lingual apex. The current study shows diversification in various morphological aspects of tongue with respect to males and females.

On the contrary, there are also similar kinds of studies conducted. One of the studies includes shape and texture of the tongue as criteria, which showed results based on the age groups. The other study includes criteria like shape of tongue and presence of fissures on the tongue. In this study, females presented with deep fissures while the males presented with shallow fissures. Because of the uniqueness of the tongue, several studies have been undertaken to prove the use tongue prints in biometric authentication along with fingerprints and iris.

**Conclusion**

The field of forensic odontology scrutinizes various dental evidence, and it confirms that individuals have some unique characteristics which can be used for evidence purpose. The dorsal surface of the tongue...
holds prominent morphological features, thereby difficult to forge and can therefore be used in forensic odontology for sex determination\(^2,\,5\). A photographic image of the lingual aspect along with the lingual impression, together can aid in forensic identification along with other proved methods\(^2\). Every dentist should therefore comprehend the forensic values and its connection with dental practice\(^3\).

A Study to Evaluate Effectiveness of Kangaroo Mother Care
on Physiological Parameters of Premature Babies in Vadodara City

Sejal Solanki1, Prachi Kachhiya1, Kamali Patel1, Vrunda Patel1, Trushali Baria1, Kinnari Jatva1, Sanjana Bhatia2
1Final Year B.Sc Nursing Student, 2Assistant Professor, Dinsha Patel College of Nursing, Nadiad, Gujarat, India

Abstract

According to WHO, mostly babies are die in their neonatal period. India, current infant mortality rate is about 32 infants per 1000 live birth. A Quasi Experimental study was conducted to evaluate the effectiveness of Kangaroo Mother care on physiological parameters of premature neonate of experimental group and control group in selected hospital in Vadodara city. Sample size for the present study was consist of 60 babies. (30 experimental and 30 control group) The instrument used for data collection are Kangaroo Mother Care Assessment Flow Sheet (KMCAFS). The data analysis was done by using descriptive and inferential statistics. The result of the present study was that most of the premature babies after receiving KMC Care, there was a significant incensement in the weight. Here the paired t-test value of temperature and weight are(t<0.050)not significant and pulse and respiration are (>0.05) significant. The study concluded that KMC is a simple and acceptable method for the mother can be continued at home and there by improves the infant growth and reduce morbidity.

Keyword: Evaluate, Effectiveness, Kangaroo Mother Care, Physiological parameter, Premature Babies.

Introduction

Preterm birth, also known as preterm birth, is the birth of a baby at less than 37 weeks gestational age. Preterm babies are at greater risk for cerebral palsy, delays in development, hearing problems, and problems seeing. These risks are greater the earlier a baby is born. Preterm birth is the most common direct cause of newborn mortality. Preterm birth and being small for gestational age (SGA), which are the reasons for low-birth-weight (LBW), are also important indirect causes of neonatal deaths. LBW contributes to 60% to 80% of all neonatal deaths.

According to WHO, mostly babies are die in their neonatal period. India, current infant mortality rate is about 32 infants per 1000 live birth. And preterm birth is considered to be the largest cause of neonatal mortality, there are many studies that highlight the importance of KMC in maintaining the premature health and improving the condition. Indeed, kangaroo mother care has positive effects on premature babies and mothers.

Need For the Study: A study has estimated that, at birth 95% of underweight infants are born in developing countries. without access to appropriate infant care the KMC may be the only alternative for this children not only for survival but to achieve a better quality of life.

Objectives:

1) To evaluate the effectiveness of Kangaroo Mother Care on Physiological parameters of premature neonates of experimental group and control group in selected hospital in Vadodara city.

2) To find out the association between the
physiological parameters of premature infants with the selected demographic variables in selected hospital in Vadodara city.

**Hypothesis**

H1: There will be a significant difference between mean post-test physiological parameters outcome score and mean pre-test physiological parameters outcome score among experimental and control group at the 0.05 level of significance.

H2: There will be a significant association between physiological parameters outcome scores and selected demographic variables of preterm baby among experimental group during KMC care at the 0.05 level of significance.

**Research Methodology**

Research Approach: Quantitative research approach is used for this present study

Research Design: The research design used for the present is quasi-experimental pre-test and post-test design with control group.

Population: patient admitted in hospital in KMC ward

Sampling Technique: Non probability purposive sampling technique.

Sample size: The sample size 60 (30 experimental group and 30 control group)

Descriptive Tool:

**Section 1:** comprised of demographics data

**Section 2:** comprised of kangaroo mother care assessment flow shit.

**Result**

The result of the present study was that most of the premature babies After receiving kangaroo mother care, there was a significant incensement in the weight.

Percentage Distribution of Preterm babies in Experimental Group According their characteristics.
1. Findings related to Mean, Mean difference, standard deviation and ‘t’ test

2. Findings related to association between selected demographic variable and physiological parameters outcome of preterm babies.

1. In temperature among age, gender, length in hospital stay, gestational age, mother education, type of delivery value (p<0.05) not significant, and birth weight value is (p>0.05) significant.

2. In pulse among all demographic variables are (p<0.05) not significant.

3. In respiration among age, gender, birth weight and education of mother are (p<0.05) not significant and gestational age, length in hospital stay and type of delivery are (p>0.05) significant. The value.

4. in weight among age, gender, birth weight and education of mother are (p<0.05) not significant and gestational age, length in hospital stay and type of delivery are(p>0.05) significant.

Conclusion

The main conclusion drawn from the present study was that most of the premature babies after receiving kangaroo mother care there was a significant incensement in the weight. Samples became familiar and found themselves comfortable and also expressed satisfaction. It is concluded that the kangaroo mother care is effective and a simple strategy to balance physiological parameters.

The Regularity of Antenatal Care through Knowledge of Pregnant Women and Support from Husbands

Sendy Ayu Mitra Uktutias¹, ⁵, Ade Ayu Mitra Ramadita Daluas¹, Sri Iswati², Cholichul Hadi³

¹Postgraduate School, Department of Human Resource Development, ²Faculty of Economics and Business, Department of Economics and Business, ³Faculty of Psychology, Department of Psychology, Universitas Airlangga, Surabaya, Indonesia, ⁵Stikes Yayasan Dr. Soetomo, Surabaya, Indonesia

Abstract

Pregnant women’s knowledge and husband’s support are factors that influence antenatal care regularity. This study aims to analyze the effect of knowledge of pregnant women and husband’s support on antenatal care regularity. This study a cross-sectional design and was conducted on 38 pregnant women as respondents using linear regression statistical tests. The result showed that there was an effect of knowledge of pregnant women and the husband’s support on the regularity of antenatal care. The better the knowledge of pregnant women about their pregnancy and the higher the support of their husbands will have an impact on the regularity of antenatal care. The implication of this research is for midwives who are at the forefront of empowering cadres and providing health education to pregnant women and husbands about the importance of regular antenatal care. Also, midwives need to improve competence through midwifery training efforts.

Keywords: knowledge, husband’s support, antenatal care, pregnant women

Introduction

Antenatal care is a health service by professionals for pregnant women during their pregnancy which is carried out in accordance with established antenatal service standards. Antenatal care is an important way to monitor and support the health of pregnant women. It is advisable to visit a midwife or doctor as early as possible so that early detection of risk factors for pregnancy can be carried out. According to the World Health Organization (WHO), antenatal care during pregnancy to detect early on the occurrence of high risks to pregnancy and childbirth can also reduce maternal mortality and monitor the condition of the fetus. Visit for pregnant women to health services are recommended once in the first trimester, 1 time in the second trimester, and at least 2 times in the third trimester.² The indicators used to assess maternal health services during pregnancy are K1 and K4. Saipudin explained that antenatal care is said to be regular if pregnant women do antenatal care >4 visits, less regular if two to 3 visits, and irregular if pregnant women only do antenatal care less than 2 visits.³

In Indonesia, the importance of antenatal care visits has not become a top priority for some pregnant women regarding their pregnancy. The result of basic health research (Riskesdas) conducted by the ministry of health shows that data on antenatal care coverage in Indonesia during the last 3 years in 2013-2015, namely in 2013 amounted to 92.7% and in 2015 amounts to 95.2%. The first antenatal care coverage in the first trimester during the last 3 years in 2013-2015 namely in 2013 amounted to 92.7% and in 2015 amounts to 95.2%. The first antenatal care coverage in the first trimester during the last 3 years in 2013-2015 namely in 2013 amounted to 92.7% and in 2015 amounts to 95.2%.
Several researchers have conducted research to determine the factors that can affect maternal Antenatal care visits during pregnancy. Factors that influence a person’s behavior in utilizing health services based on the theory of Lawrence W. Green are derived from behavioral factors and factors outside of behavior (non-behavior causes). Meanwhile, the division according to the concept and behavior of a person as suggested by Green includes predisposition factors, enabling factors, and reinforcing factors. Predisposing factors include age, level of education, employment status, parity of pregnant women, pregnancy distance, knowledge of pregnant women, and attitudes of pregnant women. Meanwhile, the enabling factors are the distance of residence, family income, and information media. Strengthening factors include husbands’ support, family support, and health worker factors. In line with it explains that maternal knowledge is a problem that often arises and results in low antenatal care coverage. Not only knowledge, research conducted, states that husband support is a very influential factor in decision making, including antenatal care.

This study focuses more on the factors of knowledge of pregnant women and husband’s support for regular antenatal care visits, that pregnant women miss antenatal care visits during their pregnancy. The purpose of this study was to analyze the effect of knowledge of pregnant women and husband’s support on the regularity of antenatal care visits.

Methods

Type and design

This study is analytical research with a cross-sectional design. This study to know the effect of the regularity of antenatal care through knowledge of pregnant women and support from husband’s.

Population and sample

The population of all pregnant women at Waru Health Care Centre of Pamekasan District with 38 respondent pregnant women with a proportional random sampling technique. This study has inclusion criteria, namely only third-trimester pregnant women or gestational age >32 weeks and willing to be respondents who will be sampled.

Results

The result of the study of research that has been conducted with 38 respondents of pregnant women is as follows.

Based on the knowledge of pregnant women and pregnancy check-ups for pregnant women in Table 2, it shows that many pregnant women who have low knowledge do not regularly perform antenatal care. Based on the knowledge of pregnant women and pregnancy check-ups for pregnant women in Table 2. It shows that many pregnant women who have low knowledge do not regularly perform antenatal care. Roger’s (1974) in Notoadmodjo. Soekidjo (2003), a theoretical review states that knowledge is a very important domain for shaping one’s action. Burhaeni S (2013) in her scientific work, explained that the aspect of knowledge is very important for the use of Antenatal Care (ANC).

**Tabel 3. Husband’s Support and Antenatal Care (ANC) visits at Waru Health Care Center of Pamekasan District**

Based on the result of linear regression in Table 4, knowledge of pregnant women and husband’s support affect the regularity of antenatal care visits with a p-value of 0.030 for knowledge pregnant women and a p-value of 0.000 for husband’s support.

**Discussion**

Antenatal Care (ANC) needs to be done because it has benefits to improve maternal health during pregnancy and childbirth. Knowledge of pregnant women regarding Antenatal Care (ANC) is still lacking. The reason for the lack of knowledge of pregnant women about Antenatal Care (ANC) at Waru Health Center Care of Pamekasan District has an educational background, namely elementary school graduates (Table 1). The theoretical review explains that highly educated people will give a more rational response to the information that comes, will think to what extent they will benefit from the idea. So, it’s undeniable, the higher a person’s education, the easier they will receive information so that in the end a lot of knowledge they have. It’s necessary to increase the knowledge of pregnant women about Antenatal Care (ANC) and risk in pregnancy to maintain a healthy pregnancy. If a risk is found, it will be detected early for immediate treatment. This research shows, If pregnant women are based on a good knowledge of health, then that pregnant woman will understand about maintaining health and have the motivation to apply good health patterns in life. According to the results of this study, which shows the higher the knowledge of pregnant women, the more regular they are in carrying out Antenatal Care (ANC). There is another factor, the husband’s support is important in implementing Antenatal Care (ANC). Tabel 3. Show that the more the husband is supportive, the more regularly he implements Antenatal Care (ANC). This research shows that the husband’s support is important in Antenatal Care (ANC) for pregnant women. Pregnant women feel comfortable and safe if their husbands.

Husband’s support is not only limited to taking women to health services to check their pregnancy. According to Friedman, there are four criteria for the support that needs to be provided by a husband, namely informational support, assessment/appreciation support, instrumental support, and emotional support. Examples of informational support are the husband gives information about the danger signs in pregnancy or the husband encourages his wife to read a book KIA. Support ratings/awards such as the husband are always asking for an explanation of examination results to the midwife. Instrumental support as husband preparing vitamin or milk for pregnant women. And emotional support as the husband soothe worried mother before delivery.

Her husband’s non-support for Antenatal Care (ANC) visits was explained in a study conducted by Evayanti because the husband didn’t know the purpose, benefits, and time of the ANC so that antenatal care visits became irregular. Low husband’s knowledge is manifested in the actions of the husband doesn’t provide
motivation to the mother to conduct regular Antenatal Care (ANC) visits by not sending the mother to do Antenatal Care (ANS), don’t look for information on the benefits of Antenatal Care (ANC), not give praise if you make regular visits. Emotionally, a husband supporting a pregnant woman will motivate the mother to go for Antenatal Care (ANC). The same study, states that family support, especially husband, plays an important role in realizing positive things and regular Antenatal Care (ANC) visits. Increased education for husbands so that the need for pregnant women to carry out Antenatal Care (ANC) visits properly and completely will be achieved.\textsuperscript{11}

Research Dinarohmayanti, Keintjem, and Losu, (2014) support this study which states that the support and role of family/husband during pregnancy can increase the readiness of pregnant women in the face of pregnancy and childbirth. The husband’s involvement during pregnancy will support the health of the mother and the baby to be born, also prevent the risks of unwanted risks. Pregnant women who receive support from the family and are followed by family income and parity will determine the caregivers during pregnancy. Thus, not only the two research variables were tested for their influence, but there were other factors such as income and parity for further research.\textsuperscript{12}

Knowledge of pregnant women can be increased by providing information through various information media that can be accepted by the community (pamphlets or leaflets). Agus and Horiuchi,\textsuperscript{13} explain in their findings that education is one of the factors influencing Antenatal Care (ANC) services for pregnant women. Research provides an explanation of the implementation of health education through counseling is one appropriate solution to increase the knowledge of pregnant women, so as to optimize the examination of pregnancy to health workers.\textsuperscript{14} Through the Pregnant Mothers Class Program, pregnant women can come face to face to study together, with the aim of increasing their knowledge and skills about Antenatal Care (ANC). Researcher, revealed that knowledge of pregnant women can be increased by empowering cadres. Health cadres are people who are known and part of the community, so it can easily provide information to pregnant women about the importance of Antenatal Care (ANC) visits, pregnancy until breastfeeding and pregnant women can receive information about it.\textsuperscript{15}

The role of the midwife is important in increasing the husband’s knowledge and support so that Antenatal Care (ANC) visits become regular. Midwives must also have the ability to communicate interactively with pregnant women and husbands during the Antenatal Care (ANC) service process. Research by Ernawati\textsuperscript{16}, states that poor communication skills of midwives with pregnant women with low educational backgrounds are one of the factors for low maternal visits. Therefore, training or improvement efforts to enhance the communication skills of midwives are needed.

\textbf{Conclusion}

Pregnant women’s knowledge and husband’s support are proven to have a significant effect on the regularity of antenatal care visits at Waru Health Care Center of Pamekasan. The implication of this research is to prioritize midwives and health workers at Waru Health Care Center of Pamekasan to promote health by providing health education about the importance of antenatal care (ANC) which is not only for pregnant women but for husbands. Midwives can empower cadres to collaborate. Midwives as front liners in reducing maternal mortality should improve competence through training, one of which is midwifery training to achieve good standards and status of maternal and child health

Delictological Approach to the Classification of Offenses: Theoretical and Legal Analysis Using the Example of Ukrainian Legislation

Sergey V. Petkov, Veronika N. Shkabaro, Oleh H. Bodnarchuk, Igor E. Ivanov, Oleksandr D. Kolomoiets

Abstract

The article analyses the problem of the concepts of crime and offense definitions, considers legal issues of their set of facts; based on the analysis of constitutional, administrative and criminal legislation, the criteria to differentiate offenses from homogeneous crimes are proposed; scientific views of lawyers are analysed; legislation improvement of the post-Soviet republics in delictology are proposed.

Key words: delict, law violation, offense, crime, qualification.

Introduction

Legal liability is a type of social responsibility that occurs for violation of legal norms. To deal with such a complex phenomenon as legal liability for committing crimes and offenses, first of all, one should analyse the theory of law, as the essence of knowledge about law, the regulator of social and economic relations.

In different countries, the complex of issues related to legal liability for offense is resolved in different ways. One and the same act may become the subject of consideration in different countries by different authorities in a different procedural order. Even jurisdiction will fall under different branches of government: executive or judicial. Execution of documents, procedure performance, etc. also differ. In many US states and other countries of the world, in accordance with traditions and well-established standards of behavior, there are different approaches to responsibility for offenses.

Therefore, the mechanical transfer of certain elements or short stories or whole mechanisms, algorithms and rules without a comprehensive study and analysis of the national law and legal consciousness of citizens on national basis is impractical, and sometimes can result in negative consequences.

Criminology is an integral part of delictology, which, in turn, is a part of sociology (the science, studying social phenomena).

Methods

The article applies methods of information search, analysis, synthesis, comparative legal and systemic structural methods.

Results and Discussion

It is well known, that basic legal principles were laid down in ancient times, but the greatest contribution to the
formation of legal axioms, presumptions and principles was made by Roman legal experts. It is a generally recognized axiom that legal liability is incurred for the committed offense.

The rule of law in a modern democratic state, legal culture and legal consciousness in society are ensured by improvement of the already existing theoretical and methodological foundations of legal liability in all spheres of public life in general, as well as the institution of state responsibility in the person of its bodies and officials to civil society and individuals, in particular.

The essence and content of the state responsibility to a person are defined in the Constitution of Ukraine, in particular in Articles 3, 8, 19, 22. The provisions of Part 1 of Article 92 of the Constitution of Ukraine set forth a constitutional approach to the classification of offenses and legal liability.

The generally accepted paradigm is a scientifically grounded and practice-proven approach that public delicts are offenses, or as they are often called delicts, according to the social significance of the committed unlawful act, they are divided into crimes and offenses. This horizontal division is the main one relative to illegal actions in the public sphere of law. In Roman law, offenses in the public interest sphere were also called “crimen” (crime), they emphasized the social danger of these the most dangerous delicts.

The most successful distinction between crime and offense was described in the Penal Code of France of 1795. In particular, it singled out: a) crimes - acts for which corporal punishment was provided; b) offenses - acts for which punishment of a corrective nature was provided.

In post-Soviet republics, the “delict” concept is not officially applied in legislation. But it is widely used in scientific and legal literature and practice. By its content and essence, a delict is a direct violation of rules of law. In the legal encyclopedia edited by academician Yu.S. Shemchushenko, offenses are defined as a socially dangerous or harmful act (act or failure to act), violating the rule of law. Its characteristic feature is the unlawfulness of actions or failure to act of the subject of social relations. We mean the violation of the established order, failure to fulfil the duties assigned to individuals and legal entities. Professor V.P. Pastukhov notes that an offense is a socially harmful, unlawful act, its implementation provides for legal liability. Socially useful actions are consistent with rules of law, socially harmful actions are considered as violation of legal norms.

As A.M. Kolodiy notes in his work “Principles of Law of Ukraine”, the public law sphere shall be considered as vertical relations (managerial), subordination relations, power - subordination. Their regulation shall be based on imperativeness principle, the rights and obligations of subjects shall be directly and exhaustively formulated in the law.

Certain steps to improve anti-delict legislation were performed during the entire period of state development after the Soviet Union decline. In particular, Ukraine has adopted a new progressive Criminal Code (2001), the Customs Code of Ukraine (2002) and a number of other regulations. Even the Criminal Procedure Code of Ukraine (2013), on the whole, can be considered as complying with European standards. But the inertia of the Soviet and even the imperial period is still present. For example, over 10 years, after the Customs Code adoption, customs regulations have undergone such changes that in 2012 a new Customs Code of Ukraine was adopted.

In the context of delict analysis as a social phenomenon, it should be noted that “legal chaos” in the legal liability sphere is unacceptable. Moreover, it is a threat to national security. In this situation, for the national legislation of Ukraine, as well as for other countries, where Soviet law was in force, it is necessary to introduce a comprehensive reform in the legal liability sphere for commission of delicts.

The constitutional basis for legal regulation of the classification of offenses and legal liability are expressed in regulations of the Constitution of Ukraine,
paragraph 22, part 1, Article 92, providing for the following: “The following are determined exclusively by the laws of Ukraine: ... civil liability basics; acts, considered as crimes, administrative or disciplinary offenses and resulting responsibility”1. According to V. B. Averyanov, very often outwardly identical actions, depending on the degree of their social danger, can serve as a basis for both administrative and criminal liability10.

Parts 2 and 3 of Article 22 of the Constitution of Ukraine clearly define that: “Constitutional rights and freedoms are guaranteed and cannot be cancelled. When adopting new laws or making changes to existing laws, it is not allowed to confine the content and scope of existing rights and freedoms”11.

Thus, in the theory of law, a delict (offense) is divided into crimes and offenses according to the public danger degree. Let us note that we mean the vertical separation of offenses. It is the public danger degree that is the cornerstone of their division into crimes and offenses. Offenses are characterized by the act harmfulness. That is, these are actions that harm public morality, the environment, and health. For instance, smoking in public places adversely affects the formation of adolescents moral qualities, harms the environment and health of other people.

In the Soviet period, offenses, depending on the branch of government that made the decision to punish them, began to be called “administrative offenses”, which is erroneous from the point of view of the theory of law. The normative understanding of an administrative violation (offense) is given by Article 9 of the Code of Ukraine on Administrative Offenses11. The normative understanding of an administrative violation (offense) is provided by Article 9 of the Code of Ukraine on Administrative Offenses11.

In European continental law countries, crime and offense are clearly differentiated. In the countries, where the rule of law prevails, there is also a clear gradation between crime and offense. In its modern interpretation, present in the legislation of the USA (and until recently - in Great Britain, Australia, Ireland and Canada), felony means a crime, more serious than a misdemeanor. In particular, high treason is considered a felony, some offenses, for example, non-payment of taxes, depending on the gravity degree, are qualified either as felony or as misdemeanor. In the countries with developed democracies, the punishment, even for offenses, is considered on a commission basis12.

But Soviet law defacto established a three-level division of offenses into “crimes”, “administrative offenses” and “disciplinary offenses”. Although scientists understand the falsity of this Soviet model, basic principles, laid down in Soviet law, are still preserved and cultivated by followers of the totalitarian command state.

In fact, illegal acts, committed by employees of institutions and departments, the responsibility for the commission of which is stipulated by the articles of the Labor Code of Ukraine is just one of the types of offenses. That is, “disciplinary offenses” are offenses under labor or military law. Here we deal with labor or military offenses, for the commission of which a person will be subject to an appropriate, but insignificant, punishment. In case of a military commission - Section XIX “Crimes against the established procedure for military service (war crimes)” of the Criminal Code of Ukraine, or a labor crime - Article 172 “Gross violation of labor legislation”, Article 271 “Violation of the requirements of labor protection legislation”, etc. In case of violations, provided for by the Criminal Code of Ukraine, the punishment will be applied under the criminal law.

A.P. Zakalyuk “Course of modern Ukrainian criminology: theory and practice” assumes that crime is a phenomenon of social life in the form of mass, relatively stable, variously conditioned criminal activity of a part of the members of this society, unacceptable and dangerous for society. In the history of criminal law, the concept of a crime has been defined differently. Moreover, the “crime”, as a socially dangerous act, is a rather dynamic category. Even in the same society, within a short period of time, approaches to understanding the criminal and
the non-criminal change significantly\textsuperscript{13}.

Crimes are characterized by the danger of the act. That is, these are acts that present a public danger and, depending on gravity, are divided into crimes of low gravity, medium gravity, grave and particularly grave. In the legislation of Ukraine, a crime (criminal offense) is a socially dangerous culpable act (act or failure to act), committed by the subject of a crime (Part 1, Article 11 of the Criminal Code of Ukraine). The act is defined as a crime based on a combination of four characteristics: public danger, guilt, wrongfulness, liability to punishment. At the same time, it shall be considered that an act or failure to act is not a crime, although formally it contains signs of any act provided for by the criminal law, but due to its insignificance does not pose a public danger, that is, it did not cause and could not cause significant harm to physical or legal a person, society or state (Part 2, Article 11 of the Criminal Code of Ukraine)\textsuperscript{7}.

The terms “criminal offense” and “offense” are synonymous. According to Article 12 “Classification of Crimes” of the Criminal Code of Ukraine, until 2020, “depending on the crime gravity, they are divided into crimes of low gravity, medium gravity, grave and particularly grave”. The classification of crimes is understood as their distribution into separate types by certain criteria. Crimes are subdivided: a) by guilt: into intentional and negligent; b) according to the degree of criminal activity completeness - to completed and uncompleted (Article 13 of the Criminal Code of Ukraine); c) their gravity - for crimes of small gravity, medium gravity, grave and especially grave (Article 12 of the Criminal Code of Ukraine)\textsuperscript{7}.

Classification of crimes under Article 12 of the Criminal Code of Ukraine, as well as the category of offense, is perceived by society in different ways. In a democratic society, this is a minor wrongful act, resulting in public responsibility, mainly in the form of a fine, or community service. At the same time, in totalitarian societies, it is precisely the understanding of responsibility for committing a misdemeanor that is distorted, as responsibility before administrative bodies, for violation of established rules of management, etc.

In particular, Ukrainian society experienced such a distortion of the matter of law in the thirties of the 20th century, when for minor misdemeanors, citizens, even minors, could be severely punished and even shot, in accordance with the Decree of the Central Executive Committee and the Council of People’s Commissars of the USSR “On the protection of property of state enterprises, collective farms and cooperation and the strengthening of public (socialist) property” dated August 7, 1932\textsuperscript{14}.

In accordance with the legislation of Ukraine (Article 9 of the Code of Administrative Offenses), a misdemeanor (administrative offense) is considered an unlawful, guilty (intentional or negligent) action or omission that infringes on public order, property, rights and freedoms of citizens, on the established management procedure and for which by law administrative liability is envisaged if this offense by its nature does not entail, according to the current legislation, criminal liability\textsuperscript{11}. As you can see, the division of illegal act into offense and crime depends on the public danger degree.

A crime is an act (offense), characterized by a danger to society, an offense is an act (misdemeanor), characterized by harm to society. An offense, like a crime, is determined by a combination of four signs: social danger, guilt, wrongfulness, liability to punishment.

Let us emphasize that the concept of “administrative offense”, as a category, in no case can be equal to “misdemeanor”. Administrative means managerial. It means that an administrative offense can only be committed by a person endowed with power - a government body official. An administrative offense by public danger degree is divided into an administrative (official) crime and an administrative (official) offense.

Classification of offenses and their characteristics shall consider fundamental constitutional provisions: recognition of the highest social value of a person, his life and health, honor and dignity of inviolability and
security, determination of the content and direction of the state activities to guarantee human rights and freedoms, the state responsibility to a person for its activity, approval and ensuring of human rights and freedoms as the main duty of the state (Article 3 of the Constitution of Ukraine); recognition and operation of the principle of the rule of law in Ukraine, the highest legal force of the Constitution of Ukraine, direct action of the norms of the Constitution of Ukraine (Article 8 of the Constitution of Ukraine); building the legal order in Ukraine on the principles of inadmissibility of coercion to do what is not provided for by legislation (Part 1, Article 19 of the Constitution of Ukraine); obliging public authorities and local self-government bodies, their officials to act only on the basis, within the powers and in the ways provided for by the Constitution and laws of Ukraine (Part 2, Article 19 of the Constitution of Ukraine); an inexhaustible list of human and civil rights and freedoms, the inadmissibility of the abolition of constitutional rights and freedoms, as well as the inadmissibility of narrowing the content and scope of existing human and civil rights and freedoms (Article 22 of the Constitution of Ukraine).

Currently, it is recommended to perform a gradual codification of the administrative legislation norms in certain areas and institutions of administrative and legal regulation. This codification process can be conditionally divided into certain stages. Certainly, it is impossible to determine a clear distinction, but we note that corresponding processes began even before the start of the administrative reform in 199815. Within legislation, it is necessary to transfer the norms of Code of Administrative Offenses to basic codes: the Land Code, Natural Resources Code, etc., as was performed in the customs legislation preparation.

**Conclusion.** The main error of national science was that the main division of delicts (offenses) according to the public danger degree was put on a par with other classifications. This misunderstanding resulted in many conflicts in legislation. Therefore, it is necessary to form a clear distinction between crimes and misdemeanors is urgent, and prevent the confusion of these concepts in one regulatory act. Legal liability for delict commission shall also be regulated. The punishment for these different, diametrically opposed actions shall be differentiated. In particular, as a punishment for crimes, it is required to apply punishment in the form of imprisonment and confiscation. For offense commission, such measures are educational measures as a warning, a fine and correctional labor are applied.

The doctrinal model development for the classification of offenses in the theory of law shall consider the needs of practice to regulate relevant sphere of public relations.

The implementation of steps to bring the legislation of Ukraine to world standards shall be comprehensive and coordinated, not create additional conflicts in the country’s legal system. The openness of this process shall be accompanied by a broad public discussion, consultations with scientists and popularization of lawmaking actions of the authorities among population.

Child Trafficking & Human Trafficking: Legal Aspects and Role of a Doctor

Shagun Thakur\textsuperscript{1}, Vikas Gurbani\textsuperscript{2}

\textsuperscript{1}Asst. Prof., \textsuperscript{2}Assoc. Prof., Dept. of F.M.T., Kalinga Institute of Medical Sciences (KIMS) & PBMH, Bhubaneswar

Abstract

Counter-trafficking measures are to be implemented at various levels and by various organisations. The medical professionals also play an important role in this area as in many cases, the victims are first identified when they require some form of medical attention.

A child victim of trafficking is any person younger than 18 years against whom the act of trafficking has been committed. The definition of child trafficking differs from that of trafficking in humans in the respect that children are considered being vulnerable not only because of their level of maturity and age but also other factors.

This article highlights the various legal aspects of child and human trafficking in India. The victim of trafficking may not himself disclose what he is going through, so there are certain points on history and examination which should arise the suspicion in the mind of the health professional. These signs and symptoms are mentioned in this article which are collected from various resources. Emergency medicine department has an important role in screening of these victims, although all the departments contribute in identifying the victims.

The article also mentions where India stands compared to its global counterparts in anti-trafficking measures.

Keywords: trafficking, child trafficking, human trafficking, doctor in trafficking, trafficking healthcare, trafficking medicine, trafficking in persons

Introduction

Child trafficking and Human Trafficking is not just a national but an international problem. Counter-trafficking measures are to be implemented at various levels and by various organisations. The medical professionals also play an important role in this area as in many cases, the victims are first identified when they require some form of medical attention. A medical professional should be aware of the signs and signals which point towards a victim of child trafficking.

India has adopted the United Nations PALERMO Protocol for Trafficking which states that trafficking in persons “shall mean the recruitment, transportation, transfer, harbouring or receipt of persons, by means of the threat or use of force or other forms of coercion, of abduction, of fraud, of deception, of the abuse of power or of a position of vulnerability or of the giving or receiving of payments or benefits to achieve the consent of a person having control over another person, for the purpose of exploitation. Exploitation shall include, at a minimum, the exploitation of the prostitution of others or other forms of sexual exploitation, forced labour or services, slavery or practices similar to slavery, servitude or the removal of organs.” \cite{1}
Exploitation shall include sexual exploitation, forced labour, slavery or the removal of organs

**Human Trafficking Vs Child Trafficking**

A child victim of trafficking is any person younger than 18 years against whom the act of trafficking has been committed. If the age of the person is unknown and there are reasons to presume that the person is a child, the person shall be considered under the definition of child, until his/her age is established. The definition of child trafficking differs from that of trafficking in humans in the respect that children are considered being vulnerable not only because of their level of maturity and age but also other factors.

The following is the data from National Crime Records Bureau of India showing the number of victims trafficked during the year 2019.²

LAWS IN RELATION TO CHILD TRAFFICKING IN INDIA [3]

- **Article 23 of the Constitution** guarantees right against exploitation, prohibits trafficking human beings and forced labour and makes their practice punishable under law

- **Article 24 of the Constitution** prohibits employment of children below 14 years of age in factories, mines or other hazardous employment

- **Indian Penal Code:**
  
  S. 366A – Procuration of a minor girl from one part of the country to another is punishable

  S.372 – Selling of girls for prostitution

  S.373 – Buying of girls for prostitution

  S.374 – Provides for punishment for compelling any person to labour against his will

**Human Trafficking (S.370 and S.370A)** after enactment in 2013 into the Criminal Law, the Bureau has started collecting data under this section

**Major Acts in relation to trafficking in India**

- The Suppression of Immoral Trafficking in Women and Girls Act, 1956 (SITA)
- Child Labour (Protection and Regulation) Act, 1986
- Immoral Traffic (Prevention) Act, 1956 (ITPA)
- Information Technology Act, 2000
- Juvenile Justice (Care and Protection of Children) Act, 2000
- Prevention of Children against Sexual Offences Act, 2012

**Other Important Acts:**

- Indecent Representation of Women (Prohibition) Act, 1986
- The Child Marriage Restraint Act, 1929
- The Narcotic Drugs and Psychotropic Substances (NDPS) Act, 1985
- The Transplantation of Human Organ Act, 1994

**3Ps of Anti-Trafficking** [4]

The 3P Index assess the effectiveness of governmental policies against human trafficking in three main areas: Prosecution, Protection and Prevention (3Ps). The ranking of country and policy score are published every year.

4th P – Partnership

Partnerships among governmental, nongovernmental and other civil society organisations, among academia, politics and industry, and among professionals from different fields of expertise are vital for comprehensive counter-trafficking efforts.

THE ROLE OF HEALTHCARE PERSONNEL IN TRAFFICKING

SCREENING PROTOCOL\textsuperscript{[5,6,8]}

The victim of trafficking may not himself disclose what he is going through, so there are certain points on history and examination which should arise the suspicion in the mind of the health professional.
Questions to Ask:

- Is anyone forcing you to do anything that you do not want to do?

- Is anyone forcing you to work or have sex against your will?

- Where do you work and what type of work do you do? Have you ever been lied to about your type of job?

- Are you allowed to freely leave your house/work?

- Has anyone threatened to hurt you/ your family or threatened to report you to the police?

- Does anyone hold your identification documents (i.e., passport or driver’s license)? Could you get it back if you wanted to do so?

- Is anyone restricting you from seeing your family and friends or tracking your movements? When was the last time you had contact with your family?

RED FLAGS (What to look for):

- Patient has no identification documents or documentation is in possession of an accompanying party

- Accompanying party insists on answering/interpreting for patient. Accompanying male is much older than young female in OB/GYN exam

- Patient is reluctant to explain his/her injuries

- Patient is unaware of his/her location

- Patient exhibits fear, anxiety, depression, submission, tension or nervousness and avoids eye contact

- Patient is under 18 years of age and engaging in commercial sex or trading sex for something of value

- Patient works and sleeps in the same place

- Patient has no money or control over money. Accompanying party pays with a lot of cash

- Patient is a runaway/ throwaway youth

PHYSICAL SIGNS:

- Frequent or recurrent UTIs

- Frequent treatment for STIs: Gonorrhoea, Chlamydia, and HIV/AIDS

- High number of sexual partners

- Multiple pregnancies/ abortions

- Maltreated previous injuries

- Burns from battery acid, hot iron or cigarettes, exposure to toxic chemicals

- Bruises, including evidence of being slapped or receiving rough treatment

- Shows of physical restraint or torture

- Branding - Tattoos or markings of ownership (ask meaning of tattoo & circumstances from which it was obtained)

- Presence of internal cotton cosmetic sponges to stop bleeding from cycle or abortion

The Philadelphia Anti-Trafficking Coalition has also suggested a guideline which can be followed in emergency department for screening of victims.[5,7] The summary of the guidelines is as follows : Red flags identified à Treat Medical Concerns à Human Trafficking Assessment à Patient in perceived danger à With the consent of the patient, call helpline or if he refuses consent, then guide him how to take help (In case of minor, follow mandatory reporting procedure.

Police – 100

Childline - 1098
ANTI-TRAFFICKING POLICY INDEX \(^3\)

TIRE-wise Placement of Countries

Department of State, USA places each country onto one of four tires, as mandated by Trafficking Victims Protection Act (TVPA). This placement is based more on the extend of government action to combat trafficking.

<table>
<thead>
<tr>
<th>TIER</th>
<th>CRITERIA</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tier 1</td>
<td>Countries whose government fully meet TVPA’s minimum standard (Prohibit trafficking, punishment sex traffickers, serious and sustain effort to eliminate trafficking)</td>
</tr>
<tr>
<td>Tier 2</td>
<td>Countries whose government do not fully meet TVPA’s minimum standard but are making significant efforts to meet those standard</td>
</tr>
<tr>
<td>Tier 2 Watchlist</td>
<td>Do not fully meet TVPA’s minimum standard but are making significant efforts to meet those standards AND</td>
</tr>
<tr>
<td></td>
<td>i) Number of victims is significant</td>
</tr>
<tr>
<td></td>
<td>ii) Failure to provide increasing efforts to combat severe forms of trafficking</td>
</tr>
<tr>
<td></td>
<td>iii) Determination based on commitments by the country to take additional future steps over the next year</td>
</tr>
<tr>
<td>Tier 3</td>
<td>Countries whose governments do not fully meet the minimum standard and are not making significant efforts to do so.</td>
</tr>
</tbody>
</table>

India is on TIRE 2 according to USA’s TVPA standards

<table>
<thead>
<tr>
<th>TIER 2</th>
<th>P</th>
<th>P1</th>
<th>P2</th>
<th>3P</th>
</tr>
</thead>
<tbody>
<tr>
<td>INDIA</td>
<td>4</td>
<td>2</td>
<td>4</td>
<td>10</td>
</tr>
</tbody>
</table>

As per the year 2019, USA has retained India on the Tier 2 list of countries in its Annual report on human trafficking, arguing that the country does not fully meet the minimum standards for its elimination even as it is making progress.

Conclusion

- The reported cases of child trafficking are only the tip of the iceberg.
- In measures to combat trafficking, the goal should be also to prevent re-trafficking.
- The healthcare personnel, mainly the emergency department personnel have an important role in identification of victims of trafficking.
- A physician equipped with skills, experience and expertise to contribute to various aspects of the counter-trafficking action will go a long way in helping with the identification of victims (and perpetrators) and also collection of evidence

Important Helpline Numbers in India:

1098 – CHILDLINE

CHILDLINE India is a project of Ministry of Women and Child Development. Childline India
foundation is a non-government organisation (NGO) in India that operates a telephone helpline called Childline, for children in distress. It was India’s first 24-hour, toll free, phone outreach service for children.

- 011-23478200 – National Commission for Protection of Child Rights
- 0674-2394041 – State Commission for Protection of Child Rights (Odisha)

Abstract

Introduction: International students are exposed to multiple mental health crisis due to social, environmental and culture shocks in foreign lands but it gets worse in presence of life-threatening disease outbreak. This research was conducted to evaluate the homesickness, anxiety and depression among Pakistani international students in Indonesia during Covid-19 Outbreak. Methods: This study was conducted on 86 random students that are pursuing their studies in different public and private universities in Indonesia. The data were collected by distributing google forms via email and social media groups and the responses from the respondents were recorded and analyzed statistically. Results: The study findings revealed that there is a correlation between Covid-19 pandemic and the development of various mental health crisis where 33 students (38.37%) developed homesickness, 11 students (12.79%) developed anxiety and 2 students (2.33%) manifested low-grade depression. Homesickness was outstandingly observed in females (72.72%) whereas anxiety was highly reported in males (90.90%). The study findings demonstrated that there is a strong negative correlation between student financial statuses and the development of homesickness (r: -0.977, P: 0.023) and anxiety (r: -0.944, P: 0.056). Conclusion: All in all, the fear to contract coronavirus, lockdowns, financial instability, death toll of citizens and medical professionals, run out of medical facilities and social media hoaxes are significant risk factors of mental health crisis among Pakistani international students in Indonesia.

Keywords: Covid-19, Pakistani International Students, Mental Health Crisis, Indonesia

Introduction

The global pandemic which is currently threatening human life and causing both social and economic difficulties in both developed and developing countries is attributed to the new type of coronavirus. The coronavirus causes diverse clinical manifestations such as pneumonia, high body temperature and respiratory impairments including difficulty in breathing and infection of the lungs(1). The majority of these viruses are known to highly affect both domestic and wild animals but some of these viruses were also reported to infect humans and cause the disease called zoonotic diseases. On 29 December 2019, the World Health Organization (WHO) has temporarily named it 2019 novel coronavirus as the coronavirus that started affecting the lower respiratory tract of different patients in Wuhan, China (2). Later on, WHO officially named it severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) which is the causative agent of Covid-19(3).

The lockdown caused by coronavirus disease outbreak is tremendously inconveniencing global citizens in various ways such mental health crisis, fear resulting from the deadliness of the new virus, financial instability, quarantine, contradicting information from different officials in high positions and misinformation.
from social media. All these factors contribute to the development of depression, homesickness, anxiety and other mental health crises that manifest incitizens but mostly in people who reside far away from their families like students who traveled abroad for further studies(4).

As global citizens are exposed to the consequences of coronavirus outbreak, mental health stability is considered as the most crucial feature of community health and wellbeing. From that perspective, depression is the highly prevalent mental disorder which doesn’t have limit to the time, place, and individual but also it involves all races and ethnicities of people from different demographic regions(5).

In response to the outbreak, the Pakistani students living in Indonesia are very scared about the virus incubation period and questioning themselves if the asymptomatic people could still buildout the infection. The serious quarantine measures in different major cities of Indonesia and their home countries which confined residents to their homes also aggravate the student’s condition by adding mental pressures. Apart from that, the reported insufficient medical protective equipments, few and unexperienced medical staff because SARS-CoV-2 is a new virus, shortage of hospital appliances and deaths of medical professionals in Pakistan causes the enormous concerns. In addition to the recent outbreak, the Pakistani students in Indonesia are exposed to psychological tension from the ongoing online classes with massive academic workload, living hand to mouth and financial instability due to the delay of their living allowances from the universities. From the above highlighted reasons, the big number of students are exposed to many environmental and academic pressures that could run them the development of various mental health crisis such as depression of various types(6).

One of the main challenges that Pakistani students experience during their stays in Indonesia is homesickness. It is explained as defined as a motivational and emotional situation which is characterized by the excessive desire and preoccupation of mind with thoughts of going back to the native countries and eventually lead to the absence of reassurance and increase the probability of developing depression and anxiety(7). Depression is a disorder that negatively affects the someone’s feeling and characterized by lethargy and the loss of appetite with increased sense of bad thinking and reduced concentration in diverse daily activities, cognitive performances and the development of insomnia(8). The study findings of published researches disclosed that the higher people get exposed to hard-pressing conditions, the lower his/her happiness will be. This was documented as a potential threat which affect people’s mental health and lead to homesickness, anxiety and depression of different degrees(7). By giving a great consideration to various published research works from different parts of the world, there are no published findings discussing about the pervasiveness of homesickness, anxiety and depression among Pakistani international students in Indonesia during Covid-19 outbreak. So, this current study is intended to light its beams on that research interest and provide primary data which will highly contribute to the continuous enrichment of the academic literatures and help the professionals to find out the effective solutions.

**Materials and Methods**

**Research design and participants**

This descriptive-analytical research was conducted in the duration of two months (from April to May 2020) on 86 (59 males and 27 females) Pakistani international students pursuing their studies in different public and private universities in Indonesia. Stratified randomization was used as a mean of sampling and collection. In this evaluation, the inclusion criteria were related to the active Pakistani international students in Indonesia who are enrolled in undergraduate, postgraduate and doctoral programs. The participants who reside in university hostels and off campus accommodations were all included in the study. As the study was carried with much consideration of the ethical clearance for research, whereby the exclusion criteria were the absence of students’ consent to be a part of this study.
Questionnaires

The distributed google forms via email and social media groups consisted of both closed-ended and open-ended questions. The forms were intentionally filled by the participants and those who filled in the forms were considered as the research participants through their intentional consents of participation. Questionnaires were employed to collect demographic data from the consented students including their personal identifications such as name, age, gender, marital status and other information like field of study, semester, level of education, living place, number of siblings and their rankings, financial and health statuses, physical exercise experience at home, hobby of reading novels, watching TV habits, the use of internet and laptop-based game playing during the day.

The questionnaires consisted of other supplementary points which examine the repeatedness of homesickness experience and the severity of homesickness. The questionnaire used to assess the depression among Pakistani international students in Indonesia consists of different scales which are lethargy, fear of contract corona, social media pressures with a lot of hoaxes, cognitive-emotion and academic motivation. Students were also asked about their health status to figure out the symptoms of anxiety like fatigue, irritability, trouble of sleeping or staying awake, panic attacks, excessive worrying and restlessness. All the responses from the respondents on each form were evaluated where the low scales indicated the normal states while from the medium to high scores in terms of symptoms were the perfect indications of homesickness, anxiety and depression of different stages.

Data Analysis

SPSS version 23.0 (SPSS Inc., Chicago, IL, USA) was employed to analyze the obtained data whereby nonparametric test was employed to test the normality and Pearson correlation was used to evaluate the correlation between the variables.

Results

The findings of the current research disclosed that there is a strong positive correlation between Covid-19 pandemic and the development of various mental health crisis among Pakistani students where the analysis of obtained data demonstrated that 40 students (46.51%) were free of any mental health problem, 33 students (38.37 %) developed homesickness, 11 students (12.79%) developed anxiety and 2 students (2.33 %) manifested low-grade depression. Of all 33 students who manifested homesickness, 24 (72.72 %) were females whereas the big number of anxious students were males and they occupied 90.90 % of all research subjects who presented anxiety.

As demonstrated by the results presented in table 1, the high prevalence of homesickness was seen among female participants whilst the anxiety was appeared in males and the equal number of low-grade depressions was observed in both sexes (1:1). In reference to the study findings presented in table 2, the research subjects that are less than 25 years of age were highly susceptible to anxiety, 9 (81.81%) whereas the informants that are aged between 25 and 30 years were vulnerable to homesickness,19 (57.57%) and the respondents above 30 years of age showed a resistance to anxiety and depression. As shown by the findings recorded in table 3, the students with financial instability (weak) manifested the symptoms of homesickness and anxiety compared to others. The development of mental health crisis in relation to the use of internet and TV watching habits as described in table 4, was highly observed among the students who frequently use internet and watch TV. Of all 33 students who developed homesickness, 18 (54.54%) of them use internet and 12(36.36%) use both internet and watch TV.

Discussion

The core results of this evaluation demonstrated that Covid-19 outbreak is highly attributed to the development of various mental health crisis in foreign students due to different environmental pressures such as the increase in number of Covid-19 cases, strict lockdown measures such as strict stay at home directives including home confinement, quarantine, and isolation, conflicting messages from authorities, social media news and other psychological tensions.

The study findings revealed great number of homesickness in studied population. This result is in agreement with the research results of Moeini who reported that homesickness is common in foreign students due to the fact that they have a desire to return in their home countries and nostalgia for their respective intimate friends and siblings. The reported homesickness should also be attributed to the loneliness during lockdowns as well as the incompatibility with the new environments. This result is also supported by the study findings published by Terry which showed the presence of homesickness in non-native students due to diversity of cultures and societal health instability.

The high prevalence of homesickness observed in females is consistent with past studies that found the vulnerability of females to homesickness in females than males. This statement could be assisted by the results obtained by other researchers who reported the high prevalence of homesickness in girls than boys. But, the result of current evaluation is also compromising with the findings of Uchenna who did not find significant gender difference in homesickness.

The observed anxiety in this evaluation is in conformity with the study results reported by a Chinese researcher from the study that was conducted on Chinese medical staffs. It should be defined by the fact that Covid-19 pandemic has become a potential stressor, particularly as this is a new viral infection which doesn’t have a vaccine or a specific treatment, fear of being infected and the big number of reported deaths globally.

In this evaluation, the prevalence of depression was equal between males and females. The observed depression in boys is in tandem with the research findings published in previous studies emphasizing that boys due to their concerns about employment and their future that could be more likely to induce depression.

In regard to the obtained results, student’s age could be considered as a major predictor of depression. This is in line with the findings from the study of Zaid and
friends which disclosed that older people should have better mental health statuses, ability to calm themselves during hard conditions and are not highly developing mental health problems due to self-counselling\textsuperscript{(15)}. Apart from the fact that every individual responds to stress in different ways, the Covid-19 pandemic and the lockdowns has caused a lot of worries, hunger, uncertainty, pending death, confusion and chaos which could drive students crazy and highly inconvenience their psychological stress and mental health\textsuperscript{(8)}.

By emphasizing on the observed findings, the correlation between the habits of using both internet and TV watching contributed to the development of mental health crisis. These results are in conformity with the study results published by Hökby that the duration spent on the Internet, web based content, the use of social platforms and watching TV programs or news highly contribute to depression and anxiety\textsuperscript{(16)}. The large negative correlation observed between mental disturbance and the use of internet and TV watching is attributed to the fact that social media and various TV stations are broadcasting depressive news and the conflicting messages between government officials and health professionals\textsuperscript{(17)}.

**Conclusion**

The conclusion that can be drawn from the results of this research is that the fear to contract coronavirus, lockdowns, financial instability, death toll of citizens and medical professionals, run out of medical facilities and social media hoaxes are significant factors in mental health crisis of Pakistani international students in Indonesia during Covid-19 pandemic. As mental health crises should be mitigated by having positive opinions and strong feelings of efficacy. From that standpoint, it is recommended to embrace the talking cure with their families, physical exercises and positive thinking to avoid unintended and irreparable consequences.

Determination the Relationship between (KLF14 rs972283) Genotype and Type 2 Diabetes in a Sample of Iraqi Patients

Shaimaa Abbas Dawood¹, Mohammed Ibrahim Nader²

¹ Scholar Researcher Laboratories of Al Shahed Mohammad Baqer Alhakim Hospital, Ministry of Health, Iraq,
² Scholar Researcher, Institute of Genetic Engineering and Biotechnology for Postgraduate Studies, University of Baghdad, Baghdad, Iraq

Abstract

This study was aimed to detect KLF14 gene polymorphism in Iraqi type 2 diabetes mellitus patients (T2DM) to found the correlation between the SNP (rs972283) polymorphism in KLF14 gene and lipid metabolism and impact on the incidence of type 2 diabetes mellitus (T2DM). The result show high Significant difference was observed in FBS level (P<0.001) in patient group (172.9 ± 79.73) and in control (81.16 ± 7.18). Cholesterol, LDL-Cholesterol and VLDL-Cholesterol mean level value in diabetic patients was significantly higher than those of control group (p<0.0001), serum HDL-Cholesterol mean value was significantly difference (P<0.05) in serum mean level of HDL between T2DM patients and healthy controls. Real time PCR (HRM) RT-PCR were used to detect SNP (rs972283) in KLR14 gene (G>A) by using specific primers, as a related with SNP (rs972283) G>A in KLF14 gene, genotypes and alleles frequencies, odds ratios, 95% confidence intervals and P values for the KLF14 gene In this study, statistical analyses of genotypic frequencies for the KLF14 (rs972283) revealed significant difference between T2DM patients and controls in the examined population. GG genotype was significantly (P = 0.0006) more frequent in the patient group. The observed G/G, A/G, and A/A genotype frequencies were 50%, 42%, and 8%, respectively. The A (wild-type) and G (variant) allele frequencies were 29% and 71%, respectively in patient group while the observed G/G, A/G, and A/A genotype frequencies were 22%, 48%, and 30, respectively and the A (wild-type) , G (variant) allele frequencies were 54% and 46%, respectively in control group (P <0.0003). GG genotype was significantly (P = 0.0006) more frequent in the patient group, Conclusion: There was a relationship between polymorphism of KLF14 gene SNP (rs972283) and the incidence of T2DM in sample of Iraqi patients.

Keywords: KLF14 rs972283, Genotype, Type 2 Diabetes

Introduction

Diabetes is a chronic disease that occurs when the pancreas does not produce enough insulin or when the body cannot effectively use the insulin it produces, Hyperglycemia, or increase in blood sugar, is a common effect of uncontrolled diabetes and over time it leads to serious damage to the body system, especially nerves and blood vessel (¹).

The global epidemic of diabetes is a major public health problem, and the number of cases has increased four times in the past 30 years (²). Incredibly, 1 in 11 adults suffered diabetes globally. It is estimated that about 463 million adults were living with diabetes mellitus worldwide in 2019, and most of them had type 2 diabetes mellitus (T2DM). Moreover, this number is expected to increase to 642 million by 2040 (³). Considering its high prevalence and rapid increasing speed, there are increasing numbers of investigations focusing on risk factors and susceptibilities for T2DM. However, the underlying etiology of T2DM remains unclear. Therefore, we conducted this meta-analysis to
further demonstrate whether genetic factors play a vital role in the pathogenesis of T2DM \(^{(4)}\) or not.

Lines of evidence suggest that genetic polymorphism plays a pivotal role in the pathogenesis of a wide range of human disorders including cancers, diabetes, cardiovascular disorders, kidney diseases, and neurodegenerative diseases \(^{(5)}\).

Several polymorphisms in candidate Kruppel-like factors that may influence susceptibility to T2DM. The transcription factor \(KLF14\), is a master trans-regulator of multiple genes that are associated with metabolic phenotypes in adipose tissue, \(KLF14\), is located on chromosome 7q32.3. Variations in these genes are associated with T2DM \(^{(4)}\).

### Materials and Methods

This study conducted during the period from 1 November 2020 until the end of March at University of Baghdad / Institute of Genetic Engineering and Biotechnology for post Graduate Studies. The study consisted of 50 patient with type 2 diabetic were selected from those attended Al Shahed mohammed Baqer alhakim Hospital. Their ages ranged between (25-65) years.

Fifty healthy controls with normal fasting blood glucose (80–110 mg/dl). And age range between (25-65) years. They were randomly selected from the people who attend the clinics for checkup also from relatives and colleagues. Questionnaire that includes information about age, sex, family history, BMI for all subjects had measured. Both groups were classified according to BMI, age, gender and family history.

### Samples collection

Amount of five ml of venous blood was withdrawn from each subject under aseptic conditions. Two ml of blood was placed in EDTA tube (1.5 mg/ml) and kept at -20 °C to be used in molecular study. The remaining 3 ml venous blood was placed into clot activator and gel serum separation tubes (5 ml) and left to stand at room temperature (18-22°C). Then, the serum separated by centrifugation at 3000 rpm for 15 minutes. Later, it was divided into three aliquots in microcentrifuge tubes for biochemical test.

#### Genomic DNA extraction:

Genomic DNA was automatedly extracted from the whole blood samples of all subjects by using Blood DNA Extraction Kit 200 (MagPurix/Taiwan).

The MagPurix technology is a state of the art platform that uses magnetic beads to extract nucleic acids from samples. The platform commits a truly walk-away automation in nucleic acid purification from samples to results. The purification process contains steps of lysis, binding, washing and elution. After genomic DNA was extracted, agarose gel electrophoresis was adopted to confirm the presence and integrity of the extracted DNA.

Fasting blood sugar FBS, Total cholesterol TC, high density lipids HDL, low density lipids LDL and Triglycride were measured using kits supplied by (Spainreact, Spain), while glycosylated hemoglobin HbA1C measured using kit supplied by (Nycocard ,Norway).

#### Genotyping:

Genotyping was carried out For SNP rs972283of \(KLF14\) gene polymorphism analysis, DNA was amplified using the forward primer 5'-GCTATTGAACCATCATTGT -3’ and Reverse primer 5’-AGCAATAACAGTCTTTAGTAATATG -3’.

The qRT-PCR-HRMwas performed in a 20 μl total volume, Primer forward 0.75 μl, Primer reverse 0.75 μl , DNA Template 3.5 μl, PCR Re Mix (Ready to use) EVA Green 10 μl and D.W. 5 μl. A total of 40 PCR cycles with denaturation at 95 °C for 15 sec., annealing for 40 Sec at 60 °C and extension at 72 °C for 20 Sec.

### Result and Discussion

All serum lipid and lipoproteins were significantly higher in diabetic patients compared to healthy control group. In Figure (1), T. Cholesterol mean level value in diabetic patients was significantly (p<0.0001) higher
than control group, this increase may be due to an increasing in the plasma concentration of VLDL and LDL, which may be due to the increase in hepatic production of VLDL or decrease in the removal of VLDL and LDL from the circulation. (Ganong, 2003).

In Figure (2) mean value of triglycerides in diabetic patients was significantly (P>0.05) increased compared to mean of control group. The elevated triglyceride levels can arise from two abnormalities, The impaired lipolysis of triglycerides and over production of VLDL and patients with type 2 diabetes have an over production of triglyceride-rich VLDL level, which is a result of high free fatty acid levels, hyperglycemia, obesity, and
insulin resistance\(^7\).

In Figure (3) LDL-Cholesterol mean value in diabetic patients was statistically significant\((p<0.0001)\) higher than the mean value of control group. The increased level of LDL in diabetic patients is due to insulin increases the number of LDL receptor, so chronic insulin deficiency might be associated with a diminished level of LDL receptor. This causes the increase in LDL particles and results in the increase in LDL-cholesterol value in diabetes mellitus\(^8\).

In Figure (4) Serum HDL-Cholesterol mean value was significantly \((p=0.0036)\). Difference in serum mean level of HDL between T2DM patients and healthy controls.
Figure (5): Comparison between control and patients in VLDL.

In Figure (5) VLDL-Cholesterol mean value in diabetic patients was significantly (P=0.00385) increased compared to mean of control group. Higher level of VLDL was the consequence of insulin resistance in which the skeletal-muscle system stimulates the conversion of energy from consumed carbohydrate to raise liver triglyceride synthesis. As a result, it will produce atherogenic TGs-rich lipoprotein units, like VLDL \((9)\).

Quantitative Real-Time Polymerase Chain Reaction - High Resolution Melting

Real-time PCR (RT-PCR) is also called quantitative PCR or qPCR. The key feature in RT-PCR is that amplification of DNA detected in real-time as PCR is in progress by the use of fluorescent reporter. The fluorescent reporter signal strength is directly proportional to the number of amplified DNA molecules \((10)\).

The current study uses qPCR-HRM assay to determine the SNP rs972283 of the \(KLF14\) gene \((G>A)\), in T2DM in Iraqi patients, by using specific designed primer and positive, negative control which ensure a high degree of specificity.

Distribution genotype and allele frequency of \(KLF14\) (rs972283 G>A) polymorphism in patients and controls.

\(KLF14\) is a master trans-regulator of multiple genes that are associated with metabolic phenotypes in adipose tissue. Table (1) illustrates genotypes and alleles frequencies, odds ratios, 95% confidence intervals and \(P\) values for the \(KLF14\) gene. In this study, statistical analyses of genotypic frequencies for the \(KLF14\) (rs972283) revealed significant difference between T2DM patients and controls in the examined population. GG genotype was significantly \((P = 0.0006)\) more frequent in the patient group.

The observed G/G, A/G, and A/A genotype frequencies were 50%, 42%, and 8%, respectively table (1). The A (wild-type) and G (variant) allele frequencies were 29% and 71%, respectively in patient group while the observed G/G, A/G, and A/A genotype frequencies were 22%, 48%, and 30, respectively and the A (wild-type), G (variant) allele frequencies were 54% and 46%, respectively in control group \((P <0.0003)\).
Table (1): Genotypes and alleles frequencies of KLF14 (rs972283 G>A) genes polymorphism in diabetic and control subjects.

Conclusion

The present case-control study focused on the contribution of KLF14 (rs972283 G>A) polymorphisms to the risk of having T2DM in Iraqi Population. The study also examined the relation between those polymorphisms and BMI and various biochemical parameters in the study sample. The results of the study can be summarized as KLF14 (rs972283 G>A) polymorphism revealed a significant difference between T2DM patients and controls; GG genotype was significantly more frequent in the patient group. The highly levels of Total Cholesterol, triglycerides, LDL and VLDL may associated with T2DM in people with risk variants in KLF14 gene.

Theoretical Study of Cyclohexane -1,2-Diamine-Oxalate-Platinum Metal Complex and Comparing with Experimental Data: DFT Calculations

Shakir D. Al-Saeedi¹, Hamid Ibrahim Abbood², Wisam ShareefIrzooqi³

¹Asst.Prof., University of Thi-Qar, College of science, Iraq, ²Prof, Al-Zahraa University for Women, Karbala, Iraq, ³Asst. Lect. Thi-Qar Education Directorate, Thi-Qar

Abstract

Theoretical studies for calculating the molecular structure and electronic properties of Cyclohexane -1,2-diamine-oxalate- platinum metal complex by using density functional theory (DFT) for get electronic properties and time dependent density functional theory (TD-DFT) for get excited state with B3LYP-SDD basis sets at the Gaussian 09 of programs. The electronic states of the system have been calculated depend on Koopmans’ theorem.

The results showed that the excitation energies of oxaliplatinum lie in the UV region of electromagnetic radiation with very high biological reactivity, where The absorption spectra of complex recorded with wavelength (344.69nm), oscillator strength (0.0002). From calculations of the HOMO - LUMO energies, energy gap, hardness and softness, all this results showed oxaliplatinum are more soft and can easily interact with enzymes because the enzymes are big soft molecules. Thus, the optimized geometry shows a good agreement with the experimental results.

Keyword: Oxaliplatinum, B3LYP/DFT-SDD calculations, quantum chemical parameter and Enzymes.

Introduction

The basic components of cells picked by nature are metals [1]. In the enzyme catalytic domain, they are commonly located and are active in various biological processes, from electron exchange to catalysis and structural functions. They are commonly used in cellular activities [2].

Platinum coordination complexes have formed a new class of active anti-cancer agents in animals, and man, the most commonly studied compound, it’s now in experimental clinical use against a wide range of human cancers[3].

In the treatment of disease disorders, metal-based compounds have been commonly used. Platinum products, such as cis-platinum Pt(NH₃)₂Cl₂, carboplatinum C₆H₁₂N₂O₄Pt and oxali-platinum C₈H₁₄N₂O₄Pt are the main of the metal-based compounds in the treatment of cancer [4]. Many metal complexes through, redesigning the current chemical structure by ligand substitution or constructing the entire new compound with improved protection, the synthesis has been synthesized. However, a handful of these drugs are currently under clinical trial due to increased focus on the clinical importance of metal-based complexes and several compounds are waiting to enter the trial.

Oxaliplatinum was discovered by Professor Yoshinori Kidani at the University of Nagoya City. Where, platinum compounds of the present generation were tested, in recent years, they have been focused on those with the 1,2-diaminocyclohexane carrier ligand,
such as oxali-platinum.

The experiments molecular biology and in vitro cytotoxic screening by the National Cancer Institute find that diaminocyclohexane platinum, such as oxaliplatinum, belongs to a separate cytotoxic family, different from cisplatin and carboplatin [5].

Oxaliplatinum is a platinum compound that, mainly by inducing intrastrand cross-links in DNA [6]. The crystal structure of the drug oxaliplatinum anticancer compound consist of planar platinum(II) center binding with ligands 1,2 cyclohexane diamine, it also has oxalate group [7].

The formula for oxaliplatinum is [Pt (R, R-DACH) (oxalate)]. Fig.1 shows DACH are diaminocyclohexane and the formula of oxalate is CO$_2$. They bind together to form oxalplatinum structure.

**Fig.1: Geometrical structure cyclohexane-1,2-diamine-oxalate-platinum (oxaliplatinum)**

**Computational Details**

In this study, the measurements were carried out, theoretically by using Gaussian 09 programs and Gauss View 5.0.8 program at the hybrid functional B3LYP together with SDD basis set possible quality for the system of interest for heavy metals use relativistic ECP, it is powerfully recommended for the heavy metals[9]. DFT depends on the energy of the ground state and all other electrical properties of the ground state that are uniquely determined by the electron density [9-10]. Additionally, the exact ground state of the system corresponds to the electronic density for minimal total energy. TD-DFT which can be used to investigate the excited-state properties and dynamics of a system in the attendance of time-dependent. TD-DFT method has been verified to be effective in deciding the spectral properties of certain transition metal complexes [11].

**Results and discussion**

The Cyclohexane-1,2-diamine-oxalate-platinum (oxaliplatinum), the structure is designed at Gaussian view 5.0.8. The resulting theoretical optimized parameters for the studied structure included bond length in angstrom A° and bond angle in degree, seen in Table 1. The relaxation showed a suitable method is used to DFT-B3LYP/ SDD basis sets in our data theoretical framework are in good agreement with the experimental data [12-13].

When we compared our calculations with experimental data. One can see, the optimized bond lengths Pt-N, Pt-O, C-C, and C=O are approximately equal with experimental values in ref. [12]. While, bond
lengths are slightly larger than the experimental values in ref. [13]. Furthermore, much of the bond angles optimized are slightly larger than the experimental values.

α from ref. [12].
β from ref. [13].

Table 2 displays the Calculated outcomes of the total energy $E_T$ (-843.0702914), $E_{HOMO}$, $E_{LUMO}$ and Egap ($E_{LUMO} - E_{HOMO}$) of the oxaliplatinum. In contrast to that, we showed a strong agreement with experimental data ref. [14], where listed in Table 2. Consequently, the present work is a suitable method a large separation was obtained between the valence and conduction bands. In our data, one can see LUMO energy (-1.1150658eV) greater than the HOMO energies (-5.852871), these results are similar to the result ref. [14]. The energy gap is a very important parameter as a symbol of the complexes biological reactivity, as can be seen in the table 2. Our Estimates, the Egap is 4.7378052eV in which the oxaliplatinum has insulating behavior. This outcome is in strong alignment with that of ref. [14], which corresponds to the high energy needed for oxaliplatinum to donate or accept an electron.

Biological activity of metal complexes can determine through study quantum chemical parameter HSAB [15-16]. Table 2 gather the calculated values hardness $H$ and softness $S$ for the oxaliplatinum complexes, the Quantum Chemical Parameter Pattern depends on the coordination and the molecular geometry of the complexes. It is important to address with HSAB the coordination tendencies of complexes against the enzymes. Soft complexes have small energy gap and can easily interact with enzyme because the enzymes are big and soft molecules.

Hard complexes have large energy gap and more complex to interact with enzymes, thus, one can note the results under study through table 3 are in good agreement with those in ref [14]. Also, from table 2 declare the results of electronic properties for our data and experimental ref. 14.
The results showed the virial ratio (-V/T = 2.1093) lies in the same range for the molecular systems, this an indication to a suitable basis set used for the relaxation of the studied metal complex.

The ionization energy IE and electron affinity EA measured values revealed the results of our data using B3LYP-SDD basis sets are in good agreement with ref. [14]. Ionization potential and electron affinity demonstrate the vibrational behavior and they can be expressed in terms of energies high molecular orbitals that are filled and low molecular orbitals that are unoccupied.

Ionization potential and electron affinity represents very important factors in symmetry, energy transfer and the stability of systems [17-18]. IE equal to (5.852871 eV) and EA equal to (1.1150658 eV) stands for closed shell system and these results are corresponding to the large value of energy gap of the compound and it has insulating behavior.

Fig.2 reflects the distribution of the HOMO and LUMO molecular orbital maps for oxaliplatinum. Where, A, B reflect present job, where red indicated negative regions with higher electronic density and green color indicated positive area. [15]. While C, D represent ref [14], where red indicated negative regions and blue color indicate positive regions. In present work one can see, the distribution map is similar with experimental data ref [14]. Where, the HOMO orbitals as an electron-donor region and LUMO orbitals as an electron-acceptor region. The LUMO distribution of oxaliplatinum presents a p-antibonding orbital spread over the oxalate group, which constitutes a special electronic feature of oxaliplatinum. Thus, the compound can be acting as oxidant and reduced relatively.
Fig. 2: Distribution of the molecular orbitals (MOs) of the oxaliplatinum maps: Present work HOMO(a) and LUMO(b). maps: Ref. [14] HOMO(c) and LUMO(d).

Fig. 3: The ESP distribution of the oxaliplatinum (ESP Counter left and 3D ESP right).

Fig. 3 illustrates the electrostatic potential ESP surfaces of Cyclohexane-1,2-diamine-oxalate-platinum Metal Complex by used to DFT-B3LYP/SDD basis sets. Oxaliplatinum ESP surfaces revealed that the potential was dragged into areas of high electronegativity. Thus, from figure 5 one can see

ESP demonstrates that, according to their mainly the high electronegativity, the charges are strongly dragged towards the oxalate group.

Excitation energy of the cyclohexane-1,2-diamine-oxalate-platinum metal complex was calculated by using the B3LYP-TD-DFT-SDD. The excitation energy of the main band appears at 3.597 eV, the oscillator strength, wave length, electronic transitions (HOMO→LUMO) and the transition characters were calculated and listed in Table 3.

Also, UV-Vis spectrum of oxaliplatinum appears at (344.69 nm), one can note, the excitation energies lie in the UV region of electromagnetic radiation with very high biological reactivity.

Conclusion

After discusses the results of the structural and electronic properties of Cyclohexane -1,2-diamine-oxalate-platinum Metal Complex using B3LYP-SSD/DFT, conclude the following:

· DFT/B3LYP-SDD basis sets used to study quantum chemical parameter and the electronic structure of the cyclohexane-1,2-diamine-oxalate-platinum (oxaliplatinum) metal complex.

· The result values of bonds and the angles are a good agreement with experimental data.

· Oxaliplatinum has insulating behavior due to $E_g$ is wide between the valence and conduction bands. Thus, the great contribution to the construction of the molecular orbitals is due to the outer electrons with few contributions from the ligands in the platinum metal. Oxalate group consist of oxygen atoms have able to interact with the receptor reactive sites due to high their negative charge densities in which they are the most electronegative atomic sites in complexes.

· A good relaxation was obtained without any imaginary frequency for the studied structure.

· Oxaliplatinum has a low electronic softness value and requires high excitation energy to transfer electrons or to accept an electron.

· Absorption spectra of oxaliplatin with wavelength 344.69nm, in the UV region.

Trend of Sex Related Crimes in Varanasi District

Shashank Shekhar Jha¹, Manoj Kumar Pathak²
¹ Junior Resident, Department of Forensic Medicine, IMS, BHU, Varanasi (UP), ² Professor and Head, Department of Forensic Medicine and Toxicology, All India Institute of Medical Sciences, Patna (Bihar)

Abstract

Introduction: Sexual harassment and sexual assault both rely on dehumanizing the intended victims. Sexual violence is a significant cause of physical and psychological harm and suffering for women and children. The Indian Penal Code (IPC) is the crucial criminal code of India.

Material and Method: Consent of the victim and accused was taken prior to examination. In case of minor, the consent from his/her parents or legal guardian was taken. SAFE (Sexual Assault Forensic Evidence) kit was used for sample collection from sexual assault victims and accused.

Observation and Result: This study includes cases 160 victims of sexual assault.

Conclusion: The present study, being a pioneer one, is relevant in the context of crime against women of all age groups in the Eastern U.P., especially of Varanasi district in socio-demographic and medico-legal paradigms. The government must set up a special unit that recruits officers specifically to deal with sexual offences, and create easy access to doctors, forensic experts, rape survivors and psychologists.

Keywords: Sexual offence, SAFE Kit, Medico-legal examination, NCRB, Criminal force.

Introduction

A Sexual offence has been defined by the Law Reform Commission of Canada (1978) as sexual contact with another person (including touching of the sexual organs of another) or touching of another with one’s sexual organs without that person’s consent. Any person may understand sexual violence as any sexual act using coercion regardless of their relationship to the victim, in any setting, including but not limited to home and work. In sexual violence, coercion constitutes an important component, which covers a whole spectrum of degrees of force. Apart from physical force, it may involve psychological intimidation, blackmail or other threats (Bancroft, J., 1974).[1]

Sexual harassment and sexual assault both rely on dehumanizing the intended victims. Sexual assault justifications tend to rely on negatively stereotyping the behaviour of the intended victim [2]. As per Crime Statistics 2018 by NCRB, Uttar Pradesh has been ranked as the worst state for women’s security and Madhya Pradesh as the state where rape is most rampant. According to the statistics, while UP registered 59,445 cases of crime against women, Madhya Pradesh registered 5,450 rapes, the maximum in 2018[3]. The Criminal Law (Amendment) Bill, 2018[4] was passed to replace the Criminal Law (Amendment) Ordinance, 2018 which was promulgated after the Kathua and Unnao rape incidents. The bill covers the same amendments as were in the ordinance. CLAA 2018 provides amendments in The Indian Penal Code, 1860, The Criminal Procedure Code, 1973, The Indian Evidence Act, 1872 and The Protection of Children from Sexual Offences Act. The

CLAA, 2018 amended IPC in two ways; firstly, made amendments to existing sections, and secondly, inserted new provisions of law.

Sexual violence is a significant cause of physical and psychological harm and suffering for women and children. The World Health Organisation (WHO) defines Sexual Violence as “any sexual act, attempt to obtain a sexual act, unwanted sexual comments/ advances and acts to traffic, or otherwise directed against a person’s sexuality, using coercion, threats of harm, or physical force, by any person regardless of relationship to the victim in any setting, including but not limited to home and work. (WHO, 2003) Sexual assault, a form of sexual violence, is a term often used synonymously with rape.[5]

The Indian Penal Code (IPC) is the crucial criminal code of India. It is broad code intended to cover all substantive aspects of criminal law. The code was drafted in 1860 on the recommendations of first law commission of India established in 1834 under the Government of India Act 1833 under the Chairmanship of Thomas Babington Macaulay[6].

Being a holy religious city for many religions, regular visit by people around the globe is paid and the approximate annual footfall of tourists, both international and domestic is around 6-6.5 lakh. According to 2011 Census of India, population of Varanasi itself was 3,676,841. [7]

Material and Methods

Present study was carried out in the Department of Forensic Medicine at Institute of Medical Sciences, Banaras Hindu University, Varanasi for 10 post-mortem cases and District Women Government Hospital, Kabirchaura, Varanasi for 150 ante-mortem cases from September 2018 to March 2020. Also, for hands-on training, visit to state-of-the-art One Stop Centre at Seth G. S. Medical College and King Edward Memorial Hospital, Parel, Mumbai for 15 days was done and some data was collected from there too. Total 160 cases of victims of alleged sexual assault were examined.

Consent of the victim and accused was taken prior to examination. In case of minor, the consent from his/her parents or legal guardian was taken. If the accused was in police custody and refused to consent for medical examination, then the examination was carried out without the consent of accused as per provisions of Section 53(1) of CrPC. Similarly if the accused was a female then she was examined as per provisions of Section 53(2) of CrPC.

SAFE (Sexual Assault Forensic Evidence) kit was used for sample collection from sexual assault victims and accused.

Inclusion Criteria:

- All alleged victims of sexual assault brought for medico-legal examination with crime registered.
- All the victims of alleged sexual assault brought for examination directly to hospital without registering the crime at concerned police station.
- Dead bodies with alleged history of sexual assault wherein informed consent from the guardian of the deceased is obtained.

Exclusion Criteria:

- Victims of alleged sexual assault who refused to give consent for medico-legal examination.

Observation and Results

This study includes cases 160 victims of sexual assault. In this region such study has not been conducted, so the present study was carried out with the view of understanding the magnitude and pattern of alleged sexual assault cases to create a sense of awareness and to suggest preventive measures.

The data was entered and analysed by using MS-Excel SPSS software package. Frequency of all variables was derived to check completeness of data. Magnitude was expressed in percentages.
Table no. 1: DISTRIBUTION OF SEXUAL ASSAULT VICTIMS AS PER GENDER AND AGE GROUP

As above table shows in total 160 cases, victim was physically assaulted in 27 (16.875%) cases, verbal threats to harm family/ kin in 4 (2.5%) cases, threat to acquire property was given in 2 (1.25%) case, blackmailing by threat to circulate photo/ video in 11 (6.875%) cases, using abusive/cheap words in 5 (3.125%) cases while no threat was used in 111 (69.375%) cases.

**Discussion**

Rape is the fourth most common crime against women in India according to NCRB records.[3] Rape in India received extensive media coverage after a fatal gang rape of a student in Delhi in December, 2012, and a village council-ordered gang rape of a young woman in West Bengal in January, 2014. Most recently a young veterinary doctor was raped, smothered and then burnt alive by a group of four people in November 2019. These incidents changed effect in policing ensured swift justice for most of the rape survivors and the complainants in cases of sexual harassment and molestation. India has been characterized as one of the “countries with the lowest per capita rates of rape”. [8]
In the present study cases below 18 years of age group, we found female preponderance 113 (70.625%) cases as compared to males 7 (29.375%) while in 40 (25%) cases victims are female while 2 (1.25%) are transgender above 18 years.

This is in agreement with the study by S. Bandyopadhay et al\textsuperscript{[9]} who observed almost 95% of cases of females as compared to 5% of males of sexual assault. Similarly our findings are consistent with other studies also Tamuli RP et al\textsuperscript{[10]} (98.43%), K. Bhowmik et al\textsuperscript{[11]} (97.08%) and Sarkar SC et al\textsuperscript{[12]} (88.9%).

![Relationship of Accused with Sexual Assault Victim](image)

**Figure No. 2: Relationship of Accused with the Sexual Assault Victim**

As per present study out of 160 victims, most common relation with survivor was friend 50 (31.25%) victims, followed by neighbour 43 (26.88%) victims and in 24 victims (15%) assailant was stranger, in 3 (1.87%) the assailant was teacher, in 5 (3.13%) victims the assailant was father, in 5 (3.13%) cases the assailant was employer. Out of 5 fathers 2 assailants were widowed. Out of 12 uncles, 2 were paternal and 1 was maternal uncle. Only 15% cases of sexual assault was committed by stranger and in 85% cases assailant was known to victim.

This finding is consistent with Rahul Jain et al\textsuperscript{[13]} who observed that in 87.5% of cases the rapist knew the victim (46.75% neighbour, 25% relatives, and 15.75% were friends) and Ian Mclean et al\textsuperscript{[2]} found that 69% of the assailants were known to the victim prior to assault.
In our study, the most reported site of offence was the house of accused i.e. 69 (43.125%) cases, Secluded area 43 (26.875%) and Survivors house 18 (11.26%) and in hotel 16 (10%) cases. Victims with known assailants are considerably more likely to be assaulted in a house/apartment where he resides than those assaulted by strangers. Victims assaulted by strangers are most likely to be assaulted outdoors.

Similarly study by Bhoi S et al\textsuperscript{14} found that maximum incidence took place at accused house in 146 cases (38.52%) followed by victims house in 127 cases (33.50%). Also our study is consistent with Rahul Jain et al\textsuperscript{13}, who found that most of the cases 46.75% and, in the study of Bijoy S et al\textsuperscript{15} 36.53% cases, where these victims were sexually assaulted in the house of the accused. Similarly as per study by Kumar Pal et al\textsuperscript{16} most incidences occurred at the house of alleged accused (31.40%).
We observed in this study that among total 160 cases, victim was physically assaulted in 27 (16.875%) cases, verbal threats to harm family/ kin in 4 (2.5%) cases, threat to acquire property was given in 2 (1.25%) case, blackmailing by threat to circulate photo/ video in 11 (6.875%) cases, using abusive/ cheap words in 5 (3.125%) cases while no threat was used in 111 (69.375%) cases.

This is consistent with Rahul Jain et al [13] (2008) and a similarly a study conducted at Massachusetts Executive Office of Public Safety and Security Research and Policy Analysis Division in 2008 [17], which concludes that for both strangers and known assaults, verbal threats were the most commonly reported type of force, reported in 58% of all assault cases.

**Conclusion**

The present study, being a pioneer one, is relevant in the context of crime against women of all age groups in the Eastern U.P., especially of Varanasi district in socio-demographic and medico-legal paradigms.

Of all the crimes, sex related crimes are the most barbarous and humiliating. Women and children remain the most vulnerable group of this crime. Justice Arijit Pasayat had observed that while a murderer destroys the physical frame of the victim, a rapist degrades and defiles the soul of helpless female.

The government must set up a special unit that recruits officers specifically to deal with sexual offences, and create easy access to doctors, forensic experts, rape survivors and psychologists. This will help victims feel confident in coming forward to seek justice. All registered offences must be dealt with by this unit within a month using fast-track courts. Predators must know that justice is swift and favourable to victims. India’s approach to curbing sexual aggression must steer clear of diminishing women, and root out reckless patriarchal attitudes instead.

The latest NCRB data for the year 2018 states, majority of cases under crimes against women out of total IPC crimes against women were registered under ‘Cruelty by Husband or His Relatives’ (31.9%) followed by ‘Assault on Women with intent to Outrage her Modesty’ (27.6%), ‘Kidnapping & Abduction of Women’ (22.5%) and ‘Rape’ (10.3%).

To conclude, the words of Robert F Kennedy seems appropriate:

> “Laws can embody standards, governments can enforce laws but the final task is not a task for government. It is a task for each and every one of us. Every time we turn our heads the other way when we see the law flouted when we tolerate what we know to be wrong, when we close our eyes and ears to the corrupt because we are too busy, or too frightened, when we fail to speak up and speak out we strike a blow against freedom and decency and justice.”

Abstract

Non-thermal atmospheric pressure plasma (N-APP) a physical method that recently had been extensively studied by researchers as a possible therapy in biomedical researches such as wound healing. In clinical dermatology, cold plasmas are mainly used for the treatment of chronic wounds and pathogen-based skin diseases, in which stimulation of tissue repair and decontamination. In this research, home-made Helium Non-Equilibrium atmospheric pressure plasma jet (He -NAPPJ), that had been generated using a DBD configuration for exceptional standardization protocol of this plasma source that was used in treatment of full-thickness skin tissue wound of normal and diabetic dogs. This clinical research in veterinary medicine is the first one in Iraq that study role of cold physical plasma in wound healing in diabetic wounds used the dogs as a model. The results were evaluated by quantitative real-time polymerase chain reaction qRT-PCR, which showed enhancement in wound healing process by cold plasma jet, by modulation of gene expression of basic-Fibroblast Growth Factor and Tumor Necrosis Factor alpha(TNF-α) in normal and diabetic dogs.

Key words: Growth factor, Skin Wound healing, non-thermal plasma jet.

Introduction

Plasma medicine is an emerging field incorporating physics, chemistry, life science, and medicine. To estimate the role of non-thermal plasma in wound healing process in this study, basic fibroblast growth factor (b-FGF) was used as a parameter, it plays a vital role in the repair of injured tissue in many studies,b-FGF has ability to promote cell division and proliferation related to injury repair and tissue reconstruction, moreover, during acute wound there is a rise in the production of b-FGF normally, which is responsible for angiogenesis, granulation tissue formation, re-epithelialization and tissue remodeling. Furthermore, Injury-induced b-FGF promotes the aggregation of monocytes, neutrophils, macrophages and fibroblasts via chemo taxis in the injured tissues (1). Tumor necrosis factor alpha (TNF-α) is a multifunctional pro-inflammatory cytokine, which is secreted mainly by monocytes and macrophages, the main supply of TNF-α are macrophages and T-cells, yet many other cells such as B-cells, neutrophils, and endothelial cells have been described to produce TNF-α. The functional relevance is broad, like the mediation of cell survival and pro-inflammatory response and, TNF-α instigates signaling pathways of the cell death (2).

Diabetes mellitus (DM) is one of the common endocrinopathy of dog characterized by hyperglycemia, glycosuria and weight loss. The treatments for diabetic wounds include surgical and non-surgical procedures. As a non-surgical treatment, the application of non-thermal plasma jet, is one of the promising methods to promote wound healing or to provide healthy wound beds for surgical treatments, a non-equilibrium
atmospheric pressure plasma jet (N-APPJ) is considered as environment friendly substances, have been studied all over the world, as reliable effects, safe, non-toxic and no adverse reactions have been reported in the treatment of wounds, but remains as dose dependent radiation. However, the interrelationship between diabetes, non-thermal plasma treatment and the wound healing process acts together with the immune system and the immunomodulatory function (3).

The aim object of this study is to demonstrate the effect of non-thermal plasma jet in treatment of diabetic wounds, through demonstration of tissue levels of gene expression of growth factors and cytokine using quantitative Real Time Polymerase chain reaction (qRT-PCR) technique, to measure the b-FGF and TNF-α gene expression level in alloxan- induced diabetic dogs compared to the normal ones. Also, studying the modulation effect of NAPPJ for both b-FGF and TNF-α.

Materials and Methods

Experimental design:

The experiments performed at the Department of surgery & obstetrics in the college of veterinary medicine, University of Baghdad, and all procedures conducted within the guidelines for humane care of laboratory animals and approved by the University of Baghdad ethics Committee (no. 1364/ P.G).

Twelve adult male dogs were used. All surgical and non-surgical procedures were performed under aseptic conditions and general anesthesia. Each dog was subjected to (4) full-thickness open cutaneous wounds of (3×3cm) of the animals back. Dogs were put into two groups: 1- The non-diabetic animal groups(N): six) The dogs were divided in two sub-groups: Non diabetic control (NC);Non diabetic treated (NT) by(N-APPJ); 2- The diabetic animal groups (D): (six) dogs were subjected to experimental induction diabetes, and after two weeks from induction they underwent the same previous procedure (grouping, wounding and treatment), and the sub- groups were: Diabetic control (DC); Diabetic treated (DT) with (N-APPJ). All the wound healing process was evaluated by Tissue level detection of (b-FGF), and (TNF-α), in consequence periods (0, 3, 7, and 14 days) post-surgery.

Induction of Experimental Diabetes:

Six dogs were placed on a fasting regimen for 24 hours before the induction of diabetes via intravenous injection of Alloxan which was dissolved in normal saline 0.9 %, at a dose of 100 mg/kg. After 32 hours, the dogs showed fasting hyperglycemia.

Non-thermal Plasma Jet System (Experimental Setup):

![Figure (2.1): Schematic representation of the DBD plasma jet system.](image-url)
In this research, the characterization of home-made Helium Non-Equilibrium atmospheric pressure plasma jet (He-NAPPP), that generated using a dielectric barrier discharge (DBD) configuration device (figure 2.1), driven by a (8 kVp−p) voltage, the frequency (12 kHz). As a working gas, Helium (He) was used in flow rates (6) slm, with 32 °C He gas temperature, plume length 40 mm. The distance is 15 mm from the distal end of Pyrex tube (DBD) and the wound surface, the power density 44 mWatt/cm², and plasma radiation energy dose 76J/cm².

**Molecular diagnosis:**

The biopsies from skin tissue of each animal were collected from normal skin and wounds of all sub-groups, and kept at deep freezing (-80 °C), then evaluated using RNA extraction kit for extract m-RNA then Real Time Polymerase chain reaction (PCR) technique for house-keeping, (b-FGF) and (TNF-α) primers as mentioned below:

**Primers:** Three primers were used in this study including the specific gene of cutaneous tissue in dogs which including Anterior Reverse glyceraldehydes-3-phosphate dehydrogenase (AR-GAPDH) gene primer that was used as Housekeeping gene (HKG) (4), anterior reverse b-Fibroblast Growth Factor (AR-FGF) (5) and anterior Reverse (AR-TNF-α) genes primers (4) that were used as target genes. The primers were used in quantification of genes expression by using Real–Time quantification Polymerase Chain Reaction (q-RTPCR) techniques based BRYT Green DNA binding dye (Promega–USA).

**The Kits used in molecular techniques** as SaMag Total RNA Extraction Kits, the GoScript™ Reverse Transcription System kit (Como–Italy), The GoScript™ Reverse Transcription System kit (Promega–USA), and GoTaq® qPCR Master Mix kit (Promega–USA).

**B. m-RNA Extraction:** m-RNA was extracted by automated nucleic acid extraction system according to with SaMag Total RNA Extraction Kit by Sacace Biotechnologies Srl Como – Italy company instructions. The extracted m-RNA samples were kept at freezing temperature (-20) C°.

**C. Examination of m-RNA Concentration and purity:** The concentration of m-RNA was measured by using NanoDrop ND-1000 spectrophotometer (thermo-fisher, USA), and according to the manufacture’s manual (NanoDrop Technologies, 2006).

**D. cDNA synthesis for easy transition to gene-specific target amplified:**

By using GoScript™ Reverse Transcription System KIT, and according to the manufacture`s manual. The following procedure is designed to convert up to 5µg of mRNA Mix and briefly centrifuge each component before use: Experimental RNA (3µl/reaction); Primer Oligo (dT)15 (1µl/reaction); Nuclease-Free Water(1µl/reaction) the Final volume was (5µl) For each reaction. The PCR component for syntheses of cDNA: Nuclease-Free Water (to a final volume of 15µl) (7.3µl); GoScript™ 5X Reaction Buffer (4.0µl); MgCl2 (1.2µl); PCR Nucleotide Mix(1µl); Recombinant RNasin® Ribonuclease Inhibitor(5.0µl); GoScript™ Reverse Transcriptase(1µl) and the final volium was (15.0µl) amount for each reaction. 15µl aliquots of the reverse transcription reaction mix to each reaction tube were added to ice. a final reaction volume of 20µl per tube

**Quantitative Real-Time PCR (q RT-PCR) master mix preparation:**

Assembling the Reaction Mix: Prepared the reaction mix by combining the GoTaq® qPCR Master Mix with cDNA, PCR primers and Nuclease-Free Water, the component and their volume used in reaction mixed of qPCR, the target genes primers TNF-α, or b-FGF were used, also the calibrator gene HKG. Each q-RT-PCR mixture reactions were prepared with (10µl) of GoTaq® qPCR Master Mix, (1µl) Forward Primer (20X), (1µl) Reverse Primer (20X), (3µl) Nuclease-Free Water, (5 µl) cDNA, and the final volume was (20µl). PCR program was used with Rotor-Gene cycler: the first step was (1) cycle of GoTaq® Hot Start Polymerase activation at (95°C) for (2 minutes), then denaturation
was used (40) cycles at (95°C) for 15 seconds, finally, Annealing and extension programmed at (60°C) for (1 minute).

**Statistical Analysis:** The data were analyzed using the following software, Microsoft excel, Minitab v17, and IBM SPSS V26. The results reported in this study were expressed as mean + _ SE. Two-way ANOVA were used to test between groups and days after treatments. Mean were compared using the least significant difference test (L.S.D).

### The Results

**Tissue level detection qRT-PCR:**

The dogs in diabetic group were kept in hyperglycemic state. The results showed slight non-significant increase in expression of (b-FGF) in wound tissue by qPCR after 14 days from alloxan-induced diabetes. While at the same days the results showed significant increase in TNF-α level in wound tissue in diabetic dogs.

**Fibroblast growth factor (b-FGF)& (TNF-α) detection:**

Table (3-1): The final result is presented as the fold change of target gene expression a. (b_FGF), b. (TNF-α) in treatment groups by using $2^{\Delta\Delta Ct}$ method(6).

Discussion

The results showed slight non-significant increase in expression of (b-FGF) in wound tissue by qPCR in hyperglycemic animals, while a significant increase in TNF-α level in wound tissue sample in diabetic dogs. This finding was explained by many researchers, who stated that the uncontrolled diabetes is characterized by hyperglycemia that has been shown to drive oxidative and nitrative stress. Hyperglycemia also stimulates expression of multiple survival factors, including (FGF-2), and vascular endothelial growth factor (VEGF), which is generally protective against endothelial cell death, which was similarly elevated in high glucose conditions (7). The elevation of in the TNF-α level has been measured in diabetic laboratory animals (rats), in study (8) used streptozotocin-induced diabetic rats, with significant increase in TNF-α messenger RNA expression were twice as high in diabetic rats than in no diabetic control rats.

In the present study it has been found that there is a relationship between the results of both (b-FGF and TNF-α). In other study the researchers examined the possible role of basic fibroblast growth factor (b-FGF or PGE2) in regulating the effects of TNF-α, they find that FGF enhanced the amount of prostaglandin (PGE2) produced in response to TNF-α between (3-11) fold, and increases TNF-α receptor expression in fibroblast cells. Glucose and (TNF-α) concentrations are increased in diabetes, these factors correlated both with diabetic endothelial cell apoptosis, vasculopathy and induced cell viability inhibition that led to the proliferative inhibition. The b-FGF associated elevation in TNF-α-induced cell death. b-FGF release by endothelial cell in high glucose goes to cell cycle progression, which makes cells more liable to TNF-α-induced cell death (9).

In the present study the level of b-FGF gene expression appeared high in both treatment sub-groups (NT &DT) when compared to control sub-groups (NC& DC) significantly at (P< 0.001) between the periods of time 0, 3, 7, and 14 days post wounding, also there was significant difference between groups (N&D) at (P< 0.001). In more details, the results showed high up-regulation of b-FGF gene expression (7.16) at 3 days post wounding compared with the zero day; (5.94) at 7 days, then normal regulation (1.48) at 14 days, post wounding in comparison with the zero day, in NT group attributed to NC group. Also in DT group attributed to DC group there were up-regulation of gene expression at (4.42) at 3 days and (4) at 7 days, while normal regulation in gene expression found at 14 days post wounding compared with the zero day. In a study (10) found that the endothelial cells treated with plasma for 30 seconds demonstrated twice as much proliferation as untreated cells, in that way they suggested that low dose non-thermal plasma enhances endothelial cell proliferation due to reactive oxygen species mediated b-FGF release. The same results found in (11) they suggested increase in b-FGF mRNA expression in murine skin wound tissue treated with CAP that was compared to control group. Also, the secretion of angiogenesis-related molecules is affected after the CAP treatment in endothelial cells, fibroblasts and keratinocytes.

This clinical study had proved the effect of AP-He-PJ in boost the gene expression of TNF-α in both treatment sub-groups (NT &DT) at 3 days, when compared to control sub-groups (NC& DC) significantly at (P<0.001), also there was significant difference between groups (N&D) at (P< 0.001). There is significant difference in (TNF-α) gene expression of treatment sub-group NT in comparison to control NC between all periods of time, the same results found in DT in comparison to control DC between the periods of time. In the same way the results in NT sub-group showed up-regulation of TNF-α gene expression (1.98) at 3 days, while there was normal regulation in gene expression at 7 and 14 days post wounding compared with the zero day. However, in DT sub-group, there were up-regulation of gene expression at 3 days (6.42±0.360), while there were slight down-regulation in gene expression at 7 and 14 days post wounding, when compared with the zero day. Many molecular researchers studied the TNF-α, they differ in explaining the role of this cytokine that involved in the process of wound healing. At wound tissues,
TNF-α is quickly released and initiates inflammation, synthesis of TNF-α was detected just after wound was developed, then increased during the first several hours, reached a peak level at day 1, and then reduced to the basal level, and they indicated that TNF-α is involved in the early healing process (12). While other studies reported the harmful effects of TNF-α were significantly amplified in the presence of high glucose. The excessive TNF-α is closely related to diabetic complications by inducing endothelial cell apoptosis under high-glucose condition, which exacerbated inhibitory effects of TNF-α by increasing its expression (9). A study (13) revealed the selective apoptotic effect of CAP on cytotoxic and T-helper cells, B-lymphocytes, and natural killer (NKT) cells may be involved in regulating the healing process, also, in vitro study by (11) demonstrated the beneficial effect of short time (60 s) application of NTP on parameters of molecules and cell function involved in wound healing in osteoblast-like cells. Their results showed the significant increase in the mRNA expression of pro-inflammatory cytokines IL-1β, IL-6, chemotactic factor IL-8, also, TNF-α and COX2 after 1 day compared to untreated cells. These mediators play an important role in wound healing managing the primary inflammation process, and the extra cellular matrix organization, which are both crucial for the entire wound regulation.

Conclusion

In conclusion, these findings not only support the fact that non-thermal plasma has a potent multifunctional agents during tissue regeneration, but also highlight the potential multimodulatory therapy advantages of non-thermal plasma. The enhancement in wound healing process by cold physical plasma jet, by modulation of gene expression of basic-Fibroblast Growth Factor and Tumor Necrosis Factor-alpha in normal and diabetic dogs.

Effect of Ammivisnagawater Extract Compared to Proximol (Halfa Bar Extract) in Treatment of induced Renal Lithiasis in a Mature Female Rabbit

Shatha Mahdi Younis1, Abdulrazaq N. Khudair2, Asia Selman. Abdullah3

1MSC Student, 2Professor, Department of Physiology / College of Veterinary Medicine/ University of Basrah, 3Assistant Professor, Department of Pharmacology and Toxicology/ College of Pharmacy / University of Basrah

Abstract

Nowadays people worldwide uses several medicinal plants especially for curing urinary lithiasis. Ammivisnaga is extensively distributed medicinal plant used for management of numerous diseases including urinary lithiasis. Cymbopogon proximus or called Halfa-bar suggested for use in medicine for the ejection of ureteric and renal calculi. Ammivisnaga and Halfa-bar found in Asia and several parts of the world. This study aimed at investigating and comparing both Ammivisnaga and Halfa-bar extracts for their antiurolithic activity using a mature female rabbit. Forty-two rabbits randomly divided into four groups. Group A negative control, group B positive control (chemically induced urolithiasis), group C like group B but treated with Ammivisnaga extract 5 ml orally twice daily for 2 weeks and group D like group B but treated with Proximol (Halfa Bar extract) 5 ml twice daily for 2 weeks also. GC-MS analysis of alcoholic extract of AmmiVisnaga revealed the detection of main alkaloids Khellin, Visnagin, adulicin and enidimine, with other compounds in lower quantity. The results show that group of induced urinary lithiasis for 14 days and 21 days showed clear body weight loss, higher consumption of drinking water and increased morning urine excretion. In addition to significant increase of blood urea, uric acid, serum creatinine and calcium levels. After 14 days of treatment with AmmiVisnaga extract and proximol we noticed reversed body weight loss and overcome low blood urea, serum uric acid, creatinine and calcium. Furthermore, urinary lithiasis groups showed clear crystallization compared to the control urine samples, but after 14 days treatment with AmmiVisnaga and proximol extracts, there was nearly clearance of the urine and disappearance of the crystals from the urine. In conclusion, AmmiVisnaga and Proximol are safe and good diuretic herbs causes improvement in the body weight, high clearance in urine crystals and amelioration in kidney function compared to untreated group.

Key words: Ammivisnaga, Proximol, Cymbopogonproximus, urinary lithiasis.

Introduction

Kidney lithiasis considered as a common disease of high number of people exhibited for many years ago until now. It causes severe pain and several disturbances in the biochemical and hematological characteristics, that urinary lithiasis may be formed due to the consumption of canned food that contain several chemical materials used as food preservative as well as drinking non-pure water for long period. Although treatment of renal stone nowadays is undertaken by new methods, such as using waves to destroy renal calculi, or by endoscopy or even surgical removal of stone. The mentioned methods have disadvantages like the need to professional people to do it, also, the high cost and possibility of relapse and reformation of the stones in the kidney. In addition to the

DOI Number: 10.37506/ijfmt.v15i4.17083
numerous side effect such as kidney tissue destruction resulting in elevation of blood pressure, hemorrhage and ureter obstruction in addition to multiple inflammations which may lead to severe sepsis. The source of stone formation can be calcium oxalate or uric acid stone$^{1, 2}$.

Therapeutic drugs such as diuretics and antibiotics were not sufficiently effective in treatment of renal stones and associated with different side effects$^{3, 4}$. Nowadays people all over the world uses several medicinal plants especially for curing urinary lithiasis, after analysis medicinal plants are found to contain several materials which can affect urolithiasis by different pathways such as relieving spasm, increasing diuresis or decreasing pain$^{5, 6}$.

Ammivisnaga L. is a short annual or biennial herb indigenous to the Mediterranean region of North Africa, Asia, and Europe$^7$. The plant also distributed throughout North America (North Carolina, Pennsylvania, Oregon, Alabama, California, Florida, and Texas), the Atlantic islands, Argentina, Mexico, and Chile. In Asia, the plant is found in Iraq, Iran, and other western and southern countries. The plant, especially its fruit, has a wide range of applications either in traditional or modern medicine$^8$.

Many common drugs developed from this plant, khella. These drugs includescromolyn, amiodarone andnifedipine. Khellin, which isolated from khella, used for the treatment of asthma and angina pectoris. Furthermore, it is used with the phototherapy for vitiligo, alopecia areata and psoriasis.

Khellincaninhibit citrate metabolism. It was reported that urinary citrate is important to reduce the recurrences of calcium oxalate urinary stones$^7$. The most popular type of urinary stone is calcium oxalate stones, constitute about 80% of total stone types and citrate is a known inhibitor of calcium oxalate crystallization$^9$.

_Cymbopogonproximus_ or called Halfa-bar is an aromatic grass extensively growing in Upper Egypt, the genus _Cymbopogon_, from Gramineae family. It was suggested for use in medicine as diuretic, abdominal or renal antispasmodic, act by relaxation of the fibers of smooth muscle without eliminating propulsivemove of the tissue; therefore, it is used for the ejection of ureteric and renal calculi$^{10}$.

This study aimed at investigating and comparing both Ammivisnaga and Halfa-bar extracts for their antiurolithic activity using a mature female rabbit. Ammivisnaga and Halfa-bar found in Asia and several parts of the world.

### Material and Methods

Current study done at the department of Physiology, Pharmacology and biochemistry of College of veterinary medicine, University of Basrah; in the period from October 2019 to March 2020. Twenty-four healthy adult female rabbits weighing 1-1.5 kg, obtained from local animal market at Basrah city, and housed in the animal house of the college of Veterinary medicine / University of Basrah. The rabbits housed separately in cages under controlled room temperature around 25°C and 12 hours dark-light cycle. The animals have free access to food and water (ad libitum) throughout the study. However, the food and water were restricted 24 hours before urine collection. Cages of the animal were cleaned regularly, and animal kept for seven days for adaptation prior to the start of the experiment.

**Preparation of AmmiVisnaga plant extract:**

Seeds of Ammivisnaga plant bought from the Basrah market. The seeds air-dried in 40°C oven, after that dried seeds were crushed. About 180g of seeds placed in 500 ml of distilled hot water and soaked for 3 days in pure water with occasional shaking at room temperature, the filtration was done using clean muslin cloth and through Whatman qualitative grade1 filter paper. The procedure repeated twice, and all the filtrate combined and called as crude extract. This extract used for administration to animals.

This crude extract of Ammivisnaga screened for the presence of different phytochemical materials by drying to harvest dried powder. After that, the dried powder soaked in 70% ethanol as a solvent and a rotary vacuum evaporator under reduced pressure used to get alcoholic
extract and to eliminate the solvent. This extract screened
for the presence of different phytochemical materials
such as alkaloids, saponin, coumarins, khillin, visnagin
and flavonoid by using GC mass.

**Experimental induction of urolithiasis**

Calcium oxalate urolithiasis was induced in the
kidney of female rabbits in both untreated and treated
groups using 2 ml of (0.75%) ethylene glycol orally
for each animal daily for 21 days and 2 ml of 1 %
ammonium chloride orally for the first 5 days only and 2
ml of disodium oxalate orally for 21 days. Control group
was drenched 2 ml of normal saline for 21 days.

Ethylene glycol administration is a common method
for the induction of experimental urolithiasis, it has been
used alone or in combination with other drugs such as
ammonium chloride for the study of kidney calcium
oxalate crystals deposition. To achieve uniformly high
rate of kidney crystal deposition, ammonium chloride
has been drenched in the first 5 days of the experiment
as it causes acidification of the urine and hence enhances
calcium oxalate crystallization.

**Animal's treatment**

The rabbits were divided randomly into four groups
(6 rabbits each), the first group (Group A) drenched
only 2 ml of normal saline daily orally throughout the
experiment period (21 days) and considered as negative
control group. The second group (group B) was drenched
ethylene glycol (0.75%) twice daily and disodium
oxalate (350 mg in 100 ml distilled water) 2ml daily
orally for 21 days. In the last week, the dose increased
to 3 ml twice daily and considered as a positive control.
The third group (group C) was drenched like group B but treated with Ammivisnaga extract 5 ml orally twice
daily for 2 weeks. The fourth group (group D) drenched
like group B but treated with Proximol (Halfa Bar
extract) 5 ml twice daily for 2 weeks also.

**Sample collection for analysis:**

Urine samples collected at the morning from all
groups and analyzed by urine strips method to know the
changes in biochemical constituents.

Blood samples were collected from all groups by
cardiac puncture to estimate renal function test including
blood urea, serum creatinine, serum uric acid and serum
calcium.

**Statistical Analysis**

Result gained in this experiment were estimated
as a mean ± standard error of the mean (SEM). The
significant variance between groups were measured by
ANOVA using the SPSS followed by post-hoc test.
The comparison between groups was estimated by least
significant difference (LSD) test (P≤ 0.05).

**Findings**

The samples collected and investigated after the
chemical induction of urinary lithiasis and after two
weeks treatment of rabbits with AmmiVisnaga and
proximol extracts.

The group of induced urinary lithiasis for 14 days
and 21 days showed clear body weight loss, higher
consumption of drinking water and increased morning
urine excretion. In addition to significant increase of
blood urea, uric acid, serum creatinine and calcium
levels (table 1).

After 14 days of treatment with AmmiVisnaga
extract and proximol we noticed reversed body weight
loss and overcome low blood urea, serum uric acid,
creatine and calcium as shown in (table 1).

After three weeks of induction, urinary
lithiasis groups showed bad effects in urine examination
significantly different from control group, these effects
includes urinary crystals, increased bilirubin, increased
urine total protein loss, decreased urinary acidity,
increased leucocyte contents, increased nitrite, increased
urobilinogen, increased blood content as well as
significant increase in urine glucose and ketone bodies.
The only parameter, which is not significantly affected,
is the urine specific gravity, as shown in (table 2).

GC-MS analysis of AmmiVisnaga extract:

GC-MS analysis of alcoholic extract of AmmiVisnaga revealed the detection of the main four components Khellin, Visnagin, adulicin and enidimine, appeared as high peaks in the figure, while the lower peaks represented other less contents of other compounds, as illustrated in figure 1.

![Figure 1: Histogram of AmmiVisnaga alcoholic extract showing the main chemical compounds.](image)

Urine Crystallization:

After 14 days and 21 days from induction, urinary lithiasis groups showed clear crystallization compared to the control urine samples, but after 14 days treatment with AmmiVisnaga and proximol extracts, there was nearly clearance of the urine and disappearance of the crystals from the urine as shown in figures 7, 8, 9, 10.

![Figure 2: Image of urine samples collected in the morning from rabbits (A) control group (B) lithogenic group after 14 days of induction showing clear crystals and (C) lithogenic group after 21 days of induction showing severe crystallization. Discussion

Results of this study showed that urine crystals formation induced by drenching ethylene glycol and ammonium chloride caused damage to the renal tissue, as in previous studies\textsuperscript{11, 12}. This damage might induced by the reactive oxygen species (ROS) which is regarded as the dangerous material produced by the crystals deposited in the renal tissue forming renal calculi\textsuperscript{9}.

In this study AmmiVisnaga extract induced significant rise in urine production (diuresis effect) compared to the control group, this may be due to the diuretic materials found in AmmiVisnaga extract which may possess several treatmental actions present in several phytochemicals. So diuretic effect of AmmiVisnaga increases urine amount is voided leading to decrease urine saturation of salts crystals and help in discharging out of the previously formed crystals\textsuperscript{16,17}. Previous studies on AmmiVisnaga revealed removing of DPPH free radicals and caused inhibition of fat peroxidation assisting its antioxidant properties\textsuperscript{13-15}.

In this experiment high calcium oxalate crystals were induced in the kidney by ethylene glycol (0.75% in the drenching water) for 21 days and ammonium chloride (1%) was given only for the first 5 days, as drenching ammonium chloride for more than 5 days will causes severe weight loss and may result in rabbits death\textsuperscript{18}. Drenching of ethylene glycol and ammonium chloride causes more crystallization in the urine as well as forms larger crystals because of hyperoxaluria. Higher water consumption and more urine excretion may happened because of kidney damage\textsuperscript{19}. Furthermore, there was significant rise in the serum creatinine, blood urea and total protein loss in the lithogenic group when compared to the control group, these overcome by AmmiVisnaga and Proximol extracts.

These results in cope with other past results recorded that crystallization of salts in the urine caused by increase in oxalate consumption and less calcium excretion in the group of induced urolithiasis was overcome by drenching AmmiVisnaga extract\textsuperscript{20, 21}.

AmmiVisnaga accelerate the recovery compared to untreated group which was obviously seen by improvement in the body weight, high clearance in urine crystals and amelioration in kidney function compared to untreated group.

This study provided us with a good knowledge on the treatment bases and its action in the urinary calculi or stones. Furthermore, the plant can be considered as safe. Previous study found no toxic effect of AmmiVisnaga extract on rats and the plant has a good history of medical uses consumed by human and regarded safe and nontoxic\textsuperscript{22}.

Result of Table 1 showed a significant effects of lithogenic treatment on blood urea, serum creatinine, uric acid and serum calcium and their overcoming and ameliorative effects by both AmmiVisnaga and proximol. Those result are consistent with previous studies on sheep\textsuperscript{23} and on rats\textsuperscript{24}.

The significant increase in serum calcium level in this study due to lithogenic treatment may be due to calcium reuptake under the effect of aldosterone\textsuperscript{25}. This explanation supported by reduction of serum calcium level by AmmiVisnaga and proximol significantly nearly to the control. Therefore, the dose of AmmiVisnaga extract and Proximol need to be adjusted or refined in the case of combined treatment.

The results of this study indicates that there is a bad effect on the Kidney function caused by the lithogenic effect indicated by significant increase in the blood urea, serum creatinine and uric acid as well as serum calcium, these effects are ameliorated by AmmiVisnaga extract and Proximol. These results are consistent with the results of previous study\textsuperscript{25}, and with other study that explained high salt consumption resulted in the formation of kidney damage, which may lead to Kidney failure\textsuperscript{26}.

When rabbits with renal impairments treated with AmmiVisnaga or proximol extracts, the high serum level of uric acid, creatinine and blood urea were regressed to the non-significant levels in comparison with the control.
Other parameter such as ketone bodies, PH, protein, Nitrite and bilirubin were increased due to lithogenic formation. Treatment with AmmiVisnaga or Proximol extracts ameliorate these parameters and restore their concentration to nearly normal levels due to their diuretic, antioxidant, anti-inflammatory and antispasmodic effects.

Conclusion

In conclusion, AmmiVisnaga and Proximol are safe and good diuretic herbs causes improvement in the body weight, high clearance in urine crystals and amelioration in kidney function compared to untreated group.

Studying the Influence of Maternal Factors on Iraqi Pediatrics Patients Presented with Neonatal Hyperbilirubinemia

Shaymaa Hasan Abbas1, Lubab Tarek Nafea1, Rasha Saadi Abbas1

1Assistant Lecturer, Department of Clinical Pharmacy, College of Pharmacy, Mustansiriyah University, Baghdad, Iraq

Abstract

Background: Hyperbilirubinemia regarded as common problem in neonates. Risk factors for elevated indirect bilirubin include maternal age, race, prematurity, and breast-feeding.

Material and Methods: This study include mothers of term newborn infants with neonatal hyperbilirubinemia requiring phototherapy and/or exchange transfusion that are combatable or have maternal-fetal ABO incompatibility to evaluate maternal contributing factors which related to development of hyperbilirubinemia in newborns.

This study found that higher serum bilirubin level (31.32 ± 2.30mg/dl) found in 28% neonate for mother were ≥30 years old. There was no significant difference found in serum bilirubin level according to parity (primi or multi). There was association between the neonatal serum bilirubin level with maternal ABO blood groups which showed highest mean of neonatal serum bilirubin reported in neonate for mothers carry blood group A and B (17.92 ± 10.32), (17.28±6.85) respectively. While a result of the association of neonatal serum bilirubin level to maternal Rh reuses factor found that there was no significant differences among them (P>0.05).

Conclusions: hyperbilirubinemia was more frequent in neonate for mothers≥30 years old. Presence of highest mean of neonatal serum bilirubin reported in neonate for mothers carry blood group A or Band Rh - women.

Keywords: Hyperbilirubinemia, Maternal factors, Neonate’s blood group.

Introduction

Hyperbilirubinemia regarded as common and non-threatening problem in neonates. Jaundice is observed during the 1st week of life in approximately 60% of term infants and 80% of preterm infants(1,2). The raises of indirect, unconjugated bilirubin are potentially neurotoxic. Thus health care providers monitor bilirubin levels and provide treatment for the newborns jaundice to prevent the growth of kernicterus (also called bilirubin encephalopathy)(3). The general presentation may be asymptomatic in physiological jaundice or ill neonate (vomiting, lethargy, poor feeding, behavioral changes, tachypnea, pale stools and dark urine)(4). Risk factors for elevated indirect bilirubin include maternal age, race (Chinese, Japanese, and Native American), maternal diabetes, prematurity, drugs (vitamin K3), altitude, polycythemia, male sex, trisomy 21, breast-feeding, and a family history(1).

In relating with “maternal-fetal ABO blood group incompatibility”, in which the mother has blood group O and the newborn has blood group A or B, in which the hemolytic disease grows in approximately 10% of such newborns and may be associated with clinically significant neonatal hyperbilirubinemia(5). The hemolytic disease of the newborn due to ABO incompatibility frequently noticed during the first pregnancy, and about 50% of infants are affected unlike rhesus hemolytic disease of the newborn which noticed in subsequent babies rather than the first baby(6). Recent study showed that there is
no need of exchange transfusion for ABO incompatible neonates and incompatible neonates needed the duration of phototherapy for ≥24 hours (7).

Material and Methods

This study is a cross-sectional study and descriptive analytic study has been done from March 2020 to December 2020 include mothers of term newborn infants (gestational age >36 weeks) with neonatal hyperbilirubinemia (serum bilirubin level more than 5 mg/dl) requiring phototherapy and/or exchange transfusion who are combatable or have maternal-fetal ABO incompatibility to evaluate causes, maternal contributing factors which related to development of hyperbilirubinemia in newborns with jaundice. Jaundice was already diagnosed clinically and laboratory inside the hospital. This study has been accomplished over a half-year, on 75 newborns and their mothers who admitted to [Neonatal and Immaturity Department] in child central teaching hospital CCTH hospital and from consultation private clinic in Baghdad, Iraq. The ethic committee of approval was done in this study. A special questionnaire was used to collect and record information from all newborns and their mothers.

The maternal data like socio-demographic and clinical parameters, and neonatal plasma bilirubin level on admission were all recorded. Finally, several laboratory tests made such as (indirect and direct bilirubin, blood type, Rh factor).

Patients Criteria:

-Inclusion Criteria:-

1- Neonates babies (age less than 1 month) with hyperbilirubinemia that require phototherapy or exchange transfusion.

2- Mothers of neonates who involved in the study.

-Exclusion Criteria:-

1- Neonate babies with any other severe diseases or with other known causes of jaundice and hemolysis.

2- Mothers with hemolytic disease or with other serious diseases.

Statistical Analysis

Statistical analysis was carried out using the Minitab 16.1 (2010). Data expressed as numbers (%) and (mean±SD). Chi-square (X^2) was to detect significant value differences among study variables.

Results

Table (1) showed the maternal socio-demographic characteristics of 75 women were delivered children with hyperbilirubinemia. Regarding maternal age the study found that 54(72%) of women were (<30 years) and 21 (28%) were (>30 years) with highly significant differences between them (P<0.01). On the other hand 13(17.3%) of women were primi parity and 62(82.7%) were multi parity and highly significant differences between them (P<0.01). Considering the smoking history, most of women had no history for smoking 63(84%) and only 12(16%) had a positive history for smoking with highly significant differences between them (P<0.01).

Of the study population, higher percentage 40(53.3%) was found in women with blood group O, while 15(20%), 11(14.7%), 9(12%) was women with blood group A, AB, B respectively and highly significant differences found between them (P<0.01).

Interestingly, most of women included in this study 48(64%) were delivered by cesarean section (C/S) while 27(36%) were delivered by vaginal delivery and significant differences found between the two types of delivery (P<0.05).

Discussion

This study was assumed to find out the contributions of each of the associated risk factors. One of the most serious clinical problems inside the hospitals with the mysterious etiology was hyperbilirubinemia between neonates; including not only a danger to infants but also taking much valuable time of laboratory and medical supervise\(^8\).

Table 1 reveals the maternal socio-demographic variables. The results showed that most of mother’s age was ≤ 30 years old while the remaining mothers was ≥ 30 with highly significant differences between them; these results compatible with Sumangala Devi D et al\(^9\).

Instead (17.3\%) of women were primi parity and (82.7\%) were multi parity and highly significant differences between them (\(P<0.01\)), the results of the study compatible with Oyapero O et al\(^9\) which showed that most women were multiparity or parity of the mothers included in this study was more than P1\(^10\). While this study is in contrast with Taneja S et al\(^11\) study which showed that most mother’s presented with primi parity rather than multi parity. Also Oyapero O et al\(^9\) study which showed that majority of the mothers of the study individuals had a 1–2 children\(^10\).

Allowing for the smoking history of mothers, data suggested significant results, the results did not reach for review of the mothers’ smoking history and did not permit us to count the accurate number of cigarettes smoking mothers. In a preliminary analysis of the data has found negative association between neonatal jaundice and other factors such as maternal smoking\(^12\).

Regarding ABO compatibilities higher percentage of mothers 53.3\% were with blood group O, while 20\%, 14.7\% and 12\% was in mothers with blood group A, AB, B respectively and highly significant differences found between them (\(P<0.01\)). These results consistent with Akanmu AS et al\(^13\) which found that blood group O of females were 54.3\% of the donor population, equally if it can be assumed that sex factor has no influence on ABO gene inheritance and blood group distribution\(^13\).

Considering mode of delivery for mothers in the study, most of mothers (64\%) were delivered by caesarian section (C/S) while 27(36\%) were delivered by vaginal delivery and significant differences found between the two types of delivery (\(P<0.05\)). Concentrating study on the use of oxytocin on mother’s babies showed that the induced labor was associated with more neonatal jaundice\(^14\). In contrast with other study that shows the delivery outcomes for cases and controls, mode of delivery did not show any statistically significant difference between vaginal delivery and caesarean delivery. About 74\% of babies delivered vaginally and 25\% caesarean delivered babies developed neonatal jaundice\(^9\).

This results of the study institute that 72\% of mothers were below 30 years old with the mean serum bilirubin was \((24.34 ± 3.08 \text{ mg/dl})\) while \((31.32 ± 2.30 \text{ mg/dl})\) serum bilirubin level found in 28\% of mothers who were equal or higher than 30 years old and highly significant level between them (\(P<0.01\)). These results well matched with Norman M et al\(^1\) and Olusanya BO et al\(^1\) which showed that mothers age was found to be statistically significant in statistical analysis and it also suggested that a higher serum bilirubin levels in
neonates who born for older mothers (more than ≥30 years old) can be linked to increased risk for neonates hyperbilirubinemia\(^{(15)}\).

The present study showed that women with primi parity the mean serum indirect bilirubin level for neonate was \((14.73 \pm 6.75 \text{ mg/dl})\) while in women with multi parity the mean was \((13.68 \pm 4.56 \text{ mg/dl})\) but no significant differences found between them \((P>0.05)\). Moreover the present study finding suggested that birth in the first pregnancy could be important risk factors in current study population , it could agree with Agarwal V etal, Ekwochi U etal, study which suggested that obstetric factors for mothers associated with an increased risk for developing hyperbilirubinemia in neonates involved primi parity\(^{(16,17)}\).

Although a number of parameters, including maternal age and parity have been studied to predict the presence of a newborn with ABO incompatibility and the development of a subsequent hyperbilirubinemia, it stills difficult to expect the real causes behind that\(^{(18)}\). We therefore aimed in this study to determine prospectively the relation between maternal factors and presence of hyperbilirubeinemia in healthy term newborns.

The previous studiesshowed the association between the neonatal serum bilirubin level and maternal ABO blood groupsand OA was more commonly associated than OB blood group\(^{(19,20)}\).

Moreover the present results showed highest mean bilirubin in neonate whom their mothers carry blood group A and B \((17.92 \pm 10.32)\), \((17.28 \pm 6.85)\) respectively, while lowest mean of the serum bilirubin in neonate for mothers carry blood AB \((10.24 \pm 4.05)\) with highly significant differences between them \((P<0.01)\). These results compatible with Sarici SU etal which found that ABO incompatibility played a major role in development of significant hyperbilirubinemia similar to previous studies. 70/150 (46.66%) babies had ABO incompatibility as compared to 6 babies (4%) who had Rh incompatibility and highly significant differences between them\(^{(21)}\).

Then again, a result of the correlation between neonatal serum bilirubin level and maternal Rh reuses factor found to be with no statistical differences among them \((P>0.05)\)\(^{(22-24)}\). These results compatible with Harry C etal which found that ABO blood group incompatibility, was seen in 70 babies as opposed to 6 babies with Rh incompatibility. ABO \((17.98)\) incompatibility resulted in higher serum bilirubin levels with the difference being statistically significant \((P=0.026)\)\(^{(25)}\).

**Conclusion**

Multiple risk factors were associated with development of significant hyperbilirubinemia. The higher percentage of mothers were with blood group O consequently the ABO blood group incompatibility between neonates and their mothers have higher chances of developing significant hyperbilirubinemia in neonates. Moreover the result of the occurrence of neonatal hyperbilirubinemia and maternal Rh reuses factor found to be with no statistical differences among them. Thus, it was concluded that an early follow up is still one of important steps to recognize the development of significant jaundice early, and if the above mentioned risk factors was diagnosed a more careful follow up and management of those babies can be prepared to prevent development of significant hyperbilirubinemia.

The Antibacterial and Antioxidant Activity of *Moringa Oleifera* Seed Oil Extract Against Some Foodborne Pathogens

Shaymaa Rajab Farhan¹, Ahmed H. AL-Azawi², Warqaa Y. Salih³, Alaa A. Abdulhassan⁴

¹Researcher, Ministry of Science and Technology, Iraq, ²Assistant Professor, ³Assistant Lecture, ⁴Engineer, Biotechnology Dept., Genetic Engineering and Biotechnology Institute for Post Graduate Studies, University of Baghdad, Baghdad, Iraq

Abstract

*Moringa oleifera* is one of the most important and useful plants because it is both a medical and nutritional plant. The aim of this study is to determine the antioxidant and antibacterial activity of *Moringa oleifera* seed oil extract. Petroleum ether solvent in Soxhlet apparatus was used to prepare the seed oil. Many tests were conducted included, Gas Chromatography-Mass Spectrum (GC-MS), evaluation of antioxidant activity utilizing 2,2- diphenyl-1-picrylhydrazyl (DPPH) assay, total phenolic content. The oil extract of *Moringa oleifera* was investigated against some foodborne pathogens include *Staphylococcus aureus*, *Bacillus cereus*, *Escherichia coli* and *Klebsiella pneumonia*. The results of GC-MS revealed to the identification of twenty two components, the prevalent compounds were Oleic acid (14.61 %), Butyric acid (11.55 %), 8-Octadecenoic acid, methyl ester (11.16 %) and 1-Pentanol (10.75 %). The radical scavenging activity of the seed oil was 75.81% in concentration 100 µl/ml, and the (EC₅₀) was 25 µl/ml. Furthermore, the total phenolic content of the seed oil extract increased gradually with the increases of concentration. The results of the antibacterial activity of *Moringa oleifera* oil extract showed that the oil extract have the antibacterial effect against all tested bacteria in all concentrations except *E. coli* and *K. pneumonia* which were resistant to the seed’s oil extract in concentration 125 µl/ml. The highest antibacterial activity was observed on *Staph. aureus*, *B. cereus*, *E. coli* and *K. pneumonia* with inhibition zone 18.50, 14.16, 11.83 and 11.33 mm in concentration 500 µl/ml respectively. Furthermore, the MIC of the oil extract was 64 µl/ml for *Staph. aureus*, 128 µl/ml for *Bacillus cereus* and 256 µl/ml for each *E. coli* and *K. pneumonia*.

Keywords: Antibacterial activity, DPPH, MIC, Moringa oleifera, Seed oil extract, Total phenol.

Introduction

Natural antioxidants have an important role in the inhibition of many diseases and improving health. It was also reported that phenolic compounds rich food may have a protective effect against certain diseases such as heart disease, inflammatory diseases, cancer and diabetes¹, ², ³. *Moringa oleifera* is a wonderful tree in the plant kingdom. It does not only possess rich nutritive values (e.g vitamin, mineral, protein, energy, carbohydrate and electrolyte) but contains a lot of medicinal value with important chemical constituents also ⁴. A number of medicinal properties have been ascribed to various parts of this tree. Most parts of this plant: root, bark, gum, leaf, fruit (pods) flowers, seed and seed oil have been used in folk medicine in Africa and South Asia ⁵. The effectiveness of *M. oleifera* as an antioxidant became evident after the identification of some natural antioxidants which include vitamin C, flavonoids, tocopherols and other phenolic compounds. It was reported that the Moringa plant provides a rich and rare combination of zeatin, quercetin, kaempferol and many other phytochemicals ⁶.
Moringa oleifera seed oil is pleasant tasting, highly edible, and resembles olive oil in its fatty acid composition. The characteristics of M. oleifera seed oil can be highly desirable especially with the current trend of replacing polyunsaturated vegetable oils with those containing high amounts of monounsaturated acids. Furthermore, M. oleifera has been found to be a potential new source of oil especially with the advent of the need for oleo-chemicals and oils/fats derived fuels (Biodiesel) all over the world. Thus, the objectives of the present study include detection of the active ingredients in Moringa oleifera seed oil cultivated in Iraq and assessment of the antibacterial and antioxidant activity of oil on some foodborne pathogens.

Materials and Methods

Chemical reagents

The chemical reagents DPPH (2,2-diphenyl-1-picrylhydrazyl), Folin Ciocalteu reagent were purchased from Sigma Aldrich chemicals (Sigma-Aldrich, Germany), Resazurin dye, Nutrient agar (Himedia, India), Muller-Hinton agar and broth (Oxoid, England).

Collection of Moringa oleifera

Moringa oleifera seed was obtained from the plantation of Al-Diwaniyah city, Iraq. The seed was identified by the specialist, Department of Biology, College of Science, University of Baghdad. The seed was washed with water and dried at room temperature, and shelled by using mortar and pestle. The husk and kernel were ground to a fine powder and stored at 4°C for further analysis.

Preparation of seeds oil extract

Soxhlet apparatus was used to extract oil from seeds, 100 g of Moringa oleifera whole crushed seeds (husk and kernel) were put in a thimble and 700 ml of petroleum ether was added within 40-60°C for 6 hours. The solution was filtered through a filter paper Whitman No.1 and evaporated under vacuum at 40°C by a rotary evaporator to get rid of petroleum ether; the oil was stored in glass vials at 4°C until analyzed.

Gas chromatography mass spectrophotometer analysis (GC-MS)

Analysis of the moringa oleifera seed oil extract was carried out on GC-MS equipment. The experimental conditions of the equipment are: HP-5MS ultra inert capillary non-polar column, dimensions: 30 mm × 0.25 mm; ID: 0.25 mm, film thickness: 0.25 μm. The flow rate of mobile gas: 1.0 ml/min. The oven temperature for the gas chromatographic part was 50°C raised to 300°C at 7°C/min for 10 min. The nature and structure of compounds were identified by the mass spectrometer. The spectrum of unidentified components was compared with the spectrum of identified components stored in the national institute standard and technology (NIST) library.

Evaluation of the Antioxidant activity (DPPH assay)

The radical scavenging activity of samples was determined according to Kedare and Singh. 5ml of a freshly prepared 0.004% of 2,2-diphenyl-1-picrylhydrazyl (DPPH) in methanol was mixed with 100 µl of different concentrations (20, 40, 60, 80 and 100 µl/ml) of the seeds oil extract, then the mixture was left to stand for 30 min. The absorbance was measured at 517 nm. All tests were performed in triplicate. The percentage of DPPH reduction was calculated as:

\[
\text{% Reduction} = \left( \frac{\text{Abs DPPH} - \text{Abs Dil.}}{\text{Abs DPPH}} \right) \times 100
\]

Where:

\[
\text{Abs DPPH} = \text{average absorption of the DPPH solution}
\]

\[
\text{Abs Dil.} = \text{average absorption of the three absorption values of each dilution.}
\]

With the obtained values, a graphic was made using Microsoft Excel. The EC₅₀ of each extract (concentration of extract or compound at which reduced 50% of DPPH) was taken from the graphic.
Determination of total phenolic contents

Total phenolic content of *Moringa oleifera* seed oil extract was determined spectrophotometrically using the Folin-Ciocalteu method described by Jayaprakasha

Two ml of Folin-Ciocalteu reagent (diluted 10 times) was mixed with 1.6 ml of 7.5% sodium carbonate solution and 0.4 ml of *Moringa oleifera* extracts. The volume was completed to 5 ml by adding distilled water. The tubes were covered with parafilm for 30 min. at room temperature, and then the absorbance was read at 760 nm spectrophotometrically.

Bacterial isolates

*Bacillus cereus*, *Staphylococcus aureus*, *Escherichia coli* and *Klebsiella pneumoniae* isolated from food, obtained from the Department of Food Sciences, College of Agricultural Engineering Sciences, University of Baghdad, and emphasize diagnoses by using VITEK-2 System.

Antibiotic susceptibility test

Kirby-Bauer method was followed as described by WHO, to carry out the antibiotics susceptibility test for 10 different antibiotics. The bacterial suspension was prepared by picking 1-2 isolated colonies of bacteria from the original culture and introduced into a test tube containing 4 ml of normal saline to produce a bacterial suspension of moderate turbidity compared with the standard turbidity solution. This approximately equals to 1.5x10^8 CFU/ml. By a sterile cotton swab, a portion of bacterial suspension was transferred and carefully and evenly spread on Mueller- Hinton agar medium, and then it was left for 10 min. Thereafter the antimicrobial discs were placed on the agar with a sterile forceps pressed firmly to ensure contact with the agar. Later the plates were inverted and incubated at 37°C for 18-24 hours. Inhibition zones developed around the discs were measured by a millimeter (mm) using a metric ruler according to Clinical Laboratories Standards Institute.

Agar well diffusion method

Agar well diffusion method was employed for the determination of this study. Muller- Hinton agar plates were swabbed (sterile cotton swabs) with broth culture of respective bacteria. Wells 6 mm diameter was made in each of these plates using a sterile cork borer. 100 µl from each concentration (125, 250 and 500 µl/ ml) of the seed oil extract was put in each hole by using micropipette and allowed to diffuse at room temperature for 30 min. The plates were incubated at 37 °C for 18-24 hours. All tests were performed in triplicate. The diameter of any resulting zone of inhibition was measured in millimeters.

Determination of the minimum inhibitory concentration (MIC) of the *Moringa oleifera* oil extract

Broth microdilution method was used to determine the MIC of *Moringa oleifera* oil extract using the 96-well microtiter plate. The extracts were prepared in a double concentration, the desired final concentration as it will be diluted with an equal amount of bacteria in broth. 200 µl of the prepared oil extract was introduced into the first wells in columns 1-4 (in row A). Rows B-H in columns 1-4 had 100µl of broth alone. Twofold serial dilutions using micropipette was done systematically down the columns 1-4 (from rows B-H). 100 µl was removed from the starting concentrations (columns 1-4 in row A) and transferred to the next row with the 100µl broth, properly mixed, and the procedure was repeated up to the last row (H) where the last 100µl was discarded. This brings the final volume in all the test wells with the extracts to 100 µl except the 5th, 7th, 9th and 11th columns which had 200 µl of the broth that served as sterility negative control (Broth only). The columns 6th, 8th, 10th and 12th served as positive control (Bacteria + Broth). 100µl of the 1x10^6 CFU/ ml bacterial inoculum was transferred into all the wells except sterility negative control columns to give us the desired final inoculum load of 5x 10^5 CFU/ml. Microtiter plates were incubated at 37°C for 18-20 hrs. After incubation, 20 µl of resazurin dye was added to all the wells and incubated for some minutes to observe any color changes. The minimum inhibitory concentrations were determined visually in broth microdilution as the lowest concentrations of the extracts at which color

...
changed from blue to pink in the resazurin broth assay.

**Statistical Analysis**

The Statistical Analysis System was used to detect the effect of different factors in study parameters. Least significant difference-LSD test was used to significant compare between means in this study.

**Results and Discussion**

Gas chromatography mass spectrophotometer analysis

The GC-MS analyses of the *Moringa oleifera* seed oil extract lead to the identification of twenty two components. The prevalent compounds were Oleic acid (14.61 %), Butyric acid (11.55 %), 8-Octadecenoic acid, methyl ester (11.16 %) and 1-Pentanol (10.75 %); all compounds were identified and listed in Table 1. Efeovbokhan in his investigation to study the effect of different solvents on composition of *Moringa oleifera* seed’s oil referred to the presence of different percentage of palmitolic acid in the seed oil extracted by different solvents. Furthermore, it was reported that oleic acid present in crude extract of *Moringa oleifera* seed oil.

DPPH assay

The antioxidant activity of oil extract was 45.21% in concentration 20 µl/ml and the activity was 75.81% in concentration 100 µl/ml as shown in Table 2. The effective concentration 50 (EC₅₀) is an important parameter to evaluate the antioxidant activity of materials and it could be used to compare the antioxidant capacity of various materials. The radical scavenging capacity (EC₅₀) of the seed oil extract was 25 µl/ml.
The antioxidant activity of seed’s oil may be attributed to the presence of 8-octadecenoic acid, methyl ester, oleic acid and Isopropyl myristate.

Total phenolic content of seed oil extract

The results of total phenolic content of seed oil extract increased gradually with increases of concentration, with significant differences (P≤0.05) as shown in Table 3. The result in the current study is disagreement with Ogbunugafor which referred in his investigation to study the antioxidant properties of *Moringa oleifera* seed oil, the total phenolic content was 40.17 ± 0.01 mg/g.

**Antibiotic susceptibility test**

The antibiotic susceptibility of the bacterial isolates was performed on ten antibiotics represented in Table 4. The antibiogram of the studied isolates revealed that *B. cereus* was resistance to Cefotaxime, Chloramphenicol, Doxycycline, Erythromycin, Penicillin and Trimethoprim, *Staph aureus* was resistance to Cefotaxime and penicillin, *E. coli* was resistance to Erythromycin, Penicillin and Tetracycline and *K. pneumonia* was resistance to Erythromycin and Penicillin, while the isolates were sensitive and intermediate to another antibiotics used in this study.

Over the past decades, overreliance and use of antibiotics have led to the emergence and dissemination of multidrug resistant strains of several groups of microorganisms. Due to the increase in resistant clinical isolates, there is a paramount need to develop new and innovative antimicrobial agents. Therefore,
researchers are looking for new leads in the discovery of better alternatives against multidrug resistant microbial strains. Among the potential sources of new agents, plants have long been investigated owing to their popular use as remedies for diverse infectious diseases because they contain many bioactive compounds that could be interest in therapeutics.

Antibacterial activity of seed oil extract
The antibacterial activity of *Moringa oleifera* seed’s oil extract was reported in Table 5. The oil extract had antibacterial effect against all tested bacteria in all concentrations except *E. coli* and *K. pneumonia* which were resistant to the seed’s oil extract in concentration 125 µl/ml. The highest antibacterial activity was observed on *Staph. aureus* with inhibition zone 10.50 ± 0.28, 13.16 ± 0.16 and 18.50 ± 0.28 mm in concentrations (125, 250 and 500 µl/ml) respectively, and the lowest effect was observed on *E. coli* with inhibition zone of 7.33 ± 0.33 mm in 250µl/ml concentration with significant difference (P≤0.05). Abdulrasheed \(^{27}\) revealed that *Moringa oleifera* seed oil was inactive against all the tested organisms even at 100% concentration. Results obtained by Othman \(^{28}\) showed that *M.oleifera* seed oil had low effect on gram positive and gram negative test bacteria.

* (P≤0.05)

The antibacterial activity of *Moringa oleifera* seed oil extract attributed to the presence of oleic acid (fatty acid) , 8-Octadecenoic acid, methyl ester (fatty acid ester) \(^{22}\), Butyric acid and Hexanoic acid, Pyrrolidine \(^{29}\), Heptadecyl heptafluorobutyrate, Isophytol \(^{30}\), and other compounds that exhibit antimicrobial activity.

**Minimum Inhibitory Concentration (MIC) of seed oil extract**

Different standard methods have been used to evaluate the antimicrobial activities of plant’s extracts. However, dilution methods have been favored over others for the determination of MIC and MBC. A method using the oxidation-reduction colorimetric indicator resazurin has been proposed for the determination of drug resistance and MIC of antimicrobial agents against pathogenic organisms \(^{31}\). The results of seed oil extract showed that the MIC was 64µl/ml for *Staph. aureus*, 128 µl/ml for *Bacillus cereus* and 256 µl/ml for each *E. coli* and *K. pneumonia* as shown in Figure 1.

Phenolic compounds of plants are of noticeable interest due to their antioxidant and antibacterial properties \(^{32,33}\). The means by which microorganisms are inhibited by phenolic compounds involves a sensitization of the phospholipids bilayer of the cell membrane, causing an increase in permeability and leakage of vital intracellular constituents, or impairment of bacterial enzyme systems. Phenolic compounds act by inhibiting the amino acid decarboxylase in target bacteria \(^{34}\).
Conclusion

*Moringa oleifera* seed oil extracts have a wide variety of fatty acid like Oleic acid, Butyric acid, 8-Octadecenoic acid, methyl ester and 1-Pentanol that show antioxidant activity and antimicrobial agent against both gram positive bacteria (*Staph. aureus* and *B. cereus*) and gram negative bacteria (*E. coli* and *K. pneumoniae*).

Abstract

Introduction: - Growth of all living organism depends on nutrition. In human being growth period is said to be from conception to adolescence and after that nutrition is required for maintenance of body. Lot of work has been done regarding role of nutrition during pregnancy, infancy and childhood but hardly any attention is paid to the group called adolescence i.e. period between childhood and adulthood. The most prevalent nutritional condition is anaemia worldwide. Prevalence in India of anemia among young girls were 56 % and this amount to an average 64 million girls at any point in time.

Aim: To determine the effectiveness of planned teaching on knowledge regarding prevention of nutritional anemia among adolescence.

Materials and Methods: A pre-experimental pre-test, post-test research design was used to conduct this study. The setting was selected in the Kasturba Vidya Mandir Sewagram, Wardha (Maharashtra) after getting ethical permission. Purposive sampling was the sampling method used to collect data from 9th standard students on the basis of structured knowledge questionnaire. After collecting pre-test data, planned teaching was given for intervention regarding prevention of nutritional anemia to adolescents. Seven days were provided to the samples for utilizing planned teaching which was organized for 45-50 minutes. Post-test information was gathered after seven days from the day of intervention. The data were described by frequency, percentage and t-test was used to describe the difference between pre-test and post-test knowledge score. Chi-square test was also used to find out the association between knowledge of 9th standard students regarding prevention of nutritional anaemia and selected demographic variables.

Results: There was a significant difference between pre-test and post-test knowledge scores interpreted that planned teaching on knowledge regarding prevention of nutritional anemia among adolescents were effective. Mean value of pretest was 10.10 and posttest was 19.08 and standard deviation values of pretest was ±2.27 and posttest was ±2.21. The calculated t-value was 19.66 and p-value was 0.000.

Conclusion: - The study was effective because the post-test knowledge score improved than the pre-test knowledge score. So the planned teaching has proved to improve 9th standard students knowledge regarding prevention of nutritional anaemia.

Key Word: avoidance, teenage and vitamin-deficiency anemia

Introduction

The teen age demographic is the window of opportunity for children to correct their dietary status.
We will avoid potential effects of nutritional problems if we act appropriately during this time.

The most prevalent nutritional condition worldwide is anaemia. The life period between 10-19 years is specified according to the WHO teenage age group. The prevalence of anaemia among teenage girls in India was 56 percent, which at any point of time amounts to an average of 64 million girls. Incidence of anaemia in university health science students to be 43%. Anemia incidence is found to be more common in students of both sexes due to many causes such as insufficient ingestion of nutrients, socio-economic background etc.

Studies performed in various regions of India found that in Madhya Pradesh, 37 % in Gujarat, 41.1 % in Karnataka, 85.4 % in Maharashtra, 21.5 % in Shimla, 56.3 % in Uttar Pradesh, 77.33 % in Andhra Pradesh, 58.4 % in Tamil Nadu and Kerala, the prevalence of anaemia was 52.5 %(19.13 % among college students and 96.5 % in tribal area). Socio-economic condition, menstrual blood loss, nutritional status, hand hygiene and worm infestation were the key risk factors found by the above reports.

Girls’ dietary requirements are usually neglected during puberty, resulting in stunting and ill health. Anaemia is one of the key implications of the physiological changes and nutritional negligence happening during this time.

Hence, present study was conducted with an aim to determine the effectiveness of planned teaching on knowledge regarding prevention of nutritional anaemia among adolescents.

When the condition progresses, anaemia causes adverse effects. It influences not only the development of teenage girls, but also their concentration, memory and achievement at school and success of school and attendance. It also induces delay in the initiation of menarche, leading to infections, affecting the immune system. If the anaemic teenage girl becomes pregnant, fetal morbidity and mortality may increase, perinatal risk may increase, low birth weight (LBW) occurrence may increase, and infant mortality rate (IMR) and maternal mortality rate (MMR) may increase (MMR). As growing pregnant adolescents compete with the growing foetus for nutrients anaemia in pregnancy will be worse than in older women.

Anemia accounts for much of the nutritional issues in worldwide. Owing to low socioeconomic status and inadequate access to health care, the incidence of anaemia is considerably higher in developing countries. The teenage phase is characterized by marked physical activity and accelerated growth spur; thus, they require extra nutritional nutrients and are at greatest risk of developing nutritional anemia.

The teenage community is more vulnerable to food problems in developed countries and adolescent girls are more vulnerable to the disease. Studies have found that the biggest nutritional problems in developed countries is adolescent anemia. India had reported a high prevalence of anemia among teenage girls, which is obviously higher than in other developed countries.

The World Health Organisation has described the era between 10 and 19 years of age as adolescence.

This time is known to be the transition from childhood to adulthood. During this phase, due to marked physical activity and rapid growth spur adolescence, significant psychological, behavioral, and physical developments require additional nutritional requirements. According to recent statistics, there are approximately 1.2 billion adolescents worldwide, representing one-fifth of the world’s total population, and the numbers are increasing. Developing countries account for about 5 million adolescents of the total adolescent population, and in India about 21% of the total population are adolescents.

Hypothesis:-

H1: There will be significant difference between pre and post-test knowledge scores of adolescents (9th standard students) on prevention of nutritional anemia.

H0: There will not be significant difference between pre and post-test knowledge scores of adolescents (9th
standard students) on prevention of nutritional anemia.

Materials and Methods

- A pre-experimental pre-test, post-test research design was used to conduct this study. The setting was selected in the Kasturba Vidya Mandir Sewagram, Wardha (Maharashtra) after getting ethical permission. The 50 9th standard students were informed and explained the objective of the study. The written informed consent dully signed individually by them was obtained.

Inclusion criteria: Those students who gave consent for participation in the study, and who were studying in 9th standard of Kasturba vidya mandir, and included male and female adolescents, and those who were available during data collection period.

Exclusion criteria: Who had participated in similar type of research.

Assumption:- Adolescents may have some knowledge regarding prevention of nutritional anemia.

Demographic variables were collected in terms of gender and dietary pattern. A structured questionnaire, which is attached in [Annexure V], has 40 multiple choice questions were used. The sections were - (i) introduction (ii) causes of nutritional anemia and (iii) and management of nutritional anemia and (iv) prevention of nutritional anemia. Each correct answer carries one mark and the total score is 40. The prepared tool was validated by 10 experts who included two from departments of statistics, one each from department of English, department of general medicine and, department of respiratory medicine and five from department of medical surgical nursing. Parallel form method was adopted for reliability test and it was found as $r=0.82$. And hence tool was reliable and valid. The data collection process was planned to gather demographic information and the knowledge regarding prevention of nutritional anemia. The planned teaching organized on (i) introduction (ii) causes of nutritional anemia and (iii) and management of nutritional anemia and (iv) prevention of nutritional anemia There were two sessions conducted for education in two groups, each session had 25 students in each group in 45 minute. Each sample required mean time of 30 minutes to complete the pretest structured questionnaire. Then the planned teaching was intervened to the sample. The post test structured questionnaire was administered after 7 days. Based on the 40 questions each study participant was asked individually for his / her answers with the same questionnaire. As collected, the responses were arranged in tabular form to conduct statistical analyzes which are mentioned in the following sections.

Statistical Analysis

The collected data were coded, tabulated, and analyzed by using descriptive statistics (mean percentage, standard deviation) and inferential statistics. Significance difference between pre and posttest readings was tested by using a t-test; association of knowledge with demographic variables was done by one way ANOVA test and independent t-test. For statistical analysis SPSS version 15.0 was used.

Results

Association of knowledge with their demographic variables are depicted in Table No.1

<table>
<thead>
<tr>
<th>Table No.1 Association of knowledge with their demographic variables</th>

<td>19.08</td>
<td>2.21</td>
<td>63.60</td>
<td></td>
<td>0.000</td>
</tr>
</tbody>
</table>

The effectivenss of planned teaching was analyzed as follows:

The mean value of the pre-test is 10.10 and the post-test is 19.08 and the standard deviation values of pre-test are ±2.27 and post-test is ±2.21. The calculated t-value is 19.66 and the p-value is 0.000 [table 2]. Hence it was statistically interpreted that the planned teaching on knowledge regarding prevention of nutritional anemia among adolescence was helpful. Thus the H 1 is accepted and H 0 is rejected in this research.

Discussion

Present study was conducted to evaluate the effectiveness of planned teaching on knowledge regarding prevention of nutritional anemia among adolescence. It intends to promote adolescence knowledge regarding prevention of nutritional anemia among adolescence. The mean value of the pre-test is 10.10 and the post-test is 19.08 and the standard deviation values of pre-test are ±2.27 and post-test is ±2.21. The calculated t-value is 19.66 and the p-value is 0.000. Hence it is statistically interpreted that the planned teaching on knowledge regarding prevention of nutritional anemia among adolescence was helpful. Similarly for a period of 6 months, pre-experimental research was carried out on 60 teenage high school girls aged 10-19 years of age studying at Handignur High Schools, Belgaum, Karnataka conducted on Effectiveness of Planned Teaching Programme on Prevention of Anaemia among School Going Adolescent Girls. Analysis of the data showed that 100% of adolescent girls in pre-test had average knowledge, whereas in post-test majority 73.33% of the adolescent girls had good knowledge and 26.67% had average knowledge, which indicates that the Planned Teaching Programme has impact in prevention of anaemia. The post test score was high and statistically significant that is the planned teaching on on Prevention of Anaemia among School Going Adolescent Girls was effective.

The present study illustrated quasi experimental research design among 50 adolescence in which majority of the sample belong to non-vegetarian i.e., 58% and 42% belong to vegetarian.

The calculated t-value is 0.04 and the p-value is 0.96 and In another similar study on Prevalence of Anemia and Its Associated Risk Factors Among Adolescent Girls of Central Kerala in which majority of the sample belong to non-vegetarian i.e., 51 and 3 belong to vegetarian. The calculated t-value is 0.853 and the p-value is 0.356.

Limitation:

The study was limited to sample size i.e., 50, which might be inadequate to generalize the study findings.
More time duration would give more relevant results with variations of any research, but the investigator planned to complete the research work within one week to get more feasibility of getting sample. Therefore, sufficient number of sample and time duration was required to establish the effect of planned teaching, in general.

**Conclusion**

Study concluded that knowledge regarding prevention of nutritional anaemia improved after administering planned teaching among adolescents.

**Acknowledgement:** Authors express their sincere thanks to all faculties of Kasturba Nursing College Sevagram, Wardha, Maharashtra India for smooth completion of my research work.

Evolution of Electronic Root Canal Length Measurement Device -A Literature Review

Shivangi Shekhar¹, P.Laxmish Mallya²
¹Post Graduate, ²Associate Professor, Department of Conservative Dentistry and Endodontics, Manipal College of Dental Sciences, Mangalore, Affiliated to Manipal Academy of Higher Education (MAHE), Manipal

Abstract

Summary: An electronic apex locator (EAL) is a device used to measure the working length (WL) of the root canal space (RCS) and proved to be a great help to the endodontist reducing radiation exposure of both patients and clinicians and providing accurate reading for the WL. Evolution of different generations of EAL helped to eradicate the shortcomings of the previous generations providing precise measurement of the WL. Electronic Apex locators are used to detect any perforations, furcation involvement, also used to detect horizontal fractures, also to detect internal or external resorption. With so many uses, it is still contraindicated in patients with pace makers and inaccurate reading in canals with common irrigants like Ethylenediamine tetraacetic acid and sodium hypochlorite. It requires dry or partially dry canals to give readings with accuracy. It also gives inaccurate reading in the presence of semi-conductive materials and hence the canals should be free of them. Though it provides almost precise measurement of the WL it cannot be replaced with radiographs but can be used as an adjunct with it. Pre- and post-operative radiographs are still necessary for the success of the endodontic treatment as it provides an idea for any periapical lesion and degree of curvature of roots. Acceptance of an electronic apex locator to determine the correct WL has still not gained approval worldwide. Lack of exposure to the technology by the operator, inadequate knowledge of the root canal anatomy and cost of the instrument are also the factors for it not gaining worldwide acceptance.

Keywords: Apex locators, Apical constriction, Endodontics, Generation, Working length

Introduction

The accomplishment of an endodontic treatment or its success depends on complete elimination of the contents from the root canal system (RCS) before shaping that include biofilm, planktonic bacteria, bacterial toxins, organic infected tissue, inorganic debris and smear layer which refers to cleaning of the root canal.¹

Shaping refers to de-roofing of the pulp chamber, removal of obstacles, pre-flaring to reach middle and apical third also smoothing the walls of the RCS. Bio mechanical preparation plays a vital role for the accomplishment of the endodontic treatment. This can be achieved with accurate endometrics. The success of endodontic treatment with periapical lesions and necrotic pulps depends on the apical end of the filling material used in root canal.²

Traditionally, radiographs were used to measure and regulate the extent of the RCS and point of termination at the minor constrictor.³ The development of the electronic apex locator came as a boon for the endodontist to evaluate the accurate working space and to reduce radiation exposure of the clinician and the patient and minimizing on the number of radiographs.⁴

An apex locator is an device applied to measure the length and position of the minor constrictor. The apical portion of the root has specific resistance to electrical current, and it is measured using a pair of electrodes which is attached to the endodontic file on one end and hooked to the lip at the other end to form an circuit.⁵
**Importance of working length:**

Working length (WL) is defined as the distance from a coronal reference point to the point at which canal preparation and obturation should terminate,” according to Glossary of Endodontic terms. \(^3,6\)

The determination of a precise WL is a crucial step in the root canal therapy. The biomechanical preparation of the RCS cannot be done correctly if the WL is not determined with accuracy. Thus, the predictable endodontic treatment success stresses on achieving a precise WL determination.\(^7\)

Over & underestimation of the WL can result in failure. Overestimated WL can lead to preparation of the RCS beyond the apex, which can bring about damage in the peri-apical area. Underestimated WL results in inadequate debridement in the canal which eventually leads to failure of the treatment causing dissatisfaction to both the dentist and the patient.\(^1\) Since determination of the WL plays a vital role in root canal treatment, some procedures may be suggested:\(^1\)

A: Application of tactile sensation using paper cones is one of the methods that is used due to their ease and relative efficacy. This technique can be inaccurate in patients with apical curvature and teeth with an open apex

B: Radiograph is a most used method for determining WL where the apex is kept 0.5-1 mm shorter than the radiographic apex. The radiographic technique has its recompenses, such as direct opinion of the RCS and the canal curvature or any incidence of any peri-apical lesions, but radiographs give a 2D view of a 3D object. In an addition, a drawback of radiation is that it can be hazardous to the dental staff, clinician and the patients.

C: Introduction of the electronic apex locators (EAL) came with advantages like reduction in number of radiographs and elimination of radiographic obstacles.

The development and the principal design of the initial apex locator’s dates back to 1942, in which Suzuki investigated the circuit on dogs and came to a conclusion there is some electrical resistance observed between the periodontal ligament (PDL) and the oral mucosa which had a persistent charge. These proceedings were taken into consideration and presented into daily clinical practice by Sunada (1962) which measured the electrical resistance between periodontal ligament and oral mucosa.\(^5\) Therefore calculation of WL should be done with accuracy, using methods that have already proven to give precise and correct results and by procedures that are easy and practical to perform and should be confirmative.\(^8\)

An understanding of the anatomy of the apex and the apical region is required to gain the idea of the WL. The structure of the minor & major constrictor changes with increase in time of life due to hard tissue deposition.\(^1\)

**Mode of action of Apex Locators:**\(^4,6\)

Electronic Apex Locators works by completing the electric circuit using the human body. There are two sides of an apex locator, one part of the circuit is connected to the oral mucosa via a clip that attaches to the lip whereas the additional part is fixed on to an endodontic instrument. The circuit gets completed when the endodontic instrument is sited in the RCS and is moved apically till it reaches the apex and touches the periodontal tissue. The system specifies that the apex has been reached when the electrical resistance of the electronic apex locator and the resistance between oral mucosa and the endodontic instrument are same.

When the tip of the endodontic instrument contacts the tissue, an electrical circuit is completed and the resistance decreases evidently and the current swiftly begins to flow. This current flow signalled by a beep or a buzzer or digital readout or pointer on the screen display. The electrical characteristic of the tooth structure is measured and a precise location of the endodontic instrument in the RCS is determined.

Classification of electronic apex locators according to Generations of EALs (Evolution of EALs) \(^3\)

1. The first-generation apex locators determine the WL of the RCS by means of the resistance technique. This generation of apex locators measured the obstruction
to the flow of direct current (resistance) and henceforth called Resistance based apex locators.

These devices gave false interpretations in obstructed and wet canals and also in carious and defective restoration, in cases with perforations and also in patients who had cardiac pacemakers. For example: The Root Canal Meter, Dentometer

2. The 2nd generation apex locators determine the WL using the impedance method. This generation of apex locators measures the obstruction to the flow of alternating current hence known as impedance-based devices. These units perform the task by utilizing the current of a single frequency.

Second generation apex locators are devices based on impedance measurement that functions on the principle that there is electrical impedance across the root canal wall as there is transparent dentin present. The tooth increases in electrical impedance across the root canal walls, which is greater apical area compared to the coronal area. At the cemento-dentinal junction the impedance level drops intensely. Examples: Endocater, Sono explorer Apex finder endoanalyzer, Digi pex

One major disadvantage of these devices was that it gave false reading of electro-conductive materials. The RCS should be completely unrestricted by any electro-conductive materials to gain correct interpretation.

3. Third Generation Electronic Apex locators are known frequency dependent apex locators. These work on the principle of comparative impedance and frequency. These electronic apex locators are based on the aspect that different locations in the RCS can give difference in impedance ranging from extremely high (8KHz) and extremely low 400(Hz) frequencies. This difference in the frequencies is seen minimum in the coronal portion of the root canal. Difference in frequencies increases as the endodontic instrument penetrate deeper into the canal. Frequencies are seen highest at cemento-dentinal junction. For examples: Apit –Endex (Osada, Japan)/ Apit or Endex

The disadvantage of this device was that it needs to be “reset” or “calibrated” for every canal. For example: The Root ZX

Other third generation apex locators include:

1. Apex Finder AFA Model 7005 (EIE Analytic Endodontics, USA).

4. The 4th Generation electronic Apex Locators are the ratio type apex locators which regulate the impedance at 5 different frequencies and they have a pulp tester which is in-built. These devices take the capacitance and resistance measurement and evaluate them with a database to estimate the distance from the apex of the root canal to the tip of the file.

Multi-frequency measurement system is a system employed to estimate the length from the tip of the endodontic instrument being used to the apical foramen by measuring changes in impedance occurring between the two electrodes. This technique apparently leads to less specimen mistake and more reliable readings.

The electronic apex locators of this particular generation are by far the most reliable in their group due to their high accurateness and dependability.

A noteworthy disadvantage of this generation devices is that, for accurate readings they require partially or completely dry canals.

e.g., Bingo 1020/, The Ray-Pex 4 and 5

5. The Fifth Generation Electronic Apex Locators is a recent measurement technique that was developed based on the judgement of the facts engaged from the electrical distinctive of the canal and additional mathematical processing. And so, 5th generation apex locators are dual frequency ratio type and they are being used currently.

These devices were introduced in 2003. It calculates resistance & capacitance of the circuit discretely. It comes with a diagnostic table which comprises the statistics of the file. It has greatest exactness in all root canal condition like bleeding, dry, wet canals.
(saline, NaOCl, EDTA). The apex locators retaining this technique experience significant problems while working in dry canals.

During any of the clinical procedure it was seen that the accuracy of electronic root canal length measurement varies in conditions in periapical lesions or any damage to the pulp.

The fifth-generation electronic apex locators come with a graphic illustration, digital read out and a signal which is audible. The pulp testing machine which is in built can be used to access tooth vitality.

These devices were introduced to handle the problems related with previous generations apex locators.

6. The Sixth Generation Electronic Apex Locators is an adaptive apex locator. The efficiency of this generation electronic apex locators in long term use are yet to be known. A main advantage of this device is eradicating the need of wetting and drying of the canal.

Adaptive 6th generation apex locators immediately adapt to wet or dry canal and is also possible to be used in canals with blood or exudate.

Additional uses of Electronic Apex Locators: 
- It has the ability to detect root perforations.
- It helps to determine the location of pulpal floor or root perforations
- It can detect horizontal fractures
- It helps to confirm an assumed periodontal or pulpal perforation
- It helps to recognize any connection between the periodontal membrane & the root canal such as internal or external resorption root fractures or cracks.
- They detect vitality of the tooth

Combination of electronic handpiece and EALs (Ex. Root ZX II) are also becoming popular as they achieve outstanding outcomes with same and exact precision as the stand-alone units. The Root ZX has been combined with a handpiece to measure root canal length with a rotary instrument being used. The handpiece uses rotary instruments made from nickel-titanium that rotate at the speed of 240-280 rpm.

Contraindications associated with Apex locators:
1. Non- Isolated Tooth with rubber-dam.
2. Immature Tooth with Open Apex.
4. Inflamed and Infected Periapical Area
5. Periapical-Periodontal lesions.
6. Severe Intra-Canal Resorption
7. Auxiliary canals

Problems associated with apex locators: 
- Root ZX can give inaccurate readings if the canal is filled with blood or exudate.
- Presence of any calcification or dentin debris can affect the accurate determination of the WL.
- The accuracy of the reading of the apex locator interferes with cardiac pacemakers.
- They do work appropriately when common irrigants in the canal such as sodium hypochlorite and EDTA are used.
- High cost of the instrument.
- Technique sensitive

Hence, the of apex locators cannot be used alone but should be just as an adjunct with pre- and post-operative radiograph as it through radiographs that a clinician can judge any periapical lesion and also the anatomy and morphology of the tooth. Radiographs are used for medico-legal records.
Conclusion

No particular method is suitable in determining the WL.\(^3\) The apex or the apical terminus is an anatomic termination point for the preparation of the root canal and obturation of the root canal and this should be determined with the assistance of both radiographs and an EAL. This will give results with precisions greater than 90%.\(^4\) Hence, appropriate familiarity of the root canal anatomy, judicious use of radiographs and the accurate use of an electronic apex locator will help clinicians to attain an expectable working length of the root canal system for further endodontic treatment.\(^5\) Though at any stage apex locators will not be to replace radiographs, but can definitely serve as an effective adjunct.

Surrogacy as an Alternative for Depressive Infertile Couples

Shyamantak Misra¹, Prafulla Chandra Mishra²
¹Research Scholar, ²Dean, School of Law, KIIT, Bhubaneswar, Odisha, India

Abstract

This piece of work aims to provide a clear picture of the available alternatives to the intending infertile couples and how far surrogacy is acceptable as an alternative to the prolonged infertility treatments that ultimately lead to depression symptoms like anxiety and other expressed emotional patterns. It’s a bestowed power on women to cherish the experience of motherhood but unfortunately not all the women are lucky enough to conceive and enjoy the joyous feeling of being a mother and experiencing motherhood. It’s usually a dubious decision to make for the intending infertile couples whether to continues with the infertility treatments to have a child of their own or opt for an alternative like Surrogacy or Adoption. This article states the need of taking up an alternative before it’s too late and emphasizes on the reasons for taking up surrogacy as an alternative above the other available ones and also mentions the reasons why couples do not opt for surrogacy so that one takes care of the same while choosing the same. The procedure to be followed by such couples while selecting this alternative has also been stated so that they find themselves in a better position than the once suffering to get through.

Keywords: Surrogacy, Infertile, Depression, Artificial reproductive techniques, Anxiety, Stress.

“Little souls find their way to you whether they are from your womb or someone else’s”. - Sheryl Crow

Introduction

The capacity to procreate a life has been bestowed by the nature to women and this experience of motherhood is cherished by every women barring a few, who suffer from certain physiological conditions or infertility problems and unfortunately cannot give birth to their own offspring. However the desire to have a child of their own leads them to search for alternatives and out of several available options, Surrogacy and Adoption are most preferred ones. Few infertile couples without opting for the available alternatives continue with their fertility treatment for years together which then on being unfruitful leads to certain symptoms of depression like anxiety and other expressed emotional patterns.

Barrenness and Its Impact:

Every couple has an inherent desire to have a genetically related or bloodrelated child of their own. In most of the religions around the world this need for a child has been emphasized on, may it be for taking forward the family traditions or performing the funeral pyre, for preserving the community they belong to and so on. A deviant behaviour in marriage that leads to adverse effects on the relationship of such married couples while pertaining to the lack of a child being involuntary may be considered as childlessness. Many research papers highlight the social or cultural, stigma and isolation suffered by the infertile married couples. Such childlessness suffered due to infertility, physiological or other psychological medical problems involves anxiety and stress. The infertility treatment that such couple or women go through involves treatment that might be very painful, expensive, and might create a strain on the relationship of such couple which is difficult to handle with patience. Even after all this there’s no guarantee

DOI Number: 10.37506/ijfmt.v15i4.17088
that you could be able to procreate a child of your own.

Ways to Overcome Childlessness:

In the ancient times people believed that children are a gift of God and if one is unable to conceive that means it’s a curse of God due to some sins that the couple might have committed. Therefore, the only way to overcome this was by performing religious rituals to appease God.\(^1\) Even second marriages to have a child was approved or to beget proved to be unsatisfactory in the long run. As we improved in legal arena, the method of adopting a child legally became a way to overcome childlessness, even then one’s wish of a genetically related child remained unfulfilled. With the development in science and technology in the field of human reproduction, various techniques were evolved like Artificial Insemination (AI), In Vitro Fertilization (IVF), Surrogacy etc.\(^2\)

According to “INDIAN SOCIETY OF ASSISTED REPRODUCTION” - “Infertility currently affects about 10-14% of the Indian population which is nearly 27.5 million couples, especially in urban areas where one out of six couples are impacted”.\(^3\)

Therefore, its high time to think of the available alternatives instead of brooding over the infertility treatment for years together that impact the physical and mental health as well. In order to reduce the rate of such couples suffering from infertility there are various available options but the point is the major reason behind not opting for any of them being the genetic link in maximum of cases. Thus, only surrogacy can fulfill the dream of having a child with genetic link too. Whereas in case of adoption the child may not have anything in similar with the adopting parents.

The reproductive environment has been revolutionized and advancement in Assisted reproductive techniques like embryo transfer methods, donor insemination etc. are the major reason behind surrogacy being the most desirable option. This process of surrogacy has been the ray of hope for thousands of infertile couples, who longed to have a kid of their own.

The word surrogate means substitute\(^4\) . Surrogate mother acts as a substitute for the genetically biological mother who is unable to give birth for various infertility problems. Thus, a surrogate mother is a person who is recruited to rent her womb and bear the child till birth and ultimately hand over the child to her employer couple.

As per the ART (Artificial Reproductive Technique) Guidelines Government of India :“Surrogacy is an arrangement in which a woman agrees to a pregnancy, achieved through assisted reproductive technology, in which neither of the gametes belong to her or her husband, with the intention of carrying it to term and handing over the child to the person or persons for whom she is acting as surrogate and a surrogate mother is a woman who agrees to have an embryo generated from the sperm of a man who is not her husband, and the oocyte for another woman implanted in her to carry the pregnancy to full term and deliver the child to its biological parents(s)”.\(^5\)

Earlier surrogacy arrangements were limited to family, friends, and close relatives as an altruistic deed (Altruistic Surrogacy). But in the past few years surrogacy has widely spread its wings across the country with financial arrangements leading to commercialization. Thus, leading to a contract of the biological functioning of a woman’s body. Surrogacy advertisements are common nowadays where the whole process of commercial surrogacy involves recruitment of Surrogate mothers and making contracts between the infertile couple and such surrogate and making huge profits out of such arrangements. This commercialization of Surrogacy in India has raised the fear of black marketing, however finally giving a child to a childless couple seems to take over all the other sins and materialistic values that one needs to sacrifice in the process.

**REASONS FOR TAKING UP SURROGACY AS AN ALTERNATIVE:**

- Surrogacy agreements benefits both the parties in need. In the surrogacy arrangement, the barren lady
gets a baby and poor lady gets monetary consideration for the same.

- Get to complete your family with genetic connection with your child using gestational surrogacy and maintain a biological relationship.

- Get a legally sound relationship and confirm your legal rights by undergoing a legally binding contract, well negotiated and signed and obtain court order prior to the birth of the child.

- Get to be a part and parcel of the whole process from conceiving to birth along with the surrogate and help her in having a healthy pregnancy, whereas in Adoption you have no idea of all these.

- Get a better assurance of success rate since surrogacy has a good track record for successfully delivering babies to the intending parents then the other fertility treatments.

- Get to raise the child from birth and can inculcate moral values from the beginning.

**REASONS FOR NOT OPTING FOR SURROGACY AS AN ALTERNATIVE:**

- The intending parents might get to go through a complex medical procedure in case of gestational surrogacy.

- The intending couple might find it overwhelming at times complying with the legal procedures involved. However, appointing trusted legal professionals for the same can be of great help.

- The Surrogacy in practice exploits women physically and emotionally.

- The surrogate mothers are mostly from poor financial background and hence unaware of their legal rights and unable to appoint lawyers for themselves. They however sign the contract in want of money and later find it difficult to escape from the contract.

- The intending couple may experience lack of patience in need of a greater sense of control over your surrogate, so you will have to trust your surrogate for the pregnancy.

To what extent the factors like Anxiety, depression, emotional distress etc. corelates to functional infertility isn’t clear yet. Many investigations showed contradictory results while demonstrating a link between infertility and psychopathology, some authors did not find significant differences, whereas few others reported greater degrees of maturity fear and interpersonal distrust, anxiety and dissatisfaction, depression, and a tendency toward somatization in women with ‘functional’ infertility.

Several descriptive studies relating to infertile couples suggests a greater susceptibility to depression and anxiety as a factor that reduces the ability to become pregnant or conceive.

**Conclusion**

Thus, the Gestational surrogacy market in India provides the barren couples with the opportunity to create offspring’s that are biologically related. It also gives the financially weak surrogate women an economic opportunity to carry a baby and get financial benefits. However, there are other less harmful ways to get benefits and create opportunities than the ones created by India’s gestational surrogacy market. Providing proper higher education to women and then proper training can make them capable for jobs that aren’t putting them at risk physically and emotionally. Further surrogacy India commodifies women unlike the Americas non-commercial surrogacy arrangements that create biological offspring’s too with a friend or family member. Since the benefits are achievable through less detrimental means the harms that occurs due to India’s gestational surrogacy market highly out weightsthe benefits.

**Ethical Clearance:** Not required, as the research article is based on surrogacy and the literature is discussed from the decided judicial decisions. The research is doctrinally undertaken.

Surrogate Motherhood: Challenges and Legal Implications

Shyamantak Misra¹, Prafulla Chandra Mishra²

¹Research Scholar, ²Dean, School of Law, KIIT, Bhubaneswar, Odisha, India

Abstract

Surrogacy wasn’t a commonly used term until the 21st century, it came up with the rising level of infertility in couples and the stringent procedure of compliance for adoption. Surrogacy has always been the choice of couples for whom genetic link is of utmost importance. At a point of time the rate of commercial surrogacy was at its peak which leads to several issues and challenges that needs to be treated on an urgent basis and obviously an enactment to guide alongside which isn’t present till date in India. However, after the passing of the Surrogacy Regulation Bill 2019 in the Lok Sabha, a hope for betterment has arose. This piece of study showcases the challenges faced since time immemorial relating to Surrogacy and how it was being tackled with, without any legislation being present in India. It also stresses on the key points of the upcoming bill of 2019 and how it would prove to be a turning point for the commercial world that developed due to the Surrogacy in India.

Keywords: Surrogacy, Altruistic Surrogacy, Commercial Surrogacy, Assisted Reproductive Technologies.

Introduction

The tremendous breakthrough in science have opened the new contours of nature whose existence have remained as secret since then. The contribution of the bio-medical sciences to the mankind is unimagined. These unprecedented advances in science come with their own attached risks and concerns whether it may be legal, moral, technical or ethical. Advances in the bio-medical sciences and the reproductive techniques have catered to the desire of the men and women who have no or little reproductive capabilities to have their children through techniques known as Assisted Reproductive Technologies (ART) methodized to achieve pregnancy by artificial means which is also termed as fertility treatment. Surrogacy is also one of those techniques which substitute the natural conception and birth and has witnessed a phenomenal growth. Surrogacy is not a new concept as far as Artificial Reproductive Technology is concerned.

Surrogacy has always been a controversial topic in India mainly due to the absence of a cohesive legislation although in ancient India it was practiced, accepted and respected as well. Its quite weird that surrogacy existed during those times but Indian Hindu Mythology widely mentions instances of surrogacy like Karthikey (the God of war), 8 the son of lord Shiva but not born out of goddesses Parvati, the Surrogate mother being Ganga. In Mahabharat Dhritarastras wife Gandhari conceived and after a long span of 2 years gave birth to a mass which was then put in a nutrient medium by Rishi Vyasa, according to whom there were 101 cells in the mass delivered by Gandhari and surprisingly those cells finally developed into hundred male and one female child.

As per the Assisted Reproductive Technologies (Regulation) Bill, 2010, which for the first time tried to get a specific legislation pertaining to the critical issues involved in Surrogacy defines Surrogacy as “an arrangement in which a woman agrees to a pregnancy, achieved through assisted reproductive technology,
in which neither of the gametes belong to her or her husband, with the intention to carry it and hand over the child to the person or persons for whom she is acting as a surrogate.”

Bad health condition of a woman which makes her pregnancy dangerous and weak uterus to hold the fetus also calls for surrogacy arrangement.

**Indian Perspective:**

Coming to the legal protection and regulation governing the law of surrogacy, the contract and other allied issues, however is considered legitimate in India and in the absence of any legislation to that effect, the only guidelines currently related to this field are those of the Indian Council of Medical Research (ICMR) in 2005 issued guidelines for accreditation, supervision and regulation of ART clinics in India. However, this could not check the abuses of exploitation of surrogate mothers in the background of no strict penal provisions and implementation. Looking into the pressing need and demand for protection against all such misuses the government appointed an expert committee has drafted a legislation known as Assisted Reproductive Technology (ART Regulation) Bill, 2010 for legalizing surrogacy.

There is an urgent need for a strong regulation is called for to meet the demand of the legislature. The 228th Report on “Need for Legislation to regulate Assisted Reproductive Technology Clinics as well as Rights and Obligations of Parties to a Surrogacy” reflects the background and the need for developing legislation to regulate this widely unregulated industry in India. The Commission said, “It seems that wombs in India are on rent, which translates into babies for foreigners and dollars for Indian surrogate mothers.” The approach “The parents construct the child biologically, while the child constructs the parents socially” has been widely reflected in the works of many scholars while dealing with surrogacy and related aspects. This certainly reflects, the complexities involving the parentage and legitimacy of the child and rights that would come with this report.

As stated above issues majorly arose due to the commercialization of surrogacy and after a thorough research recently the Minister of Family and Health Welfare, Dr. Harsh Vardhan introduced the Surrogacy Regulation Bill 2019.

On July 5, 2019: Cabinet approved the surrogacy regulation Bill 2019

On July 15, 2019: It was introduced in the lower house.

The Special features of this bill are:

- It aims at banning commercial surrogacy and legalizing only the altruistic surrogacy (involves no monetary compensation only the medical expenses).
- It has fixed the criteria’s relating to the persons going for the same. It’s for Intending couples who suffer from proven infertility, for any condition or diseases fixed under the regulations or altruistic one.
- Certificate of essentiality and certificate of eligibility are both required.
- Appropriate authorities are to be appointed by the Central and State government within 90 days of the Bill becoming an Act.
- Surrogacy clinics cannot undertake surrogacy related procedures unless registered under the appropriate authority.
- National and State surrogacy Boards would be constituted.
- Penalties have been fixed for the offences under this act.

**Surrogacy- Issues and Concerns:**

Surrogacy raises serious issues concerning legal rights of the parties concerned and parenthood i.e. paternity and maternity rights, guardianship and custody of the child along with the matters relating to maintenance and financial support. Whether the human body is an object that is possessed by an individual
and is that individual the owner of her body so as to be entitled to put it through abuse i.e. undergoing artificial reproductive techniques for procreation is a pertinent question.

The legitimacy and legal status of the babies born out of ART technique and the question as to who are the legal father and mother of the child is a matter which needs address. The status of the ova donor and the sperm donor is not clear. The succession rights and the citizenship of the baby raise huge concern as well. The concern regarding the surrogate mother to recover to normal life after the handing over of the child to the commissioning parents raises an issue as to the responsibility of the surrogacy clinics whether they can be made liable for their fault or not if afterwards the surrogate still persists with health problems.

Current International Scenario:

Risking the life is another very critical issue in a country where no doubt the health care sector is very advanced but the womb lent might not be taken proper care of and the contractual terms might not be sound enough to insure you about your health. So that is why it is a tourist place for surrogacy and instances are many which put spotlight on the murky commercial surrogacy market. The practice of surrogacy is popular beyond the borders or territorial jurisdiction of the government of the commissioning parents. Australian parents prefer surrogacy the most amongst the other nationals of the world and India, Thailand and some other Asian countries have been the most viable cost-effectivetourist spots for them and thus are usually preferred to USA where the best facilities and proper regulatory environment is available.

In this backdrop, another very pertinent question that rises here –Is not it a forced removal of indigenous children from the community, going overseas and asking for a womb to brought up your intended offspring for reasons not so befitting and if question being raised which woman, would willingly, freely, rent out their womb with availability of other choices for earning enough money and to live decently?

Analyzing the global trend in various countries it is found that in the U.K, USA surrogacy is highly regulated and comparatively costlier to other countries whereas, in Germany and Canada, surrogacy is outlawed or prohibited. In a series of controversies surrounding surrogacy and question of citizenship of the baby born out of such procedure, the German authorities refused to give passports to children born of surrogate procedures. In an article under the Sydney herald “Babies left in limbo as India struggles with demand for surrogacy” (2008) the story of a German couple, Jan Balaz and Susan Lohle, in the wait of their twin sons, Nikolas and Leonard, have been trapped in citizenship limbo is highlighted owing to the issues of claiming citizenship of German and who were denied passport because , German nationality is determined by the birth mother. These issues left the slow-moving Indian judicial system to wrestle with their citizenship status. When born to an Indian surrogate mother, the Constitution of India entitles the Indian citizenship, but it remains critical as to what happens if the biological mother is a foreign citizen and the child applies for citizenship of that country and is denied? This question when raised by a Bench led by Justice Ranjan Gogoi in the above case, the concept of dual citizenship for surrogate children which is not allowed in India, whether could be considered in any circumstances? This dual citizenship can give limited entitlements to such children.

Judicial Analysis:

The Supreme Court, in the 2008 case of Baby Manji Yamada v. Union of India, discussed surrogacy and noted that “commercial surrogacy is reaching industrial proportions because of the ready availability of poor surrogates. It mentioned the Commissions for Protection of Child Rights Act, 2005 but stopped short of demanding that the government take immediate action to regulate the whole surrogacy industry, and not just address the issue of the rights of the child once it is born”. In Jan Balaz v. Anand Municipality, the Court held that Surrogate babies born in India are Indians.
In K Kalaisevi v Chennai Port Trust\(^1\), the court stated that “Surrogacy is a well-known method of reproduction whereby a woman agrees to become pregnant for the purpose of gestating and giving birth to a child she will not raise but hand over to a contracted party. She may be the child's genetic mother (the more traditional form for surrogacy) or she may be, as a gestational carrier, carry the pregnancy to delivery after having been implanted with an embryo. In some cases, surrogacy is the only available option for parents who wish to have a child that is biologically related to them.” This was also stated in Sadhna Agarwal v. state of Chhattisgarh\(^2\) and 5 other cases which are “State of Punjab v. Sodhi Sukhdev Singh, AIR 1961 SC 493, p. 502 27 Liverpool and London SP&I; Association v. M.V. Sea Success & Asso. Ltd. (2004) 9 SCC 512 (para 65) 28 Senior Electric Inspector v. Laxminarayan Chopra, AIR 1962 SC 159, p. 163 W.P.(S)No.4927/2016 Manji Yamada v. Union of India.”

**Suggestion and Conclusion**

From all the above discussed matters it can be rightly said that surrogacy being and awarding experience for infertile intending couples cannot be banned completely due to the large number of issues and challenges arising because of it but can be curbed and minimized if dealt in the right way. However, the Surrogacy Regulation Bill 2019 might rise to our expectations by doing the needful since it has the proviso of banning the commercial surrogacy, reducing the complicacies involved as well as giving a remarkable boost to the adoption Industry which might further reduced the number of uncared or orphaned children. All this depends on the implementation procedure of the same. Thus, it is suggested to tighten and provide a stricter method of implementation of the provisions of the Surrogacy Regulation Bill 2019 if it turns out to be the only legislation in India on Surrogacy.

**Ethical Clearance:** Not required, as the research article is based on surrogacy and the literature is discussed from the decided judicial decisions. The research is doctrinally undertaken.

Red Dragon Fruit (*Hylocereus Polyrhizus*) to Reduce Cholesterol Level in People With Excessive Nutritional Status

Siti Fadlilah¹, Adi Sucipto¹, Mohamad Judha¹, Tia Amestiasih¹, Cornelia Dede Yoshima Nekada¹, Eko Mindarsih¹, Cipta Pramana²

¹The Lecturer at The Nursing Programme Study, Universitas Respati Yogyakarta, Indonesia, ²The Lecturer at The Medical Faculty Tarumanagara University, Jakarta Indonesia

Abstract

**Background:** Nutritional status is closely related to high cholesterol levels. High cholesterol levels as a trigger for other metabolic diseases. Fruits high in fiber and vitamin C can be used to keep blood cholesterol levels regularly.

**Aim:** To determine the effect of red dragon fruit on blood cholesterol levels in people with excessive nutritional status.

**Methods:** Research used an experimental approach with a pretest and post-test control group design. The sample consisted of 2 groups, namely the control group and the intervention group, with 50 respondents in each group. The sample was taken using purposive sampling. The intervention group got red dragon fruit juice for seven days. Blood cholesterol levels are measured by laboratory tested using intravenous blood. The statistical test used the Paired T-Test and Independent T-Test.

**Results:** The difference mean posttest-pretest control group and intervention groups were 13.56 mmHg and -13.06 mmHg. The analysis of pretest-posttest blood cholesterol levels among the control and intervention groups were p=0.514 and p=0.035. The difference between the control group and the intervention group was 0.022.

**Conclusion:** Red dragon fruit is effective in reducing blood cholesterol levels in people with excessive nutritional status.

**Keywords:** Cholesterol, *Hylocereus polyrhizus*, obesity, overweight, phytotherapy.

Introduction

The incidence of obesity in the world has doubled since 1980. Worldwide in 2014, it showed that > 1.9 billion adults aged > 18 years were overweight, of which > 600 million people were obese. The highest prevalence of overweight is in the United States, and the lowest is in the South-East Asia region.¹ Indonesia's 2018 basic health research shows that from 2007 to 2018, the proportion of overweight in adults aged > 18 years has increased, from 8.6% to 13.6%. The ratio of obesity at age > 18 years from 2007 to 2018 has also increased, namely 10.5% to 21.8%.² Nutritional status is more capable of leading to dyslipidemia, an increased risk of coronary heart disease (CHD), diabetes mellitus, and other serious diseases. More nutritional status is also closely related to dyslipidemia, one of which is high cholesterol levels.³,⁴,⁵

Cholesterol is one of the most important substances in the human body. There are two types of cholesterol in the blood, namely bad cholesterol and good cholesterol.⁶ Bad cholesterol in the body is Low-Density Lipoprotein (LDL) cholesterol, triglycerides, and lipoproteins. High-Density Lipoproteins (HDL) is a type of good cholesterol that is harmless in the body. Normal total cholesterol levels in the blood are less than 200 mg/dL or 160-200 mg/dL.⁷ High blood cholesterol levels
in the long term are bad for the body. Long-term LDL buildup causes atherosclerosis, which blocks blood flow and is an indicator of heart disease risk. World Health Organization data shows that 17 million people (31%) each year die from Cardiovascular Diseases (CVDs) worldwide. The prevalence of heart disease in Indonesia in 2018 reached 1.5%. Management to prevent the accumulation of cholesterol levels in the can use pharmacologic and non-pharmacological treatments.

It decreased cholesterol levels with a nonpharmacologic diet combined with herbal medicines or components of active substances in fruits or vegetables. One of the fruits that can lower cholesterol levels is dragon fruit. Dragon fruit is rich in antioxidants (anthocyanins, polyphenols, vitamin C, vitamin E) and is high in fiber. Dragon fruit can reduce total cholesterol, triglycerides, and LDL cholesterol levels in rats with hypercholesterolemia, dyslipidemia, and diabetes mellitus.

Dragon fruit is a plant that is easy to grow and cultivate in Indonesia. Dragon fruit is also cheap and easy to consume. Researchers are interested in examining the benefits of dragon fruit on cholesterol levels. Based on the results of a preliminary study, people with excessive nutritional status are found. After measuring cholesterol levels in these 10 people, there were 6 people with cholesterol levels > 200mg/dL, 2 people with cholesterol levels > 190mg/dL (<200mg/dL) and 2 people with cholesterol levels of 178mg/dL. The results of other interviews were as many as eight people who did not make good pharmacological or non-pharmacological efforts. One person had consumed cholesterol-lowering drugs, and one person took herbal medicine for approximately six months.

Methods

1. Study Design and Participants

This study used a experimental approach with a pretest and post-test control group design. The study was conducted on excessive nutritional status in the Kebumen, Central Java, Indonesia, in June 2020.

The independent variable was dragon fruit juice. The dependent variable is the total cholesterol level. The sample consisted of 2, namely the control group and the intervention group. The control group did not get any treatment, while the intervention group received dragon fruit juice. The number of samples in each group was 50 people who were selected by purposive sampling method. The inclusion criteria were age 20-60 years, BMI ≥ 25.0, and willingness to become respondents. The exclusion criteria were smoking, consuming alcohol, consuming cholesterol medication, consuming vitamin C regularly, consuming high fiber fruit regularly, diabetes mellitus, and gastritis. The drop-out criterion does not follow the research process from the beginning or the first day to the last day.

During the research process, the respondents were arranged in their diets and activities. Respondents got a diet of carbohydrates and protein. Respondents are not allowed to consume foods high in fat. The activities that are allowed are light and moderate. Select samples of excessive nutritional status by measuring height and weight directly, then calculating BMI. The digital weight scales used have been tested for calibration at the Legal Metrology Unit of Yogyakarta City with the certificate number 212/MET/TE-72/II/2020. Microtoice has conducted a calibration test at the Legal Metrology Unit of Yogyakarta City with certificate number 212/MET/UP- 20/II/ 2020.

2. Instruments and Data Collection

The intervention group was given dragon fruit juice. Red dragon fruit juice is a fruit drink made by separating the skin’s red dragon fruit flesh. The red dragon fruit flesh was weighed using a digital food scale with a dose of 2.86 g / kg. Then it is blended for about 30 seconds with the addition of water as much as +/- 70 ml without adding sugar. The red dragon fruit that has been blended is put into a drinking glass and is directly consumed by the respondents. Dragon fruit juice is given once a day for 7 days and is given in the afternoon at 16.00-17.00 WIB on an empty stomach or a maximum of lunch around 12.30 WIB. Dragon fruit juice was made directly
in front of the respondents so that it was consumed fresh.

Total cholesterol level is the total amount of cholesterol in the blood measured using a digital cholesterol test strip or an auto check. Cholesterol tests were carried out in the peripheral blood vessels or one of the respondent’s fingertips, namely the index, middle, and ring fingers, previously disinfected. Cholesterol levels were measured pretest and post-test in the morning around 07.00-09.00 WIB or after respondents had fasted for approximately 9-12 hours. Cholesterol levels were measured using a three cc median cubital vein and checked in the laboratory. The pretest cholesterol levels were measured on day one before the intervention. Post-test cholesterol levels were measured after the respondent was given intervention for seven days or was carried out on the 8th day. Sampling blood was carried out according to standard operating procedures. The data is recapitulated in the observation sheet.

### 3. Data Analysis and Ethical Consideration

All respondents stated their willingness to become respondents by signing informed consent. The research was conducted after obtaining an ethical clearance letter with letter number 084.3/ FIKES/PL/III/2020 and research permit number 900.2/ FIKES/PL/V/2020. Univariate data were presented with minimum, maximum, mean, and frequencies-percentages for categorical variables. Before the bivariate test, the normality test was carried out using the Shapiro-Wilk test. The results showed that the data were normally distributed (p > 0.05) to analyze the pretest and post-test; each group used a Paired T-Test. The differences between groups were measured using the Independent T-Test.

*Tested using Pearson
Table 1 shows that most of the respondents are adult, female, and have an obese nutritional status, namely 24 people (66.67%), 34 people (94.44%), and 25 people (69.44%). The bivariate test results between age, sex, and nutritional status with the pretest value of cholesterol levels were $p=0.010$, $p=0.883$, and $p=0.695$. The results showed a significant relationship between age and pretest cholesterol levels, while gender and nutritional status had no significant relationship.

**Tested using Paired Samples Test
Table 2 shows the results of differences in respondents’ characteristics with changes in cholesterol levels in the pretest and post-test in each group. There was no difference between adults and the elderly in the control and intervention groups with changes in pretest-posttest cholesterol levels with p=0.276 and p=0.133. Although statistically there is no difference, seen from the difference between the mean posttest-pretest in the control group, it shows that the elderly have increased cholesterol levels more than adults (62 mg/dl> 1.31 mg). Whereas in the intervention group, the reduction in cholesterol levels in the elderly was more than in adults (13.71 mg/dl> 12.63 mg/dl).

Judging from gender, in the control and intervention groups, there was no difference between men and women with changes in pretest-posttest cholesterol levels with p=0.307 and p=0.121. Although statistically, there is no difference, seen from the results of the mean posttest-pretest difference in the intervention group, it shows that there is a decrease in cholesterol levels more than women (24.5 mg/dl> 11.63 mg). Based on nutritional status, there was no difference between overweight and obesity in the control and intervention groups with changes in pretest-posttest cholesterol levels with p=0.302 and p=0.132. Although statistically, there is no difference, seen from the difference between the mean post-test-pretest in the control and intervention groups, there is a decrease in cholesterol levels more than overweight.

*** Paired T-Test

*** *Independent T-Test

Table 3 shows an increase in the average cholesterol level between the pretest and post-test in the control group, which was 13.56 mg/dl. In contrast, there was a decrease in cholesterol levels between the pretest and post-test in the intervention group, as much as 13.06 mg/dl. The bivariate test results in the control group obtained p=0.514, indicating no difference in cholesterol levels in the pretest and post-test. The intervention group showed red dragon fruit juice on total cholesterol levels in people with excessive nutritional status with p=0.035. The comparison between the control group and the intervention group obtained p=0.022, indicating a difference in the two groups, namely, the intervention group had a decrease in cholesterol levels.
Discussion

Cholesterol is one of the most important fat components in the body, found in cell membranes in all body tissues. Cholesterol is produced naturally by the body, namely in the liver, which builds cell walls and makes hormones. Apart from being produced naturally by the body, cholesterol is also obtained from the food consumed daily. Total cholesterol is the total amount of cholesterol in the body, namely High-Density Lipoprotein (HDL), Low-Density Lipoprotein, and other lipid components. The range of normal values for total cholesterol levels in the body has 3 categories, namely normal values <200mg/dl, high enough 200-239 mg/dl, and high cholesterol levels> 240 mg/dl. Measuring total cholesterol levels on the first day and the eighth day when the respondent has fasted for approximately 9-12 hours. Researchers gave red dragon fruit juice with a fruit pulp dose of 2.86 g/kg body weight for each person. This dosage is following the results of previous studies.12

Total cholesterol levels in the blood can be influenced by several factors, namely genetic factors, diet and lifestyle, body weight, age, physical activity, smoking, and certain diseases.16 This study did not consider all the risk factors that affect cholesterol levels in this study, only attention to age, gender, and the problem of nutritional status. Respondents are not allowed to consume high-fat foods during the study because it will affect the results. The content of foods that contain cholesterol is fried, meat, brain, offal (intestines, liver, kidney, lungs, heart), egg yolk, seafood. Cholesterol in the body is also produced by the liver.17

Table 1 shows that the mean pretest cholesterol level in the elderly is higher than that of adults with a 5.22 mg/dl difference. The bivariate test results show a significant relationship between age and cholesterol levels (p=0.010). Increasing age is a factor in improving cholesterol levels. Cholesterol levels tend to grow at the age of more than 20 years. With age, there will be an increase in LDL production and a decrease in the level of fractional clearance of LDL, responsible for the rise in blood cholesterol levels in the long term.18 Previous studies show that cholesterol levels get higher with age.19,20 This study’s results do not support the survey results. There is no relationship between age and cholesterol levels, where all ages risk increasing cholesterol levels.21

At the start of menopause, cholesterol levels begin to fall in women, and after that, cholesterol levels will increase as in men. After 50 years, cholesterol levels in men tend to continue to grow.22 This is consistent with the study results, although the number of men but the mean cholesterol level of men was higher by a difference of 17.47 mg/dl. Statistically, there was no relationship between gender and cholesterol levels in respondents (p=0.883), supporting previous studies with the results that there was no relationship between sex and cholesterol levels (p=0.847). The absence of a relationship in this study was due to an unbalanced ratio between men and women. The majority of the study samples were adults and had not yet menopause.

Table 1 shows that the higher the BMI value, the higher the mean total cholesterol level but does not reach the cholesterol level limit in the reasonably high category (> 200 mg/dl). However, statistically, there is no relationship between excess nutritional status and cholesterol levels (p=0.695). Excess weight can harm health. Being overweight can raise triglyceride levels and lower HDL.21 Biochemical disturbances can also occur due to excess nutrition or obesity, which causes an increase in cholesterol, triglyceride, blood sugar, and insulin levels.23 The study results supported previous studies: there was no relationship between excess nutritional status and total cholesterol levels.4,24

Table 2 shows no difference in respondents characteristics with changes in cholesterol levels post-test-pretest in all aspects. This indicates that cholesterol levels in the control and intervention groups are not influenced by age, sex, and nutritional status. Table 3 shows the pretest value of total cholesterol levels between the control and treatment groups, namely the minimum value and the mean value in the normal
category. In contrast, the maximum value is categorized as high enough and in the high class. So it can be interpreted that respondents with nutritional status in this study had an average total cholesterol level in the standard type (<200 mg/dl). The results also showed the same effects on total cholesterol levels post-test in the control and treatment groups. The minimum value and the mean value indicate typical values. In contrast, the maximum value is included in the high category in the control group and the intervention group’s high enough category. The minimum, maximum, and mean values in the intervention group were lower than in the control group.

Table 3 shows a difference between the pretest and post-test total cholesterol values in the intervention group (p=0.035) and is strengthened by a decrease in the mean value of 13.06 mg/dl. Meanwhile, the control group showed no significant difference between the pretest and post-test total cholesterol levels (p=514), and there was an increase of 13.56 mg/dl. This indicates that dragon fruit juice is effective in reducing cholesterol levels in people with excessive nutritional status. The research supports previous studies that red dragon fruit juice on total cholesterol levels in hypercholesterolemic men and women with diabetes mellitus.12,13

Red dragon fruit contains many substances that are beneficial to health. Dragon fruit content is rich in antioxidants (anthocyanins, polyphenols, vitamin C, and vitamin E) and high fiber content, which controls blood cholesterol levels.10 The content in 100 grams of red dragon fruit is 10.1 grams of fiber and 9.4 mg of vitamin C. The fiber content in dragon fruit can reduce fat absorption, especially cholesterol, to lower cholesterol levels. In this case, the long-term effect can provide benefits in preventing heart attacks and strokes. High fiber content can reduce cholesterol in the blood by inhibiting the re-absorption of bile acids in the intestine as compensation for the liver to synthesize more bile acids and require cholesterol. The liver will multiply receptors to capture cholesterol from the blood.12,25

Vitamin C plays a role in cholesterol metabolism, which increases the rate of removal of cholesterol removal in the form of bile acids, increases HDL levels, and plays a role in reducing bile acids’ re-absorption. The content of vitamin C in dragon fruit can prevent coronary heart disease by inhibiting LDL oxidation, and vitamin C have the effect of avoiding HDL damage due to lipid peroxidase, free radical formation, and increased bile acid excretion.26,27,28 The anthocyanin content of 8.8 mg/100gr is useful for reducing the risk of cardiovascular disease. The anthocyanin content in dragon fruit can also provide a cholesterol-lowering effect by inhibiting CETP and inhibiting the HMG-CoA reductase enzyme. Therefore, cholesterol concentrations in the liver and plasma are expected.11,29 Nurses can promote complementary therapies through consumption of red dragon fruit which is used to keep blood cholesterol levels normal. This can be used as a preventive measure in the occurrence of other diseases.

This study had several constraints. The difficulty in this research is maintaining the freshness of the juice to be given. Good juices are those that are made and consumed at a distance of no more than 2 hours. To overcome this, the researchers prepared the juice directly in front of the respondents.

**Conclusion**

The results showed that red dragon fruit effectively reduced total cholesterol levels in people of excessive nutritional status. This study’s results can further increase the intake of healthy nutrients from fruit to keep cholesterol levels regular. Normal cholesterol levels can prevent dangerous metabolic diseases.

Abstract

Background: Human Immunodeficiency Virus infection is a chronic disease that threatens the health of millions of people in the world and causing disability. One of the factors that caused disability is HIV muscle wasting, causing a decrease in quality of life that interfere the daily activities and even increased mortality. Proper physical exercise is needed to prevent and treat muscle wasting.

Methods: This study using human subjects with clinical stage II HIV infection. Subjects were grouped into two: Intervention (n = 9) that subjects who get moderate-intensity physical exercise (HIVA) for 8 weeks and Control (n = 9) as subjects were observed for 8 weeks. Muscles samples were taken from the vastus lateralis muscle biopsies that performed 24 hours after the last physical exercise, immunohistochemical examination with monoclonal antibody anti-Pax7, anti-MyoD1 and anti-myogenin and measurement of thigh circumference.

Results: There were significant increase in regeneration of skeletal muscle in the intervention group (increasing of Pax7, MyoD1 and myogenin) than the control group and significant increase in quadriceps muscles mass as measured by thigh circumference (p < 0.001).

Conclusion: HIVA physical exercise of moderate intensity increases skeletal muscle regeneration in clinical stage II HIV infection through the increasing of Pax7, MyoD1, myogenin expression and followed by an increase of quadriceps muscles mass.

Introduction

Human Immunodeficiency Virus/ Acquired Immunodeficiency Syndrome (HIV/AIDS) is a health risk for millions of people who are currently a pandemic.

The percentage of HIV infection in Indonesia, the highest reported in the age group 25-49 years (69.1%)¹, leads to reduced life quality due to muscle wasting. Hence, people with HIV / AIDS cannot perform daily activities and participate in society’s social members. People with HIV / AIDS will experience impairment and disability due to their progression ². The impact of HIV infection in the form of muscle-wasting disease progression, increased mortality, loss of muscle protein mass, weakness, impaired function ³,⁴, and decreased aerobic capacity ⁵ were also a predictor of mortality.
The quadriceps muscle is one muscle that is essential to maintaining the function of ambulation, so it needs physical exercise to prevent the progression of muscle wasting and stimulate the regeneration process\(^3\). Vastus lateralis muscle represents quadriceps muscle because the strength is essential for weight-bearing and ambulation. It can show the response to physical exercise intervention and the biopsy’s safest\(^6\).

Skeletal muscle mass represented a person’s physical performance\(^7\). Physical exercise is known to increase muscle mass, improve protein balance through a mechanical signal, chemically maintain or increase muscle mass\(^8\), and increase muscle strength. Skeletal muscle strength is a determinant of a person’s functional capacity, providing a higher level of independence and quality of life\(^9\). In this study, patients with HIV infection clinical stage II performed HIVA aerobic physical exercise (The name of tailored physical therapy is HIVA). This study aimed to compare the effect of HIVA exercise in skeletal muscle regeneration and muscle mass in HIV infection clinical stage II patients through increased expression of Pax7, MyoD, and Myogenin.

**Materials and Methods**

**Participants**

The subjects in this study were male of HIV infection clinical stage II, aged 21-50 years, who came to the outpatient clinic of infectious unit Dr. Soetomo General Hospital. Human Immunodeficiency Virus infection clinical stage II is HIV infection defined by WHO criteria \(^10\). All study subjects get antiretroviral therapy. The ethics committee of Dr. Soetomo General Hospital Surabaya approved the study protocol of this research. (No: 258/Panke.KKE/IV/2015).

All participants in this study provided written informed consent.

**Physical Exercise Protocol.**

The subjects in the intervention group were given a physical exercise as aerobics with a frequency of 2 times per week, intensity 60-70% of maximum heart rate, duration of 23 minutes (warm-up, and stretching 6 minutes, the core exercise 13 minutes and cooling-down 4 minutes) for eight weeks. The time adjusted with an intensity of 60-70% maximal heart rate.

**Vastus lateralis muscle biopsy procedure.**

Materials needed in this study are: muscle tissue biopsy results of vastus lateralis, anti-TNF-α monoclonal antibody clone 52B83, Novus Biological product (NB600-1422), anti-calcineurin monoclonal antibody clone 2G8 Novus Biological product (H0005530-M03), anti-Pax7 monoclonal antibody clone 1E12 Novus Biological product (H00005081-M05), anti-NF-κB p65 monoclonal antibody clone 112A1021 Novus Biological product (NB100-56712), anti-MyoD1 monoclonal antibody clone 5.8A Dako product (M3512),

At the point of the bottom third of the line connecting the SIAS-patella performed muscle biopsy. Local anesthesia by injection of Lidocaine 2%, skin sterilized with povidone-iodine. Muscle biopsy using a reusable Medcore gun and Unicore needle size 16G. Specimen storage with formalin 10%. Each slide of the vastus lateralis muscle was viewed under light microscopy, 400 times magnification, counted the number of satellite cells showing Pax-7, Myo D, and Myogenin in 10 fields of view, then the averaged per field of view.

**Statistic Analysis**

Statistical analysis is using the SPSS program. To determine the homogeneity of the data in each group, using the one-sample Kolmogorov-Smirnov test and determining the data normality using the Shapiro-Wilk test. Thigh circumference before and after the physical exercise comparison in each group using a paired t-test. The alteration of thigh circumference after the physical exercise among the two groups used the Lavene test. The significance level was at \( p \leq 0.05 \).

**Results**

The characteristics of the subjects showed in Table 1. Before intervention, there were no significant differences between age, Body Mass Index, and Thigh
Circumference between the intervention and control groups.
